$$\nabla^\mathbf{E}_{\widetilde{\mathbf{X}}_1}\widetilde{\mathbf{u}}_1 - \nabla^\mathbf{E}_{\widetilde{\mathbf{X}}_2}\widetilde{\mathbf{u}}_2 = \nabla^\mathbf{E}_{\widetilde{\mathbf{X}}_1-\widetilde{\mathbf{X}}_2}\widetilde{\mathbf{u}}_1 + \nabla^\mathbf{E}_{\widetilde{\mathbf{X}}_2}(\widetilde{\mathbf{u}}_1-\widetilde{\mathbf{u}}_2).$$

The first term vanishes upon restriction to ∂M, since $\widetilde{\mathbf{X}}_1-\widetilde{\mathbf{X}}_2$ vanishes on ∂M and the connection is $C^\infty(M)$-linear in its vector argument. For each $x\in\partial M$, the value of $\nabla^\mathbf{E}_{\widetilde{\mathbf{X}}_1-\widetilde{\mathbf{X}}_2}\widetilde{\mathbf{u}}_1$ at x depends only on $(\widetilde{\mathbf{X}}_1-\widetilde{\mathbf{X}}_2)_x$, which is zero.
We now show that the second term also vanishes upon restriction to ∂M. Set $\mathbf{w}:=\widetilde{\mathbf{u}}_1-\widetilde{\mathbf{u}}_2$. Then $\mathbf{w}\restriction_{\partial M}=0$.

Since the argument is local, take a local frame $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ of $\mathbf{E}$ near a point of ∂M and write $\mathbf{w} = \sum_{a=1}^{r} w^a \mathbf{e}_a$. Since $\mathbf{w}$ vanishes on ∂M and the vectors $\mathbf{e}_1(x),\dots,\mathbf{e}_r(x)$ form a basis of $\mathbf{E}_x$ for each x, we have $w^a \restriction_{\partial M} = 0$ for every a.

Now, using the Leibniz rule for the connection,

$$\nabla^{\mathbf{E}}_{\widetilde{\mathbf{X}}_2} \mathbf{w} = \sum_{a=1}^{r} \widetilde{\mathbf{X}}_2(w^a)\mathbf{e}_a + \sum_{a=1}^{r} w^a \nabla^{\mathbf{E}}_{\widetilde{\mathbf{X}}_2} \mathbf{e}_a.$$

Upon restriction to ∂M, the second summand vanishes because $w^a \restriction_{\partial M} = 0$. For the first summand, use $\widetilde{\mathbf{X}}_2 \restriction_{\partial M} = \mathbf{X}$ and the fact that $\mathbf{X}$ is tangent to ∂M. Since $w^a \restriction_{\partial M} = 0$, we have $\mathbf{X}(w^a \restriction_{\partial M}) = 0$, and therefore $\widetilde{\mathbf{X}}_2(w^a) \restriction_{\partial M} = 0$. Thus $(\nabla^{\mathbf{E}}_{\widetilde{\mathbf{X}}_2} \mathbf{w}) \restriction_{\partial M} = 0$. This proves that $\nabla^{\mathbf{E}\restriction_{\partial M}}_{\mathbf{X}} \mathbf{u}$ is well defined.

We now prove that $\nabla^{\mathbf{E}\restriction_{\partial M}}$ is a connection. Let $f \in C^\infty(\partial M)$, $\mathbf{X},\mathbf{Y} \in \mathfrak{X}(\partial M)$, and $\mathbf{u},\mathbf{v} \in \Gamma(\mathbf{E}\restriction_{\partial M})$. Take smooth extensions of these objects to a neighborhood of ∂M. Since $\nabla^{\mathbf{E}}$ is $C^\infty(M)$-linear in its vector argument, we obtain $\nabla^{\mathbf{E}\restriction_{\partial M}}_{f\mathbf{X}+\mathbf{Y}} \mathbf{u} = f\nabla^{\mathbf{E}\restriction_{\partial M}}_{\mathbf{X}} \mathbf{u} + \nabla^{\mathbf{E}\restriction_{\partial M}}_{\mathbf{Y}} \mathbf{u}$. Likewise, using the Leibniz rule in the section argument,

$$\nabla^{\mathbf{E}\restriction_{\partial M}}_{\mathbf{X}}(f\mathbf{u}) = \mathbf{X}(f)\mathbf{u} + f\nabla^{\mathbf{E}\restriction_{\partial M}}_{\mathbf{X}} \mathbf{u}.$$

Therefore, $\nabla^{\mathbf{E}\restriction_{\partial M}}$ is a connection on $\mathbf{E}\restriction_{\partial M}$.

Finally, suppose that $\nabla^{\mathbf{E}}$ is compatible with $\mathbf{h}_{\mathbf{E}}$. Let $\mathbf{X} \in \mathfrak{X}(\partial M)$ and $\mathbf{u},\mathbf{v} \in \Gamma(\mathbf{E}\restriction_{\partial M})$. Take extensions $\widetilde{\mathbf{X}},\widetilde{\mathbf{u}},\widetilde{\mathbf{v}}$ as before. By compatibility of $\nabla^{\mathbf{E}}$ with $\mathbf{h}_{\mathbf{E}}$,

$$\widetilde{\mathbf{X}}\big(\mathbf{h}_{\mathbf{E}}(\widetilde{\mathbf{u}},\widetilde{\mathbf{v}})\big) = \mathbf{h}_{\mathbf{E}}(\nabla^{\mathbf{E}}_{\widetilde{\mathbf{X}}}\widetilde{\mathbf{u}},\widetilde{\mathbf{v}}) + \mathbf{h}_{\mathbf{E}}(\widetilde{\mathbf{u}},\nabla^{\mathbf{E}}_{\widetilde{\mathbf{X}}}\widetilde{\mathbf{v}}).$$

Upon restriction to ∂M, the left-hand side becomes $\mathbf{X}\big(\mathbf{h}_{\mathbf{E}\restriction_{\partial M}}(\mathbf{u},\mathbf{v})\big)$, while the right-hand side becomes

$$\mathbf{h}_{\mathbf{E}\restriction_{\partial M}}(\nabla^{\mathbf{E}\restriction_{\partial M}}_{\mathbf{X}}\mathbf{u},\mathbf{v}) + \mathbf{h}_{\mathbf{E}\restriction_{\partial M}}(\mathbf{u},\nabla^{\mathbf{E}\restriction_{\partial M}}_{\mathbf{X}}\mathbf{v}).$$

Therefore, $\nabla^{\mathbf{E}\restriction_{\partial M}}$ is compatible with the restricted bundle metric. □

Henceforth, when we write $W^{m,p}(\partial M,\mathbf{E}\restriction_{\partial M})$, we understand that this space is constructed on the Riemannian manifold ∂M using the restricted bundle $\mathbf{E}\restriction_{\partial M}$, the restricted bundle metric $\mathbf{h}_{\mathbf{E}\restriction_{\partial M}}$, and the induced connection $\nabla^{\mathbf{E}\restriction_{\partial M}}$.

9.4.1 The trace operator

In a boundary chart, restriction of a section to ∂M is expressed through the trace of its components on the flat boundary. We use Theorem 3.7.1, Lemma 3.6.8, and Corollary 3.7.3, proved in the section on Euclidean traces in Chapter 3. In particular, components localized in a half-ball are extended by zero within $\mathbb{R}^n_+$ before taking the trace. We retain the convention fixed there for writing $\gamma_0 D^\beta v$ on the flat face of a half-ball.

Before stating the global result, recall that, when we write $W^{k,p}(\partial M,\mathbf{E}\restriction_{\partial M})$, we use the induced connection on the restricted bundle $\mathbf{E}\restriction_{\partial M} \to \partial M$, constructed in Lemma 9.4.11. This matters because the trace of a section in $\mathbf{E}$ will take values in a Sobolev space on $\mathbf{E}\restriction_{\partial M}$.

Theorem 9.4.12. (Integer-order trace theorem for vector bundles) Let $(M,\mathbf{g})$ be a compact Riemannian manifold with nonempty boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle of finite rank, equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. Let $m\geq 1$ and $1\leq p<\infty$. Then the restriction operator

$$\gamma_0\colon \Gamma(\mathbf{E})\longrightarrow \Gamma(\mathbf{E}\restriction_{\partial M}),\qquad \gamma_0(\mathbf{u})=\mathbf{u}\restriction_{\partial M},$$

admits a unique continuous linear extension

$$\mathbf{Tr}\colon W^{m,p}(M,\mathbf{E})\longrightarrow W^{m-1,p}(\partial M,\mathbf{E}\restriction_{\partial M}).$$

In particular, there is a constant $C>0$ such that

$$\|\mathbf{Tr}(\mathbf{u})\|_{W^{m-1,p}(\partial M,\mathbf{E}\restriction_{\partial M})}\leq C\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}$$

for every $\mathbf{u}\in W^{m,p}(M,\mathbf{E})$.

Proof. We first prove the estimate for smooth sections. Since ∂M is compact, take a finite family of regular coordinate half-balls $(U_\alpha,\varphi_\alpha)_{\alpha=1}^N$ covering ∂M. Write $B_\alpha^+:=\varphi_\alpha(U_\alpha\cap\operatorname{Int}(M))$ and $B'_\alpha:=\varphi_\alpha(U_\alpha\cap\partial M)$. Refining if necessary, we may assume that $\overline{U_\alpha}$ lies in the domain of a smooth local frame $(\mathbf{e}_{1,\alpha},\dots,\mathbf{e}_{r,\alpha})$ trivializing $\mathbf{E}$. Take a smooth partition of unity $(\psi_\alpha)_{\alpha=1}^N$, defined on a neighborhood of ∂M, subordinate to the charts U_α and such that $\operatorname{supp}\psi_\alpha\Subset U_\alpha$.

Let $\mathbf{u}\in\Gamma(\mathbf{E})$. On U_α write $\mathbf{u}=\sum_{a=1}^r u_\alpha^a\mathbf{e}_{a,\alpha}$. Then $\psi_\alpha\mathbf{u}=\sum_{a=1}^r\psi_\alpha u_\alpha^a\mathbf{e}_{a,\alpha}$. For each component, define $f_\alpha^a:=(\psi_\alpha u_\alpha^a)\circ\varphi_\alpha^{-1}$ on B_α^+. Since $\operatorname{supp}\psi_\alpha\Subset U_\alpha$, the function f_α^a vanishes on a neighborhood of the spherical part of B_α^+. Let $\widetilde{f}_\alpha^a$ be its extension by zero to $\mathbb{R}^n_+$. By Lemma 3.6.8, $\widetilde{f}_\alpha^a\in W^{m,p}(\mathbb{R}^n_+)$, and moreover $\|\widetilde{f}_\alpha^a\|_{W^{m,p}(\mathbb{R}^n_+)}=\|f_\alpha^a\|_{W^{m,p}(B_\alpha^+)}$. Applying Theorem 3.7.1 to $\widetilde{f}_\alpha^a$, and using continuity of restriction from $W^{m-1,p}(\mathbb{R}^{n-1})$ to $W^{m-1,p}(B'_\alpha)$, gives

$$\left\|(\gamma_0\widetilde{f}_\alpha^a)\restriction_{B'_\alpha}\right\|_{W^{m-1,p}(B'_\alpha)}\leq C_\alpha\|f_\alpha^a\|_{W^{m,p}(B_\alpha^+)}.$$

For smooth $\mathbf{u}$, $(\gamma_0\widetilde{f}_\alpha^a)\restriction_{B'_\alpha}$ agrees with $(f_\alpha^a)\restriction_{B'_\alpha}$, since $\widetilde{f}_\alpha^a=f_\alpha^a$ near B'_α within the half-space. Summing over a and using local equivalence of norms in the regular coordinate half-ball gives

$$\sum_{a=1}^r\left\|(\gamma_0\widetilde{f}_\alpha^a)\restriction_{B'_\alpha}\right\|_{W^{m-1,p}(B'_\alpha)}\leq C'_\alpha\|\psi_\alpha\mathbf{u}\|_{W^{m,p}(U_\alpha,\mathbf{E}\restriction_{U_\alpha})}.$$

On the other hand, applying local equivalence of norms on the manifold without boundary ∂M to the restricted bundle $\mathbf{E}\restriction_{\partial M}\to\partial M$ gives

$$\|(\psi_\alpha\mathbf{u})\restriction_{\partial M}\|_{W^{m-1,p}(U_\alpha\cap\partial M,\mathbf{E}\restriction_{U_\alpha\cap\partial M})}\leq C''_\alpha\sum_{a=1}^r\left\|(\gamma_0\widetilde{f}_\alpha^a)\restriction_{B'_\alpha}\right\|_{W^{m-1,p}(B'_\alpha)}.$$

Therefore,

$$\|(\psi_\alpha\mathbf{u})\restriction_{\partial M}\|_{W^{m-1,p}(U_\alpha\cap\partial M,\mathbf{E}\restriction_{U_\alpha\cap\partial M})}\leq C'''_\alpha\|\psi_\alpha\mathbf{u}\|_{W^{m,p}(U_\alpha,\mathbf{E}\restriction_{U_\alpha})}.$$

Now using Lemma 9.4.9, applied to the fixed function ψ_α, there is a constant $C''''_\alpha>0$ such that

$\|\psi_\alpha \mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \leq C''''_\alpha \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}$. Since restricting the global norm to U_α gives a value no greater than the global norm, we conclude that

$$\|(\psi_\alpha \mathbf{u}) \restriction_{\partial M}\|_{W^{m-1,p}(U_\alpha \cap \partial M, \mathbf{E}\restriction_{U_\alpha \cap \partial M})} \leq C''''_\alpha \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

Since there are finitely many charts and $\sum_{\alpha=1}^{N} \psi_\alpha = 1$ on a neighborhood of ∂M, we have $\mathbf{u} \restriction_{\partial M} = \sum_{\alpha=1}^{N} (\psi_\alpha \mathbf{u}) \restriction_{\partial M}$. Using the triangle inequality and local equivalence of norms on $\mathbf{E} \restriction_{\partial M}$ gives a constant $C > 0$ such that

$$\|\mathbf{u} \restriction_{\partial M}\|_{W^{m-1,p}(\partial M, \mathbf{E}\restriction_{\partial M})} \leq C \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}$$

for every $\mathbf{u} \in \Gamma(\mathbf{E})$.

The preceding estimate shows that restriction is a continuous linear operator from $\Gamma(\mathbf{E}) \cap W^{m,p}(M,\mathbf{E})$ to $W^{m-1,p}(\partial M, \mathbf{E} \restriction_{\partial M})$. Theorem 9.4.8 states that its domain is dense in $W^{m,p}(M,\mathbf{E})$, while the target space is Banach. Theorem B.2.36 therefore gives a unique continuous linear extension

$$\mathbf{Tr}\colon W^{m,p}(M,\mathbf{E}) \longrightarrow W^{m-1,p}(\partial M, \mathbf{E} \restriction_{\partial M})$$

and preserves the estimate

$$\|\mathbf{Tr}(\mathbf{u})\|_{W^{m-1,p}(\partial M, \mathbf{E}\restriction_{\partial M})} \leq C \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

□

Figure 9.1. The trace theorem generalizes the idea of restricting a smooth function to the boundary of a manifold. Here $\Omega \subseteq T^2$ is an open subset of the torus whose closure $\overline{\Omega}$ is a manifold with boundary. The blue region represents Ω, while its boundary $\partial\Omega$ is shown in dark blue. The graph of the function $u\colon \overline{\Omega} \longrightarrow \mathbb{R}$ is shown in red and its trace on $\partial\Omega$ in dark red.

9.4.2 Intrinsic Sobolev–Slobodeckij spaces and the exact trace

The integer-order trace theorem gives an estimate in $W^{m-1,p}(\partial M, \mathbf{E}\restriction_{\partial M})$, but this regularity does not fully describe the image. Restriction to a hypersurface loses exactly $\frac{1}{p}$ derivatives. To formulate this assertion without choosing charts or frames, we compare values of a section in different fibers by parallel transport for the induced connection on the boundary.

The construction is presented first on a closed manifold of positive dimension, since ∂M is such a manifold. Let N be a compact Riemannian manifold without boundary, and let $\mathbf{F} \longrightarrow N$ be a smooth vector bundle with a bundle metric and a compatible connection. If N is disconnected, the following definitions apply to the restrictions of these data to each component; compactness ensures that there are only finitely many. For $s > 0$ and $1 \leq p < \infty$, if $N = N_1 \sqcup \cdots \sqcup N_q$, the global norm is defined by

$$\|\mathbf{v}\|_{W^{s,p}(N,\mathbf{F})} := \left(\sum_{\ell=1}^{q} \|\mathbf{v}\restriction_{N_\ell}\|^p_{W^{s,p}(N_\ell, \mathbf{F}\restriction_{N_\ell})} \right)^{\frac{1}{p}}.$$

In dimension zero, set $W^{s,p}(N,\mathbf{F}) := L^p(N,\mathbf{F})$ for every $s > 0$; this is then a finite sum of fibers, with no difference seminorm.

Definition 9.4.13. (Intrinsic Gagliardo seminorm for sections) Let $(N, \mathbf{h})$ be a compact connected Riemannian manifold without boundary of dimension $d \geq 1$, and let $\mathbf{F} \longrightarrow N$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_\mathbf{F}$ and a compatible connection $\nabla^\mathbf{F}$. Set

$$\rho_N := \min\{1, \mathrm{inj}(N)\}.$$

The compact manifold N is complete, and Proposition 2.13.15 shows that the pointwise injectivity radius is continuous and positive. Its minimum on N is therefore strictly positive. For $0 < \sigma < 1$, $1 \leq p < \infty$, and $\mathbf{v} \in L^p(N,\mathbf{F})$ define

$$[\mathbf{v}]_{W^{\sigma,p}(N,\mathbf{F})} := \left(\int_N \int_{\{y \in N \,|\, 0 < d_\mathbf{h}(x,y) < \rho_N\}} \frac{|\mathbf{v}(x) - \mathbf{v}(y)|^p_{\mathbf{h}_\mathbf{F};x,y}}{d_\mathbf{h}(x,y)^{d+\sigma p}} \, d\lambda_\mathbf{h}(y) \, d\lambda_\mathbf{h}(x) \right)^{\frac{1}{p}}. \tag{9.69}$$

The fiberwise separation in the numerator is that of Definition 9.2.4; thus

$$|\mathbf{v}(x) - \mathbf{v}(y)|_{\mathbf{h}_\mathbf{F};x,y} = \left| \mathbf{v}(x) - P^\mathbf{F}_{\gamma_{xy},1\to 0}\mathbf{v}(y) \right|_{\mathbf{h}_\mathbf{F}(x)},$$

where γ_{xy} is the unique short minimizing geodesic from x to y. Transport depends smoothly on (x,y) in the region $0 < d_\mathbf{h}(x,y) < \rho_N$, so the integrand is measurable. Changing a representative on a null set $Z \subseteq N$ changes the integrand only on $(Z \times N) \cup (N \times Z)$, which has zero product measure by Theorem B.6.17. Define

$$W^{\sigma,p}(N,\mathbf{F}) := \left\{ \mathbf{v} \in L^p(N,\mathbf{F}) \,\middle|\, [\mathbf{v}]_{W^{\sigma,p}(N,\mathbf{F})} < \infty \right\}$$

and equip it with the norm

$$\|\mathbf{v}\|_{W^{\sigma,p}(N,\mathbf{F})} := \|\mathbf{v}\|_{L^p(N,\mathbf{F})} + [\mathbf{v}]_{W^{\sigma,p}(N,\mathbf{F})}.$$

If $s = k + \sigma$, with $k \in \mathbb{N}_0$ and $0 < \sigma < 1$, set

$$\mathbf{F}_k := T^{(0,k)}(TN) \otimes \mathbf{F}$$

with its product metric and connection, and define

$$W^{s,p}(N,\mathbf{F}) := \left\{ \mathbf{v} \in W^{k,p}(N,\mathbf{F}) \,\middle|\, [\nabla_w^k \mathbf{v}]_{W^{\sigma,p}(N,\mathbf{F}_k)} < \infty \right\}, \tag{9.70}$$

with

$$\|\mathbf{v}\|_{W^{s,p}(N,\mathbf{F})} := \|\mathbf{v}\|_{W^{k,p}(N,\mathbf{F})} + [\nabla_w^k \mathbf{v}]_{W^{\sigma,p}(N,\mathbf{F}_k)}. \tag{9.71}$$

For $s \in \mathbb{N}_0$, retain the preceding intrinsic definition of $W^{s,p}(N,\mathbf{F})$ using weak covariant derivatives.

The seminorm of order $0 < \sigma < 1$ is the version, for a fixed smooth connection, of the covariant fractional spaces considered in [127, Definition 6.4]; higher orders are obtained by applying it to $\nabla_w^k \mathbf{v}$ with the product connection. Its relationship with Euclidean theory is established by the following localized characterization.

Lemma 9.4.14. (Independence of the comparison radius) Let $(N,\mathbf{h})$ be a compact connected Riemannian manifold without boundary of dimension $d \geq 1$, and let $\mathbf{F} \to N$ be a smooth vector bundle with a bundle metric and a compatible connection. Let $0 < \sigma < 1$, $1 \leq p < \infty$, and $0 < r_1 \leq r_2 \leq \operatorname{inj}(N)$. Denote by $[\mathbf{v}]_{\sigma,p;r_i}$ the expression in (9.69) with r_i in place of ρ_N. There are constants $c, C > 0$, independent of v, such that

$$c\left(\|\mathbf{v}\|_{L^p(N,\mathbf{F})} + [\mathbf{v}]_{\sigma,p;r_1}\right) \leq \|\mathbf{v}\|_{L^p(N,\mathbf{F})} + [\mathbf{v}]_{\sigma,p;r_2} \leq C\left(\|\mathbf{v}\|_{L^p(N,\mathbf{F})} + [\mathbf{v}]_{\sigma,p;r_1}\right).$$

Proof. The first inequality follows from inclusion of the regions of integration. In the region $r_1 \leq d_{\mathbf{h}}(x,y) < r_2$, the isometry property of parallel transport and the inequality $|a-b|^p \leq 2^{p-1}(|a|^p + |b|^p)$ give

$$\frac{|\mathbf{v}(x) - \mathbf{v}(y)|^p_{\mathbf{h}_\mathbf{F};x,y}}{d_{\mathbf{h}}(x,y)^{d+\sigma p}} \leq 2^{p-1} r_1^{-d-\sigma p} \left(|\mathbf{v}(x)|^p_{\mathbf{h}_\mathbf{F}} + |\mathbf{v}(y)|^p_{\mathbf{h}_\mathbf{F}}\right).$$

Integrating over $N \times N$ and using $\lambda_{\mathbf{h}}(N) < \infty$ bounds the contribution of this region by $C\|\mathbf{v}\|^p_{L^p(N,\mathbf{F})}$. This proves the second inequality. □

The following Euclidean fact will control the lower-order terms that arise when a covariant derivative is expressed in a frame.

Lemma 9.4.15. (Fractional control by one integer-order derivative) Let $0 < \sigma < 1$ and $1 \leq p < \infty$. There is $C > 0$ such that

$$\|f\|_{W^{\sigma,p}(\mathbb{R}^d)} \leq C\|f\|_{W^{1,p}(\mathbb{R}^d)}$$

for every $f \in W^{1,p}(\mathbb{R}^d)$. Moreover, if $a \in C_c^\infty(\mathbb{R}^d)$, then

$$\|af\|_{W^{\sigma,p}(\mathbb{R}^d)} \leq C_a\|f\|_{W^{\sigma,p}(\mathbb{R}^d)}.$$

Proof. By Proposition 6.2.2 and Lemma 6.2.4, for $\|z\| < 1$ we have

$$\|\tau_z f - f\|^p_{L^p(\mathbb{R}^d)} \le \|z\|^p \|Df\|^p_{L^p(\mathbb{R}^d,\mathbb{R}^d)},$$

while for $\|z\| \ge 1$ we use $\|\tau_z f - f\|^p_{L^p(\mathbb{R}^d)} \le 2^p \|f\|^p_{L^p(\mathbb{R}^d)}$. The resulting radial integrals are

$$\int_0^1 r^{p(1-\sigma)-1}\, dr < \infty, \qquad \int_1^\infty r^{-\sigma p-1}\, dr < \infty.$$

This proves the first assertion.
For the second, write

$$a(x)f(x) - a(y)f(y) = a(x)(f(x) - f(y)) + (a(x) - a(y))f(y).$$

The first term is controlled by $\|a\|_{L^\infty(\mathbb{R}^d)}[f]_{W^{\sigma,p}(\mathbb{R}^d)}$. For the second, use

$$|a(x) - a(y)| \le C_a \min\{1, \|x - y\|\};$$

the same separation into $\|x-y\| < 1$ and $\|x-y\| \ge 1$ gives a bound by $C_a\|f\|_{L^p(\mathbb{R}^d)}$. Together with the estimate L^p, this yields the result. □

Lemma 9.4.16. (Local comparison of transport and components) Let $(N, \mathbf{h})$ be a compact connected Riemannian manifold without boundary, and let $\mathbf{F} \to N$ be a smooth vector bundle with a bundle metric and a compatible connection. Let (U, φ) be a regular coordinate ball in N. Suppose that there is a geodesically convex normal ball U' such that $\overline{U} \subseteq U'$, $\operatorname{diam}_{\mathbf{h}}(U') < \rho_N$, and both φ and the smooth frame $(\mathbf{e}_1, \dots, \mathbf{e}_r)$ of $\mathbf{F}$ extend to U'. Write $\mathbf{v} = \sum_{a=1}^{r} v^a \mathbf{e}_a$ on U. If $0 < \sigma < 1$ and $1 \le p < \infty$, there are constants $c, C > 0$, independent of $\mathbf{v}$, such that

$$\begin{aligned} c \sum_{a=1}^{r} \|v^a \circ \varphi^{-1}\|_{W^{\sigma,p}(\varphi(U))} &\le \|\mathbf{v}\|_{L^p(U,\mathbf{F})} + [\mathbf{v}]_{W^{\sigma,p}(U,\mathbf{F})} \\ &\le C \sum_{a=1}^{r} \|v^a \circ \varphi^{-1}\|_{W^{\sigma,p}(\varphi(U))}, \end{aligned} \tag{9.72}$$

where the middle seminorm integrates only over pairs of points in U.

Proof. Set $\Omega := \varphi(U)$. In the chart and frame, transport from y to x is represented by a matrix $G(x, y)$. If $c_{xy} := \varphi \circ \gamma_{xy}$, the local parallel transport equation, Proposition 2.7.18, is a linear equation whose coefficient matrices are the connection matrices evaluated along $\dot{c}_{xy}$. Those matrices are bounded on the compact set under consideration, and the length of c_{xy} is comparable to $d_{\mathbf{h}}(x, y)$. The integral form of the equation and Grönwall's inequality in Lemma 1.8.19 therefore give

$$\|G(x, y) - I\| \le C_0 d_{\mathbf{h}}(x, y). \tag{9.73}$$

The same estimate holds for $G(x, y)^{-1} = G(y, x)$.
Uniform equivalence of the bundle norm and the component norm on $\overline{U}$ allows us to deduce from (9.73)

the two inequalities

$$|\mathbf{v}(x)-\mathbf{v}(y)|_{\mathbf{h_F};x,y} \le C_1\big(|v^\flat(x)-v^\flat(y)|+d_{\mathbf{h}}(x,y)|v^\flat(y)|\big), \tag{9.74}$$

$$|v^\flat(x)-v^\flat(y)| \le C_1\big(|\mathbf{v}(x)-\mathbf{v}(y)|_{\mathbf{h_F};x,y}+d_{\mathbf{h}}(x,y)|v^\flat(y)|\big), \tag{9.75}$$

where $v^\flat=(v^1,\dots,v^r)$. On a coordinate ball with compact closure there are constants $c_2, C_2>0$ such that

$$c_2\|\varphi(x)-\varphi(y)\| \le d_{\mathbf{h}}(x,y) \le C_2\|\varphi(x)-\varphi(y)\|, \qquad c_2\,dz \le d\lambda_{\mathbf{h}} \le C_2\,dz.$$

Divide the pth powers in (9.74) and (9.75) by $d_{\mathbf{h}}(x,y)^{d+\sigma p}$ and integrate. The error term is controlled by $\|\mathbf{v}\|^p_{L^p(U,\mathbf{F})}$, since, uniformly in y,

$$\int_{\varphi(U)} \frac{\|z-w\|^p}{\|z-w\|^{d+\sigma p}}\,dz \le C\int_0^{C_2\operatorname{diam}(U)} r^{p(1-\sigma)-1}\,dr<\infty.$$

Comparison of the L^p norms completes both inequalities in (9.72). □

Lemma 9.4.17. (Multiplication by smooth functions) Let $(N,\mathbf{h})$ be a compact connected Riemannian manifold without boundary, and let $\mathbf{F}\to N$ be a smooth vector bundle with a bundle metric and a compatible connection. Let $s>0$, $s\notin\mathbb{N}$, $1\le p<\infty$, and $\chi\in C^\infty(N)$. There is a constant $C_{\chi,s,p}>0$ such that

$$\|\chi\mathbf{v}\|_{W^{s,p}(N,\mathbf{F})} \le C_{\chi,s,p}\|\mathbf{v}\|_{W^{s,p}(N,\mathbf{F})}.$$

Proof. First suppose that $0<s<1$. Compatibility of parallel transport with scalar multiplication gives

$$\begin{aligned}|\chi(x)\mathbf{v}(x)-\chi(y)\mathbf{v}(y)|_{\mathbf{h_F};x,y} \le{}& |\chi(x)|\,|\mathbf{v}(x)-\mathbf{v}(y)|_{\mathbf{h_F};x,y}\\ &+|\chi(x)-\chi(y)|\,|\mathbf{v}(y)|_{\mathbf{h_F}}.\end{aligned}$$

Since N is compact, χ is bounded and Lipschitz. The second term is integrated using $\int_0^{\rho_N} r^{p(1-s)-1}\,dr<\infty$, exactly as in the preceding proof.

Now let $s=k+\sigma$, with $k\ge 1$. The iterated Leibniz rule expresses $\nabla^k_w(\chi\mathbf{v})$ as a finite sum of contractions of $\nabla^{k-j}\chi$ with $\nabla^j_w\mathbf{v}$. The term $j=k$ is controlled by the case of order σ applied to $\nabla^k_w\mathbf{v}$. If $j<k$, then $\nabla^j_w\mathbf{v}\in W^{1,p}(N,\mathbf{F}_j)$. Let us justify this assertion and, at the same time, the Leibniz rule just used. By Theorem 9.1.48, there is a sequence of smooth sections $(\mathbf{v}_\nu)$ converging to $\mathbf{v}$ in $W^{k,p}(N,\mathbf{F})$. For $j<k$, the identities

$$\nabla^j\mathbf{v}_\nu \longrightarrow \nabla^j_w\mathbf{v}, \qquad \nabla(\nabla^j\mathbf{v}_\nu)=\nabla^{j+1}\mathbf{v}_\nu \longrightarrow \nabla^{j+1}_w\mathbf{v}$$

hold in the corresponding spaces L^p. Lemma 9.1.12, applied to the bundle $\mathbf{F}_j$, shows that $\nabla^j_w\mathbf{v}$ belongs to $W^{1,p}(N,\mathbf{F}_j)$ and its first weak derivative is $\nabla^{j+1}_w\mathbf{v}$. The Leibniz formula for $\mathbf{v}_\nu$ passes to the limit in L^p because its coefficients are the smooth bounded derivatives of χ; this establishes the same formula for $\mathbf{v}$.

Now localize in a finite cover and apply a fixed cutoff equal to one on the support of each localization. The cut-off components, extended by zero, belong to $W^{1,p}(\mathbb{R}^d)$; Lemma 9.4.15 then applies on $\mathbb{R}^d$. The cross term from the extension is controlled by the positive distance of the support from the chart boundary. Lemma 9.4.16 allows us to return to the intrinsic seminorm. In each frame, contractions with $\nabla^{k-j}\chi$ are

finite sums of multiplications by smooth coefficients; the second part of the same Euclidean lemma controls them. The derivatives of χ are bounded and the family of charts is finite, so every term is controlled by $C\|\mathbf{v}\|_{W^{s,p}(N,\mathbf{F})}$. The integer-order part of the norm is controlled directly by the same Leibniz rule, the uniform bounds on the derivatives of χ, and the definition of $W^{k,p}(N,\mathbf{F})$. This completes the estimate of the integer-order norm and the fractional seminorm appearing in (9.71). □

Proposition 9.4.18. (Localized characterization of the intrinsic norm) Let $(N,\mathbf{h})$ be a compact connected Riemannian manifold without boundary of dimension $d \geq 1$, and let $\mathbf{F} \to N$ be a smooth vector bundle of rank r with a bundle metric and a compatible connection. Let $s > 0$, $s \notin \mathbb{N}$, and $1 \leq p < \infty$. Choose a finite cover $(U_i,\varphi_i)_{i=1}^N$ of N by regular coordinate balls as in Lemma 9.4.16, a partition of unity $(\psi_i)_{i=1}^N$ with $\operatorname{supp}\psi_i \Subset U_i$, and frames $(\mathbf{e}_{i,1},\dots,\mathbf{e}_{i,r})$ defined on neighborhoods of $\overline{U_i}$. Write

$$\psi_i\mathbf{v} = \sum_{a=1}^{r} v_i^a \mathbf{e}_{i,a} \qquad \text{in } U_i$$

and denote by $\widetilde{v}_i^a$ the extension of $v_i^a \circ \varphi_i^{-1}$ by zero to $\mathbb{R}^d$. There are constants $c,C > 0$, independent of $\mathbf{v}$, such that

$$c\|\mathbf{v}\|_{W^{s,p}(N,\mathbf{F})} \leq \sum_{i=1}^{N}\sum_{a=1}^{r} \|\widetilde{v}_i^a\|_{W^{s,p}(\mathbb{R}^d)} \leq C\|\mathbf{v}\|_{W^{s,p}(N,\mathbf{F})}. \tag{9.76}$$

In particular, the intrinsically defined space is independent of the charts, frames, and partition used to compute the localized norm.

Proof. First consider $0 < s < 1$. Lemma 9.4.17 controls $\psi_i\mathbf{v}$ by $\mathbf{v}$, and Lemma 9.4.16 controls its components inside $\varphi_i(U_i)$. Since $K_i := \varphi_i(\operatorname{supp}\psi_i) \Subset \varphi_i(U_i)$, extension by zero creates no singularity at the chart boundary. If $z \in K_i$ and $w \notin \varphi_i(U_i)$, then $\|z-w\| \geq \delta_i > 0$, and the cross part of the seminorm is bounded by

$$2\int_{K_i} |(v_i^a \circ \varphi_i^{-1})(z)|^p \left(\int_{\mathbb{R}^d\setminus\varphi_i(U_i)} \frac{dw}{\|z-w\|^{d+sp}}\right) dz \leq C\delta_i^{-sp}\|v_i^a \circ \varphi_i^{-1}\|^p_{L^p(\varphi_i(U_i))}.$$

The last inequality uses polar coordinates centered at z; the radial integral is $\displaystyle\int_{\delta_i}^{\infty} r^{-sp-1}\,dr = (sp)^{-1}\delta_i^{-sp}$. This proves the second inequality in (9.76).

For the reverse inequality, use $\mathbf{v} = \displaystyle\sum_{i=1}^{N} \psi_i\mathbf{v}$. The triangle inequality reduces the estimate to each section $\psi_i\mathbf{v}$. Pairs of points contained in U_i are controlled by (9.72). If one point belongs to the support of ψ_i and the other to $N \setminus U_i$, their distance is at least $\operatorname{dist}_{\mathbf{h}}(\operatorname{supp}\psi_i, N\setminus U_i) > 0$; this part is controlled by the L^p norm, as in Lemma 9.4.14. This proves the first inequality when $0 < s < 1$.

Let $s = k + \sigma$, with $k \geq 1$. In each chart, formula (9.39), applied to the localized section $\psi_i\mathbf{v}$, gives the triangular expression

$$(\nabla_w^k(\psi_i\mathbf{v}))^a_{i_1\dots i_k} = \partial_{i_k}\cdots\partial_{i_1} v_i^a + \sum_{b=1}^{r}\sum_{|\beta|\leq k-1} (B_{k,\beta})^a_{b\,i_1\dots i_k}\partial^\beta v_i^b. \tag{9.77}$$

The coefficients and all derivatives used are bounded on the fixed compact sets. Lemma 9.4.15 controls each derivative of order at most $k-1$ in $W^{\sigma,p}$ by the $W^{k,p}$ norm, and its second assertion permits multiplication by the coefficients $B_{k,\beta}$ after inserting a cutoff equal to one on the support under consideration. Consequently,

(9.77) and the formula obtained by solving for the partial derivatives of order k give, in both directions,

$$\sum_{a=1}^{r} \|\widetilde{v}_i^a\|_{W^{k+\sigma,p}(\mathbb{R}^d)} \le C\|\psi_i \mathbf{v}\|_{W^{k+\sigma,p}(N,\mathbf{F})}$$

and

$$\|\psi_i \mathbf{v}\|_{W^{k+\sigma,p}(N,\mathbf{F})} \le C \sum_{a=1}^{r} \|\widetilde{v}_i^a\|_{W^{k+\sigma,p}(\mathbb{R}^d)}.$$

Identity (9.39) was established directly for weak covariant derivatives; thus (9.77) holds almost everywhere for the given section. Its inverse form is obtained by algebraically solving for the leading partial derivatives, without approximation in the fractional norm. Comparison of the fractional part of the components of $\nabla_w^k(\psi_i \mathbf{v})$ with its intrinsic seminorm follows by applying Lemma 9.4.16 to the bundle $\mathbf{F}_k$ for pairs contained in U_i. The section $\nabla_w^k(\psi_i \mathbf{v})$ is supported in $\operatorname{supp}\psi_i \Subset U_i$; if only one of the two points is in U_i, the positive distance from the complement controls this part of the seminorm by the L^p norm, exactly as in the case $0 < s < 1$. This gives the full intrinsic seminorm. Summing over the finite family of charts yields (9.76) for every k. □

Corollary 9.4.19. (Functional structure and density) Let $(N, \mathbf{h})$ be a compact connected Riemannian manifold without boundary, and let $\mathbf{F} \to N$ be a smooth vector bundle with a bundle metric and a compatible connection. Let $s > 0$ and $1 \le p < \infty$. Then $W^{s,p}(N, \mathbf{F})$ is a Banach space. It is separable for $1 \le p < \infty$, reflexive for $1 < p < \infty$, and $\Gamma(\mathbf{F})$ is dense in it.

Proof. Proposition 9.4.18 identifies the norm with a finite norm of Euclidean localizations. If $(\mathbf{v}_j)$ is Cauchy, each localized component converges in the Banach space $W^{s,p}(\mathbb{R}^d)$ by Theorem 6.2.3. The change-of-frame relations and the identity $\sum_{i=1}^{N} \psi_i = 1$, valid for each $\mathbf{v}_j$, pass to the limit in L^p and reconstruct a section $\mathbf{v} \in L^p(N, \mathbf{F})$. The first inequality in (9.76) shows that $\mathbf{v}_j \to \mathbf{v}$ in $W^{s,p}(N, \mathbf{F})$.
For density, approximate each $\widetilde{v}_i^a$ in $W^{s,p}(\mathbb{R}^d)$ by functions in $C_c^\infty(\mathbb{R}^d)$ using the same theorem, and multiply the approximations by a fixed cutoff supported in $\varphi_i(U_i)$ and equal to one on K_i. Reconstruction in the frame $\mathbf{e}_{i,a}$ and summation over i, a give smooth sections; the localized estimate proves convergence. Separability follows from this same finite representation. For $1 < p < \infty$, the map

$$\mathbf{v} \longmapsto \left(\mathbf{v}, \frac{\mathbf{v}(x) - P^{\mathbf{F}}_{\gamma_{xy},1\to 0}\mathbf{v}(y)}{d_{\mathbf{h}}(x,y)^{\frac{d}{p}+\sigma}} \right)$$

realizes the case $0 < s < 1$ as a closed subspace of a product of reflexive L^p spaces. The image is closed because the norm induced by that product is equivalent to the norm already proved complete. For $s = k + \sigma$, consider in the same product the vector formed by $\mathbf{v}, \nabla_w \mathbf{v}, \dots, \nabla_w^k \mathbf{v}$ and the parallel difference quotient of $\nabla_w^k \mathbf{v}$. Closedness of weak covariant derivatives and the preceding completeness again show that the image is closed. A closed subspace of a finite product of reflexive L^p spaces is reflexive. □

Remark 9.4.20. (Dependence on the connection) The seminorm in (9.69) records the connection and is therefore geometrically natural. Nevertheless, two smooth compatible connections on the same compact bundle yield the same space with equivalent norms. Indeed, Proposition 9.4.18 compares both norms with

the same Euclidean localizations; the constants may differ because they depend on the local connection matrices.

We now apply this construction to $N = \partial M$ and $\mathbf{F} = \mathbf{E} \restriction_{\partial M}$, with the induced metric and the connection from Lemma 9.4.11. The resulting fractional regularity is therefore intrinsic to the geometric data of the boundary.

Theorem 9.4.21. (Exact intrinsic trace for vector bundles) Let $(M, \mathbf{g})$ be a compact Riemannian manifold with nonempty smooth boundary, and let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle of finite rank, equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. If $m \in \mathbb{N}$ and $1 < p < \infty$, restriction of smooth sections extends uniquely to a continuous surjective linear operator

$$\mathbf{Tr} : W^{m,p}(M, \mathbf{E}) \longrightarrow W^{m-\frac{1}{p},p}(\partial M, \mathbf{E} \restriction_{\partial M}). \tag{9.78}$$

There is a continuous linear operator

$$\mathbf{Ex} : W^{m-\frac{1}{p},p}(\partial M, \mathbf{E} \restriction_{\partial M}) \longrightarrow W^{m,p}(M, \mathbf{E}) \tag{9.79}$$

such that $\mathbf{TrEx} = I$. In particular, there are constants $C_1, C_2 > 0$ such that

$$\|\mathbf{Tru}\|_{W^{m-\frac{1}{p},p}(\partial M, \mathbf{E}\restriction_{\partial M})} \leq C_1 \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}$$

and

$$\|\mathbf{Exv}\|_{W^{m,p}(M,\mathbf{E})} \leq C_2 \|\mathbf{v}\|_{W^{m-\frac{1}{p},p}(\partial M, \mathbf{E}\restriction_{\partial M})}.$$

Proof. If $\dim M = 1$, the boundary is a finite set and, under the preceding convention, the target space is the finite sum of the fibers of $\mathbf{E}$ over its points. On each interval component, the fundamental theorem of calculus and Hölder's inequality bound endpoint evaluation by the $W^{1,p}$ norm, and therefore by the $W^{m,p}$ norm. Choosing smooth sections supported in disjoint neighborhoods of the endpoints with prescribed values there gives a linear coretraction; its continuity is automatic because the target space is finite-dimensional. For the rest of the proof, assume that $\dim M \geq 2$.

Set $s := m - \frac{1}{p} = (m-1) + (1 - \frac{1}{p})$; since $1 < p < \infty$, its fractional part belongs to $(0,1)$. Choose the regular half-balls, frames, and finite partition $(\psi_\alpha)_{\alpha=1}^N$ from the proof of Theorem 9.4.12, refined so that the tangential charts of ∂M satisfy the hypotheses of Proposition 9.4.18.

First let $\mathbf{u} \in \Gamma(\mathbf{E})$. In a chart write

$$\psi_\alpha \mathbf{u} = \sum_{a=1}^{r} f_\alpha^a \mathbf{e}_{\alpha,a}, \qquad v_\alpha^a := f_\alpha^a \circ \varphi_\alpha^{-1} \quad \text{in } B_\alpha^+.$$

Each v_α^a vanishes on a neighborhood of the spherical part. Its extension by zero $\widetilde{v}_\alpha^a$ to $\mathbb{R}_+^n$ belongs to $W^{m,p}(\mathbb{R}_+^n)$ by Lemma 3.6.8, and

$$\|\widetilde{v}_\alpha^a\|_{W^{m,p}(\mathbb{R}_+^n)} = \|v_\alpha^a\|_{W^{m,p}(B_\alpha^+)}.$$

Apply the operator $\mathcal{E}_m$ from Corollary 3.6.4. The identification $W^{m,p}(\mathbb{R}^n) = H^{m,p}(\mathbb{R}^n)$ in Theorem 6.3.10,

followed by Theorem 6.7.2, gives

$$\begin{aligned}\|\operatorname{tr}(\mathcal{E}_m \widetilde{v}_\alpha^a)\|_{B_{p,p}^{m-\frac{1}{p}}(\mathbb{R}^{n-1})} &\le C\|\mathcal{E}_m \widetilde{v}_\alpha^a\|_{H^{m,p}(\mathbb{R}^n)} \\ &\le C'\|v_\alpha^a\|_{W^{m,p}(B_\alpha^+)}.\end{aligned}$$

Since $m-\frac{1}{p}$ is not an integer, Theorem 6.3.14 identifies $B_{p,p}^{m-\frac{1}{p}}(\mathbb{R}^{n-1})$ with $W^{m-\frac{1}{p},p}(\mathbb{R}^{n-1})$. On the flat ball, the preceding trace agrees with $(v_\alpha^a)\restriction_{B'_\alpha}$. Two extensions of $\widetilde{v}_\alpha^a$ agreeing on the half-space have the same trace: approximate in $W^{m,p}(\mathbb{R}^n_+)$ by functions smooth up to the boundary and use continuity of both trace operators; equivalently, apply the locality recorded in Lemma 3.7.2. Since $\widetilde{v}_\alpha^a$ vanishes on a relative neighborhood of the complement of B'_α in the boundary of the half-space, the same lemma shows that the trace vanishes there. Thus $\operatorname{tr}(\mathcal{E}_m \widetilde{v}_\alpha^a)$ is exactly the extension by zero of the trace on B'_α.

The localized characterization in Proposition 9.4.18 now gives, with $s = m - \frac{1}{p}$,

$$\begin{aligned}\|\mathbf{u}\restriction_{\partial M}\|_{W^{s,p}(\partial M,\mathbf{E}\restriction_{\partial M})} &\le C \sum_{\substack{1\le\alpha\le N\\ 1\le a\le r}} \|\operatorname{tr}(\mathcal{E}_m \widetilde{v}_\alpha^a)\|_{W^{s,p}(\mathbb{R}^{n-1})} \\ &\le C \sum_{\substack{1\le\alpha\le N\\ 1\le a\le r}} \|v_\alpha^a\|_{W^{m,p}(B_\alpha^+)} \\ &\le C \sum_{\alpha=1}^{N} \|\psi_\alpha \mathbf{u}\|_{W^{m,p}(U_\alpha,\mathbf{E})} \\ &\le C\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.\end{aligned}$$

The third line uses local equivalence between partial and covariant derivatives; the fourth uses continuity of multiplication by each ψ_α and finiteness of the atlas. The constants can be chosen simultaneously because only finitely many charts, frames, and cutoffs are involved.

Theorem 9.4.8 and Corollary 9.4.19 allow restriction to extend uniquely and continuously to all of $W^{m,p}(M,\mathbf{E})$. The continuous inclusion

$$W^{m-\frac{1}{p},p}(\partial M,\mathbf{E}\restriction_{\partial M}) \hookrightarrow W^{m-1,p}(\partial M,\mathbf{E}\restriction_{\partial M})$$

follows directly from the definition. By uniqueness of extension from smooth sections, the resulting operator agrees with that in Theorem 9.4.12.

We construct the coretraction. Retain the preceding cover and choose a partition of unity (ϑ_α) on ∂M with $\operatorname{supp}\vartheta_\alpha \Subset U_\alpha \cap \partial M$. For $\mathbf{v} \in W^{m-\frac{1}{p},p}(\partial M,\mathbf{E}\restriction_{\partial M})$ write

$$\vartheta_\alpha \mathbf{v} = \sum_{a=1}^{r} g_\alpha^a \mathbf{e}_{\alpha,a}$$

and extend $g_\alpha^a \circ (\varphi_\alpha\restriction_{\partial M})^{-1}$ by zero to $\mathbb{R}^{n-1}$; denote this extension by $\widetilde{g}_\alpha^a$. Proposition 9.4.18 controls the sum of the $W^{m-\frac{1}{p},p}(\mathbb{R}^{n-1})$ norms of these extensions by the norm of $\mathbf{v}$.

Apply to each component the coretraction ex from Theorem 6.7.2. The result belongs to $H^{m,p}(\mathbb{R}^n) = W^{m,p}(\mathbb{R}^n)$. Choose a cutoff $\chi_\alpha \in C_c^\infty(\mathbb{R}^n)$ whose support, intersected with the upper half-space, lies in the coordinate region, and whose restriction to the hyperplane equals one on a neighborhood of the supports

of all localized components. Multiply $\operatorname{ex}\widetilde{g}_\alpha^a$ by χ_α, transport it to the chart, reconstruct it with the frame $\mathbf{e}_{\alpha,a}$, and extend it by zero outside U_α. Denote the resulting global section by $\mathbf{V}_\alpha$. The support of the factor $\chi_\alpha \operatorname{ex}\widetilde{g}_\alpha^a$ is separated from the artificial part of the chart boundary; thus its transport to U_α and extension by zero have weak derivatives through order m without boundary terms. This follows from the same compactly supported test argument as in Lemma 3.6.8. The Euclidean multiplier bounds and local equivalence of norms give

$$\|\mathbf{V}_\alpha\|_{W^{m,p}(M,\mathbf{E})} \le C_\alpha \sum_{a=1}^{r} \|\widetilde{g}_\alpha^a\|_{W^{m-\frac{1}{p},p}(\mathbb{R}^{n-1})}.$$

Define

$$\mathbf{Exv} := \sum_{\alpha=1}^{N} \mathbf{V}_\alpha.$$

The sum is finite, so the localized estimate proves continuity. Since $\chi_\alpha = 1$ on the support of the boundary data and $\operatorname{tr}\operatorname{ex} = I$, we have

$$\mathbf{TrV}_\alpha = \vartheta_\alpha \mathbf{v}.$$

Summing over α gives $\mathbf{TrExv} = \sum_{\alpha=1}^{N} \vartheta_\alpha \mathbf{v} = \mathbf{v}$. This proves both surjectivity and the stated estimates. □

Theorem 9.4.22. (Higher-order traces) Let $(M,\mathbf{g})$ be a compact Riemannian manifold with nonempty boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank, equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. Let $m \ge 1$ and $1 \le p < \infty$. For each $0 \le j \le m-1$, the smooth restriction operator

$$\mathbf{u} \longmapsto \gamma_0(\nabla^j \mathbf{u}) = (\nabla^j \mathbf{u}) \restriction_{\partial M}, \qquad \mathbf{u} \in \Gamma(\mathbf{E}),$$

extends uniquely to a continuous linear operator

$$\mathbf{Tr}_j \colon W^{m,p}(M,\mathbf{E}) \longrightarrow W^{m-j-1,p}\left(\partial M, \left(T^{(0,j)}(TM) \otimes \mathbf{E}\right) \restriction_{\partial M}\right).$$

Consequently, the operator

$$\mathcal{T}_m \colon W^{m,p}(M,\mathbf{E}) \longrightarrow \bigoplus_{j=0}^{m-1} W^{m-j-1,p}\left(\partial M, \left(T^{(0,j)}(TM) \otimes \mathbf{E}\right) \restriction_{\partial M}\right),$$

defined by $\mathcal{T}_m \mathbf{u} := \left(\mathbf{Tr}_0 \mathbf{u}, \mathbf{Tr}_1 \mathbf{u}, \dots, \mathbf{Tr}_{m-1} \mathbf{u}\right)$ is linear and continuous. If $1 < p < \infty$, we also have the sharper estimate

$$\mathbf{Tr}_j \colon W^{m,p}(M,\mathbf{E}) \longrightarrow W^{m-j-\frac{1}{p},p}\left(\partial M, \left(T^{(0,j)}(TM) \otimes \mathbf{E}\right) \restriction_{\partial M}\right)$$

for every $j \in \{0,\dots,m-1\}$.

Proof. Fix $0 \le j \le m-1$ and write $\mathbf{F}_j := T^{(0,j)}(TM) \otimes \mathbf{E}$. This bundle is equipped with the product metric and induced connection. Moreover, $\mathbf{F}_j \restriction_{\partial M} = \left(T^{(0,j)}(TM) \otimes \mathbf{E}\right) \restriction_{\partial M}$.
Let $\mathbf{u} \in W^{m,p}(M,\mathbf{E})$. By Theorem 9.4.8, there is $(\mathbf{u}_\nu) \subseteq \Gamma(\mathbf{E})$ such that $\mathbf{u}_\nu \to \mathbf{u}$ in $W^{m,p}(M,\mathbf{E})$. For smooth

sections, the recursive definition of covariant differentiation gives

$$\nabla^s(\nabla^j \mathbf{u}_\nu) = \nabla^{s+j}\mathbf{u}_\nu, \qquad 0 \le s \le m-j,$$

after the natural identification of cotangent factors. Consequently, $(\nabla^j \mathbf{u}_\nu)$ is Cauchy in $W^{m-j,p}(M,\mathbf{F}_j)$. Its limit in L^p is $\nabla^j_w \mathbf{u}$; closedness of weak covariant derivatives then shows that $\nabla^j_w \mathbf{u} \in W^{m-j,p}(M,\mathbf{F}_j)$ and its successive derivatives are those expected. Moreover,

$$\|\nabla^j_w \mathbf{u}\|_{W^{m-j,p}(M,\mathbf{F}_j)} \le \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

Since $m-j \ge 1$, we may apply Theorem 9.4.12 to the bundle $\mathbf{F}_j \to M$. This gives a continuous linear operator

$$\mathbf{Tr}^{\mathbf{F}_j} : W^{m-j,p}(M,\mathbf{F}_j) \longrightarrow W^{m-j-1,p}(\partial M, \mathbf{F}_j \restriction_{\partial M}).$$

For $\mathbf{u} \in W^{m,p}(M,\mathbf{E})$, define $\mathbf{Tr}_j \mathbf{u} := \mathbf{Tr}^{\mathbf{F}_j}(\nabla^j_w \mathbf{u})$. Then

$$\|\mathbf{Tr}_j \mathbf{u}\|_{W^{m-j-1,p}(\partial M, \mathbf{F}_j\restriction_{\partial M})} \le C\|\nabla^j_w \mathbf{u}\|_{W^{m-j,p}(M,\mathbf{F}_j)} \le C\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

This proves that $\mathbf{Tr}_j$ is linear and continuous.

If $1 < p < \infty$, instead apply Theorem 9.4.21 to the bundle $\mathbf{F}_j$ at order $m-j$. Since $\nabla^j_w \mathbf{u} \in W^{m-j,p}(M,\mathbf{F}_j)$, we obtain

$$\|\mathbf{Tr}_j \mathbf{u}\|_{W^{m-j-\frac{1}{p},p}(\partial M, \mathbf{F}_j\restriction_{\partial M})} \le C\|\nabla^j_w \mathbf{u}\|_{W^{m-j,p}(M,\mathbf{F}_j)} \le C\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

After composition with the continuous inclusion into $W^{m-j-1,p}(\partial M, \mathbf{F}_j \restriction_{\partial M})$, the resulting operator and the one defined by the integer-order theorem agree on smooth sections and, by density, throughout $W^{m,p}(M,\mathbf{E})$. We now show that this operator extends smooth restriction. If $\mathbf{u} \in \Gamma(\mathbf{E})$, then $\nabla^j_w \mathbf{u} = \nabla^j \mathbf{u}$, and by the definition of the trace operator in Theorem 9.4.12, we have $\mathbf{Tr}^{\mathbf{F}_j}(\nabla^j \mathbf{u}) = (\nabla^j \mathbf{u}) \restriction_{\partial M} = \gamma_0(\nabla^j \mathbf{u})$. Thus $\mathbf{Tr}_j$ extends the smooth operator $\mathbf{u} \mapsto \gamma_0(\nabla^j \mathbf{u})$.

Uniqueness follows from density of smooth sections in $W^{m,p}(M,\mathbf{E})$. Finally, equip the direct sum $\bigoplus_{j=0}^{m-1} W^{m-j-1,p}(\partial M, \mathbf{F}_j \restriction_{\partial M})$ with any of the equivalent product norms. Since each $\mathbf{Tr}_j$ is linear and continuous, there is a constant $C_j > 0$ such that $\|\mathbf{Tr}_j \mathbf{u}\|_{W^{m-j-1,p}(\partial M, \mathbf{F}_j\restriction_{\partial M})} \le C_j \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}$. Summing over $j \in \{0,\dots,m-1\}$ gives

$$\|\mathcal{T}_m \mathbf{u}\| \le \left(\sum_{j=0}^{m-1} C_j\right) \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

Therefore, $\mathcal{T}_m$ is linear and continuous. □

The integration-by-parts formula motivating this construction explains why $\mathcal{T}_m$ is the appropriate boundary operator. Green's formula for ∇^s contains terms of the form

$$\sum_{j=0}^{s-1} (-1)^{s-1-j} \int_{\partial M} \left\langle \nabla^j \mathbf{F}, \iota_{\boldsymbol{\nu}}\big((\mathrm{tr}_{\mathbf{g}} \circ \nabla)^{s-1-j} \mathbf{G}\big) \right\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}} d\lambda_{\tilde{\mathbf{g}}}.$$

Thus the quantities arising naturally on the boundary are restrictions of $\nabla^j \mathbf{F}$ to ∂M, with $0 \le j \le s-1$. This is

why, to characterize $W_0^{m,p}(M,\mathbf{E})$ when $m \geq 2$, vanishing of the trace of $\mathbf{u}$ is insufficient: the traces of its covariant derivatives through order $m-1$ must vanish as well.

Theorem 9.4.23. (Characterization of $W_0^{m,p}(M,\mathbf{E})$ by traces) Let $(M,\mathbf{g})$ be a compact Riemannian manifold with nonempty boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank, equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. Let $m \geq 1$ and $1 \leq p < \infty$. Then $W_0^{m,p}(M,\mathbf{E}) = \ker(\mathcal{T}_m)$. That is,

$$W_0^{m,p}(M,\mathbf{E}) = \left\{ \mathbf{u} \in W^{m,p}(M,\mathbf{E}) \middle| \mathbf{Tr}_j \mathbf{u} = 0 \text{ for every } 0 \leq j \leq m-1 \right\}.$$

Proof. We first prove that $W_0^{m,p}(M,\mathbf{E}) \subseteq \ker(\mathcal{T}_m)$. Let $\mathbf{u} \in W_0^{m,p}(M,\mathbf{E})$. By definition, there is a sequence $(\mathbf{u}_k)_{k\in\mathbb{N}} \subseteq \Gamma_{c,\mathrm{Int}(M)}(\mathbf{E})$ such that $\mathbf{u}_k \to \mathbf{u}$ in $W^{m,p}(M,\mathbf{E})$. Since each $\mathbf{u}_k$ has compact support contained in $\mathrm{Int}(M)$, there is a neighborhood of ∂M on which $\mathbf{u}_k$ vanishes. Thus, for every $0 \leq j \leq m-1$, $\nabla^j \mathbf{u}_k$ also vanishes on a neighborhood of ∂M. Consequently, $\mathbf{Tr}_j \mathbf{u}_k = 0$. Using continuity of $\mathbf{Tr}_j$ gives $\mathbf{Tr}_j \mathbf{u} = \lim_{k\to\infty} \mathbf{Tr}_j \mathbf{u}_k = 0$. Since this holds for every $0 \leq j \leq m-1$, it follows that $\mathbf{u} \in \ker(\mathcal{T}_m)$.

We now prove the reverse inclusion. Let $\mathbf{u} \in \ker(\mathcal{T}_m)$. Take a finite open cover $(U_\alpha)_{\alpha=1}^N$ of M consisting of regular coordinate balls contained in $\mathrm{Int}(M)$ and regular coordinate half-balls near ∂M. Let $(\psi_\alpha)_{\alpha=1}^N$ be a smooth partition of unity subordinate to this cover, with $\operatorname{supp}\psi_\alpha \Subset U_\alpha$. Since $\mathbf{u} = \sum_{\alpha=1}^N \psi_\alpha \mathbf{u}$, it suffices to prove that $\psi_\alpha \mathbf{u} \in W_0^{m,p}(M,\mathbf{E})$ for each $\alpha \in \{1,\dots,N\}$.

Fix $\alpha \in \{1,\dots,N\}$. First we prove that $\mathbf{Tr}_j(\psi_\alpha \mathbf{u}) = 0$ for every $0 \leq j \leq m-1$. Since $\mathbf{u} \in \ker(\mathcal{T}_m)$, we have $\mathbf{Tr}_t \mathbf{u} = 0$ for every $0 \leq t \leq m-1$. By Theorem 9.4.8, there is a sequence $(\mathbf{v}_k)_{k\in\mathbb{N}} \subseteq \Gamma(\mathbf{E})$ such that $\mathbf{v}_k \to \mathbf{u}$ in $W^{m,p}(M,\mathbf{E})$. By continuity of the higher-order traces, given by Theorem 9.4.22, we obtain $\mathbf{Tr}_t \mathbf{v}_k \to \mathbf{Tr}_t \mathbf{u} = 0$ in $W^{m-t-1,p}\left(\partial M, \left(T^{(0,t)}(TM)\otimes\mathbf{E}\right)\restriction_{\partial M}\right)$ for every $0 \leq t \leq m-1$.

Now fix $j \in \{0,\dots,m-1\}$. For smooth sections, the iterated Leibniz rule for the product connection gives, up to the natural permutations of covariant indices,

$$\nabla^j(\psi_\alpha \mathbf{v}_k) = \sum_{t=0}^{j} \binom{j}{t} (\nabla^{j-t}\psi_\alpha) \otimes \nabla^t \mathbf{v}_k.$$

More precisely, this equality means that the right-hand side represents a finite sum of terms obtained from $(\nabla^{j-t}\psi_\alpha)\otimes\nabla^t\mathbf{v}_k$ by permutations of the j covariant indices. Restricting to ∂M gives

$$\mathbf{Tr}_j(\psi_\alpha \mathbf{v}_k) = \sum_{t=0}^{j} \binom{j}{t} \left((\nabla^{j-t}\psi_\alpha)\restriction_{\partial M}\right) \otimes \mathbf{Tr}_t \mathbf{v}_k,$$

again up to those index permutations. This notation suffices for the estimate we need, because index permutations are pointwise isometries, and tensor multiplication by the fixed smooth sections $(\nabla^{j-t}\psi_\alpha)\restriction_{\partial M}$ is continuous on the corresponding Sobolev spaces over the compact manifold ∂M. Since $\mathbf{Tr}_t \mathbf{v}_k \to 0$ for every $0 \leq t \leq j$, we conclude that $\mathbf{Tr}_j(\psi_\alpha \mathbf{v}_k) \to 0$ in $W^{m-j-1,p}\left(\partial M, \left(T^{(0,j)}(TM)\otimes\mathbf{E}\right)\restriction_{\partial M}\right)$.

On the other hand, the map $\mathbf{v} \longmapsto \mathbf{Tr}_j(\psi_\alpha \mathbf{v})$ is continuous from $W^{m,p}(M,\mathbf{E})$ to that same space: this follows from continuity of multiplication by ψ_α on $W^{m,p}(M,\mathbf{E})$, given by Lemma 9.4.9, and continuity of $\mathbf{Tr}_j$. Since $\mathbf{v}_k \to \mathbf{u}$ in $W^{m,p}(M,\mathbf{E})$, we have $\mathbf{Tr}_j(\psi_\alpha \mathbf{v}_k) \to \mathbf{Tr}_j(\psi_\alpha \mathbf{u})$. By uniqueness of the limit, $\mathbf{Tr}_j(\psi_\alpha \mathbf{u}) = 0$. Since j was arbitrary, we obtain $\mathbf{Tr}_j(\psi_\alpha \mathbf{u}) = 0$ for every $0 \leq j \leq m-1$.

Now consider the two types of charts. If U_α is a regular coordinate ball contained in $\mathrm{Int}(M)$, then $\psi_\alpha \mathbf{u}$ has

compact support contained in $\mathrm{Int}(M)$. Take a function $\chi_\alpha \in C_c^\infty(\mathrm{Int}(M))$ such that $\chi_\alpha \equiv 1$ on a neighborhood of $\mathrm{supp}(\psi_\alpha)$. By Theorem 9.4.8, there is a sequence $(\mathbf{z}_k)_{k\in\mathbb{N}} \subseteq \Gamma(\mathbf{E})$ such that $\mathbf{z}_k \to \psi_\alpha \mathbf{u}$ in $W^{m,p}(M,\mathbf{E})$. By Lemma 9.4.9, we have $\chi_\alpha \mathbf{z}_k \to \chi_\alpha \psi_\alpha \mathbf{u} = \psi_\alpha \mathbf{u}$ in $W^{m,p}(M,\mathbf{E})$. Moreover, each $\chi_\alpha \mathbf{z}_k$ is a smooth section with compact support contained in $\mathrm{Int}(M)$. Therefore, $\psi_\alpha \mathbf{u} \in W_0^{m,p}(M,\mathbf{E})$.

Now suppose that U_α is a regular coordinate half-ball. Write $B_\alpha^+ := \varphi_\alpha(U_\alpha \cap \mathrm{Int}(M))$ and $B'_\alpha := \varphi_\alpha(U_\alpha \cap \partial M)$. Take a smooth local frame $(\mathbf{e}_{1,\alpha},\dots,\mathbf{e}_{r,\alpha})$ of $\mathbf{E}$ on U_α, and write locally $\psi_\alpha \mathbf{u} = \sum_{a=1}^{r} w_\alpha^a \mathbf{e}_{a,\alpha}$. Set $q_\alpha^a := w_\alpha^a \circ \varphi_\alpha^{-1}$ on B_α^+, and denote by $\widetilde{q}_\alpha^a$ its extension by zero to $\mathbb{R}_+^n$. Since $\operatorname{supp}\psi_\alpha \Subset U_\alpha$, each q_α^a vanishes outside a compact subset of $B_\alpha^+ \cup B'_\alpha$ lying at positive distance from the spherical part of B_α^+. Thus we may use the preceding convention for these functions.

We want to prove that each q_α^a belongs to the closure of $C_c^\infty(B_\alpha^+)$ in $W^{m,p}(B_\alpha^+)$. By Corollary 3.7.3, it suffices to prove that $\gamma_0 D^\beta q_\alpha^a = 0$ on B'_α, in the sense of the preceding convention, for every $|\beta| \le m-1$ and every a. Explicitly, we must prove that $(\gamma_0 D^\beta \widetilde{q}_\alpha^a) \restriction_{B'_\alpha} = 0$.

We prove this by induction on ℓ. For $\ell = 0$, the equality $\mathbf{Tr}_0(\psi_\alpha \mathbf{u}) = 0$ means that the trace of $\psi_\alpha \mathbf{u}$ vanishes as a section of $\mathbf{E} \restriction_{\partial M}$. In the boundary chart and chosen frame, the trace operator was constructed precisely by taking components, extending them by zero to the half-space, and applying the half-space trace. Therefore, $(\gamma_0 \widetilde{q}_\alpha^a) \restriction_{B'_\alpha} = 0$ for every a.

Suppose that $(\gamma_0 D^\beta \widetilde{q}_\alpha^a) \restriction_{B'_\alpha} = 0$ has been proved for every $|\beta| \le \ell - 1$ and every a, where $1 \le \ell \le m-1$. Since $\mathbf{Tr}_\ell(\psi_\alpha \mathbf{u}) = 0$, the local components of the trace of $\nabla^\ell(\psi_\alpha \mathbf{u})$ vanish on B'_α. By Lemma 9.1.28, applied in the chart $(U_\alpha, \varphi_\alpha)$ and frame $(\mathbf{e}_{1,\alpha},\dots,\mathbf{e}_{r,\alpha})$, we have locally

$$(\nabla^\ell(\psi_\alpha \mathbf{u}))^a_{i_1\dots i_\ell} = \partial_{i_\ell}\cdots\partial_{i_1} w_\alpha^a + \sum_{b=1}^{r}\sum_{|\beta|\le \ell-1} (B_\beta)^a_{b\, i_1\dots i_\ell}\, \partial^\beta w_\alpha^b.$$

To pass this identity to traces, first fix the supports of the approximation. Choose $\chi_\alpha \in C_c^\infty(U_\alpha)$ equal to one near $\operatorname{supp}\psi_\alpha$ and take $\mathbf{z}_k \in \Gamma(\mathbf{E})$ with $\mathbf{z}_k \to \psi_\alpha \mathbf{u}$ in $W^{m,p}(M,\mathbf{E})$, by Theorem 9.4.8. Then $\mathbf{v}_k = \chi_\alpha \mathbf{z}_k$ converges to the same limit in that space by Lemma 9.4.9, and all its supports lie in the fixed compact set $\operatorname{supp}\chi_\alpha$. Denote its coordinate components by $q_{\alpha,k}^a$. Local equivalence of norms and Lemma 3.6.8 give

$$\widetilde{q}_{\alpha,k}^a \longrightarrow \widetilde{q}_\alpha^a \quad \text{in } W^{m,p}(\mathbb{R}_+^n).$$

Here extension by zero is from the half-ball to the half-space, across its spherical part; the fixed compact set is separated from that part, and the flat boundary is not crossed.

For $|\beta| \le \ell$, $D^\beta \widetilde{q}_{\alpha,k}^a \to D^\beta \widetilde{q}_\alpha^a$ in $W^{m-|\beta|,p}(\mathbb{R}_+^n)$, and by continuity of the trace,

$$\gamma_0 D^\beta \widetilde{q}_{\alpha,k}^a \longrightarrow \gamma_0 D^\beta \widetilde{q}_\alpha^a \quad \text{in } W^{m-|\beta|-1,p}(\mathbb{R}^{n-1}).$$

All these spaces embed continuously into $W^{m-\ell-1,p}(\mathbb{R}^{n-1})$. Multiply the coefficients B_β, expressed in the chart, by a cutoff equal to one near the fixed compact set; they then extend to smooth compactly supported coefficients on $\mathbb{R}^n$. Multiplication by them, before and after taking the trace, is continuous. Moreover, the components of $\nabla^\ell \mathbf{v}_k$ converge in $W^{m-\ell,p}(\mathbb{R}_+^n)$, since the covariant derivative of order ℓ is continuous from $W^{m,p}(M,\mathbf{E})$ to $W^{m-\ell,p}(M, T^{(0,\ell)}(TM)\otimes\mathbf{E})$, as proved in Theorem 9.4.22. Apply the local identity to $\mathbf{v}_k$ and take limits in $W^{m-\ell-1,p}(\mathbb{R}^{n-1})$, then restrict to B'_α. This gives exactly the required trace identity for $\psi_\alpha \mathbf{u}$, including when $p = 1$.

Now fix a multi-index γ with $|\gamma| = \ell$. Choose an ordered block $(i_1, \dots, i_\ell)$ in which the index q appears exactly γ_q times. Since weak partial derivatives commute, the leading term of the corresponding component is

$$\partial_{i_\ell} \cdots \partial_{i_1} q_\alpha^a = D^\gamma q_\alpha^a.$$

Taking the trace of that component on B'_α gives

$$0 = \gamma_0(D^\gamma \widetilde{q}_\alpha^a) + \sum_{b=1}^{r} \sum_{|\beta| \le \ell - 1} \gamma_0\left(\widetilde{B}_\beta \, D^\beta \widetilde{q}_\alpha^b\right) \quad \text{in } B'_\alpha,$$

where $\widetilde{B}_\beta$ denotes the smooth coefficient expressed in the chart. The left-hand side is zero because it is a component of $\mathbf{Tr}_\ell(\psi_\alpha \mathbf{u})$. For each term in the sum, compatibility of the trace with multiplication by a smooth function gives

$$\gamma_0\left(\widetilde{B}_\beta \, D^\beta \widetilde{q}_\alpha^b\right) = \widetilde{B}_\beta \restriction_{B'_\alpha} \gamma_0\left(D^\beta \widetilde{q}_\alpha^b\right) = 0,$$

since $|\beta| \le \ell - 1$ and the induction hypothesis applies. This compatibility uses the same sequence with fixed support: if $v_k \to v$ in $W^{m-|\beta|,p}(\mathbb{R}^n_+)$, both $\gamma_0(\widetilde{B}_\beta v_k)$ and $(\widetilde{B}_\beta|_{\mathbb{R}^{n-1}})\gamma_0 v_k$ converge in $W^{m-|\beta|-1,p}(\mathbb{R}^{n-1})$ by the multiplication and trace bounds. They agree for each smooth k; uniqueness of the limit proves the identity used. Consequently,

$$\gamma_0 \left(D^\gamma \widetilde{q}_\alpha^a\right) \restriction_{B'_\alpha} = 0$$

for every $|\gamma| = \ell$ and every a. This completes the induction.

Thus $\gamma_0 D^\beta q_\alpha^a = 0$ on B'_α, in the sense of the preceding convention, for every $|\beta| \le m - 1$ and every a. By Corollary 3.7.3, each q_α^a belongs to the closure of $C_c^\infty(B_\alpha^+)$ in $W^{m,p}(B_\alpha^+)$. Hence, for each a there is a sequence $(\varphi_k^a)_{k \in \mathbb{N}} \subseteq C_c^\infty(B_\alpha^+)$ such that $\varphi_k^a \to q_\alpha^a$ in $W^{m,p}(B_\alpha^+)$.

On $U_\alpha \cap \mathrm{Int}(M)$ define $\mathbf{s}_k := \sum_{a=1}^{r} (\varphi_k^a \circ \varphi_\alpha)\mathbf{e}_{a,\alpha}$. Since each φ_k^a has compact support contained in B_α^+, each $\mathbf{s}_k$ extends by zero to a smooth section with compact support contained in $\mathrm{Int}(M)$. By local equivalence of norms in the regular coordinate half-ball, we have $\mathbf{s}_k \to \psi_\alpha \mathbf{u}$ in $W^{m,p}(M, \mathbf{E})$. Therefore, $\psi_\alpha \mathbf{u} \in W_0^{m,p}(M, \mathbf{E})$.

We have proved that $\psi_\alpha \mathbf{u} \in W_0^{m,p}(M, \mathbf{E})$ for each $\alpha \in \{1, \dots, N\}$. Since $\mathbf{u} = \sum_{\alpha=1}^{N} \psi_\alpha \mathbf{u}$, we conclude that $\mathbf{u} \in W_0^{m,p}(M, \mathbf{E})$. This proves that $\ker(\mathcal{T}_m) \subseteq W_0^{m,p}(M, \mathbf{E})$ and completes the proof. □

9.4.3 Embeddings for sections on compact manifolds with boundary

The localization principle transfers to manifolds with boundary the embeddings established earlier for bundles over manifolds without boundary. In interior charts, the argument of Theorems 9.2.1 and 9.2.2 is repeated. In a boundary chart, the localized section is represented by Sobolev functions on a half-ball; extension by zero from Lemma 3.6.8 allows us to regard them as functions on the half-space, where the continuous and compact parts of Theorem 3.6.6 apply. A smooth partition of unity then combines the local estimates.

Theorem 9.4.24. (Sobolev embedding for bundles over manifolds with boundary) Let $(M, \mathbf{g})$ be a compact Riemannian manifold of dimension n with nonempty smooth boundary, and let $\mathbf{E} \to M$ be a smooth real or complex vector bundle of finite rank, equipped with a bundle metric $\mathbf{h}_\mathbf{E}$ (Hermitian in the complex case)

and a compatible connection $\nabla^{\mathbf{E}}$. Let $j \geq 0$ and $m \geq 1$ be integers and $1 \leq p, q < \infty$ such that

$$j + m - \frac{n}{p} \geq j - \frac{n}{q}.$$

Then the inclusion

$$W^{j+m,p}(M, \mathbf{E}) \hookrightarrow W^{j,q}(M, \mathbf{E})$$

is continuous.

Proof. Choose a finite cover $(U_\alpha, \varphi_\alpha)_{\alpha=1}^N$ consisting of regular coordinate balls contained in $\mathrm{Int}(M)$ and regular coordinate half-balls centered on ∂M. Refining the cover, assume that $\overline{U_\alpha}$ lies in the domain of a smooth local frame $(\mathbf{e}_{1,\alpha}, \dots, \mathbf{e}_{r,\alpha})$ of $\mathbf{E}$. Take a smooth partition of unity $(\psi_\alpha)_{\alpha=1}^N$ subordinate to the cover, with $\operatorname{supp} \psi_\alpha \Subset U_\alpha$.

Let $\mathbf{u} \in W^{j+m,p}(M, \mathbf{E})$. By Lemma 9.4.9, each $\psi_\alpha \mathbf{u}$ belongs to $W^{j+m,p}(M, \mathbf{E})$ and there is $C_0 > 0$, independent of $\mathbf{u}$ and α, such that

$$\|\psi_\alpha \mathbf{u}\|_{W^{j+m,p}(M,\mathbf{E})} \leq C_0 \|\mathbf{u}\|_{W^{j+m,p}(M,\mathbf{E})}.$$

On U_α write

$$\psi_\alpha \mathbf{u} = \sum_{a=1}^{r} u_\alpha^a \mathbf{e}_{a,\alpha}$$

and set $v_\alpha^a := u_\alpha^a \circ \varphi_\alpha^{-1}$. By Lemmas 9.1.44 and 9.4.5, the norm defined by covariant derivatives is equivalent to the sum of the component norms; here we use compatibility of $\nabla^{\mathbf{E}}$ with $\mathbf{h}_{\mathbf{E}}$. In the complex case they apply to the real and imaginary parts. Thus there are constants $c_\alpha, C_\alpha > 0$ such that

$$c_\alpha \sum_{a=1}^{r} \|v_\alpha^a\|_{W^{j+m,p}(\Omega_\alpha)} \leq \|\psi_\alpha \mathbf{u}\|_{W^{j+m,p}(U_\alpha, \mathbf{E}\restriction_{U_\alpha})}$$

and

$$\|\psi_\alpha \mathbf{u}\|_{W^{j,q}(U_\alpha, \mathbf{E}\restriction_{U_\alpha})} \leq C_\alpha \sum_{a=1}^{r} \|v_\alpha^a\|_{W^{j,q}(\Omega_\alpha)},$$

where $\Omega_\alpha := \varphi_\alpha(U_\alpha)$ in an interior chart and $\Omega_\alpha := \varphi_\alpha(U_\alpha \cap \mathrm{Int}(M))$ in a boundary chart.

If U_α is interior, the support of v_α^a is contained in $\varphi_\alpha(\operatorname{supp} \psi_\alpha) \Subset \Omega_\alpha$. Thus $v_\alpha^a \in W_0^{j+m,p}(\Omega_\alpha)$, and we proceed exactly as in the proof of Theorem 9.2.1: apply Theorem 3.3.16 to each localized component. This gives a constant $K_\alpha > 0$ such that

$$\|v_\alpha^a\|_{W^{j,q}(\Omega_\alpha)} \leq K_\alpha \|v_\alpha^a\|_{W^{j+m,p}(\Omega_\alpha)}.$$

Suppose that U_α is a boundary chart. Then $\Omega_\alpha = B_\alpha^+$ is a half-ball. Since $\operatorname{supp} \psi_\alpha \Subset U_\alpha$, there is a compact set $K_\alpha \subseteq B_\alpha^+ \cup B_\alpha'$ lying at positive distance from the spherical part of B_α^+ such that $v_\alpha^a = 0$ almost everywhere on $B_\alpha^+ \setminus K_\alpha$ for every a. By Lemma 3.6.8, the extension by zero $\widetilde{v}_\alpha^a$ belongs to $W^{j+m,p}(\mathbb{R}_+^n)$ and

$$\|\widetilde{v}_\alpha^a\|_{W^{j+m,p}(\mathbb{R}_+^n)} = \|v_\alpha^a\|_{W^{j+m,p}(B_\alpha^+)}.$$

Moreover, all these extensions have support in a fixed compact subset of $\overline{\mathbb{R}_+^n}$ depending only on the chart

and ψ_α. Theorem 3.6.6 gives a constant $K_\alpha > 0$ such that

$$\|\widetilde{v}_\alpha^a\|_{W^{j,q}(\mathbb{R}^n_+)} \le K_\alpha \|\widetilde{v}_\alpha^a\|_{W^{j+m,p}(\mathbb{R}^n_+)}.$$

Restricting to B_α^+ gives

$$\|v_\alpha^a\|_{W^{j,q}(B_\alpha^+)} \le K_\alpha \|v_\alpha^a\|_{W^{j+m,p}(B_\alpha^+)}.$$

In both types of charts, local equivalence of norms gives

$$\|\psi_\alpha \mathbf{u}\|_{W^{j,q}(M,\mathbf{E})} \le \frac{C_\alpha K_\alpha}{c_\alpha} \|\psi_\alpha \mathbf{u}\|_{W^{j+m,p}(M,\mathbf{E})} \le C'_\alpha \|\mathbf{u}\|_{W^{j+m,p}(M,\mathbf{E})}.$$

Since the cover is finite and $\mathbf{u} = \sum_{\alpha=1}^{N} \psi_\alpha \mathbf{u}$, it follows that

$$\|\mathbf{u}\|_{W^{j,q}(M,\mathbf{E})} \le \sum_{\alpha=1}^{N} \|\psi_\alpha \mathbf{u}\|_{W^{j,q}(M,\mathbf{E})} \le C \|\mathbf{u}\|_{W^{j+m,p}(M,\mathbf{E})}.$$

□

Theorem 9.4.25. (Rellich–Kondrashov for bundles over manifolds with boundary) Let $(M, \mathbf{g})$ be a compact Riemannian manifold of dimension n with nonempty smooth boundary, and let $\mathbf{E} \to M$ be a smooth real or complex vector bundle of finite rank, equipped with a bundle metric $\mathbf{h}_\mathbf{E}$ (Hermitian in the complex case) and a compatible connection $\nabla^\mathbf{E}$. Let $j \ge 0$ and $m \ge 1$ be integers and $1 \le p, q < \infty$ such that

$$j + m - \frac{n}{p} > j - \frac{n}{q}.$$

Then the inclusion

$$W^{j+m,p}(M,\mathbf{E}) \hookrightarrow W^{j,q}(M,\mathbf{E})$$

is compact.

Proof. Let $(\mathbf{u}_k)_{k\in\mathbb{N}}$ be a bounded sequence in $W^{j+m,p}(M,\mathbf{E})$. Use the cover, partition of unity, and frames from the preceding proof. For each α and each a, define

$$v_{\alpha,k}^a := (\psi_\alpha \mathbf{u}_k)_\alpha^a \circ \varphi_\alpha^{-1}.$$

Continuity of multiplication by ψ_α and local equivalence of norms show that $(v_{\alpha,k}^a)_k$ is bounded in $W^{j+m,p}(\Omega_\alpha)$. These comparisons use compatibility of $\nabla^\mathbf{E}$ with $\mathbf{h}_\mathbf{E}$, as in Lemmas 9.1.44 and 9.4.5. If the bundle is complex, apply the Euclidean results to the real and imaginary parts of the components.

If U_α is an interior chart, proceed as in the proof of Theorem 9.2.2: Theorem 3.4.2 gives a subsequence converging in $W^{j,q}(\Omega_\alpha)$.

If U_α is a boundary chart, extend each $v_{\alpha,k}^a$ by zero to $\mathbb{R}^n_+$. Lemma 3.6.8 shows that the extensions form a bounded sequence in $W^{j+m,p}(\mathbb{R}^n_+)$ and their supports lie in the same compact subset of $\overline{\mathbb{R}^n_+}$, determined by $\operatorname{supp}\psi_\alpha$. The compact part of Theorem 3.6.6 gives a subsequence converging in $W^{j,q}(\mathbb{R}^n_+)$. Restricting to B_α^+ gives a subsequence converging in $W^{j,q}(B_\alpha^+)$.

Since the numbers of charts and components are finite, successive extractions give a single subsequence, again denoted by $(\mathbf{u}_k)$, for which all sequences $(v^a_{\alpha,k})_k$ are Cauchy in $W^{j,q}(\Omega_\alpha)$. Local equivalence of norms implies that $(\psi_\alpha \mathbf{u}_k)_k$ is Cauchy in $W^{j,q}(U_\alpha, \mathbf{E}\restriction_{U_\alpha})$ for each α. Therefore,

$$\|\mathbf{u}_k - \mathbf{u}_\ell\|_{W^{j,q}(M,\mathbf{E})} \le \sum_{\alpha=1}^{N} \|\psi_\alpha(\mathbf{u}_k - \mathbf{u}_\ell)\|_{W^{j,q}(M,\mathbf{E})} \longrightarrow 0$$

as $k, \ell \to \infty$. Since $W^{j,q}(M,\mathbf{E})$ is complete, the subsequence converges. This proves compactness. □

Corollary 9.4.26. (Embeddings and the critical exponent) Under the geometric hypotheses of the preceding theorems, let $j \ge 0$ and $m \ge 1$ be integers, and let $1 \le p < n/m$. Then

$$W^{j+m,p}(M,\mathbf{E}) \hookrightarrow W^{j,q}(M,\mathbf{E})$$

continuously for $1 \le q \le p^*_m := \dfrac{np}{n-mp}$, and compactly for $1 \le q < p^*_m$.

Proof. Since $mp < n$, the condition $j + m - \dfrac{n}{p} \ge j - \dfrac{n}{q}$ is equivalent to $q \le p^*_m$, and the strict inequality is equivalent to $q < p^*_m$. Apply Theorems 9.4.24 and 9.4.25, respectively. □

The scalar case follows by taking the trivial rank-one bundle with its canonical metric and connection.

Corollary 9.4.27. (Sobolev embedding on compact manifolds with boundary) Let $(M,\mathbf{g})$ be a compact Riemannian manifold of dimension n with nonempty smooth boundary. Let $j \ge 0$ and $m \ge 1$ be integers and $1 \le p, q < \infty$ such that $j + m - \dfrac{n}{p} \ge j - \dfrac{n}{q}$. Then the inclusion

$$W^{j+m,p}(M) \hookrightarrow W^{j,q}(M)$$

is continuous.

Proof. Apply Theorem 9.4.24 to the trivial bundle $M \times \mathbb{R} \to M$, equipped with the usual metric and the connection induced by the exterior differential. Under the canonical identification of its sections with functions, the Sobolev norms agree with the scalar norms. □

Corollary 9.4.28. (Rellich–Kondrashov on compact manifolds with boundary) Let $(M,\mathbf{g})$ be a compact Riemannian manifold of dimension n with nonempty smooth boundary. Let $j \ge 0$ and $m \ge 1$ be integers and $1 \le p, q < \infty$ such that $j + m - \frac{n}{p} > j - \frac{n}{q}$. Then the inclusion

$$W^{j+m,p}(M) \hookrightarrow W^{j,q}(M)$$

is compact.

Proof. This is the case of Theorem 9.4.25 corresponding to the trivial rank-one bundle. □

Corollary 9.4.29. (Compact embedding with a decrease of one order) Let $(M,\mathbf{g})$ be a compact Riemannian manifold with possibly empty smooth boundary, and let $\mathbf{E}\to M$ be a smooth real or complex vector bundle of finite rank, equipped with a bundle metric $\mathbf{h_E}$ (Hermitian in the complex case) and a compatible connection $\nabla^{\mathbf{E}}$. For every integer $m\geq 1$ and every $1\leq p<\infty$, the inclusions

$$W^{m,p}(M,\mathbf{E})\hookrightarrow W^{m-1,p}(M,\mathbf{E}),\qquad W_0^{m,p}(M,\mathbf{E})\hookrightarrow W_0^{m-1,p}(M,\mathbf{E})$$

are compact. Here $W_0^{0,p}(M,\mathbf{E})=L^p(M,\mathbf{E})$.

Proof. In Theorems 9.2.2 and 9.4.25, take $j=m-1$, a gain of one derivative, and the same exponent p in the source and target. The inequality between indices reduces to $1>0$, giving the first inclusion for every $1\leq p<\infty$, including $p=1$.
For the second, if $\mathbf{u}\in W_0^{m,p}(M,\mathbf{E})$, choose $\mathbf{u}_\nu\in\Gamma_{c,\mathrm{Int}(M)}(\mathbf{E})$ with $\mathbf{u}_\nu\to\mathbf{u}$ in $W^{m,p}(M,\mathbf{E})$. The inequality $\|\mathbf{v}\|_{W^{m-1,p}(M,\mathbf{E})}\leq\|\mathbf{v}\|_{W^{m,p}(M,\mathbf{E})}$ implies that the same convergence holds in $W^{m-1,p}(M,\mathbf{E})$; by definition, $\mathbf{u}\in W_0^{m-1,p}(M,\mathbf{E})$. By the first inclusion, a bounded sequence in $W_0^{m,p}$ has a subsequence converging in $W^{m-1,p}$. All its terms belong to $W_0^{m-1,p}$, and this subspace is closed by definition, so the limit also belongs to it. The subspace norm is the induced norm, proving the asserted compactness. □

Remark 9.4.30. (Total orders and dependence of the constants) In terms of total orders, the two preceding theorems state that

$$W^{m,p}(M,\mathbf{E})\hookrightarrow W^{k,q}(M,\mathbf{E})\quad\text{is compact if}\quad m>k\geq 0,\quad 1\leq p,q<\infty,\quad m-\frac{n}{p}>k-\frac{n}{q}.$$

This formulation is obtained by substituting $j=k$ and replacing the gain of derivatives by $m-k$. The same assertion holds with subscript zero in both source and target: continuity of the inclusion carries smooth approximations supported in the interior into $W^{k,q}$, and closedness of $W_0^{k,q}$ retains the limit. If $(m-k)p<n$, the strict condition is equivalent to $q<np/(n-(m-k)p)$; at the critical exponent, only continuity has been asserted in the corresponding Sobolev theorems.
The continuity constants depend on m,k,p,q, M, $\mathbf{g}$, and the smooth data $\mathbf{E}$, $\mathbf{h_E}$, $\nabla^{\mathbf{E}}$. In the proofs they arise from a fixed finite cover, derivatives of its partition functions, and bounds on the coefficients of the metrics, their inverses, and the connections through the orders used. They do not depend on the section or the sequence index. For a varying family of geometric data, uniformity of these constants requires control of those bounds and the charts; compactness of each manifold separately does not provide a uniform constant for the entire family. No assertion in this paragraph includes infinite exponents; embeddings into continuous and Hölder sections are treated separately.

Corollary 9.4.31. (First-order embeddings for the Dirichlet space) Let $(M,\mathbf{g})$ be a compact Riemannian manifold of dimension n with nonempty smooth boundary, and let $\mathbf{E}\to M$ be a smooth real vector bundle of finite rank, equipped with a bundle metric $\mathbf{h_E}$ and a connection $\nabla^{\mathbf{E}}$ compatible with $\mathbf{h_E}$. Let $1\leq q<n$ and define $q^*:=\dfrac{nq}{n-q}$. Then

$$W_0^{1,q}(M,\mathbf{E})\hookrightarrow L^\ell(M,\mathbf{E})$$

continuously for every $1\leq\ell\leq q^*$, and compactly for every $1\leq\ell<q^*$.

Proof. The continuous inclusion follows from Theorem 9.4.24 with $j = 0$ and $m = 1$. The compact inclusion follows from Theorem 9.4.25. In both cases it suffices to restrict the inclusion operators to the closed subspace $W_0^{1,q}(M, \mathbf{E}) \subseteq W^{1,q}(M, \mathbf{E})$. □

To formulate Morrey's embedding up to the boundary, we need to extend the notation of Definition 9.2.6. We do not use the seminorm defined by minimizing geodesics, since that formulation assumes the manifold has no boundary. Instead, we use the Euclidean extension norms already fixed for $C^{k,\alpha}(\overline{\Omega})$.

Definition 9.4.32. (Hölder sections up to the boundary) Let $(M, \mathbf{g})$ be a compact Riemannian manifold with nonempty smooth boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of rank r, equipped with a bundle metric and a compatible connection. Choose a finite cover $(U_\lambda, \varphi_\lambda)_{\lambda=1}^N$ consisting of regular interior coordinate balls and regular boundary coordinate half-balls, a smooth partition of unity $(\psi_\lambda)_{\lambda=1}^N$ subordinate to it, with $\operatorname{supp}\psi_\lambda \Subset U_\lambda$, and local frames $(\mathbf{e}_{\lambda,1}, \dots, \mathbf{e}_{\lambda,r})$ defined on neighborhoods of $\overline{U_\lambda}$. Set

$$\Omega_\lambda := \begin{cases} \varphi_\lambda(U_\lambda), & U_\lambda \subseteq \operatorname{Int}(M), \\ \varphi_\lambda(U_\lambda \cap \operatorname{Int}(M)), & U_\lambda \cap \partial M \neq \varnothing. \end{cases}$$

If $\mathbf{u} \in \Gamma^k(\mathbf{E})$ and

$$\psi_\lambda \mathbf{u} = \sum_{a=1}^{r} u_\lambda^a \mathbf{e}_{\lambda,a} \qquad \text{in } U_\lambda,$$

define

$$\|\mathbf{u}\|_{\Gamma_{\mathcal{A}}^{k,\alpha}(\mathbf{E})} := \sum_{\lambda=1}^{N} \sum_{a=1}^{r} \|u_\lambda^a \circ \varphi_\lambda^{-1}\|_{C^{k,\alpha}(\overline{\Omega_\lambda})}, \tag{9.80}$$

where $k \in \mathbb{N}_0$, $0 < \alpha < 1$, and $\mathcal{A}$ represents the chosen set of local data. Denote by $\Gamma_{\mathcal{A}}^{k,\alpha}(\mathbf{E})$ the space of sections of class C^k up to the boundary for which (9.80) is finite.

Proposition 9.4.33. (Independence of the Hölder norm up to the boundary) Let $(M, \mathbf{g})$ be a compact Riemannian manifold with nonempty smooth boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Let $k \in \mathbb{N}_0$ and $0 < \alpha < 1$. The space and topology in Definition 9.4.32 are independent of the chosen cover, partition of unity, charts, and frames. Moreover, the resulting space is Banach. Henceforth we denote it by $\Gamma^{k,\alpha}(\mathbf{E})$ and omit the subscript $\mathcal{A}$ from its norm.

Proof. Let $\mathcal{A}$ and $\widetilde{\mathcal{A}}$ be two choices of local data. Use a tilde for objects in the second system. For an index μ of $\widetilde{\mathcal{A}}$, the identity $\sum_{\lambda=1}^{N} \psi_\lambda = 1$ gives

$$\widetilde{\psi}_\mu \mathbf{u} = \sum_{\substack{1 \le \lambda \le N \\ U_\lambda \cap \widetilde{U}_\mu \neq \varnothing}} \widetilde{\psi}_\mu \psi_\lambda \mathbf{u}. \tag{9.81}$$

The sum is finite. On an overlap write

$$\mathbf{e}_{\lambda,a} = \sum_{b=1}^{r} (G_{\mu\lambda})^b{}_a \, \widetilde{\mathbf{e}}_{\mu,b}$$

and denote the coordinate change on its domain by

$$\Phi_{\lambda\mu} := \varphi_\lambda \circ \widetilde{\varphi}_\mu^{-1}$$

. If $f_\lambda^a := u_\lambda^a \circ \varphi_\lambda^{-1}$, the component b of the corresponding summand in (9.81), transported to the chart $\widetilde{\varphi}_\mu$, is

$$\left[(\widetilde{\psi}_\mu G_{\mu\lambda})^b_{\ a} \circ \widetilde{\varphi}_\mu^{-1}\right] \left(f_\lambda^a \circ \Phi_{\lambda\mu}\right). \tag{9.82}$$

We explain precisely why this expression defines a continuous operator between the extension norms. The support of the first factor lies in a compact subset of the domain of the coordinate change. In the chart $\widetilde{\varphi}_\mu$, choose a smooth cutoff equal to one on a neighborhood of that compact set, with support still contained in the same domain. Changes of charts on a manifold with boundary extend smoothly to Euclidean open sets containing those compact sets; for two boundary charts the extension crosses the flat face, while in an overlap with an interior chart the compact set lies away from that face. Take an extension $F_\lambda^a \in C^{k,\alpha}(\mathbb{R}^n)$ of f_λ^a. After inserting the preceding cutoff, (9.82) is the restriction of a product of a smooth compactly supported function and F_λ^a composed with a smooth diffeomorphism.
Denote by $T_{\mu\lambda}^{ba} f_\lambda^a$ the function on the right-hand side of (9.82). The Faà di Bruno formula in Theorem 1.1.19 controls derivatives of the composition through order k. For derivatives of order k, we also use

$$[fg]_{C^{0,\alpha}(K)} \le \|f\|_{C^0(K)} [g]_{C^{0,\alpha}(K)} + \|g\|_{C^0(K)} [f]_{C^{0,\alpha}(K)}$$

and the fact that a smooth map is Lipschitz on a compact set. We obtain a constant $C_{\lambda\mu} > 0$ such that

$$\|T_{\mu\lambda}^{ba} f_\lambda^a\|_{C^{k,\alpha}(\overline{\widetilde{\Omega}_\mu})} \le C_{\lambda\mu} \|f_\lambda^a\|_{C^{k,\alpha}(\overline{\Omega_\lambda})}.$$

The inequality is first obtained for an extension F_λ^a, and then the infimum over all extensions is taken in the norm definition.
Sum over the finitely many overlaps, components, and indices. The maximum of the preceding constants is finite, and (9.81) gives

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\widetilde{\mathcal{A}}}(\mathbf{E})} \le C \|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\mathcal{A}}(\mathbf{E})}.$$

Interchanging the two systems gives the reverse inequality.
We prove completeness. If $(\mathbf{u}_j)_{j\in\mathbb{N}}$ is Cauchy for one of these norms, each family of localized components converges in the Banach space $C^{k,\alpha}(\overline{\Omega_\lambda})$, whose completeness was established in Proposition 3.5.4. Reconstruct the limits in each frame, multiply them by cutoffs equal to one on the supports of ψ_λ, and extend them by zero outside U_λ. The finite sum of the resulting sections defines a section $\mathbf{u}$ of class C^k up to the boundary. Since $\mathbf{u}_j = \sum_{\lambda=1}^{N} \psi_\lambda \mathbf{u}_j$, the same transfer estimate shows that $\mathbf{u}_j \to \mathbf{u}$ in $\Gamma^{k,\alpha}(\mathbf{E})$. □

Theorem 9.4.34. (Sobolev–Morrey embedding for bundles over manifolds with boundary) Let $(M, \mathbf{g})$ be a compact Riemannian manifold of dimension n with nonempty smooth boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank, equipped with a bundle metric and a compatible connection. Let $m \in \mathbb{N}$, $1 \le p < \infty$, $k \in \mathbb{N}_0$, and $0 < \alpha < 1$. If

$$k + \alpha \le m - \frac{n}{p}, \tag{9.83}$$

then each element of $W^{m,p}(M,\mathbf{E})$ has a unique representative in $\Gamma^{k,\alpha}(\mathbf{E})$, and there is $C>0$ such that

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le C\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}. \tag{9.84}$$

The restriction of this representative to ∂M agrees with **Tru**.

Proof. Use the local data from Definition 9.4.32. For $\mathbf{u}\in W^{m,p}(M,\mathbf{E})$ write

$$\psi_\lambda \mathbf{u} = \sum_{a=1}^{r} u_\lambda^a \mathbf{e}_{\lambda,a} \qquad \text{in } U_\lambda$$

and set $v_\lambda^a := u_\lambda^a \circ \varphi_\lambda^{-1}$. Continuity of multiplication by ψ_λ, local equivalence between ordinary and covariant derivatives, and finiteness of the family give a constant $C_0>0$, independent of $\mathbf{u}$, such that

$$\sum_{\lambda=1}^{N}\sum_{a=1}^{r} \|v_\lambda^a\|_{W^{m,p}(\Omega_\lambda)} \le C_0\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}. \tag{9.85}$$

If U_λ is an interior chart, the support of v_λ^a is compact in Ω_λ and therefore $v_\lambda^a \in W_0^{m,p}(\Omega_\lambda)$. Theorem 3.5.7 gives

$$\|v_\lambda^a\|_{C^{k,\alpha}(\overline{\Omega_\lambda})} \le C_\lambda \|v_\lambda^a\|_{W^{m,p}(\Omega_\lambda)}. \tag{9.86}$$

Suppose that U_λ is a boundary chart and write $\Omega_\lambda = B_\lambda^+$. There is a compact set

$$K_\lambda \subseteq B_\lambda^+ \cup B_\lambda'$$

containing the essential supports of all components v_λ^a and lying at positive distance from the spherical part of ∂B_λ^+. Lemma 3.6.8 permits extension of v_λ^a by zero across that spherical part, but not across the flat face. Denote this first extension by w_λ^a. Then

$$w_\lambda^a \in W^{m,p}(\mathbb{R}^n_+), \qquad \|w_\lambda^a\|_{W^{m,p}(\mathbb{R}^n_+)} = \|v_\lambda^a\|_{W^{m,p}(B_\lambda^+)}.$$

Now apply the extension operator

$$\mathcal{E}_m \colon W^{m,p}(\mathbb{R}^n_+) \longrightarrow W^{m,p}(\mathbb{R}^n)$$

from Corollary 3.6.4. Choose $R_\lambda>0$ and $\chi_\lambda \in C_c^\infty(B_{\mathrm{euc}}(0,2R_\lambda))$ such that $\chi_\lambda = 1$ on a neighborhood of K_λ, and define

$$T_\lambda v_\lambda^a := \chi_\lambda \mathcal{E}_m w_\lambda^a.$$

This function belongs to $W_0^{m,p}(B_{\mathrm{euc}}(0,2R_\lambda))$, its restriction to B_λ^+ agrees with v_λ^a, and

$$\|T_\lambda v_\lambda^a\|_{W^{m,p}(B_{\mathrm{euc}}(0,2R_\lambda))} \le C_\lambda' \|v_\lambda^a\|_{W^{m,p}(B_\lambda^+)}.$$

Theorem 3.5.7, applied to $T_\lambda v_\lambda^a$, and the definition of the extension norm give

$$\|v_\lambda^a\|_{C^{k,\alpha}(\overline{B_\lambda^+})} \le C_\lambda'' \|v_\lambda^a\|_{W^{m,p}(B_\lambda^+)}. \tag{9.87}$$

For each λ, the continuous representatives of $v_\lambda^1,\dots,v_\lambda^r$ reconstruct a localized section $\mathbf{s}_\lambda$ on U_λ. This sec-

tion agrees almost everywhere with $\psi_\lambda \mathbf{u}$ and, since its components vanish outside the fixed compact set determined by $\operatorname{supp}(\psi_\lambda)$, it extends by zero to a global section of class C^k up to the boundary. Define the global representative by

$$\widetilde{\mathbf{u}} := \sum_{\lambda=1}^{N} \mathbf{s}_\lambda.$$

The sum is finite and agrees almost everywhere with $\sum_{\lambda=1}^{N} \psi_\lambda \mathbf{u} = \mathbf{u}$. Definition 9.4.32, the local estimates, and (9.85) give

$$\|\widetilde{\mathbf{u}}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le C \sum_{\lambda=1}^{N} \sum_{a=1}^{r} \|v_\lambda^a\|_{W^{m,p}(\Omega_\lambda)} \le C' \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

If two representatives continuous up to the boundary define the same class in $L^p(M,\mathbf{E})$, the relative set where they differ is open. Every nonempty relative coordinate ball or half-ball has positive Riemannian volume, so that set is empty. This proves uniqueness.

It remains to identify restriction to the boundary. By Theorem 9.4.8, choose $(\mathbf{u}_j)_{j\in\mathbb{N}} \subseteq \Gamma(\mathbf{E})$ such that $\mathbf{u}_j \to \mathbf{u}$ in $W^{m,p}(M,\mathbf{E})$. Applying (9.84) to differences shows that $\mathbf{u}_j$ converges to the preceding representative in $\Gamma^{k,\alpha}(\mathbf{E})$ and, in particular, uniformly on ∂M. On the other hand, continuity in Theorem 9.4.12 implies

$$\mathbf{u}_j \restriction_{\partial M} = \mathbf{Tr}\mathbf{u}_j \longrightarrow \mathbf{Tr}\mathbf{u} \qquad \text{in } L^p(\partial M, \mathbf{E} \restriction_{\partial M}).$$

Uniform convergence gives the same limit in L^p; uniqueness of the limit identifies the restriction of the representative with the trace. □

Theorem 9.4.35. (Rellich–Kondrashov into Hölder sections up to the boundary) Let $(M,\mathbf{g})$ be a compact Riemannian manifold of dimension n with nonempty smooth boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Let $m \in \mathbb{N}$, $1 \le p < \infty$, $k \in \mathbb{N}_0$, and $0 < \alpha < 1$. If

$$k + \alpha < m - \frac{n}{p},$$

then the embedding

$$W^{m,p}(M,\mathbf{E}) \hookrightarrow \Gamma^{k,\alpha}(\mathbf{E})$$

is compact.

Proof. Let $(\mathbf{u}_j)_{j\in\mathbb{N}}$ be a bounded sequence in $W^{m,p}(M,\mathbf{E})$, and use the localizations from the preceding proof. In an interior chart, each component sequence is bounded in $W_0^{m,p}(\Omega_\lambda)$; Theorem 3.5.10 gives a subsequence converging in $C^{k,\alpha}(\overline{\Omega_\lambda})$.

In a boundary chart, apply to each component the operator T_λ constructed in the preceding proof. The functions $T_\lambda v_{\lambda,j}^a$ form a bounded sequence in $W_0^{m,p}(B_{\mathrm{euc}}(0,2R_\lambda))$. The same Euclidean theorem gives a subsequence converging in $C^{k,\alpha}(\overline{B_{\mathrm{euc}}(0,2R_\lambda)})$; upon restriction, the original components converge in $C^{k,\alpha}(\overline{B_\lambda^+})$. There are only finitely many charts and components. A diagonal extraction produces a single subsequence for which all localized components are Cauchy in their Hölder spaces. By (9.80), the subsequence is Cauchy in $\Gamma^{k,\alpha}(\mathbf{E})$ and converges by completeness established in Proposition 9.4.33. □

Corollary 9.4.36. (Regularity exponents up to the boundary) Let $(M,\mathbf{g})$ be a compact Riemannian manifold of dimension n with nonempty smooth boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Let $m\in\mathbb{N}$ and $1\le p<\infty$, and let $\sigma := m-\frac{n}{p}>0$.

(a) If $\sigma=\ell+\theta$, with $\ell\in\mathbb{N}_0$ and $0<\theta<1$, then

$$W^{m,p}(M,\mathbf{E})\hookrightarrow \Gamma^{\ell,\theta}(\mathbf{E})$$

continuously, and the embedding into $\Gamma^{\ell,\beta}(\mathbf{E})$ is compact for every $0<\beta<\theta$.

(b) If $\sigma=s\in\mathbb{N}$, then, for every $0<\alpha<1$,

$$W^{m,p}(M,\mathbf{E})\hookrightarrow \Gamma^{s-1,\alpha}(\mathbf{E})$$

compactly and, in particular, continuously.

Proof. For $\sigma=\ell+\theta$, the Sobolev–Morrey theorem up to the boundary, Theorem 9.4.34, applied with $k=\ell$ and $\alpha=\theta$, gives the continuous embedding. If $0<\beta<\theta$, then

$$\ell+\beta<m-\frac{n}{p},$$

and Theorem 9.4.35 gives the compact embedding into $\Gamma^{\ell,\beta}(\mathbf{E})$.
If $\sigma=s\in\mathbb{N}$ and $0<\alpha<1$, then

$$(s-1)+\alpha<s=m-\frac{n}{p}.$$

Applying the Rellich–Kondrashov theorem up to the boundary once more with $k=s-1$ gives the compact, and hence continuous, embedding into $\Gamma^{s-1,\alpha}(\mathbf{E})$. □

9.5 The weak Kato inequality

Earlier we proved Kato's inequality for smooth sections. We now extend it to sections in $W^{m,p}(M,\mathbf{E})$ by Theorem 9.4.8. When $1<p<\infty$, reflexivity of the $L^p(M,\mathbf{F})$ spaces of sections of finite-rank bundles allows us to extract the weakly convergent subsequences needed. To include the case $p=1$, where $L^1(M,\mathbf{F})$ is not reflexive, we use the Dunford–Pettis theorem.

Recall that, if $(X,\mathcal{A},\mu)$ is a measure space, a family $\mathcal{F}\subseteq L^1(X,\mathcal{A},\mu)$ is uniformly integrable if $\sup_{f\in\mathcal{F}}\|f\|_{L^1(X)}<\infty$ and, for every $\varepsilon>0$, there is $\delta>0$ such that $\int_A |f|\,d\mu<\varepsilon$ for any $f\in\mathcal{F}$ and $A\in\mathcal{A}$ with $\mu(A)<\delta$.

Theorem 9.5.1. (Dunford–Pettis) Let $(X,\mathcal{A},\mu)$ be a finite measure space. A family $\mathcal{F}\subseteq L^1(X,\mathcal{A},\mu)$ has weakly compact closure in $L^1(X,\mathcal{A},\mu)$ if and only if $\mathcal{F}$ is uniformly integrable.

This is the classical form of the Dunford–Pettis criterion for a finite measure; see [22].

By Theorem B.7.7, the weak topology of $L^1(X,\mathcal{A},\mu)$ agrees with $\sigma(L^1(X,\mathcal{A},\mu),L^\infty(X,\mathcal{A},\mu))$. Thus the preceding statement is equivalent to the classical formulation using L^1–L^∞ duality.

Theorem 9.5.2. (Dunford–Pettis for vector bundles) Let $(M, \mathbf{g})$ be a compact Riemannian manifold with or without boundary, and let $\mathbf{E} \to M$ be a smooth real vector bundle of finite rank equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$. For a family $\mathcal{F} \subseteq L^1(M, \mathbf{E})$, the following assertions are equivalent:

(a) The weak closure of $\mathcal{F}$ in $L^1(M, \mathbf{E})$ is compact.

(b) The family $|\mathcal{F}|_{\mathbf{h}_{\mathbf{E}}} := \{|\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}} \mid \mathbf{u} \in \mathcal{F}\} \subseteq L^1(M)$ is uniformly integrable.

Proof. Since M is compact, there is a finite open cover $(U_\alpha)_{\alpha=1}^N$ of M with a local trivialization of $\mathbf{E}$ defined over each U_α, together with a smooth partition of unity $(\chi_\alpha)_{\alpha=1}^N$ subordinate to this cover. On each U_α fix a smooth local orthonormal frame $(\mathbf{e}_{\alpha,1}, \dots, \mathbf{e}_{\alpha,r})$.
For $\alpha \in \{1, \dots, N\}$ and $a \in \{1, \dots, r\}$, define

$$T_{\alpha,a} \colon L^1(M, \mathbf{E}) \longrightarrow L^1(U_\alpha), \qquad T_{\alpha,a}(\mathbf{u}) := \langle \chi_\alpha \mathbf{u}, \mathbf{e}_{\alpha,a} \rangle_{\mathbf{h}_{\mathbf{E}}}.$$

Since

$$|T_{\alpha,a}(\mathbf{u})| \le \chi_\alpha |\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}} \le |\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}},$$

we have

$$\|T_{\alpha,a}(\mathbf{u})\|_{L^1(U_\alpha)} \le \|\mathbf{u}\|_{L^1(M,\mathbf{E})}.$$

Thus $T_{\alpha,a}$ is linear and norm continuous. By Proposition B.11.12, it is also continuous for the weak topologies.
First suppose that the weak closure $C := \overline{\mathcal{F}}^{\sigma(L^1(M,\mathbf{E}),(L^1(M,\mathbf{E}))')}$ is compact. Weak continuity of $T_{\alpha,a}$ implies that $T_{\alpha,a}(C)$ is weakly compact in $L^1(U_\alpha)$ and contains $T_{\alpha,a}(\mathcal{F})$. By the Hahn–Banach theorem, $(L^1(U_\alpha))'$ separates points of $L^1(U_\alpha)$; by Proposition B.11.7, the weak topology of this space is Hausdorff. Consequently, $T_{\alpha,a}(C)$ is weakly closed. Thus

$$\overline{T_{\alpha,a}(\mathcal{F})}^{\sigma(L^1(U_\alpha),(L^1(U_\alpha))')} \subseteq T_{\alpha,a}(C),$$

and the weak closure of $T_{\alpha,a}(\mathcal{F})$ is compact. Theorem 9.5.1 shows that each family $T_{\alpha,a}(\mathcal{F})$ is uniformly integrable.
For every $\mathbf{u} \in \mathcal{F}$, since

$$\mathbf{u} = \sum_{\alpha=1}^N \chi_\alpha \mathbf{u}$$

and, on U_α,

$$\chi_\alpha \mathbf{u} = \sum_{a=1}^r T_{\alpha,a}(\mathbf{u}) \mathbf{e}_{\alpha,a},$$

we have

$$|\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}} \le \sum_{\alpha=1}^N |\chi_\alpha \mathbf{u}|_{\mathbf{h}_{\mathbf{E}}} \le \sum_{\alpha=1}^N \sum_{a=1}^r |T_{\alpha,a}(\mathbf{u})|.$$

In particular,

$$\sup_{\mathbf{u}\in\mathcal{F}} \|\mathbf{u}\|_{L^1(M,\mathbf{E})} \le \sum_{\alpha=1}^N \sum_{a=1}^r \sup_{\mathbf{u}\in\mathcal{F}} \|T_{\alpha,a}(\mathbf{u})\|_{L^1(U_\alpha)} < \infty.$$

Given $\varepsilon > 0$, for each $(\alpha, a) \in \{1, \dots, N\} \times \{1, \dots, r\}$ there is $\delta_{\alpha,a} > 0$ such that

$$\int_A |T_{\alpha,a}(\mathbf{u})|\, d\lambda_{\mathbf{g}} < \frac{\varepsilon}{Nr}$$

for every $\mathbf{u} \in \mathcal{F}$ and every measurable set $A \subseteq U_\alpha$ with $\lambda_{\mathbf{g}}(A) < \delta_{\alpha,a}$. Taking

$$\delta := \min_{\substack{1 \le \alpha \le N \\ 1 \le a \le r}} \delta_{\alpha,a},$$

if $A \subseteq M$ is measurable and $\lambda_{\mathbf{g}}(A) < \delta$, then

$$\int_A |\mathbf{u}|_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \le \sum_{\alpha=1}^{N} \sum_{a=1}^{r} \int_{A \cap U_\alpha} |T_{\alpha,a}(\mathbf{u})|\, d\lambda_{\mathbf{g}} < \varepsilon$$

for every $\mathbf{u} \in \mathcal{F}$. Consequently, $|\mathcal{F}|_{\mathbf{h_E}}$ is uniformly integrable.
Conversely, suppose that $|\mathcal{F}|_{\mathbf{h_E}}$ is uniformly integrable. Since

$$|T_{\alpha,a}(\mathbf{u})| \le |\mathbf{u}|_{\mathbf{h_E}},$$

we have

$$\sup_{\mathbf{u} \in \mathcal{F}} \|T_{\alpha,a}(\mathbf{u})\|_{L^1(U_\alpha)} \le \sup_{\mathbf{u} \in \mathcal{F}} \|\mathbf{u}\|_{L^1(M,\mathbf{E})} < \infty.$$

Moreover, given $\varepsilon > 0$, there is $\delta > 0$ such that, if $A \subseteq U_\alpha$ is measurable and $\lambda_{\mathbf{g}}(A) < \delta$, then

$$\int_A |T_{\alpha,a}(\mathbf{u})|\, d\lambda_{\mathbf{g}} \le \int_A |\mathbf{u}|_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} < \varepsilon$$

for every $\mathbf{u} \in \mathcal{F}$. Thus each family $T_{\alpha,a}(\mathcal{F})$ is uniformly integrable. Theorem 9.5.1 implies that its weak closure

$$K_{\alpha,a} := \overline{T_{\alpha,a}(\mathcal{F})}^{\sigma(L^1(U_\alpha),(L^1(U_\alpha))')}$$

is compact.
Consider the finite product

$$\mathbb{X} := \prod_{\alpha=1}^{N} \prod_{a=1}^{r} L^1(U_\alpha)$$

equipped, for example, with the norm

$$\|(f_{\alpha,a})_{\alpha,a}\|_{\mathbb{X}} := \sum_{\alpha=1}^{N} \sum_{a=1}^{r} \|f_{\alpha,a}\|_{L^1(U_\alpha)}.$$

Since the product has finitely many factors, the topology of this norm agrees with the product topology. By Proposition B.11.14, the weak topology of $\mathbb{X}$ agrees with the product of the weak topologies of the factors. Consequently,

$$K := \prod_{\alpha=1}^{N} \prod_{a=1}^{r} K_{\alpha,a}$$

is weakly compact in $\mathbb{X}$.

Define

$$T\colon L^1(M,\mathbf{E}) \longrightarrow \mathbb{X}, \qquad T(\mathbf{u}) := (T_{\alpha,a}(\mathbf{u}))_{\alpha,a},$$

and

$$S\colon \mathbb{X} \longrightarrow L^1(M,\mathbf{E}), \qquad S((f_{\alpha,a})_{\alpha,a}) := \sum_{\alpha=1}^{N}\sum_{a=1}^{r} \widetilde{f_{\alpha,a}\mathbf{e}_{\alpha,a}},$$

where the tilde denotes extension by zero outside U_α. The operator S is linear and satisfies

$$\|S((f_{\alpha,a})_{\alpha,a})\|_{L^1(M,\mathbf{E})} \le \sum_{\alpha=1}^{N}\sum_{a=1}^{r} \|f_{\alpha,a}\|_{L^1(U_\alpha)} = \|(f_{\alpha,a})_{\alpha,a}\|_{\mathbb{X}}.$$

Thus S is norm continuous and, by Proposition B.11.12, is continuous from the weak topology of $\mathbb{X}$ to the weak topology of $L^1(M,\mathbf{E})$. Since K is weakly compact, $S(K)$ is weakly compact in $L^1(M,\mathbf{E})$.
Finally, for every $\mathbf{u} \in L^1(M,\mathbf{E})$,

$$S(T(\mathbf{u})) = \sum_{\alpha=1}^{N}\sum_{a=1}^{r} \widetilde{\langle \chi_\alpha \mathbf{u}, \mathbf{e}_{\alpha,a}\rangle_{\mathbf{h}_\mathbf{E}} \mathbf{e}_{\alpha,a}} = \sum_{\alpha=1}^{N} \chi_\alpha \mathbf{u} = \mathbf{u}$$

almost everywhere. Since $T(\mathcal{F}) \subseteq K$, it follows that $\mathcal{F} = S(T(\mathcal{F})) \subseteq S(K)$. Again by Hahn–Banach and Proposition B.11.7, the weak topology of $L^1(M,\mathbf{E})$ is Hausdorff. Thus the compact set $S(K)$ is weakly closed. Consequently, the weak closure of $\mathcal{F}$ is contained in $S(K)$ and is a weakly closed subset of this compact set. Therefore, the weak closure of $\mathcal{F}$ is compact. □

We need the following consequence of weak lower semicontinuity of convex functionals.

Lemma 9.5.3. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{F} \to M$ be a vector bundle of finite rank equipped with a bundle metric $\mathbf{h}_\mathbf{F}$, let $1 \le p < \infty$, and let p' be the conjugate exponent of p. For every nonnegative function $\varphi \in L^{p'}(M)$, the functional

$$\Phi_\varphi\colon L^p(M,\mathbf{F}) \longrightarrow [0,\infty), \qquad \Phi_\varphi(\mathbf{Z}) := \int_M \varphi |\mathbf{Z}|_{\mathbf{h}_\mathbf{F}}\, d\lambda_\mathbf{g},$$

is convex, norm continuous, and lower semicontinuous with respect to $\sigma(L^p(M,\mathbf{F}),(L^p(M,\mathbf{F}))')$.

Proof. Convexity follows from the triangle inequality in the fibers. Moreover, for any $\mathbf{Z},\mathbf{W} \in L^p(M,\mathbf{F})$, Hölder's inequality (Proposition B.7.9) implies

$$|\Phi_\varphi(\mathbf{Z}) - \Phi_\varphi(\mathbf{W})| \le \int_M \varphi |\mathbf{Z}-\mathbf{W}|_{\mathbf{h}_\mathbf{F}}\, d\lambda_\mathbf{g} \le \|\varphi\|_{L^{p'}(M)} \|\mathbf{Z}-\mathbf{W}\|_{L^p(M,\mathbf{F})}.$$

Thus Φ_φ is norm continuous. Since it is also convex, Corollary B.11.17 implies that it is lower semicontinuous with respect to $\sigma(L^p(M,\mathbf{F}),(L^p(M,\mathbf{F}))')$. □

By Lemma 7.2.5, we know that, for a smooth section $\mathbf{u}$, $|\mathbf{u}|_{\mathbf{h}_\mathbf{E}}$ admits a weak derivative almost everywhere on M. Now that we have the concept of a *weak covariant derivative*, it is natural to ask whether this almost-everywhere defined classical derivative agrees with a weak derivative. The following proposition answers this question, which will be important in proving our weak version of Kato's inequality.

Lemma 9.5.4. (Classical and weak derivatives of the modulus of a smooth section) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{F}\to M$ be a smooth real vector bundle of finite rank equipped with a bundle metric $\mathbf{h_F}$ and a compatible connection $\nabla^{\mathbf{F}}$. Let $1\le p<\infty$ and $\mathbf{v}\in\Gamma(\mathbf{F})$. Then $|\mathbf{v}|_{\mathbf{h_F}}\in W^{1,p}_{\mathrm{loc}}(M)$ and $\nabla_w|\mathbf{v}|_{\mathbf{h_F}}=\nabla|\mathbf{v}|_{\mathbf{h_F}}$ almost everywhere on M, where the right-hand side denotes the classical covariant derivative defined almost everywhere. Moreover, $\left|\nabla_w|\mathbf{v}|_{\mathbf{h_F}}\right|_{\mathbf{g}}\le|\nabla^{\mathbf{F}}\mathbf{v}|_{\mathbf{g},\mathbf{h_F}}$ almost everywhere. If, in addition, $\mathbf{v}\in L^p(M,\mathbf{F})$ and $\nabla^{\mathbf{F}}\mathbf{v}\in L^p(M,T^*M\otimes\mathbf{F})$, then $|\mathbf{v}|_{\mathbf{h_F}}\in W^{1,p}(M)$. In particular, this last conclusion holds automatically when M is compact.

Proof. By Lemma 7.2.5, $\nabla|\mathbf{v}|_{\mathbf{h_F}}$ exists almost everywhere on M. Define the measurable 1-form G by

$$G(x):=\begin{cases}\nabla|\mathbf{v}|_{\mathbf{h_F}}(x), & |\mathbf{v}(x)|_{\mathbf{h_F}}>0,\\ 0, & |\mathbf{v}(x)|_{\mathbf{h_F}}=0.\end{cases}$$

On the set where $|\mathbf{v}|_{\mathbf{h_F}}>0$, the classical Kato inequality, Theorem 7.2.6, applied with $s=0$, gives $|G|_{\mathbf{g}}=\left|\nabla|\mathbf{v}|_{\mathbf{h_F}}\right|_{\mathbf{g}}\le|\nabla^{\mathbf{F}}\mathbf{v}|_{\mathbf{g},\mathbf{h_F}}$. On the set where $|\mathbf{v}|_{\mathbf{h_F}}=0$, this inequality also holds by the definition of G. Consequently, $|G|_{\mathbf{g}}\le|\nabla^{\mathbf{F}}\mathbf{v}|_{\mathbf{g},\mathbf{h_F}}$ almost everywhere on M.
For each $\varepsilon>0$, consider the smooth function

$$f_\varepsilon:=\sqrt{|\mathbf{v}|^2_{\mathbf{h_F}}+\varepsilon^2}-\varepsilon.$$

On the open set where $|\mathbf{v}|_{\mathbf{h_F}}>0$, the chain rule implies

$$\nabla f_\varepsilon=\frac{|\mathbf{v}|_{\mathbf{h_F}}}{\sqrt{|\mathbf{v}|^2_{\mathbf{h_F}}+\varepsilon^2}}\nabla|\mathbf{v}|_{\mathbf{h_F}}=\frac{|\mathbf{v}|_{\mathbf{h_F}}}{\sqrt{|\mathbf{v}|^2_{\mathbf{h_F}}+\varepsilon^2}}G.$$

If $|\mathbf{v}|_{\mathbf{h_F}}=0$ at a point, the smooth function $|\mathbf{v}|^2_{\mathbf{h_F}}$ attains its minimum there, and hence $\nabla|\mathbf{v}|^2_{\mathbf{h_F}}=0$. Consequently,

$$\nabla f_\varepsilon=\frac{\nabla|\mathbf{v}|^2_{\mathbf{h_F}}}{2\sqrt{|\mathbf{v}|^2_{\mathbf{h_F}}+\varepsilon^2}}=0$$

at that point. Thus throughout M we have

$$\nabla f_\varepsilon=\frac{|\mathbf{v}|_{\mathbf{h_F}}}{\sqrt{|\mathbf{v}|^2_{\mathbf{h_F}}+\varepsilon^2}}G.$$

Since

$$0\le\frac{|\mathbf{v}|_{\mathbf{h_F}}}{\sqrt{|\mathbf{v}|^2_{\mathbf{h_F}}+\varepsilon^2}}\le 1,$$

it follows that $|\nabla f_\varepsilon|_{\mathbf{g}}\le|G|_{\mathbf{g}}\le|\nabla^{\mathbf{F}}\mathbf{v}|_{\mathbf{g},\mathbf{h_F}}$.
Moreover, $\nabla f_\varepsilon\longrightarrow G$ as $\varepsilon\to 0^+$ pointwise on M, since on the set where $|\mathbf{v}|_{\mathbf{h_F}}>0$ the preceding quotient converges to 1, while on the set where $|\mathbf{v}|_{\mathbf{h_F}}=0$ both 1-forms vanish. Let $K\subseteq M$ be compact. Since $\mathbf{v}$ is smooth, $|\nabla^{\mathbf{F}}\mathbf{v}|_{\mathbf{g},\mathbf{h_F}}\in L^p(K)$ and, by the dominated convergence theorem, $\nabla f_\varepsilon\longrightarrow G$ in $L^p(K,T^*M)$.
On the other hand, $0\le f_\varepsilon\le|\mathbf{v}|_{\mathbf{h_F}}$ and $f_\varepsilon\longrightarrow|\mathbf{v}|_{\mathbf{h_F}}$ pointwise. Again by dominated convergence, $f_\varepsilon\longrightarrow|\mathbf{v}|_{\mathbf{h_F}}$ in

$L^p(K)$.
Now let $\eta \in \Gamma_{c,\mathrm{Int}(M)}(T^*M)$ and choose a compact set K containing the support of η. Since f_ε is smooth,

$$\int_M \langle \nabla f_\varepsilon, \eta \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} = \int_M f_\varepsilon \nabla^* \eta \, d\lambda_{\mathbf{g}}.$$

The preceding strong convergences and Hölder's inequality allow us to pass to the limit and obtain

$$\int_M \langle G, \eta \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} = \int_M |\mathbf{v}|_{\mathbf{h_F}} \nabla^* \eta \, d\lambda_{\mathbf{g}}.$$

By the definition of weak covariant derivatives and local Sobolev spaces,

$$|\mathbf{v}|_{\mathbf{h_F}} \in W^{1,p}_{\mathrm{loc}}(M) \qquad \text{and} \qquad \nabla_w |\mathbf{v}|_{\mathbf{h_F}} = G$$

almost everywhere.
It remains to identify G with the classical derivative. On the set where $|\mathbf{v}|_{\mathbf{h_F}} > 0$, this equality holds by the definition of G itself. If $|\mathbf{v}|_{\mathbf{h_F}} = 0$ at a point where the classical derivative exists, the nonnegative function $|\mathbf{v}|_{\mathbf{h_F}}$ attains its minimum there, so $\nabla |\mathbf{v}|_{\mathbf{h_F}} = 0 = G$.
Since the classical derivative exists almost everywhere, we conclude that $\nabla_w |\mathbf{v}|_{\mathbf{h_F}} = \nabla |\mathbf{v}|_{\mathbf{h_F}}$ almost everywhere on M. The estimate already obtained for G gives

$$\left| \nabla_w |\mathbf{v}|_{\mathbf{h_F}} \right|_{\mathbf{g}} \leq |\nabla^{\mathbf{F}} \mathbf{v}|_{\mathbf{g},\mathbf{h_F}}$$

almost everywhere.
Finally, if $\mathbf{v} \in L^p(M,\mathbf{F})$ and $\nabla^{\mathbf{F}} \mathbf{v} \in L^p(M, T^*M \otimes \mathbf{F})$, the preceding weak identity therefore implies that $|\mathbf{v}|_{\mathbf{h_F}} \in W^{1,p}(M)$. □

Theorem 9.5.5. (Weak Kato inequality) Let $(M,\mathbf{g})$ be a compact Riemannian manifold with or without boundary, and let $\mathbf{E} \to M$ be a smooth real vector bundle of finite rank equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. Let $m \in \mathbb{N}$, $1 \leq p < \infty$, and $\mathbf{u} \in W^{m,p}(M,\mathbf{E})$. Then, for every $s \in \{0,\dots,m-1\}$, $|\nabla_w^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \in W^{1,p}(M)$ and

$$\left| \nabla_w |\nabla_w^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \right|_{\mathbf{g}} \leq |\nabla_w^{s+1} \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$$

almost everywhere on M, where $\nabla_w^0 \mathbf{u} := \mathbf{u}$.

Proof. Fix $s \in \{0,\dots,m-1\}$. By Theorem 9.1.48 if $\partial M = \varnothing$, or Theorem 9.4.8 if $\partial M \neq \varnothing$, there is a sequence $(\mathbf{u}_k)_{k\in\mathbb{N}} \subseteq \Gamma(\mathbf{E}) \cap W^{m,p}(M,\mathbf{E})$ such that $\mathbf{u}_k \to \mathbf{u}$ in $W^{m,p}(M,\mathbf{E})$. The reverse triangle inequality in the fibers implies

$$\left| |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} - |\nabla_w^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \right| \leq |\nabla^s \mathbf{u}_k - \nabla_w^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}},$$

so that $|\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \to |\nabla_w^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ in $L^p(M)$.
By Lemma 9.5.4, each function $|\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}}$ admits a first weak covariant derivative agreeing almost everywhere with its classical derivative. Kato's inequality for smooth sections, Theorem 7.2.6, gives

$$\left| \nabla_w |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \right|_{\mathbf{g}} \leq |\nabla^{s+1} \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}}$$

almost everywhere. Since $|\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \in L^p(M)$ and $|\nabla^{s+1}\mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \in L^p(M)$, we conclude that $|\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \in W^{1,p}(M)$.

Moreover, again by the reverse triangle inequality,

$$\left| |\nabla^{s+1}\mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} - |\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \right| \leq |\nabla^{s+1}\mathbf{u}_k - \nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}},$$

so that $|\nabla^{s+1}\mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \to |\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ in $L^p(M)$. In particular, the sequence $\left(\nabla_w |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}}\right)_{k\in\mathbb{N}}$ is bounded in $L^p(M, T^*M)$.

If $1 < p < \infty$, reflexivity of $L^p(M, T^*M)$ allows us to extract a subsequence, which we continue to denote in the same way, and find $\mathbf{Z} \in L^p(M, T^*M)$ such that

$$\nabla_w |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \rightharpoonup \mathbf{Z} \quad \text{in } L^p(M, T^*M).$$

Now suppose that $p = 1$. Since $|\nabla^{s+1}\mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \to |\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ in $L^1(M)$, the family

$$\left\{ |\nabla^{s+1}\mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \;\middle|\; k \in \mathbb{N} \right\}$$

is uniformly integrable. Convergence in $L^1(M)$ implies that this family is bounded in $L^1(M)$. On the other hand, given $\varepsilon > 0$, there is $N \in \mathbb{N}$ such that

$$\left\| |\nabla^{s+1}\mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} - |\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \right\|_{L^1(M)} < \frac{\varepsilon}{2}$$

for every $k \geq N$. Since every function in $L^1(M)$ has an integral absolutely continuous with respect to $\lambda_{\mathbf{g}}$, and only the functions $|\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}, |\nabla^{s+1}\mathbf{u}_1|_{\mathbf{g},\mathbf{h_E}}, \ldots, |\nabla^{s+1}\mathbf{u}_{N-1}|_{\mathbf{g},\mathbf{h_E}}$ are involved, there is $\delta > 0$ such that $\lambda_{\mathbf{g}}(A) < \delta$ implies

$$\int_A |\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} < \frac{\varepsilon}{2}$$

and

$$\int_A |\nabla^{s+1}\mathbf{u}_j|_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} < \varepsilon$$

for every $j \in \{1, \ldots, N-1\}$. For $k \geq N$ we obtain

$$\int_A |\nabla^{s+1}\mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \leq \left\| |\nabla^{s+1}\mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} - |\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \right\|_{L^1(M)} + \int_A |\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} < \varepsilon.$$

Thus the preceding family is uniformly integrable. Since

$$\left| \nabla_w |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \right|_{\mathbf{g}} \leq |\nabla^{s+1}\mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}},$$

the family

$$\left\{ \left| \nabla_w |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \right|_{\mathbf{g}} \;\middle|\; k \in \mathbb{N} \right\}$$

is also uniformly integrable. Theorem 9.5.2, applied to the bundle T^*M, implies that the weak closure of $\{\nabla_w |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \mid k \in \mathbb{N}\}$ in $L^1(M, T^*M)$ is compact. By the Eberlein–Šmulian theorem (Theorem B.11.36), there

are a subsequence and $\mathbf{Z} \in L^1(M, T^*M)$ such that

$$\nabla_w |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \rightharpoonup \mathbf{Z} \quad \text{in } L^1(M, T^*M).$$

Thus in both cases, after extracting a subsequence if necessary, we may assume that

$$\nabla_w |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \rightharpoonup \mathbf{Z} \quad \text{in } L^p(M, T^*M)$$

for some $\mathbf{Z} \in L^p(M, T^*M)$.
Let $\eta \in \Gamma_{c,\mathrm{Int}(M)}(T^*M)$. Since $\nabla_w |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}}$ is the weak covariant derivative of $|\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}}$, we have

$$\int_M \left\langle \nabla_w |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}}, \eta \right\rangle_\mathbf{g} d\lambda_\mathbf{g} = \int_M |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \nabla^* \eta \, d\lambda_\mathbf{g}.$$

Weak convergence of the left-hand side and strong convergence $|\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \to |\nabla^s_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}$ in $L^p(M)$ allow us to pass to the limit, since $\nabla^* \eta \in L^{p'}(M)$, with the interpretation $p' = \infty$ when $p = 1$, and by Hölder's inequality (Proposition B.7.9)

$$\left| \int_M \left(|\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}} - |\nabla^s_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \right) \nabla^* \eta \, d\lambda_\mathbf{g} \right| \leq \left\| |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}} - |\nabla^s_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \right\|_{L^p(M)} \|\nabla^* \eta\|_{L^{p'}(M)} \longrightarrow 0.$$

Consequently,

$$\int_M \langle \mathbf{Z}, \eta \rangle_\mathbf{g} \, d\lambda_\mathbf{g} = \int_M |\nabla^s_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \nabla^* \eta \, d\lambda_\mathbf{g}.$$

By the definition of weak covariant derivatives, $|\nabla^s_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \in W^{1,p}(M)$ and $\mathbf{Z} = \nabla_w |\nabla^s_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}$.
Finally, let $\varphi \in C^\infty_c(\mathrm{Int}(M))$ be nonnegative. By Lemma 9.5.3,

$$\int_M \varphi \left| \nabla_w |\nabla^s_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \right|_\mathbf{g} d\lambda_\mathbf{g} \leq \liminf_{k\to\infty} \int_M \varphi \left| \nabla_w |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \right|_\mathbf{g} d\lambda_\mathbf{g}.$$

Kato's inequality for smooth sections and convergence $|\nabla^{s+1} \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \to |\nabla^{s+1}_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}$ in $L^p(M)$ imply

$$\liminf_{k\to\infty} \int_M \varphi \left| \nabla_w |\nabla^s \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \right|_\mathbf{g} d\lambda_\mathbf{g} \leq \lim_{k\to\infty} \int_M \varphi |\nabla^{s+1} \mathbf{u}_k|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} = \int_M \varphi |\nabla^{s+1}_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g},$$

where the last convergence follows from Hölder's inequality in Proposition B.7.9, since $\varphi \in L^{p'}(M)$. Thus

$$\int_M \varphi \left(\left| \nabla_w |\nabla^s_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \right|_\mathbf{g} - |\nabla^{s+1}_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \right) d\lambda_\mathbf{g} \leq 0$$

for every nonnegative $\varphi \in C^\infty_c(\mathrm{Int}(M))$. Since the function in parentheses belongs to $L^1_{\mathrm{loc}}(\mathrm{Int}(M))$, we conclude that

$$\left| \nabla_w |\nabla^s_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \right|_\mathbf{g} \leq |\nabla^{s+1}_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}$$

almost everywhere on $\mathrm{Int}(M)$. Since ∂M has measure zero, the inequality also holds almost everywhere on M. □

Remark 9.5.6. The restriction $p < \infty$ comes from the use of Theorem 9.4.8, since smooth sections are not, in general, dense in $W^{m,\infty}(M, \mathbf{E})$ in its norm.

Corollary 9.5.7. (Weak Kato inequality) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{E}\to M$ be a smooth real vector bundle of finite rank equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. Let $m\in\mathbb{N}$, $1\le p<\infty$, and $\mathbf{u}\in W^{m,p}(M,\mathbf{E})$. Then, for every $s\in\{0,\dots,m-1\}$, we have $|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\in W^{1,p}(M)$ and $\left|\nabla_w|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\right|_{\mathbf{g}}\le|\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ almost everywhere on M.

Proof. Apply a smooth exhaustion to the manifold $\mathrm{Int}(M)$, which has no boundary: choose increasing open sets $(\Omega_j)_{j\in\mathbb{N}}$ with smooth boundary, $\overline{\Omega_j}\Subset\mathrm{Int}(M)$ and $\mathrm{Int}(M)=\bigcup_{j\in\mathbb{N}}\Omega_j$. If M is already compact, the preceding theorem also gives the conclusion directly; the exhaustion allows all cases to be treated by the same interior argument. By Proposition 9.1.26, for every $j\in\mathbb{N}$ and every $r\le m$ we have $\mathbf{u}\restriction_{\Omega_j}\in W^{m,p}(\Omega_j,\mathbf{E}\restriction_{\Omega_j})$ and $\nabla_w^r(\mathbf{u}\restriction_{\Omega_j})=(\nabla_w^r\mathbf{u})\restriction_{\Omega_j}$ almost everywhere on Ω_j. Identifying Ω_j with the interior of the compact manifold with boundary $\overline{\Omega_j}$, Theorem 9.5.5 implies that $|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\restriction_{\Omega_j}\in W^{1,p}(\Omega_j)$ and there is $\mathbf{v}_j\in L^p(\Omega_j,T^*\Omega_j)$ such that $\mathbf{v}_j=\nabla_w|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ on Ω_j and $|\mathbf{v}_j|_{\mathbf{g}}\le|\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ almost everywhere on Ω_j.
If $j\le k$, then $|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\restriction_{\Omega_j}$ is the restriction of $|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\restriction_{\Omega_k}$ to Ω_j, and by Proposition 9.1.26 the weak derivative of this restriction is $\mathbf{v}_k\restriction_{\Omega_j}$, while by definition it is also $\mathbf{v}_j$. Uniqueness of the weak covariant derivative gives $\mathbf{v}_k\restriction_{\Omega_j}=\mathbf{v}_j$ almost everywhere on Ω_j. Thus there is a measurable section $\mathbf{v}$ of T^*M such that $\mathbf{v}\restriction_{\Omega_j}=\mathbf{v}_j$ almost everywhere on Ω_j for every $j\in\mathbb{N}$. Since $|\mathbf{v}|_{\mathbf{g}}\le|\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ almost everywhere on each Ω_j and $\mathrm{Int}(M)=\bigcup_{j\in\mathbb{N}}\Omega_j$, this inequality holds almost everywhere on M, since ∂M has zero n-dimensional measure. Extend $\mathbf{v}$ by any value, for example zero, on ∂M, giving $\int_M|\mathbf{v}|_{\mathbf{g}}^p\,d\lambda_{\mathbf{g}}\le\int_M|\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}^p\,d\lambda_{\mathbf{g}}<\infty$ and consequently $\mathbf{v}\in L^p(M,T^*M)$.
Finally, let $\mathbf{X}\in\Gamma_{c,\mathrm{Int}(M)}(T^*M)$. Since $\mathrm{supp}(\mathbf{X})$ is a compact subset of the interior and $(\Omega_j)_{j\in\mathbb{N}}$ is an increasing exhaustion of it, there is $j\in\mathbb{N}$ such that $\mathrm{supp}(\mathbf{X})\subseteq\Omega_j$. Since $\mathbf{v}\restriction_{\Omega_j}=\mathbf{v}_j$ and $\mathbf{v}_j$ is the weak derivative of $|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\restriction_{\Omega_j}$, we have

$$\int_M\langle\mathbf{v},\mathbf{X}\rangle_{\mathbf{g}}\,d\lambda_{\mathbf{g}}=\int_{\Omega_j}\langle\mathbf{v}_j,\mathbf{X}\rangle_{\mathbf{g}}\,d\lambda_{\mathbf{g}}=\int_{\Omega_j}|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\nabla^*\mathbf{X}\,d\lambda_{\mathbf{g}}=\int_M|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\nabla^*\mathbf{X}\,d\lambda_{\mathbf{g}}.$$

The first and last equalities follow because $\mathrm{supp}(\mathbf{X})\subseteq\Omega_j$ and, by locality of ∇^*, $\mathrm{supp}(\nabla^*\mathbf{X})\subseteq\mathrm{supp}(\mathbf{X})$. Thus $\mathbf{v}=\nabla_w|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$. Since $|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\in L^p(M)$ and $\mathbf{v}\in L^p(M,T^*M)$, we conclude that $|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\in W^{1,p}(M)$, and the inequality $\left|\nabla_w|\nabla_w^s\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}\right|_{\mathbf{g}}\le|\nabla_w^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ holds almost everywhere on M. □

9.6 The Poincaré inequality in the compact case

The Poincaré inequality controls the L^p norm of a section, and hence its Sobolev norm, solely in terms of its first weak covariant derivative. More precisely, an estimate of the form $\|\mathbf{u}\|_{W^{1,p}(M,\mathbf{E})}\le C\|\nabla_w^{\mathbf{E}}\mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})}$ is equivalent, by the definition of the Sobolev norm, to estimating $\|\mathbf{u}\|_{L^p(M,\mathbf{E})}$ by $\|\nabla_w^{\mathbf{E}}\mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})}$. Such an estimate, however, cannot hold throughout $W^{1,p}(M,\mathbf{E})$ when the connection admits nonzero parallel sections.

The trivial bundle immediately exhibits this obstruction. If M is a compact Riemannian manifold and $\mathbf{E}=M\times\mathbb{R}$ is equipped with the trivial metric and connection, and $u\equiv c$ with $c\neq0$, then $u\in W^{1,p}(M)$ and $\nabla_w u=0$, while $\|u\|_{L^p(M)}>0$. In a general vector bundle, the same obstruction is given by the kernel of the weak covariant derivative, that is, the sections $\mathbf{u}$ satisfying $\nabla_w^{\mathbf{E}}\mathbf{u}=0$. Thus the Poincaré inequality does not control a section absolutely, but only modulo the space of parallel sections.

This observation allows a unified treatment of the different forms of the inequality. One possibility is to project each section onto the kernel of the connection and estimate the difference between the section and its parallel component. For the trivial bundle over a connected manifold, the kernel consists of constant functions and the corresponding projection is precisely the mean. Another possibility is to impose a homogeneous Dirichlet condition: if every connected component of the manifold has nonempty boundary, no nonzero parallel section can have zero trace. Both formulations remove the same obstruction by different mechanisms.

We begin by describing the space of parallel sections and a continuous projection onto it. For this we need a preliminary lemma about functions whose weak derivative is 0.

Lemma 9.6.1. (Functions with zero weak covariant derivative) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $1 \le p < \infty$, and let $u \in W^{1,p}(M)$. If

$$\nabla_w u = 0$$

almost everywhere on M, then u is constant almost everywhere on each connected component of M. In particular, if M is connected, there is $c \in \mathbb{R}$ such that $u = c$ almost everywhere on M.

Proof. If $\dim M = 0$, the assertion is immediate. Henceforth suppose that $\dim M = n \ge 1$ and fix a connected component M_α of M.

By Proposition 1.2.11, M_α admits a countable open cover by regular coordinate balls and regular coordinate half-balls; write this cover as

$$(U_i, \varphi_i)_{i \in I}.$$

For each $i \in I$, define

$$\Omega_i := \varphi_i\big(U_i \cap \operatorname{Int}(M)\big).$$

Then Ω_i is an open ball or an open half-ball in $\mathbb{R}^n$, as appropriate; in particular, Ω_i is connected.

We now examine the situation locally. Since $u \in W^{1,p}(M)$ and $\nabla_w u = 0$ almost everywhere on M, Proposition 9.1.26 implies that

$$u \restriction_{U_i} \in W^{1,p}(U_i) \quad \text{and} \quad \nabla_w(u \restriction_{U_i}) = (\nabla_w u) \restriction_{U_i} = 0 \quad \text{almost everywhere on } U_i.$$

If M has boundary, the preceding application is justified by the identification described in Section 9.4. Indeed, $u \restriction_{\operatorname{Int}(M)}$ belongs to $W^{1,p}(\operatorname{Int}(M))$ and its weak covariant derivative agrees almost everywhere with $(\nabla_w u) \restriction_{\operatorname{Int}(M)} = 0$. Apply the proposition to the manifold without boundary $\operatorname{Int}(M)$ and the open set $U_i \cap \operatorname{Int}(M) = \operatorname{Int}(U_i)$. Using that identification again, now on U_i, gives the preceding assertions: the test sections have compact support in $\operatorname{Int}(U_i)$ and $U_i \cap \partial M$ has zero Riemannian measure, so both membership in $W^{1,p}$ and the identity of weak derivatives are preserved.

Since we are dealing with scalar functions, the covariant derivative agrees with the differential. Thus, applying Lemmas 9.1.44 and 9.4.5 to the trivial rank-one bundle, we find that the local representation

$$v_i := u \circ \varphi_i^{-1}$$

belongs to $W^{1,p}(\Omega_i)$ and satisfies

$$D_j v_i = 0 \quad \text{almost everywhere on } \Omega_i, \qquad j = 1, \dots, n.$$

In other words, all first Euclidean weak derivatives of v_i vanish almost everywhere.
By Lemma 3.1.5, there is a constant $c_i \in \mathbb{R}$ such that

$$v_i = c_i \quad \text{almost everywhere on } \Omega_i.$$

Returning to the manifold, this means that

$$u = c_i \quad \text{almost everywhere on } U_i \cap \mathrm{Int}(M).$$

We claim that in fact also

$$u = c_i \quad \text{almost everywhere on } U_i.$$

Indeed, if U_i is a regular coordinate ball, then $U_i \subseteq \mathrm{Int}(M)$ and there is nothing to prove. If U_i is a regular coordinate half-ball, then

$$U_i \setminus \big(U_i \cap \mathrm{Int}(M)\big) = U_i \cap \partial M.$$

Under the chart φ_i, this set corresponds to the flat face of a half-ball, which has zero n-dimensional Lebesgue measure. Since Riemannian measure in coordinates is given by $\sqrt{\det(\mathbf{g})}\, d\lambda_n$, with a smooth strictly positive factor, it follows that $U_i \cap \partial M$ also has zero Riemannian measure. Therefore,

$$u = c_i \quad \text{almost everywhere on } U_i.$$

We now show that the local constants agree on overlaps. Let $i, j \in I$ be such that $U_i \cap U_j \neq \varnothing$. Since $U_i \cap U_j$ is a nonempty open subset of the manifold M_α, there is $x \in U_i \cap U_j$. If $x \in \mathrm{Int}(M)$, some open neighborhood of x in M lies in $\mathrm{Int}(M)$, and hence

$$(U_i \cap U_j) \cap \mathrm{Int}(M) \neq \varnothing.$$

If $x \in \partial M$, since $U_i \cap U_j$ is open in the manifold with boundary, its expression in half-ball coordinates contains a small half-ball; in particular, it also contains points of $\mathrm{Int}(M)$. In either case,

$$(U_i \cap U_j) \cap \mathrm{Int}(M)$$

is a nonempty open subset of $\mathrm{Int}(M)$ and therefore has positive Riemannian measure.
But on that set we have, almost everywhere,

$$u = c_i \qquad \text{and} \qquad u = c_j.$$

It follows that $c_i = c_j$. Thus the constants $\{c_i\}_{i \in I}$ are compatible on nonempty intersections.
Since M_α is connected, we conclude that all constants c_i agree with a single constant, denoted by c_α. Moreover, since the cover is countable, the union of the exceptional null sets where the local equalities may fail still has measure zero. Therefore,

$$u = c_\alpha \quad \text{almost everywhere on } M_\alpha.$$

Since the connected component M_α was arbitrary, we conclude that u is constant almost everywhere on

each connected component of M. In particular, if M is connected, there is $c \in \mathbb{R}$ such that

$$u = c \quad \text{almost everywhere on } M.$$

□

Proposition 9.6.2. (The space of parallel sections and its projection) Let $(M, \mathbf{g})$ be a compact Riemannian manifold of dimension n with or without boundary, and let $\mathbf{E} \to M$ be a smooth real vector bundle of finite rank equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. For fixed $1 \le p < \infty$, define $\mathcal{K}(\mathbf{E}) := \left\{ \mathbf{v} \in W^{1,p}(M, \mathbf{E}) \middle| \nabla^{\mathbf{E}}_w \mathbf{v} = 0 \right\}$. Then this definition is independent of the exponent p, the space $\mathcal{K}(\mathbf{E})$ is finite-dimensional, and there is a continuous linear projection $\mathsf{P}_{\mathbf{E}} \colon L^p(M, \mathbf{E}) \longrightarrow \mathcal{K}(\mathbf{E})$.
More precisely, if $(\sigma_1, \dots, \sigma_N)$ is an orthonormal basis of $\mathcal{K}(\mathbf{E})$ with respect to the inner product of $L^2(M, \mathbf{E})$, one may take $\mathsf{P}_{\mathbf{E}} \mathbf{u} := \sum_{j=1}^{N} \left(\int_M \langle \mathbf{u}, \sigma_j \rangle_{\mathbf{h_E}} \, d\lambda_{\mathbf{g}} \right) \sigma_j$, with the convention $\mathsf{P}_{\mathbf{E}} = 0$ when $\mathcal{K}(\mathbf{E}) = \{0\}$.

Proof. If $\mathbf{v} \in \mathcal{K}(\mathbf{E})$, the weak Kato inequality, Corollary 9.5.7, implies that $|\mathbf{v}|_{\mathbf{h_E}} \in W^{1,p}(M)$ and $\left| \nabla_w |\mathbf{v}|_{\mathbf{h_E}} \right|_{\mathbf{g}} \le |\nabla^{\mathbf{E}}_w \mathbf{v}|_{\mathbf{g}, \mathbf{h_E}} = 0$ almost everywhere. Lemma 9.6.1 shows that $|\mathbf{v}|_{\mathbf{h_E}}$ is constant almost everywhere on each connected component of M. Since M is compact and has finitely many connected components, it follows that $\mathbf{v} \in L^\infty(M, \mathbf{E})$. Consequently, $\mathbf{v} \in L^q(M, \mathbf{E})$ for every $1 \le q < \infty$ and, since $\nabla^{\mathbf{E}}_w \mathbf{v} = 0$ is independent of the integrability exponent, we have $\mathbf{v} \in W^{1,q}(M, \mathbf{E})$ and $\nabla^{\mathbf{E}}_w \mathbf{v} = 0$ for every q. This proves that the kernel under consideration is independent of p.
Consider the closed ball $B := \left\{ \mathbf{v} \in \mathcal{K}(\mathbf{E}) \middle| \|\mathbf{v}\|_{L^p(M,\mathbf{E})} \le 1 \right\}$. Since $\nabla^{\mathbf{E}}_w \mathbf{v} = 0$ for every $\mathbf{v} \in \mathcal{K}(\mathbf{E})$, the norms $L^p(M, \mathbf{E})$ and $W^{1,p}(M, \mathbf{E})$ agree on $\mathcal{K}(\mathbf{E})$. By Corollary 9.4.29, applied with $m = 1$, B is relatively compact in $L^p(M, \mathbf{E})$. Moreover, B is closed in $L^p(M, \mathbf{E})$: if $\mathbf{v}_k \in B$ and $\mathbf{v}_k \to \mathbf{v}$ in $L^p(M, \mathbf{E})$, then $\nabla^{\mathbf{E}}_w \mathbf{v}_k = 0 \to 0$ in $L^p(M, T^*M \otimes \mathbf{E})$ and, by Lemma 9.1.12, $\mathbf{v} \in W^{1,p}(M, \mathbf{E})$ and $\nabla^{\mathbf{E}}_w \mathbf{v} = 0$. Thus B is compact, and consequently $\mathcal{K}(\mathbf{E})$ is finite-dimensional.
Every element of $\mathcal{K}(\mathbf{E})$ belongs to $L^\infty(M, \mathbf{E})$ and, in particular, to $L^2(M, \mathbf{E})$, so a basis $(\sigma_1, \dots, \sigma_N)$ orthonormal with respect to the inner product of $L^2(M, \mathbf{E})$ may be chosen. For $\mathbf{u} \in L^p(M, \mathbf{E})$, the integrals in the definition of $\mathsf{P}_{\mathbf{E}} \mathbf{u}$ are well defined and, denoting the conjugate exponent of p by p', with $p' = \infty$ if $p = 1$, Hölder's inequality (Proposition B.7.9) gives $\|\mathsf{P}_{\mathbf{E}} \mathbf{u}\|_{L^p(M,\mathbf{E})} \le \sum_{j=1}^{N} \|\sigma_j\|_{L^p(M,\mathbf{E})} \|\sigma_j\|_{L^{p'}(M,\mathbf{E})} \|\mathbf{u}\|_{L^p(M,\mathbf{E})}$. Thus $\mathsf{P}_{\mathbf{E}}$ is linear and continuous. Finally, if $\mathbf{v} \in \mathcal{K}(\mathbf{E})$, its expansion in the orthonormal basis $(\sigma_1, \dots, \sigma_N)$ shows that $\mathsf{P}_{\mathbf{E}} \mathbf{v} = \mathbf{v}$, so $\mathsf{P}_{\mathbf{E}}$ is a projection onto $\mathcal{K}(\mathbf{E})$. □

The Poincaré inequality can now be formulated as an estimate for a section modulo its parallel component.

Theorem 9.6.3. (Poincaré inequality modulo the kernel of the connection) Let $(M, \mathbf{g})$ be a compact Riemannian manifold of dimension n with or without boundary, and let $\mathbf{E} \to M$ be a smooth real vector bundle of finite rank equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. If $1 \le p < \infty$, then there is a constant $C_P > 0$, depending only on M, $\mathbf{g}$, $\mathbf{E}$, $\mathbf{h_E}$, $\nabla^{\mathbf{E}}$, p, and the projection $\mathsf{P}_{\mathbf{E}}$, such that $\|\mathbf{u} - \mathsf{P}_{\mathbf{E}} \mathbf{u}\|_{L^p(M,\mathbf{E})} \le C_P \|\nabla^{\mathbf{E}}_w \mathbf{u}\|_{L^p(M, T^*M \otimes \mathbf{E})}$ for every $\mathbf{u} \in W^{1,p}(M, \mathbf{E})$.
Consequently, $\|\mathbf{u}\|_{\nabla^{\mathbf{E}}, p} := \|\nabla^{\mathbf{E}}_w \mathbf{u}\|_{L^p(M, T^*M \otimes \mathbf{E})}$ defines a norm on $\ker(\mathsf{P}_{\mathbf{E}}) \cap W^{1,p}(M, \mathbf{E})$ equivalent to the usual norm of $W^{1,p}(M, \mathbf{E})$.

Proof. Suppose, for a contradiction, that the inequality is false. Then, for each $k \in \mathbb{N}$, there is $\mathbf{u}_k \in W^{1,p}(M,\mathbf{E})$ such that $\|\mathbf{u}_k - \mathsf{P}_{\mathbf{E}}\mathbf{u}_k\|_{L^p(M,\mathbf{E})} > k\|\nabla^{\mathbf{E}}_w \mathbf{u}_k\|_{L^p(M,T^*M\otimes\mathbf{E})}$. Define $\mathbf{v}_k := \dfrac{\mathbf{u}_k - \mathsf{P}_{\mathbf{E}}\mathbf{u}_k}{\|\mathbf{u}_k - \mathsf{P}_{\mathbf{E}}\mathbf{u}_k\|_{L^p(M,\mathbf{E})}}$. Since $\mathsf{P}_{\mathbf{E}}^2 = \mathsf{P}_{\mathbf{E}}$ and $\nabla^{\mathbf{E}}_w(\mathsf{P}_{\mathbf{E}}\mathbf{u}_k) = 0$, we have $\mathsf{P}_{\mathbf{E}}\mathbf{v}_k = 0$, $\|\mathbf{v}_k\|_{L^p(M,\mathbf{E})} = 1$, and $\|\nabla^{\mathbf{E}}_w \mathbf{v}_k\|_{L^p(M,T^*M\otimes\mathbf{E})} < \dfrac{1}{k}$. In particular, $(\mathbf{v}_k)$ is bounded in $W^{1,p}(M,\mathbf{E})$.

By Corollary 9.4.29, applied with $m = 1$, after passing to a subsequence there is $\mathbf{v} \in L^p(M,\mathbf{E})$ such that $\mathbf{v}_k \to \mathbf{v}$ in $L^p(M,\mathbf{E})$. On the other hand, $\nabla^{\mathbf{E}}_w \mathbf{v}_k \to 0$ in $L^p(M, T^*M \otimes \mathbf{E})$ and, by Lemma 9.1.12, we have $\mathbf{v} \in W^{1,p}(M,\mathbf{E})$ and $\nabla^{\mathbf{E}}_w \mathbf{v} = 0$. Therefore, $\mathbf{v} \in \mathcal{K}(\mathbf{E})$.

Continuity of $\mathsf{P}_{\mathbf{E}}$ on $L^p(M,\mathbf{E})$ and the identity $\mathsf{P}_{\mathbf{E}}\mathbf{v}_k = 0$ imply $\mathsf{P}_{\mathbf{E}}\mathbf{v} = 0$. However, since $\mathbf{v} \in \mathcal{K}(\mathbf{E})$ and $\mathsf{P}_{\mathbf{E}}$ is the identity on $\mathcal{K}(\mathbf{E})$, we also have $\mathsf{P}_{\mathbf{E}}\mathbf{v} = \mathbf{v}$. Consequently, $\mathbf{v} = 0$, contradicting $\|\mathbf{v}\|_{L^p(M,\mathbf{E})} = \lim\limits_{k\to\infty} \|\mathbf{v}_k\|_{L^p(M,\mathbf{E})} = 1$. This proves the inequality.

If $\mathbf{u} \in \ker(\mathsf{P}_{\mathbf{E}}) \cap W^{1,p}(M,\mathbf{E})$, then $\mathbf{u} - \mathsf{P}_{\mathbf{E}}\mathbf{u} = \mathbf{u}$ and therefore $\|\mathbf{u}\|_{L^p(M,\mathbf{E})} \le C_P \|\nabla^{\mathbf{E}}_w \mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})}$. This gives $\|\nabla^{\mathbf{E}}_w \mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})} \le \|\mathbf{u}\|_{W^{1,p}(M,\mathbf{E})} \le (1 + C_P^p)^{\frac{1}{p}} \|\nabla^{\mathbf{E}}_w \mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})}$, proving equivalence of norms. □

Corollary 9.6.4. (Poincaré inequality with the mean) Let $(M,\mathbf{g})$ be a compact connected Riemannian manifold of dimension n with or without boundary, and let $1 \le p < \infty$. Then there is a constant $C_P > 0$ such that $\|u - \overline{u}\|_{L^p(M)} \le C_P \|\nabla_w u\|_{L^p(M,T^*M)}$ for every $u \in W^{1,p}(M)$, where $\overline{u} := \dfrac{1}{\lambda_{\mathbf{g}}(M)} \displaystyle\int_M u \, d\lambda_{\mathbf{g}}$.

Proof. For the trivial bundle $M \times \mathbb{R}$ equipped with the trivial connection, the space $\mathcal{K}(M \times \mathbb{R})$ consists of constant functions and has dimension 1. Since the constant function 1 satisfies $\|1\|_{L^2(M)} = \lambda_{\mathbf{g}}(M)^{\frac{1}{2}}$, the function $\sigma = \lambda_{\mathbf{g}}(M)^{-\frac{1}{2}}$ has unit norm in $L^2(M)$, so $\{\sigma\}$ is an orthonormal basis of $\mathcal{K}(M \times \mathbb{R})$. Consequently, $\mathsf{P}_{M\times\mathbb{R}} u = \left(\displaystyle\int_M u \, \lambda_{\mathbf{g}}(M)^{-\frac{1}{2}} \, d\lambda_{\mathbf{g}} \right) \lambda_{\mathbf{g}}(M)^{-\frac{1}{2}} = \dfrac{1}{\lambda_{\mathbf{g}}(M)} \displaystyle\int_M u \, d\lambda_{\mathbf{g}} = \overline{u}$. The result follows from Theorem 9.6.3. □

Remark 9.6.5. If M is disconnected and $M_1, \dots, M_\ell$ are its connected components, the kernel of the weak derivative consists of functions constant on each component. Consequently, the projection onto this kernel is given by $\mathsf{P}_{M\times\mathbb{R}} u = \displaystyle\sum_{i=1}^{\ell} \left(\frac{1}{\lambda_{\mathbf{g}}(M_i)} \int_{M_i} u \, d\lambda_{\mathbf{g}} \right) \mathbf{1}_{M_i}$.

This expression corresponds to subtracting the mean on each connected component. In particular, the global mean gives the correct formulation only when M is connected.

There are geometric situations in which a vector bundle admits no nontrivial parallel sections. In such cases the kernel of the weak covariant derivative is trivial, and the Poincaré inequality takes a particularly simple form.

Corollary 9.6.6. (The case without parallel sections) Let $(M,\mathbf{g})$ be a compact Riemannian manifold of dimension n with or without boundary, and let $\mathbf{E} \to M$ be a smooth real vector bundle of finite rank with a bundle metric and a compatible connection. Let $1 \le p < \infty$. If $\mathcal{K}(\mathbf{E}) = \{0\}$, then there is a constant $C_P > 0$ such that $\|\mathbf{u}\|_{L^p(M,\mathbf{E})} \le C_P \|\nabla^{\mathbf{E}}_w \mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})}$ for every $\mathbf{u} \in W^{1,p}(M,\mathbf{E})$. In particular, $\|\nabla^{\mathbf{E}}_w \mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})}$ defines a norm on $W^{1,p}(M,\mathbf{E})$ equivalent to the usual Sobolev norm.

Proof. If $\mathcal{K}(\mathbf{E}) = \{0\}$, then $\mathsf{P}_{\mathbf{E}} = 0$ and the result follows directly from Theorem 9.6.3. □

The preceding formulation removes the parallel component of a section by a projection. When the manifold

has boundary, another natural possibility is to impose a homogeneous Dirichlet condition. To prove the corresponding inequality, we need to relate the trace of a section to the trace of its bundle norm.

Lemma 9.6.7. (Compatibility of the trace with the bundle norm) Let $(M, \mathbf{g})$ be a compact Riemannian manifold with nonempty boundary, and let $\mathbf{E} \to M$ be a smooth real vector bundle of finite rank equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. If $1 \leq p < \infty$ and $\mathbf{u} \in W^{1,p}(M, \mathbf{E})$, then $|\mathbf{u}|_{\mathbf{h_E}} \in W^{1,p}(M)$ and $\operatorname{Tr}(|\mathbf{u}|_{\mathbf{h_E}}) = |\mathbf{Tr}(\mathbf{u})|_{\mathbf{h_E}}$ almost everywhere on ∂M.

Proof. By Corollary 9.5.7, we have $|\mathbf{u}|_{\mathbf{h_E}} \in W^{1,p}(M)$. By the Meyers–Serrin theorem for vector bundles on manifolds with boundary, Theorem 9.4.8, there is a sequence $(\mathbf{u}_k) \subseteq \Gamma(\mathbf{E}) \cap W^{1,p}(M, \mathbf{E})$ such that $\mathbf{u}_k \to \mathbf{u}$ in $W^{1,p}(M, \mathbf{E})$. The reverse triangle inequality implies $\big\| |\mathbf{u}_k|_{\mathbf{h_E}} - |\mathbf{u}|_{\mathbf{h_E}} \big\|_{L^p(M)} \leq \|\mathbf{u}_k - \mathbf{u}\|_{L^p(M,\mathbf{E})} \to 0$.
Applying Corollary 9.5.7 once more, now to each $\mathbf{u}_k$, gives $|\mathbf{u}_k|_{\mathbf{h_E}} \in W^{1,p}(M)$ and

$$\big|\nabla_w |\mathbf{u}_k|_{\mathbf{h_E}}\big|_{\mathbf{g}} \leq |\nabla^{\mathbf{E}}_w \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}}$$

almost everywhere. Since $\nabla^{\mathbf{E}}_w \mathbf{u}_k \to \nabla^{\mathbf{E}}_w \mathbf{u}$ in $L^p(M, T^*M \otimes \mathbf{E})$, the sequence $\big(\nabla_w |\mathbf{u}_k|_{\mathbf{h_E}}\big)$ is bounded in $L^p(M, T^*M)$.
If $1 < p < \infty$, reflexivity of $L^p(M, T^*M)$ gives a subsequence and an element $\mathbf{Z} \in L^p(M, T^*M)$ such that

$$\nabla_w |\mathbf{u}_k|_{\mathbf{h_E}} \rightharpoonup \mathbf{Z} \qquad \text{in } L^p(M, T^*M).$$

If $p = 1$, convergence $|\nabla^{\mathbf{E}}_w \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \to |\nabla^{\mathbf{E}}_w \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ in $L^1(M)$ implies that the family

$$\Big\{ |\nabla^{\mathbf{E}}_w \mathbf{u}_k|_{\mathbf{g},\mathbf{h_E}} \;\Big|\; k \in \mathbb{N} \Big\}$$

is uniformly integrable. The weak Kato inequality then shows that

$$\Big\{ \big|\nabla_w |\mathbf{u}_k|_{\mathbf{h_E}}\big|_{\mathbf{g}} \;\Big|\; k \in \mathbb{N} \Big\}$$

is also uniformly integrable. By Theorem 9.5.2, applied to the bundle T^*M, the weak closure of $\{\nabla_w |\mathbf{u}_k|_{\mathbf{h_E}} \mid k \in \mathbb{N}\}$ in $L^1(M, T^*M)$ is compact. The Eberlein–Šmulian theorem (Theorem B.11.36) therefore allows us to extract a subsequence and find $\mathbf{Z} \in L^1(M, T^*M)$ such that

$$\nabla_w |\mathbf{u}_k|_{\mathbf{h_E}} \rightharpoonup \mathbf{Z} \qquad \text{in } L^1(M, T^*M).$$

Thus in both cases, after passing to a subsequence, we may assume that $\nabla_w |\mathbf{u}_k|_{\mathbf{h_E}} \rightharpoonup \mathbf{Z}$ in $L^p(M, T^*M)$ for some $\mathbf{Z} \in L^p(M, T^*M)$. For every $\eta \in \Gamma_{c,\mathrm{Int}(M)}(T^*M)$, since $\nabla_w |\mathbf{u}_k|_{\mathbf{h_E}}$ is the weak covariant derivative of $|\mathbf{u}_k|_{\mathbf{h_E}}$, we have

$$\int_M \big\langle \nabla_w |\mathbf{u}_k|_{\mathbf{h_E}}, \eta \big\rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} = \int_M |\mathbf{u}_k|_{\mathbf{h_E}} \nabla^* \eta \, d\lambda_{\mathbf{g}}.$$

Since $\eta \in L^{p'}(M, T^*M)$ and $\nabla^* \eta \in L^{p'}(M)$, with the convention $p' = \infty$ when $p = 1$, weak convergence of $\nabla_w |\mathbf{u}_k|_{\mathbf{h_E}}$ allows passage to the limit on the left-hand side. On the right-hand side we use strong convergence

$|\mathbf{u}_k|_{\mathbf{h_E}} \to |\mathbf{u}|_{\mathbf{h_E}}$ in $L^p(M)$; indeed, by Hölder's inequality,

$$\left| \int_M (|\mathbf{u}_k|_{\mathbf{h_E}} - |\mathbf{u}|_{\mathbf{h_E}}) \nabla^* \eta \, d\lambda_{\mathbf{g}} \right| \leq \big\| |\mathbf{u}_k|_{\mathbf{h_E}} - |\mathbf{u}|_{\mathbf{h_E}} \big\|_{L^p(M)} \|\nabla^* \eta\|_{L^{p'}(M)} \longrightarrow 0.$$

Consequently,

$$\int_M \langle \mathbf{Z}, \eta \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} = \int_M |\mathbf{u}|_{\mathbf{h_E}} \nabla^* \eta \, d\lambda_{\mathbf{g}},$$

so that $\mathbf{Z} = \nabla_w |\mathbf{u}|_{\mathbf{h_E}}$.
Consider the isometric embedding

$$J_1 : W^{1,p}(M) \longrightarrow L^p(M) \times L^p(M, T^*M), \qquad J_1(w) := (w, \nabla_w w),$$

where the product is equipped with the norm ℓ^p, whose topology agrees with the product topology. Strong convergence $|\mathbf{u}_k|_{\mathbf{h_E}} \to |\mathbf{u}|_{\mathbf{h_E}}$ in $L^p(M)$ also implies weak convergence in that space and, together with $\nabla_w |\mathbf{u}_k|_{\mathbf{h_E}} \rightharpoonup \nabla_w |\mathbf{u}|_{\mathbf{h_E}}$ in $L^p(M, T^*M)$, Proposition B.11.14 gives

$$J_1(|\mathbf{u}_k|_{\mathbf{h_E}}) \rightharpoonup J_1(|\mathbf{u}|_{\mathbf{h_E}})$$

in $L^p(M) \times L^p(M, T^*M)$. By Theorem 9.1.14, applied to the trivial bundle, the image of J_1 is closed. Proposition B.11.13 then shows that this convergence is also weak in the image of J_1. Since $J_1 \colon W^{1,p}(M) \longrightarrow \mathrm{Im}(J_1)$ is an isometric isomorphism, its inverse $J_1^{-1} \colon \mathrm{Im}(J_1) \longrightarrow W^{1,p}(M)$ is linear and continuous and, by Proposition B.11.12, is continuous for the weak topologies. Applying J_1^{-1} to the preceding convergence, we conclude that

$$|\mathbf{u}_k|_{\mathbf{h_E}} \rightharpoonup |\mathbf{u}|_{\mathbf{h_E}} \qquad \text{in } W^{1,p}(M).$$

By Theorem 9.4.12, applied respectively to the trivial bundle and to $\mathbf{E}$, the trace operators $\mathrm{Tr} \colon W^{1,p}(M) \longrightarrow L^p(\partial M)$ and $\mathbf{Tr} \colon W^{1,p}(M, \mathbf{E}) \longrightarrow L^p(\partial M, \mathbf{E}\restriction_{\partial M})$ are linear and continuous. By Proposition B.11.12, the operator Tr is continuous for the weak topologies, so $\mathrm{Tr}(|\mathbf{u}_k|_{\mathbf{h_E}}) \rightharpoonup \mathrm{Tr}(|\mathbf{u}|_{\mathbf{h_E}})$ in $L^p(\partial M)$. On the other hand, continuity of $\mathbf{Tr}$ and convergence $\mathbf{u}_k \to \mathbf{u}$ in $W^{1,p}(M, \mathbf{E})$ imply $\mathbf{Tr}(\mathbf{u}_k) \to \mathbf{Tr}(\mathbf{u})$ in $L^p(\partial M, \mathbf{E}\restriction_{\partial M})$. The reverse triangle inequality then gives

$$|\mathbf{Tr}(\mathbf{u}_k)|_{\mathbf{h_E}} \longrightarrow |\mathbf{Tr}(\mathbf{u})|_{\mathbf{h_E}} \qquad \text{in } L^p(\partial M).$$

To justify this identity for each smooth section $\mathbf{u}_k$, fix k and use the smooth functions

$$f_{k,\varepsilon} := \sqrt{|\mathbf{u}_k|^2_{\mathbf{h_E}} + \varepsilon^2} - \varepsilon, \qquad \varepsilon > 0.$$

The proof of Lemma 9.5.4, applied on the compact set M, proves that $f_{k,\varepsilon} \to |\mathbf{u}_k|_{\mathbf{h_E}}$ in $W^{1,p}(M)$ for every $1 \leq p < \infty$: the functions and their derivatives converge in L^p by dominated convergence. Continuity of the trace then gives $\mathrm{Tr}(f_{k,\varepsilon}) \to \mathrm{Tr}(|\mathbf{u}_k|_{\mathbf{h_E}})$ in $L^p(\partial M)$. Since $f_{k,\varepsilon}$ is smooth, its trace is its restriction, and the inequality

$$0 \leq |\mathbf{u}_k|_{\mathbf{h_E}} - f_{k,\varepsilon} \leq \varepsilon$$

proves that these restrictions converge uniformly on ∂M to $|\mathbf{u}_k \restriction_{\partial M}|_{\mathbf{h_E}}$. Since ∂M has finite measure, convergence also holds in $L^p(\partial M)$. Uniqueness of the limit gives $\mathrm{Tr}(|\mathbf{u}_k|_{\mathbf{h_E}}) = |\mathbf{Tr}(\mathbf{u}_k)|_{\mathbf{h_E}}$ almost everywhere on ∂M for every k. The preceding strong convergence also implies weak convergence, so the same sequence

$\operatorname{Tr}(|\mathbf{u}_k|_{\mathbf{h_E}}) = |\mathbf{Tr}(\mathbf{u}_k)|_{\mathbf{h_E}}$ converges weakly both to $\operatorname{Tr}(|\mathbf{u}|_{\mathbf{h_E}})$ and to $|\mathbf{Tr}(\mathbf{u})|_{\mathbf{h_E}}$. Uniqueness of the weak limit finally gives

$$\operatorname{Tr}(|\mathbf{u}|_{\mathbf{h_E}}) = |\mathbf{Tr}(\mathbf{u})|_{\mathbf{h_E}}$$

almost everywhere on ∂M. □

We can now prove the Poincaré inequality for sections satisfying a homogeneous Dirichlet condition.

Theorem 9.6.8. (Poincaré inequality in $W^{1,p}_0(M,\mathbf{E})$) Let $(M,\mathbf{g})$ be a compact Riemannian manifold of dimension n with nonempty smooth boundary, and suppose that every connected component of M has nonempty boundary. Let $\mathbf{E} \to M$ be a smooth real vector bundle of finite rank equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. If $1 \le p < \infty$, then there is a constant $C_P > 0$, depending only on M, $\mathbf{g}$, $\mathbf{E}$, $\mathbf{h_E}$, $\nabla^{\mathbf{E}}$, and p, such that $\|\mathbf{u}\|_{L^p(M,\mathbf{E})} \le C_P \|\nabla^{\mathbf{E}}_w \mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})}$ for every $\mathbf{u} \in W^{1,p}_0(M,\mathbf{E})$. Consequently, $\|\mathbf{u}\|_{\nabla^{\mathbf{E}},p} := \left(\int_M |\nabla^{\mathbf{E}}_w \mathbf{u}|^p_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}\right)^{\frac{1}{p}}$ defines a norm on $W^{1,p}_0(M,\mathbf{E})$ equivalent to the usual norm of $W^{1,p}(M,\mathbf{E})$.

Proof. Suppose, for a contradiction, that the inequality is false. Then there is a sequence $(\mathbf{u}_k) \subseteq W^{1,p}_0(M,\mathbf{E})$ such that $\|\mathbf{u}_k\|_{L^p(M,\mathbf{E})} = 1$ for every $k \in \mathbb{N}$ and $\|\nabla^{\mathbf{E}}_w \mathbf{u}_k\|_{L^p(M,T^*M\otimes\mathbf{E})} \to 0$. In particular, $(\mathbf{u}_k)$ is bounded in $W^{1,p}(M,\mathbf{E})$. By Corollary 9.4.29, applied with $m = 1$, after passing to a subsequence there is $\mathbf{u} \in L^p(M,\mathbf{E})$ such that $\mathbf{u}_k \to \mathbf{u}$ in $L^p(M,\mathbf{E})$.

Since $\nabla^{\mathbf{E}}_w \mathbf{u}_k \to 0$ in $L^p(M, T^*M \otimes \mathbf{E})$ and the weak covariant derivative is a closed operator from $L^p(M,\mathbf{E})$ to $L^p(M, T^*M \otimes \mathbf{E})$, we have $\mathbf{u} \in W^{1,p}(M,\mathbf{E})$ and $\nabla^{\mathbf{E}}_w \mathbf{u} = 0$. Therefore, $\mathbf{u}_k \to \mathbf{u}$ in $W^{1,p}(M,\mathbf{E})$. This step uses only strong convergence and closedness of the weak derivative, Lemma 9.1.12, and is also valid for $p = 1$; it does not require reflexivity. Since $W^{1,p}_0(M,\mathbf{E})$ is a closed subspace of $W^{1,p}(M,\mathbf{E})$, it follows that $\mathbf{u} \in W^{1,p}_0(M,\mathbf{E})$ and, by Theorem 9.4.23 applied with $m = 1$, $\mathbf{Tr}(\mathbf{u}) = 0$.

Write $M = \bigsqcup_{i=1}^{\ell} M_i$, where $M_1, \dots, M_\ell$ are the connected components of M. By the weak Kato inequality, Corollary 9.5.7, we have $|\mathbf{u}|_{\mathbf{h_E}} \in W^{1,p}(M)$ and $\left|\nabla_w |\mathbf{u}|_{\mathbf{h_E}}\right|_{\mathbf{g}} \le |\nabla^{\mathbf{E}}_w \mathbf{u}|_{\mathbf{g},\mathbf{h_E}} = 0$ almost everywhere. Lemma 9.6.1 implies that, for each $i \in \{1,\dots,\ell\}$, there is a constant $c_i \ge 0$ such that $|\mathbf{u}|_{\mathbf{h_E}} = c_i$ almost everywhere on M_i.

By Lemma 9.6.7, $\operatorname{Tr}(|\mathbf{u}|_{\mathbf{h_E}}) = |\mathbf{Tr}(\mathbf{u})|_{\mathbf{h_E}} = 0$ almost everywhere on ∂M. Since $\partial M_i \neq \varnothing$ and the trace of the constant function c_i on ∂M_i is c_i, we conclude that $c_i = 0$ for each $i \in \{1,\dots,\ell\}$. Thus $|\mathbf{u}|_{\mathbf{h_E}} = 0$ almost everywhere on M and consequently $\mathbf{u} = 0$ almost everywhere.

However, convergence $\mathbf{u}_k \to \mathbf{u}$ in $L^p(M,\mathbf{E})$ implies $\|\mathbf{u}\|_{L^p(M,\mathbf{E})} = \lim_{k\to\infty} \|\mathbf{u}_k\|_{L^p(M,\mathbf{E})} = 1$, a contradiction. Thus there is $C_P > 0$ such that $\|\mathbf{u}\|_{L^p(M,\mathbf{E})} \le C_P \|\nabla^{\mathbf{E}}_w \mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})}$ for every $\mathbf{u} \in W^{1,p}_0(M,\mathbf{E})$.

Finally, for every $\mathbf{u} \in W^{1,p}_0(M,\mathbf{E})$ we have $\|\nabla^{\mathbf{E}}_w \mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})} \le \|\mathbf{u}\|_{W^{1,p}(M,\mathbf{E})} \le (1 + C_P^p)^{\frac{1}{p}} \|\nabla^{\mathbf{E}}_w \mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})}$, so $\|\cdot\|_{\nabla^{\mathbf{E}},p}$ is a norm equivalent to the usual norm of $W^{1,p}(M,\mathbf{E})$. □

10

Distributions on vector bundles

Distribution theory on a manifold must respect the geometry of the space while extending the duality used in the Euclidean case. For scalar functions, a distribution can be viewed as a continuous functional on test functions. On a vector bundle, the natural formulation requires pairing test sections of the dual bundle and controlling their support and covariant derivatives.

We first develop the topology of spaces of compactly supported smooth sections. We then use it to define bundle-valued distributions, their restrictions, their support, and the distributional action of differential operators. The formal adjoint allows an operator to be transferred to the test section, just as integration by parts defines distributional derivatives on $\mathbb{R}^n$.

This framework will be needed later to introduce Sobolev spaces of real order and operators defined by functional calculus, since it allows their elements and equations to be interpreted without recourse to particular coordinates.

Duality as a defining principle

Schwartz's theory taught us that a singular object can be understood through its action on test functions. On a vector bundle, this idea requires care concerning which fibers are paired, which measure permits integration, and how an operator is transferred to the test factor. The result is a theory that preserves the local nature of distributions while respecting the global geometry of the bundle. This duality will underlie elliptic regularity and the kernel theorem appearing at the end of the chapter [131].

10.1 The space of test sections

In this section, we construct the spaces of test sections associated with a smooth vector bundle. The idea parallels the construction of $\mathcal{D}(\Omega)$ in the Euclidean case, but the C^m norms are now defined using covariant derivatives and bundle metrics. This formulation allows us to work intrinsically while retaining the functional properties needed to define bundle-valued distributions.

For a boundary chart, its image Ω is a relatively open subset of the closed half-space. The notation $C^\infty(\Omega)$ means smoothness up to the boundary, and $\mathcal{D}(\Omega)$ allows compact supports meeting it. Its dual is understood with this convention. All interiors and neighborhoods of compact subsets of a manifold are taken in its relative

topology. The extension by zero of a compactly supported function from a relatively open subset to the half-space is smooth; to extend it across the geometric boundary, we use Lemma B.12.19.

Definition 10.1.1. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{E}\longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$, let ∇^{TM} be a connection on TM, and let $\nabla^{\mathbf{E}}$ be a connection on $\mathbf{E}$. Let $K\subseteq M$ be compact. For each $\varphi\in\Gamma^m(\mathbf{E})$, define

$$\|\varphi\|_{C^m(K)} := \max_{0\le j\le m}\sup_{x\in K}|\nabla^j\varphi(x)|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}},$$

where $\nabla^j\varphi$ denotes the covariant derivative of order j of φ, regarded as a section of the tensor bundle $T^{(0,j)}(TM)\otimes\mathbf{E}$ and induced by the connections ∇^{TM} and $\nabla^{\mathbf{E}}$ as in Definition 9.1.1. The norm $|\cdot|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}$ is the norm induced by $\mathbf{g}$ and $\mathbf{h}_{\mathbf{E}}$ on the corresponding tensor bundles; see Proposition 9.1.2.
Also define

$$\Gamma_K^m(\mathbf{E}) := \{\varphi\in\Gamma^m(\mathbf{E})\mid \operatorname{supp}(\varphi)\subseteq K\}.$$

When $m=\infty$, we write

$$\Gamma_K(\mathbf{E}) := \{\varphi\in\Gamma(\mathbf{E})\mid \operatorname{supp}(\varphi)\subseteq K\}.$$

For each $m\in\mathbb{N}_0$, the quantity $\|\cdot\|_{C^m(K)}$ defines a norm on $\Gamma_K^m(\mathbf{E})$. The triangle inequality and homogeneity are immediate. If $\|\varphi\|_{C^m(K)}=0$, then in particular $\varphi=0$ on K. Since $\operatorname{supp}(\varphi)\subseteq K$, it follows that $\varphi=0$ on $M\setminus K$, and hence $\varphi=0$ throughout M.

Although the preceding definition uses a Riemannian metric, a bundle metric, and auxiliary connections, the resulting topology on $\Gamma_K^m(\mathbf{E})$ is independent of these choices. This matters because the subsequent constructions should depend on the bundle and manifold, rather than on particular auxiliary data.

Theorem 10.1.2. Let M be a smooth manifold with or without boundary, let $\mathbf{g}$ and $\widetilde{\mathbf{g}}$ be two Riemannian metrics on M, let ∇^{TM} and $\widetilde{\nabla}^{TM}$ be two connections on TM, let $\mathbf{E}\longrightarrow M$ be a smooth vector bundle of finite rank, let $\mathbf{h}_{\mathbf{E}}$ and $\widetilde{\mathbf{h}}_{\mathbf{E}}$ be two smooth bundle metrics on $\mathbf{E}$, and let $\nabla^{\mathbf{E}}$ and $\widetilde{\nabla}^{\mathbf{E}}$ be two connections on $\mathbf{E}$. Also, let $K\subseteq M$ be compact. Then the norms $\|\cdot\|_{C^m(K)}$ and $\|\cdot\|_{\widetilde{C^m}(K)}$ are equivalent on $\Gamma_K^m(\mathbf{E})$.

Proof. For $\mathbf{u}\in\Gamma_K^m(\mathbf{E})$, write

$$\|\mathbf{u}\|_{C^m(K)} = \max_{0\le j\le m}\sup_{x\in K}|\nabla^j\mathbf{u}(x)|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}},\qquad \|\mathbf{u}\|_{\widetilde{C^m}(K)} = \max_{0\le j\le m}\sup_{x\in K}|\widetilde{\nabla}^j\mathbf{u}(x)|_{\widetilde{\mathbf{g}},\widetilde{\mathbf{h}}_{\mathbf{E}}}.$$

Applying Lemma 9.2.16 with the integer m gives a constant $C_m>0$ such that, for every $x\in K$,

$$\sum_{j=0}^{m}|\widetilde{\nabla}^j\mathbf{u}(x)|^2_{\widetilde{\mathbf{g}},\widetilde{\mathbf{h}}_{\mathbf{E}}}\le C_m\sum_{j=0}^{m}|\nabla^j\mathbf{u}(x)|^2_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}.$$

Therefore

$$\max_{0\le j\le m}|\widetilde{\nabla}^j\mathbf{u}(x)|^2_{\widetilde{\mathbf{g}},\widetilde{\mathbf{h}}_{\mathbf{E}}}\le C_m(m+1)\max_{0\le j\le m}|\nabla^j\mathbf{u}(x)|^2_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}.$$

Taking the supremum over $x\in K$, we obtain

$$\|\mathbf{u}\|_{\widetilde{C^m}(K)}\le\sqrt{C_m(m+1)}\,\|\mathbf{u}\|_{C^m(K)}.$$

The reverse argument, interchanging the data with and without tildes, produces a constant $\widetilde{C} > 0$ such that

$$\|\mathbf{u}\|_{C^m(K)} \leq \widetilde{C}\,\|\mathbf{u}\|_{\widetilde{C}^m(K)}.$$

These two inequalities give the asserted comparison constants. □

To prove that $\Gamma_K^m(\mathbf{E})$ is complete, we adapt the Euclidean argument to uniform limits of sections and their covariant derivatives. This intrinsic formulation will later allow passage to the limit in covariant identities.

Lemma 10.1.3. (Uniform limit of continuous sections) Let M be a smooth manifold with or without boundary, and let $\mathbf{F} \longrightarrow M$ be a vector bundle of finite rank equipped with a continuous bundle metric $\mathbf{h_F}$. Let $(\mathbf{s}_n)_{n\in\mathbb{N}}$ be a sequence of continuous sections of $\mathbf{F}$, and suppose that there exists a section $\mathbf{s}\colon M \longrightarrow \mathbf{F}$ such that

$$\|\mathbf{s}_n - \mathbf{s}\|_{L^\infty(M,\mathbf{F})} \longrightarrow 0.$$

Then $\mathbf{s}$ is continuous.

Proof. Fix $p \in M$. Choose a local trivialization $\Psi\colon \mathbf{F}\restriction_U \longrightarrow U \times \mathbb{K}^r$ over an open neighborhood U of p, where r is the rank of $\mathbf{F}$ and $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$. Also choose an open neighborhood V of p such that $\overline{V} \subseteq U$ and $\overline{V}$ is compact.
For each $n \in \mathbb{N}$, write $\Psi(\mathbf{s}_n(x)) = (x, u_n(x))$ and $\Psi(\mathbf{s}(x)) = (x, u(x))$ for $x \in U$, where $u_n, u\colon U \longrightarrow \mathbb{K}^r$.
Since the bundle metric $\mathbf{h_F}$ is continuous and $\overline{V}$ is compact, the norms induced by $\mathbf{h_F}$ on the fibers of $\mathbf{F}\restriction_{\overline{V}}$ are uniformly equivalent to the Euclidean norm on $\mathbb{K}^r$. Thus there exists a constant $C > 0$ such that

$$|u_n(x) - u(x)| \leq C\,|\mathbf{s}_n(x) - \mathbf{s}(x)|_{\mathbf{h_F}}$$

for every $x \in \overline{V}$ and every $n \in \mathbb{N}$.
Consequently,

$$\|u_n - u\|_{C^0(\overline{V},\mathbb{K}^r)} \leq C\|\mathbf{s}_n - \mathbf{s}\|_{L^\infty(M,\mathbf{F})} \longrightarrow 0.$$

Thus $u_n \to u$ uniformly on $\overline{V}$. Since each u_n is continuous, u is also continuous on V. Therefore $\mathbf{s}$ is continuous on V.
Since $p \in M$ was arbitrary, we conclude that $\mathbf{s}$ is continuous throughout M. □

Proposition 10.1.4. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h_E}$, let ∇^{TM} be a connection on TM, let $\nabla^{\mathbf{E}}$ be a connection on $\mathbf{E}$, and let $K \subseteq M$ be compact. For each $m \in \mathbb{N}_0$, the space $\left(\Gamma_K^m(\mathbf{E}), \|\cdot\|_{C^m(K)}\right)$ is a Banach space.

Proof. We use the convention $\nabla^0\boldsymbol{\varphi} = \boldsymbol{\varphi}$. For each $r \in \{0,\dots,m\}$, denote by $\mathbf{F}_r := T^{(0,r)}(TM) \otimes \mathbf{E}$ the tensor bundle in which $\nabla^r\boldsymbol{\varphi}$ takes values. This bundle is equipped with the connection induced by ∇^{TM} and $\nabla^{\mathbf{E}}$, and the bundle metric induced by $\mathbf{g}$ and $\mathbf{h_E}$.
Let $(\boldsymbol{\varphi}_n)_{n\in\mathbb{N}}$ be a Cauchy sequence in $\Gamma_K^m(\mathbf{E})$. Fix $r \in \{0,\dots,m\}$.
If $x \in M \setminus K$, since $\operatorname{supp}(\boldsymbol{\varphi}_n) \subseteq K$, there is an open neighborhood of x on which $\boldsymbol{\varphi}_n$ vanishes. Thus $\nabla^r\boldsymbol{\varphi}_n(x) = 0$. Consequently, $\nabla^r\boldsymbol{\varphi}_n$ vanishes on $M \setminus K$ for every $n \in \mathbb{N}$.

Moreover, for any $n, p \in \mathbb{N}$,

$$\|\nabla^r \varphi_n - \nabla^r \varphi_p\|_{L^\infty(M, T^{(0,r)}(TM)\otimes \mathbf{E})} = \|\nabla^r \varphi_n - \nabla^r \varphi_p\|_{C^0(K, T^{(0,r)}(TM)\otimes \mathbf{E})} \leq \|\varphi_n - \varphi_p\|_{C^m(K)}.$$

Since $(\varphi_n)_{n\in\mathbb{N}}$ is Cauchy in $\Gamma_K^m(\mathbf{E})$, it follows that $(\nabla^r \varphi_n)_{n\in\mathbb{N}}$ is uniformly Cauchy on M.
For each $x \in M$, the sequence $(\nabla^r \varphi_n(x))_{n\in\mathbb{N}}$ is Cauchy in the fiber $(\mathbf{F}_r)_x$, which is a finite-dimensional normed vector space and hence complete. Define

$$\mathbf{A}_r(x) := \lim_{n\to\infty} \nabla^r \varphi_n(x), \qquad x \in M.$$

This gives a section $\mathbf{A}_r \colon M \longrightarrow \mathbf{F}_r$.
Let us show that convergence is uniform. Let $\varepsilon > 0$. Since $(\nabla^r \varphi_n)_{n\in\mathbb{N}}$ is uniformly Cauchy, there exists $N \in \mathbb{N}$ such that, if $n, p \geq N$, then

$$\|\nabla^r \varphi_n - \nabla^r \varphi_p\|_{L^\infty(M, T^{(0,r)}(TM)\otimes \mathbf{E})} < \varepsilon.$$

Fix $n \geq N$ and let $p \to \infty$. For each $x \in M$,

$$\left|\nabla^r \varphi_n(x) - \mathbf{A}_r(x)\right|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \leq \varepsilon.$$

Taking the supremum over $x \in M$ gives

$$\|\nabla^r \varphi_n - \mathbf{A}_r\|_{L^\infty(M, T^{(0,r)}(TM)\otimes \mathbf{E})} \leq \varepsilon.$$

Therefore $\nabla^r \varphi_n \to \mathbf{A}_r$ uniformly on M.
Since each $\nabla^r \varphi_n$ is continuous, Lemma 10.1.3 implies that $\mathbf{A}_r$ is continuous. Moreover, since $\nabla^r \varphi_n = 0$ on $M \setminus K$ for every n, passage to the limit gives $\mathbf{A}_r = 0$ on $M \setminus K$.
Define $\varphi := \mathbf{A}_0$. Then φ is a continuous section of $\mathbf{E}$ and vanishes on $M \setminus K$. Since K is compact and hence closed, it follows that $\operatorname{supp}(\varphi) \subseteq K$.
It remains to prove that φ is of class C^m and that $\nabla^r \varphi = \mathbf{A}_r$ for every $r \in \{0, \ldots, m\}$.
Fix $r \in \{0, \ldots, m-1\}$. Consider the bundle $\mathbf{F}_r = T^{(0,r)}(TM)\otimes\mathbf{E}$ with the induced connection. Let $\gamma \colon [a, b] \longrightarrow M$ be a smooth curve, and let $t, t_0 \in [a, b]$.
Since $\varphi_n \in \Gamma_K^m(\mathbf{E})$ and $r \leq m-1$, the section $\nabla^r \varphi_n$ is of class C^1 as a section of $\mathbf{F}_r$. Apply Lemma 2.7.21 to the section $\nabla^r \varphi_n$ restricted to γ. We obtain

$$P^{\mathbf{F}_r}_{\gamma, t\to t_0}\big(\nabla^r \varphi_n(\gamma(t))\big) - \nabla^r \varphi_n(\gamma(t_0))$$

$$= \int_{t_0}^{t} P^{\mathbf{F}_r}_{\gamma, \tau\to t_0}\left(\nabla^{\mathbf{F}_r}_{\dot\gamma(\tau)}\big(\nabla^r \varphi_n\big)(\gamma(\tau))\right) d\tau.$$

By the definition of the higher-order covariant derivative, under the identification $T^*M\otimes\mathbf{F}_r \cong T^{(0,r+1)}(TM)\otimes \mathbf{E}$ we have $\nabla^{\mathbf{F}_r}(\nabla^r \varphi_n) = \nabla^{r+1}\varphi_n$. Therefore

$$\nabla^{\mathbf{F}_r}_{\dot\gamma(\tau)}\big(\nabla^r \varphi_n\big)(\gamma(\tau)) = \iota^{\mathrm{prim}}_{\dot\gamma(\tau)}\left(\nabla^{r+1}\varphi_n(\gamma(\tau))\right),$$

where ι_v^{prim} denotes contraction in the first covariant factor; that is,

$$\big(\iota_v^{\mathrm{prim}} A\big)(X_1,\dots,X_r) = A(v,X_1,\dots,X_r).$$

Thus

$$P^{\mathbf{F}_r}_{\gamma,t\to t_0}\big(\nabla^r \boldsymbol{\varphi}_n(\gamma(t))\big) - \nabla^r \boldsymbol{\varphi}_n(\gamma(t_0))$$
$$= \int_{t_0}^{t} P^{\mathbf{F}_r}_{\gamma,\tau\to t_0}\Big(\iota^{\mathrm{prim}}_{\dot\gamma(\tau)}\big(\nabla^{r+1}\boldsymbol{\varphi}_n(\gamma(\tau))\big)\Big)\,d\tau.$$

We let $n\to\infty$ in this identity. Since $\nabla^r\boldsymbol{\varphi}_n \to \mathbf{A}_r$ uniformly on M, the left-hand side converges to

$$P^{\mathbf{F}_r}_{\gamma,t\to t_0}\big(\mathbf{A}_r(\gamma(t))\big) - \mathbf{A}_r(\gamma(t_0)).$$

Let us now check that we can also pass to the limit in the integral. For fixed t and t_0, consider the compact interval between them. The function

$$\tau \longmapsto P^{\mathbf{F}_r}_{\gamma,\tau\to t_0}\circ \iota_{\dot\gamma(\tau)}$$

is continuous and takes values in the space of linear operators between finite-dimensional vector spaces. Thus there is a constant $C>0$ such that

$$\Big\| P^{\mathbf{F}_r}_{\gamma,\tau\to t_0}\circ \iota_{\dot\gamma(\tau)}\Big\| \le C$$

for every τ between t_0 and t.
Consequently,

$$\left|\int_{t_0}^{t} P^{\mathbf{F}_r}_{\gamma,\tau\to t_0}\Big(\iota_{\dot\gamma(\tau)}\big(\nabla^{r+1}\boldsymbol{\varphi}_n(\gamma(\tau)) - \mathbf{A}_{r+1}(\gamma(\tau))\big)\Big)\,d\tau\right|$$
$$\le C\,|t-t_0|\,\|\nabla^{r+1}\boldsymbol{\varphi}_n - \mathbf{A}_{r+1}\|_{L^\infty(M,T^{(0,r+1)}(TM)\otimes\mathbf{E})}.$$

The right-hand side converges to 0, since $\nabla^{r+1}\boldsymbol{\varphi}_n\to\mathbf{A}_{r+1}$ uniformly on M. Therefore

$$P^{\mathbf{F}_r}_{\gamma,t\to t_0}\big(\mathbf{A}_r(\gamma(t))\big) - \mathbf{A}_r(\gamma(t_0))$$
$$= \int_{t_0}^{t} P^{\mathbf{F}_r}_{\gamma,\tau\to t_0}\Big(\iota_{\dot\gamma(\tau)}\big(\mathbf{A}_{r+1}(\gamma(\tau))\big)\Big)\,d\tau.$$

This identity has exactly the form in Lemma 2.7.22, applied to the bundle $\mathbf{F}_r$, the section $\mathbf{A}_r$, and the tensor $\mathbf{A}_{r+1}$ viewed as an element of $\Gamma^0(T^*M\otimes\mathbf{F}_r)$. We conclude that $\mathbf{A}_r$ is of class C^1 and that $\nabla^{\mathbf{F}_r}\mathbf{A}_r = \mathbf{A}_{r+1}$.
Using this compatibility, we prove by induction on $r\in\{0,\dots,m\}$ that $\boldsymbol{\varphi}\in\Gamma^r(\mathbf{E})$ and $\nabla^r\boldsymbol{\varphi}=\mathbf{A}_r$.
For $r=0$, the assertion is immediate, since $\boldsymbol{\varphi}=\mathbf{A}_0$ and $\mathbf{A}_0$ is continuous.
Now suppose the assertion holds for some $r\in\{0,\dots,m-1\}$. Then $\boldsymbol{\varphi}\in\Gamma^r(\mathbf{E})$ and $\nabla^r\boldsymbol{\varphi}=\mathbf{A}_r$. Since we have just proved that $\mathbf{A}_r$ is of class C^1 and $\nabla^{\mathbf{F}_r}\mathbf{A}_r=\mathbf{A}_{r+1}$, the definition of higher-order covariant derivative gives $\boldsymbol{\varphi}\in\Gamma^{r+1}(\mathbf{E})$ and $\nabla^{r+1}\boldsymbol{\varphi}=\mathbf{A}_{r+1}$.
By induction, $\boldsymbol{\varphi}\in\Gamma^m(\mathbf{E})$ and $\nabla^r\boldsymbol{\varphi}=\mathbf{A}_r$ for every $r\in\{0,\dots,m\}$.
Since we also have $\operatorname{supp}(\boldsymbol{\varphi})\subseteq K$, we conclude that $\boldsymbol{\varphi}\in\Gamma^m_K(\mathbf{E})$.

Finally, for each $r \in \{0,\dots,m\}$, $\nabla^r \varphi_n \to \nabla^r \varphi$ uniformly on K. Therefore

$$\|\varphi_n - \varphi\|_{C^m(K)} = \max_{0\le r\le m} \|\nabla^r \varphi_n - \nabla^r \varphi\|_{C^0(K,T^{(0,r)}(TM)\otimes \mathbf{E})} \longrightarrow 0.$$

Thus every Cauchy sequence in $\Gamma_K^m(\mathbf{E})$ converges in $\Gamma_K^m(\mathbf{E})$. We conclude that $\left(\Gamma_K^m(\mathbf{E}), \|\cdot\|_{C^m(K)}\right)$ is a Banach space. □

Having constructed the Banach space $\Gamma_K^m(\mathbf{E})$ for each finite order, we pass to the space of smooth sections supported in K. This space is described by the countable family of norms C^m, rather than by a single norm.

Definition 10.1.5. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h_E}$, and let $K \subseteq M$ be compact. Equip $\Gamma_K(\mathbf{E})$ with the locally convex topology induced by the family of seminorms

$$\mathbf{u} \longmapsto \|\mathbf{u}\|_{C^m(K)}, \qquad m \in \mathbb{N}_0.$$

This is the topology of uniform convergence on K of sections and all their covariant derivatives.

Lemma 10.1.6. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h_E}$, and let $K \subseteq M$ be compact. Then the topology on $\Gamma_K(\mathbf{E})$ generated by the family of seminorms $(\|\cdot\|_{C^m(K)})_{m\in\mathbb{N}_0}$ has as a local base at 0 the family of sets

$$V_{K,m,\ell} := \left\{ \mathbf{u} \in \Gamma_K(\mathbf{E}) \;\middle|\; \|\mathbf{u}\|_{C^m(K)} < \frac{1}{\ell} \right\}, \qquad m \in \mathbb{N}_0, \quad \ell \in \mathbb{N}.$$

Consequently, a neighborhood base at $\mathbf{u} \in \Gamma_K(\mathbf{E})$ is given by

$$\mathbf{u} + V_{K,m,\ell} = \left\{ \mathbf{v} \in \Gamma_K(\mathbf{E}) \;\middle|\; \|\mathbf{u}-\mathbf{v}\|_{C^m(K)} < \frac{1}{\ell} \right\}.$$

Proof. By Definition B.10.18 of the topology induced by seminorms, a local base at 0 consists of sets of the form

$$U = \left\{ \mathbf{u} \in \Gamma_K(\mathbf{E}) \;\middle|\; \|\mathbf{u}\|_{C^{m_1}(K)} < \varepsilon_1, \dots, \|\mathbf{u}\|_{C^{m_q}(K)} < \varepsilon_q \right\}.$$

Let $m := \max\{m_1,\dots,m_q\}$. Then, since the norms C^m increase with the order,

$$\|\mathbf{u}\|_{C^{m_i}(K)} \le \|\mathbf{u}\|_{C^m(K)} \qquad \forall i \in \{1,\dots,q\}.$$

Choose $\ell \in \mathbb{N}$ such that $\frac{1}{\ell} < \min\{\varepsilon_1,\dots,\varepsilon_q\}$. If $\mathbf{u} \in V_{K,m,\ell}$, then

$$\|\mathbf{u}\|_{C^{m_i}(K)} \le \|\mathbf{u}\|_{C^m(K)} < \frac{1}{\ell} < \varepsilon_i$$

for every $i \in \{1,\dots,q\}$. Therefore $V_{K,m,\ell} \subseteq U$.
This proves that the family $V_{K,m,\ell}$ is a local base at 0. The general case follows by translation, since translations are homeomorphisms of a topological vector space. □

Proposition 10.1.7. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{E}\to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$, and let $K\subseteq M$ be compact. For $\mathbf{u},\mathbf{v}\in\Gamma_K(\mathbf{E})$, define

$$d_K(\mathbf{u},\mathbf{v}) := \sum_{m=0}^{\infty} \frac{1}{2^m}\frac{\|\mathbf{u}-\mathbf{v}\|_{C^m(K)}}{1+\|\mathbf{u}-\mathbf{v}\|_{C^m(K)}}.$$

Then the following properties hold:

(a) d_K is a translation-invariant metric on $\Gamma_K(\mathbf{E})$.

(b) The topology on $\Gamma_K(\mathbf{E})$ generated by the family of seminorms $(\|\cdot\|_{C^m(K)})_{m\in\mathbb{N}_0}$ agrees with the topology induced by d_K.

(c) $(\Gamma_K(\mathbf{E}),d_K)$ is complete.

In particular, $\Gamma_K(\mathbf{E})$ is a Fréchet space.

Proof. Consider the countable family of seminorms

$$p_m(\mathbf{u}) := \|\mathbf{u}\|_{C^m(K)}, \qquad m\in\mathbb{N}_0,$$

defined on $\Gamma_K(\mathbf{E})$. In fact, each p_m is a norm on $\Gamma_K(\mathbf{E})$: if $p_m(\mathbf{u})=0$, then in particular $\mathbf{u}=0$ on K; since $\operatorname{supp}(\mathbf{u})\subseteq K$, it follows that $\mathbf{u}=0$ on $M\setminus K$, and hence $\mathbf{u}=0$ throughout M. Thus the family $(p_m)_{m\in\mathbb{N}_0}$ separates points.

Properties (a) and (b) are therefore a special case of Proposition B.10.24. The metric constructed there, applied to the family $(p_m)_{m\in\mathbb{N}_0}$, is precisely d_K; hence d_K is translation invariant and induces the locally convex topology generated by the norms $\|\cdot\|_{C^m(K)}$.

It remains to prove completeness. We use sequential completeness of projective intersections. First observe that, within the Hausdorff topological vector space $Y:=\Gamma_K^0(\mathbf{E})$, we have the algebraic equality

$$\Gamma_K(\mathbf{E}) = \bigcap_{m\in\mathbb{N}_0} \Gamma_K^m(\mathbf{E}).$$

If a section belongs to $\Gamma_K(\mathbf{E})$, it is smooth and therefore belongs to $\Gamma_K^m(\mathbf{E})$ for every $m\in\mathbb{N}_0$. Conversely, if a section belongs to $\Gamma_K^m(\mathbf{E})$ for every $m\in\mathbb{N}_0$, it is of class C^m for every m, hence smooth, and its support is contained in K.

For each $m\in\mathbb{N}_0$, the space $\Gamma_K^m(\mathbf{E})$ is Banach by Proposition 10.1.4. Moreover, the inclusion

$$\Gamma_K^m(\mathbf{E}) \hookrightarrow \Gamma_K^0(\mathbf{E})$$

is continuous, since

$$\|\mathbf{u}\|_{C^0(K)} \le \|\mathbf{u}\|_{C^m(K)}.$$

On the other hand, the topology on $\Gamma_K(\mathbf{E})$ generated by the norms $\|\cdot\|_{C^m(K)}$ agrees with the projective topology associated with the natural inclusions

$$\iota_m\colon \Gamma_K(\mathbf{E}) \longrightarrow \Gamma_K^m(\mathbf{E}), \qquad m\in\mathbb{N}_0.$$

This is because that topology is, by definition, the initial topology making all the inclusions ι_m continuous, or equivalently the topology generated by the seminorms $\mathbf{u} \mapsto \|\iota_m(\mathbf{u})\|_{C^m(K)} = \|\mathbf{u}\|_{C^m(K)}$; see Definition B.10.39 and Definition B.10.18.
Applying Proposition 4.2.4 and reindexing the family $\{\Gamma_K^m(\mathbf{E})\}_{m\in\mathbb{N}_0}$ by $n = m+1$, we conclude that $\Gamma_K(\mathbf{E})$ is sequentially complete in this projective topology. Since this same topology is induced by the translation-invariant metric d_K, a sequence is Cauchy with respect to d_K if and only if it is Cauchy in the corresponding vector topology. By sequential completeness, every Cauchy sequence for d_K converges in $\Gamma_K(\mathbf{E})$; since d_K induces the topology, this is convergence in the metric d_K. Therefore $(\Gamma_K(\mathbf{E}), d_K)$ is complete.
Finally, $\Gamma_K(\mathbf{E})$ is locally convex because its topology is generated by seminorms, Hausdorff because the family $(p_m)_{m\in\mathbb{N}_0}$ separates points, metrizable by d_K, and complete by what we have just proved. By the definition of a Fréchet space, or equivalently by Theorem B.10.38, we conclude that $\Gamma_K(\mathbf{E})$ is a Fréchet space. □

Proposition 10.1.8. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_\mathbf{E}$, and let $K, L \subseteq M$ be compact sets such that $K \subseteq L$. Then:

(a) for each $m \in \mathbb{N}_0$, the natural inclusion $\Gamma_K^m(\mathbf{E}) \hookrightarrow \Gamma_L^m(\mathbf{E})$ is an isometry onto its image, that is,

$$\|\mathbf{u}\|_{C^m(L)} = \|\mathbf{u}\|_{C^m(K)} \qquad \forall \mathbf{u} \in \Gamma_K^m(\mathbf{E});$$

(b) the topology on $\Gamma_K^m(\mathbf{E})$ agrees with the subspace topology induced by $\Gamma_L^m(\mathbf{E})$;

(c) the Fréchet topology on $\Gamma_K(\mathbf{E})$ agrees with the subspace topology induced by $\Gamma_L(\mathbf{E})$;

(d) the images of $\Gamma_K^m(\mathbf{E})$ in $\Gamma_L^m(\mathbf{E})$ and of $\Gamma_K(\mathbf{E})$ in $\Gamma_L(\mathbf{E})$ are closed.

Proof. Let $\mathbf{u} \in \Gamma_K^m(\mathbf{E})$. Since $\operatorname{supp}(\mathbf{u}) \subseteq K$, we have $\mathbf{u} = 0$ on the open subset $M \setminus K$. Thus, for each $j \in \{0, \dots, m\}$, we also have $\nabla^j \mathbf{u} = 0$ on $M \setminus K$. In particular, on $L \setminus K$ all covariant derivatives of $\mathbf{u}$ up to order m vanish. This gives

$$\sup_{x\in L} |\nabla^j \mathbf{u}(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}} = \sup_{x\in K} |\nabla^j \mathbf{u}(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \qquad 0 \le j \le m.$$

Taking the maximum over $0 \le j \le m$ yields $\|\mathbf{u}\|_{C^m(L)} = \|\mathbf{u}\|_{C^m(K)}$. This proves (a).
Part (b) follows immediately from (a), since the norm on $\Gamma_L^m(\mathbf{E})$ restricted to the subspace $\Gamma_K^m(\mathbf{E})$ agrees with the intrinsic norm of $\Gamma_K^m(\mathbf{E})$.
For (c), recall that the topology on $\Gamma_K(\mathbf{E})$ is induced by the family of norms $\|\cdot\|_{C^m(K)}$, with $m \in \mathbb{N}_0$, whereas the topology on $\Gamma_L(\mathbf{E})$ is induced by the family $\|\cdot\|_{C^m(L)}$, with $m \in \mathbb{N}_0$. By (a), restricting the latter norms to $\Gamma_K(\mathbf{E})$ gives exactly the family $\|\cdot\|_{C^m(K)}$. Therefore the topologies agree.
For (d), let $\mathbf{u}_j \in \Gamma_K^m(\mathbf{E})$ be a sequence converging to $\mathbf{u} \in \Gamma_L^m(\mathbf{E})$. In particular, $\mathbf{u}_j \to \mathbf{u}$ uniformly on L. Since $\mathbf{u}_j = 0$ on $L \setminus K$, we also have $\mathbf{u} = 0$ there; outside L the section $\mathbf{u}$ already vanishes, so $\operatorname{supp}\mathbf{u} \subseteq K$. This proves closedness of the image at the C^m level. If $\mathbf{u}_j \in \Gamma_K(\mathbf{E})$ converges to $\mathbf{u}$ in $\Gamma_L(\mathbf{E})$, the seminorm $C^0(L)$ gives the same argument. Thus both images are closed. □

Definition 10.1.9. Let M be a smooth manifold with or without boundary, and let $\mathbf{E} \longrightarrow M$ be a smooth

vector bundle. Fix an increasing exhaustion of M by compact sets

$$K_1 \subseteq K_2 \subseteq \cdots \subseteq M, \qquad K_n \subseteq \operatorname{Int}(K_{n+1}), \qquad M = \bigcup_{n=1}^{\infty} K_n.$$

(a) For each $m \in \mathbb{N}_0$, equip the space $\Gamma^m(\mathbf{E})$ with the locally convex topology generated by the family of seminorms

$$p_{n,j}(u) := \sup_{x \in K_n} |\nabla^j u(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}}, \qquad n \in \mathbb{N}, \quad 0 \le j \le m.$$

(b) Equip the space $\Gamma(\mathbf{E})$ with the locally convex topology generated by the family of seminorms

$$p_{n,m}(u) := \max_{0 \le j \le m} \sup_{x \in K_n} |\nabla^j u(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}}, \qquad n \in \mathbb{N}, \quad m \in \mathbb{N}_0.$$

(c) For each $m \in \mathbb{N}_0$, equip the space $\Gamma_c^m(\mathbf{E})$ with the final locally convex topology associated with the inclusions

$$\Gamma_{K_n}^m(\mathbf{E}) \hookrightarrow \Gamma_c^m(\mathbf{E}), \qquad n \in \mathbb{N}.$$

In other words,

$$\Gamma_c^m(\mathbf{E}) = \varinjlim_{n \in \mathbb{N}} \Gamma_{K_n}^m(\mathbf{E}).$$

By Proposition 10.1.8, the inclusions are embeddings with closed image. Since each $\Gamma_{K_n}^m(\mathbf{E})$ is a Banach space, $\Gamma_c^m(\mathbf{E})$ is a strict LB inductive limit and, in particular, a strict LF space.

(d) Equip the space $\Gamma_c(\mathbf{E})$ with the final locally convex topology associated with the inclusions

$$\Gamma_{K_n}(\mathbf{E}) \hookrightarrow \Gamma_c(\mathbf{E}), \qquad n \in \mathbb{N}.$$

That is,

$$\Gamma_c(\mathbf{E}) = \varinjlim_{n \in \mathbb{N}} \Gamma_{K_n}(\mathbf{E}).$$

By Proposition 10.1.8, the inclusions are embeddings with closed image. Since each $\Gamma_{K_n}(\mathbf{E})$ is a Fréchet space, $\Gamma_c(\mathbf{E})$ is a strict LF space.

Proposition 10.1.10. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank. The topologies defined in 10.1.9 are independent of the chosen metrics, connections, and increasing exhaustion by compact sets.

Proof. Independence of the metrics and auxiliary connections follows from Theorem 10.1.2. On each fixed compact set $K \subseteq M$, the norms $C^m(K)$ constructed using two different choices of metrics and connections are equivalent. Thus, for each fixed m, both choices generate the same topology on $\Gamma_K^m(\mathbf{E})$ and $\Gamma_K(\mathbf{E})$.
It remains to justify independence of the exhaustion. Let $(K_n)_{n\in\mathbb{N}}$ and $(L_q)_{q\in\mathbb{N}}$ be two increasing exhaustions of M by compact sets, with $K_n \subseteq \operatorname{Int}(K_{n+1})$, $L_q \subseteq \operatorname{Int}(L_{q+1})$, $M = \bigcup_{n=1}^{\infty} K_n$, and $M = \bigcup_{q=1}^{\infty} L_q$.
First show that each compact set in one exhaustion lies in a compact set of the other. Fix $n \in \mathbb{N}$. Since

$M = \bigcup_{q=1}^{\infty} L_q$ and $L_q \subseteq \mathrm{Int}(L_{q+1})$, the open subsets $\mathrm{Int}(L_q)$ cover M. In particular, they cover the compact set K_n. By compactness, there exist $q_1, \dots, q_s$ such that

$$K_n \subseteq \bigcup_{\alpha=1}^{s} \mathrm{Int}(L_{q_\alpha}).$$

If $q_0 := \max\{q_1, \dots, q_s\}$, then, since the family (L_q) is increasing,

$$K_n \subseteq L_{q_0}.$$

The same argument, interchanging K and L, shows that for each $q \in \mathbb{N}$ there exists $n_0 \in \mathbb{N}$ such that $L_q \subseteq K_{n_0}$. Now consider the topology on $\Gamma^m(\mathbf{E})$. For the exhaustion (K_n), it is generated by the seminorms

$$p^K_{n,j}(\mathbf{u}) := \sup_{x \in K_n} |\nabla^j \mathbf{u}(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}}, \qquad n \in \mathbb{N}, \quad 0 \le j \le m,$$

whereas for the exhaustion (L_q), it is generated by the seminorms

$$p^L_{q,j}(\mathbf{u}) := \sup_{x \in L_q} |\nabla^j \mathbf{u}(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}}, \qquad q \in \mathbb{N}, \quad 0 \le j \le m.$$

If $K_n \subseteq L_{q_0}$, then $p^K_{n,j}(\mathbf{u}) \le p^L_{q_0,j}(\mathbf{u})$ for every $\mathbf{u} \in \Gamma^m(\mathbf{E})$. Thus every basic neighborhood defined using the exhaustion (K_n) contains a basic neighborhood defined using the exhaustion (L_q). The reverse argument, using the fact that each L_q lies in some K_{n_0}, gives the reverse inclusion between the topologies. Thus both exhaustions induce the same topology on $\Gamma^m(\mathbf{E})$. The same reasoning applies to $\Gamma(\mathbf{E})$, using the seminorms

$$p^K_{n,r}(\mathbf{u}) := \max_{0 \le j \le r} \sup_{x \in K_n} |\nabla^j \mathbf{u}(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}}$$

and their counterparts associated with (L_q).

We now prove independence of the exhaustion for the spaces with compact support. Denote by τ^m_K the final locally convex topology on $\Gamma^m_c(\mathbf{E})$ associated with the family $(\Gamma^m_{K_n}(\mathbf{E}))_{n\in\mathbb{N}}$, and by τ^m_L the final locally convex topology associated with the family $(\Gamma^m_{L_q}(\mathbf{E}))_{q\in\mathbb{N}}$.

We prove $\tau^m_K = \tau^m_L$ using the maximality property in Theorem 4.4.1. For each $n \in \mathbb{N}$, choose $q_0 \in \mathbb{N}$ such that $K_n \subseteq L_{q_0}$. Then the inclusion

$$\Gamma^m_{K_n}(\mathbf{E}) \hookrightarrow \Gamma^m_c(\mathbf{E})$$

viewed with the topology τ^m_L is continuous, since it factors as

$$\Gamma^m_{K_n}(\mathbf{E}) \hookrightarrow \Gamma^m_{L_{q_0}}(\mathbf{E}) \hookrightarrow (\Gamma^m_c(\mathbf{E}), \tau^m_L),$$

where the first arrow is continuous by Proposition 10.1.8 and the second by the definition of τ^m_L as a final locally convex topology.

Thus τ^m_L is a locally convex topology on $\Gamma^m_c(\mathbf{E})$ making all the inclusions $\Gamma^m_{K_n}(\mathbf{E}) \hookrightarrow \Gamma^m_c(\mathbf{E})$ continuous. Since τ^m_K is the finest topology with this property, we obtain $\tau^m_L \subseteq \tau^m_K$. Interchanging the exhaustions (K_n) and (L_q) gives $\tau^m_K \subseteq \tau^m_L$. Consequently, $\tau^m_K = \tau^m_L$.

The same argument proves independence of the topology on $\Gamma_c(\mathbf{E})$. If $K_n \subseteq L_{q_0}$, the inclusion

$$\Gamma_{K_n}(\mathbf{E}) \hookrightarrow \Gamma_{L_{q_0}}(\mathbf{E})$$

is continuous by Proposition 10.1.8; hence the final locally convex topology defined by the exhaustion (L_q) makes all the inclusions $\Gamma_{K_n}(\mathbf{E}) \hookrightarrow \Gamma_c(\mathbf{E})$ continuous. By maximality in Theorem 4.4.1, one topology contains the other. Interchanging the exhaustions gives the reverse containment, so the two agree. □

Definition 10.1.11. Let M be a smooth manifold with or without boundary, and let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle. Define

$$\mathcal{D}(M,\mathbf{E}) := \Gamma_c(\mathbf{E}),$$

and equip this space with the strict locally convex inductive topology

$$\mathcal{D}(M,\mathbf{E}) = \varinjlim_{n\in\mathbb{N}} \Gamma_{K_n}(\mathbf{E}),$$

where $(K_n)_{n\in\mathbb{N}}$ is an increasing exhaustion of M by compact sets. By Proposition 10.1.10, this topology is independent of the chosen exhaustion. In particular, $\mathcal{D}(M,\mathbf{E})$ is an LF space.

The LF structure of $\mathcal{D}(M,\mathbf{E})$ gives a concrete description of sequential convergence: a sequence converges if and only if all its terms are supported in a common compact set and converge uniformly there together with all their covariant derivatives.

Corollary 10.1.12. Let M be a smooth manifold with or without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle. Let $\varphi_n, \varphi \in \mathcal{D}(M,\mathbf{E})$, with $n \in \mathbb{N}$. Then $\varphi_n \to \varphi$ in $\mathcal{D}(M,\mathbf{E})$ if and only if there exists a compact set $K \subseteq M$ such that:

(a) $\operatorname{supp}(\varphi_n) \subseteq K$ for every $n \in \mathbb{N}$ and $\operatorname{supp}(\varphi) \subseteq K$;

(b) for every $k \in \mathbb{N}_0$,

$$\|\varphi_n - \varphi\|_{C^k(K)} \to 0 \qquad \text{when } n \to \infty.$$

Proof. By definition, $\mathcal{D}(M,\mathbf{E})$ is the LF space generated by the sequence of Fréchet spaces $\Gamma_{K_n}(\mathbf{E})$. By the corresponding part of Theorem 4.4.6, the sequence φ_n converges to φ in $\mathcal{D}(M,\mathbf{E})$ if and only if there exists an index $N \in \mathbb{N}$ such that

$$\{\varphi\} \cup \{\varphi_n \mid n \in \mathbb{N}\} \subseteq \Gamma_{K_N}(\mathbf{E})$$

and, moreover, $\varphi_n \to \varphi$ in the Fréchet topology of $\Gamma_{K_N}(\mathbf{E})$.
The first condition means that all supports lie in the compact set K_N. Taking $K = K_N$ gives (a). On the other hand, the topology on $\Gamma_{K_N}(\mathbf{E})$ is induced by the family of seminorms $\|\cdot\|_{C^k(K_N)}$, with $k \in \mathbb{N}_0$. By the characterization of convergence in seminorm-induced topologies, Proposition B.10.23, convergence $\varphi_n \to \varphi$ in $\Gamma_{K_N}(\mathbf{E})$ is equivalent to

$$\|\varphi_n - \varphi\|_{C^k(K_N)} \to 0 \qquad \text{for every } k \in \mathbb{N}_0.$$

This proves (b).
Conversely, suppose there exists a compact set $K \subseteq M$ satisfying (a) and (b). Since $(K_n)_{n\in\mathbb{N}}$ is an increasing

exhaustion with $K_n \subseteq \mathrm{Int}(K_{n+1})$, there exists $N \in \mathbb{N}$ such that $K \subseteq K_N$. Then $\varphi_n, \varphi \in \Gamma_{K_N}(\mathbf{E})$ for every n.
Fix $k \in \mathbb{N}_0$. Since the sections $\varphi_n - \varphi$ are supported in K, they vanish on $M \setminus K$. Thus all their covariant derivatives also vanish on $M \setminus K$. In particular,

$$\|\varphi_n - \varphi\|_{C^k(K_N)} = \|\varphi_n - \varphi\|_{C^k(K)}.$$

By hypothesis (b), the right-hand side tends to 0. Since this holds for every $k \in \mathbb{N}_0$, we obtain $\varphi_n \to \varphi$ in $\Gamma_{K_N}(\mathbf{E})$. Applying Theorem 4.4.6 once again, we conclude that $\varphi_n \to \varphi$ in $\mathcal{D}(M, \mathbf{E})$. □

10.2 Distributions on vector bundles

With these tools, we are ready to define distributions in the setting of vector bundles.

Definition 10.2.1. Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let W be a finite-dimensional $\mathbb{K}$-vector space ($\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$).
Denote by $\mathcal{D}'(M, \mathbf{E}, W)$ the space of all continuous $\mathbb{K}$-linear maps

$$\mathbf{F} \colon \mathcal{D}(M, \mathbf{E}^*) \longrightarrow W$$

.
Equip $\mathcal{D}'(M, \mathbf{E}, W)$ with the weak-$*$ topology, defined as the initial topology associated with the family of evaluation maps

$$\mathrm{ev}_\varphi \colon \mathcal{D}'(M, \mathbf{E}, W) \longrightarrow W, \qquad \mathrm{ev}_\varphi(\mathbf{F}) = \mathbf{F}(\varphi), \qquad \varphi \in \mathcal{D}(M, \mathbf{E}^*),$$

that is, the topology generated by sets of the form

$$\mathrm{ev}_\varphi^{-1}(U) = \{\mathbf{F} \in \mathcal{D}'(M, \mathbf{E}, W) \mid \mathbf{F}(\varphi) \in U\},$$

where $\varphi \in \mathcal{D}(M, \mathbf{E}^*)$ and $U \subseteq W$ is open.
Elements of $\mathcal{D}'(M, \mathbf{E}, W)$ are called **distributions** on $\mathbf{E}$ with values in W.
When $W = \mathbb{K}$, we simply write $\mathcal{D}'(M, \mathbf{E})$, and if in addition $\mathbf{E} = T^{(0,0)}(TM)$, we write $\mathcal{D}'(M)$.

Remark 10.2.2. The weak-$*$ topology on $\mathcal{D}'(M, \mathbf{E}, W)$ agrees with the topology of pointwise convergence on $\mathcal{D}(M, \mathbf{E}^*)$. Thus a sequence $(\mathbf{F}_n)_{n \in \mathbb{N}} \subseteq \mathcal{D}'(M, \mathbf{E}, W)$ converges to $\mathbf{F} \in \mathcal{D}'(M, \mathbf{E}, W)$ if and only if

$$\mathbf{F}_n(\varphi) \to \mathbf{F}(\varphi) \qquad \forall \varphi \in \mathcal{D}(M, \mathbf{E}^*).$$

More generally, a net $(\mathbf{F}_\alpha)_\alpha$ converges to $\mathbf{F}$ if and only if

$$\mathbf{F}_\alpha(\varphi) \to \mathbf{F}(\varphi) \qquad \forall \varphi \in \mathcal{D}(M, \mathbf{E}^*).$$

Proposition 10.2.3. Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, let W be a finite-dimensional $\mathbb{K}$-vector space, and let $N := \dim W$. Then there exists a natural

isomorphism of topological vector spaces

$$\mathcal{D}'(M,\mathbf{E},W)\cong\mathcal{D}'(M,\mathbf{E})^N,$$

where the right-hand side is equipped with the product topology.

Proof. Let $\{w_1,\dots,w_N\}$ be a basis of W and $\{w^1,\dots,w^N\}$ the induced dual basis. Given $\mathbf{F}\in\mathcal{D}'(M,\mathbf{E},W)$, define

$$\mathbf{F}_j := w^j\circ\mathbf{F}\in\mathcal{D}'(M,\mathbf{E}),\qquad j\in\{1,\dots,N\}.$$

Then, for every $\varphi\in\mathcal{D}(M,\mathbf{E}^*)$, we have

$$\mathbf{F}(\varphi)=\sum_{j=1}^{N}\mathbf{F}_j(\varphi)\,w_j.$$

This defines a linear isomorphism

$$\mathcal{D}'(M,\mathbf{E},W)\longrightarrow\mathcal{D}'(M,\mathbf{E})^N.$$

Moreover, by the definition of the weak-$*$ topology, convergence in $\mathcal{D}'(M,\mathbf{E},W)$ is equivalent to componentwise convergence, showing that this isomorphism is a homeomorphism. □

Remark 10.2.4. In particular, there is a natural identification

$$\mathcal{D}'(M,\mathbf{E},W)\cong\mathcal{D}'(M,\mathbf{E})\otimes W,$$

which, upon choosing a basis of W, reduces to the preceding identification with a finite product.

Continuity can be characterized as follows, analogously to the Euclidean case.

Theorem 10.2.5. Let M be a smooth manifold with or without boundary, $\mathbf{E}\longrightarrow M$ a smooth vector bundle, and W a finite-dimensional $\mathbb{K}$-vector space equipped with a norm $|\cdot|_W$. Let $\mathbf{F}\colon\mathcal{D}(M,\mathbf{E}^*)\longrightarrow W$ be a linear operator. Then the following properties are equivalent:

(a) $\mathbf{F}$ is continuous.

(b) If $\{\varphi_k\}_{k\in\mathbb{N}}$ converges to φ in $\mathcal{D}(M,\mathbf{E}^*)$, then

$$\lim_{k\to\infty}\mathbf{F}(\varphi_k)=\mathbf{F}(\varphi).$$

(c) For every compact set $K\subseteq M$, the restriction $\mathbf{F}\restriction_{\mathcal{D}_K(M,\mathbf{E}^*)}$ is continuous.

(d) For every compact set $K\subseteq M$, there exist $m\in\mathbb{N}_0$ and $c_K>0$ such that

$$|\mathbf{F}(\varphi)|_W\le c_K\|\varphi\|_{C^m(K)}\qquad\forall\varphi\in\mathcal{D}_K(M,\mathbf{E}^*).$$

Proof. (a)⇒(b). Let $\{\varphi_k\}_{k\in\mathbb{N}}$ be a sequence in $\mathcal{D}(M,\mathbf{E}^*)$ such that $\varphi_k\to\varphi$. Continuity of $\mathbf{F}$ directly gives

$$\mathbf{F}(\varphi_k)\longrightarrow\mathbf{F}(\varphi).$$

(b)⇒(c). Let $K \subseteq M$ be a compact set. Consider the canonical inclusion

$$\iota\colon \mathcal{D}_K(M,\mathbf{E}^*) \hookrightarrow \mathcal{D}(M,\mathbf{E}^*),$$

which is continuous by construction of the inductive topology.
Let $\{\varphi_k\}_{k\in\mathbb{N}}$ be a sequence in $\mathcal{D}_K(M,\mathbf{E}^*)$ such that $\varphi_k \to \varphi$ in $\mathcal{D}_K(M,\mathbf{E}^*)$. Then $\varphi_k \to \varphi$ in $\mathcal{D}(M,\mathbf{E}^*)$, and by (b),

$$\mathbf{F}(\varphi_k) \longrightarrow \mathbf{F}(\varphi).$$

This shows that the restriction $\mathbf{F}\restriction_{\mathcal{D}_K(M,\mathbf{E}^*)}$ is sequentially continuous. Since $\mathcal{D}_K(M,\mathbf{E}^*)$ is a Fréchet space, it is in particular metrizable, and Proposition B.10.10 shows that sequential continuity implies continuity. Therefore $\mathbf{F}\restriction_{\mathcal{D}_K(M,\mathbf{E}^*)}$ is continuous.
(c)⇒(a). Let $\{K_n\}_{n\in\mathbb{N}}$ be an exhausting sequence of compact sets such that

$$\mathcal{D}(M,\mathbf{E}^*) = \varinjlim_{n\in\mathbb{N}} \mathcal{D}_{K_n}(M,\mathbf{E}^*).$$

By hypothesis, for every $n \in \mathbb{N}$ the restriction $\mathbf{F}\restriction_{\mathcal{D}_{K_n}(M,\mathbf{E}^*)}$ is continuous.
By the definition of the inductive topology (Theorem 4.4.1), a linear operator

$$\mathbf{F}\colon \mathcal{D}(M,\mathbf{E}^*) \longrightarrow W$$

is continuous if and only if all its restrictions to the spaces $\mathcal{D}_{K_n}(M,\mathbf{E}^*)$ are continuous. We conclude that $\mathbf{F}$ is continuous.

(c)⇒(d). Let $K \subseteq M$ be a compact set. Then $\mathcal{D}_K(M,\mathbf{E}^*)$ is a locally convex topological vector space whose topology is generated by the increasing family of seminorms

$$\|\varphi\|_{C^m(K)}, \qquad m \in \mathbb{N}_0.$$

By (c), the restriction $\mathbf{F}\restriction_{\mathcal{D}_K(M,\mathbf{E}^*)}$ is continuous. Applying Theorem B.10.25 gives $m \in \mathbb{N}_0$ and $c_K > 0$ such that

$$|\mathbf{F}(\varphi)|_W \leq c_K \|\varphi\|_{C^m(K)} \qquad \forall \varphi \in \mathcal{D}_K(M,\mathbf{E}^*).$$

(d)⇒(c). Let $K \subseteq M$ be compact. Suppose the estimate in (d) holds. If $\{\varphi_k\}_{k\in\mathbb{N}}$ converges to φ in $\mathcal{D}_K(M,\mathbf{E}^*)$, then in particular

$$\|\varphi_k - \varphi\|_{C^m(K)} \longrightarrow 0$$

for every $m \in \mathbb{N}_0$. Applying the estimate in (d), we obtain

$$|\mathbf{F}(\varphi_k) - \mathbf{F}(\varphi)|_W \leq c_K \|\varphi_k - \varphi\|_{C^m(K)} \longrightarrow 0.$$

This shows that $\mathbf{F}\restriction_{\mathcal{D}_K(M,\mathbf{E}^*)}$ is continuous.

□

With this in mind, we define the order of a distribution:

Definition 10.2.6. Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, let W be a finite-dimensional vector space, and let $\mathbf{F}\colon \mathcal{D}(M,\mathbf{E}^*) \longrightarrow W$ be a distribution.
Let $K \subseteq M$ be a compact set. By part (d) of Theorem 10.2.5, there exist $m_K \in \mathbb{N}_0$ and $C_K > 0$ such that

$$|\mathbf{F}(\boldsymbol{\varphi})|_W \le C_K \|\boldsymbol{\varphi}\|_{C^{m_K}(K)} \qquad \forall \boldsymbol{\varphi} \in \mathcal{D}_K(M,\mathbf{E}^*).$$

The least integer m_K satisfying this inequality is called the *order* of $\mathbf{F}$ on the compact set K.
We say that $\mathbf{F}$ is a distribution of *order* m on M if m is the least nonnegative integer such that, for every compact set $K \subseteq M$, there exists a constant $C_K > 0$ with

$$|\mathbf{F}(\boldsymbol{\varphi})|_W \le C_K \|\boldsymbol{\varphi}\|_{C^{m}(K)} \qquad \forall \boldsymbol{\varphi} \in \mathcal{D}_K(M,\mathbf{E}^*).$$

If no such integer m exists, we say that $\mathbf{F}$ is a distribution of infinite order.

Lemma 10.2.7. (Approximation with controlled enlargement of the support) Let M be a smooth manifold with or without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle. If $K \subseteq \operatorname{Int} L$ are compact, then for each $\mathbf{u} \in \Gamma^m_K(\mathbf{E})$ there exists a sequence $\mathbf{u}_j \in \Gamma_L(\mathbf{E})$ such that $\mathbf{u}_j \to \mathbf{u}$ in the $C^m(L)$ norm.

Proof. If $\dim M = 0$, every section is smooth, and it suffices to take $\mathbf{u}_j = \mathbf{u}$. Suppose that $\dim M = n \ge 1$. Choose an open subset V with $K \subseteq V \Subset \operatorname{Int} L$, a finite cover of $\overline{V}$ by trivializing charts relatively compact in $\operatorname{Int} L$, and functions $\rho_a \in C^\infty_c(M)$ subordinate to these charts, indexed by $a \in \{1,\dots,N\}$, whose sum is one on a neighborhood of K. Then $\mathbf{u} = \sum_{a=1}^{N} \rho_a \mathbf{u}$. In each chart, the support of the components of $\rho_a \mathbf{u}$ is a compact subset of its coordinate domain; in particular, it is separated from its artificial boundaries.
Fix a nonnegative mollifier $\eta \in C^\infty_c(B(0,1))$ with integral one, and set $\eta_\varepsilon(z) = \varepsilon^{-n}\eta(z/\varepsilon)$. In an interior chart, each component f extends by zero to $\mathbb{R}^n$ as a compactly supported function of class C^m. The convolution $\eta_\varepsilon * f$ converges to f uniformly together with derivatives of order at most m.
In a boundary chart, first extend f by zero within $\mathbb{H}^n = \{x \in \mathbb{R}^n \mid x_n \ge 0\}$, only across the artificial boundaries of the chart. This extension remains of class C^m up to the boundary and has compact support in $\mathbb{H}^n$. Denote by f_0 its measurable extension by zero to the lower half-space, and define

$$f_\varepsilon(x) := (\eta_\varepsilon * f_0)(x + 2\varepsilon e_n), \qquad x \in \mathbb{H}^n.$$

The convolution is smooth on $\mathbb{R}^n$. Moreover, for $x_n \ge 0$ and $z \in \operatorname{supp}\eta$, the last coordinate of $x + 2\varepsilon e_n - \varepsilon z$ is at least ε. Thus, for every $\alpha \in \mathbb{N}_0^n$ with $|\alpha| \le m$, we may differentiate using only interior values of f, obtaining

$$D^\alpha f_\varepsilon(x) = \int_{\mathbb{R}^n} \eta(z) D^\alpha f(x + 2\varepsilon e_n - \varepsilon z)\, dz.$$

The derivatives $D^\alpha f$ are uniformly continuous on the half-space, since they are continuous up to the boundary and compactly supported. Since $|2\varepsilon e_n - \varepsilon z| \le 3\varepsilon$ in this integral and $\int \eta = 1$, it follows that

$$\max_{|\alpha| \le m} \sup_{x \in \mathbb{H}^n} |D^\alpha f_\varepsilon(x) - D^\alpha f(x)| \longrightarrow 0.$$

In either type of chart, the support of the approximant lies in the neighborhood of radius 3ε of the original

support, taken in the corresponding coordinate model. For each support, we can choose a slightly larger compact set still contained in the chart domain. Taking ε sufficiently small ensures that all approximants are supported in these fixed compact sets. They are then transferred to the bundle and extended by zero outside their charts; the resulting sections are smooth and supported in $\operatorname{Int} L$. Equivalence of coordinate and covariant norms on these compact sets, given by Theorem 10.1.2, turns convergence of the components into C^m convergence of the sections. Since there are only finitely many charts and components, choose a common sequence $\varepsilon_j \downarrow 0$ and sum the approximants. This gives $\mathbf{u}_j \in \Gamma_L(\mathbf{E})$ with $\mathbf{u}_j \to \mathbf{u}$ in $C^m(L)$. □

Remark 10.2.8. Let $\mathbf{F}\colon \mathcal{D}(M,\mathbf{E}^*) \to W$ be a distribution of global order m. For $\mathbf{u} \in \Gamma_K^m(\mathbf{E}^*)$, choose a compact set L with $K \subseteq \operatorname{Int} L$ and, by the preceding lemma, $\mathbf{u}_j \in \Gamma_L(\mathbf{E}^*)$ with $\mathbf{u}_j \to \mathbf{u}$ in $C^m(L)$. The order estimate on L shows that $(\mathbf{F}(\mathbf{u}_j))$ is Cauchy; define

$$\widetilde{\mathbf{F}}(\mathbf{u}) := \lim_j \mathbf{F}(\mathbf{u}_j).$$

The value is independent of L and the approximation. Indeed, for two choices L_1, L_2, take a compact set L_3 containing both in its interior. The differences of the two approximants converge to zero in $C^m(L_3)$, and the order estimate on L_3 forces the limits to agree. This gives a unique continuous linear extension

$$\widetilde{\mathbf{F}}\colon \Gamma_c^m(\mathbf{E}^*) \longrightarrow W$$

agreeing with $\mathbf{F}$ on $\mathcal{D}(M,\mathbf{E}^*)$. For each compact set K, its restriction to $\Gamma_K^m(\mathbf{E}^*)$ is continuous because, choosing L as above, $\|\mathbf{u}\|_{C^m(L)} = \|\mathbf{u}\|_{C^m(K)}$.

We give some examples of distributions.

Example 10.2.9. We present two fundamental examples of distributions. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle. Fix an auxiliary bundle metric $\mathbf{h}_{\mathbf{E}}$ on $\mathbf{E}$, and denote by $\mathbf{h}_{\mathbf{E}}^*$ the dual metric on $\mathbf{E}^*$.

(a) The Dirac delta. Let $p \in M$. Define

$$\delta_p\colon \mathcal{D}(M,\mathbf{E}^*) \longrightarrow \mathbf{E}_p^*, \qquad \delta_p(\boldsymbol{\varphi}) := \boldsymbol{\varphi}(p).$$

Let $K \subseteq M$ be compact and $\boldsymbol{\varphi} \in \mathcal{D}_K(M,\mathbf{E}^*)$. If $p \notin K$, then $\delta_p(\boldsymbol{\varphi}) = 0$. If $p \in K$, we have

$$|\delta_p(\boldsymbol{\varphi})|_{\mathbf{h}_{\mathbf{E}}^*(p)} = |\boldsymbol{\varphi}(p)|_{\mathbf{h}_{\mathbf{E}}^*(p)} \le \sup_{x\in K} |\boldsymbol{\varphi}(x)|_{\mathbf{h}_{\mathbf{E}}^*(x)} \le \|\boldsymbol{\varphi}\|_{C^0(K,\mathbf{E}^*)}.$$

In either case, there exists $C_K = 1$ such that

$$|\delta_p(\boldsymbol{\varphi})|_{\mathbf{h}_{\mathbf{E}}^*(p)} \le C_K \|\boldsymbol{\varphi}\|_{C^0(K,\mathbf{E}^*)}.$$

By part (d) of Theorem 10.2.5, δ_p is continuous. Moreover, since the estimate holds with $m = 0$ for every compact set K, we conclude that δ_p is a distribution of order 0.

(b) Locally integrable sections. Let $\mathbf{f} \in L^1_{\mathrm{loc}}(M,\mathbf{E})$. Define

$$\mathbf{T}_{\mathbf{f}}(\boldsymbol{\varphi}) := \int_M \boldsymbol{\varphi}(\mathbf{f})\, d\lambda_{\mathbf{g}}, \qquad \boldsymbol{\varphi} \in \mathcal{D}(M,\mathbf{E}^*).$$

Let $K \subseteq M$ be compact and $\varphi \in \mathcal{D}_K(M, \mathbf{E}^*)$. Then

$$|\mathbf{T}_\mathbf{f}(\varphi)| \leq \int_K |\varphi(x)(\mathbf{f}(x))|\, d\lambda_\mathbf{g}(x) \leq \int_K |\varphi(x)|_{\mathbf{h}^*_\mathbf{E}(x)}\, |\mathbf{f}(x)|_{\mathbf{h}_\mathbf{E}(x)}\, d\lambda_\mathbf{g}(x).$$

Hence

$$|\mathbf{T}_\mathbf{f}(\varphi)| \leq \|\varphi\|_{C^0(K,\mathbf{E}^*)} \int_K |\mathbf{f}(x)|_{\mathbf{h}_\mathbf{E}(x)}\, d\lambda_\mathbf{g}(x).$$

Since $\mathbf{f} \in L^1_{\mathrm{loc}}(M, \mathbf{E})$, the integral is finite; denoting it by C_K, we obtain

$$|\mathbf{T}_\mathbf{f}(\varphi)| \leq C_K \|\varphi\|_{C^0(K,\mathbf{E}^*)}.$$

By part (d) of Theorem 10.2.5, $\mathbf{T}_\mathbf{f}$ is continuous and, since it depends only on the norm C^0, is a distribution of order 0.

Although every locally integrable section can be viewed as a distribution, we may ask when a distribution is induced by such a section. Because of their significance, these distributions have a special name, which we record in the following definition:

Definition 10.2.10. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle. A distribution $\mathbf{T}\colon \mathcal{D}(M, \mathbf{E}^*) \longrightarrow \mathbb{K}$ is called *regular* if there exists $\mathbf{f} \in L^1_{\mathrm{loc}}(M, \mathbf{E})$ such that

$$\mathbf{T}(\varphi) = \int_M \varphi(\mathbf{f})\, d\lambda_\mathbf{g} \qquad \forall \varphi \in \mathcal{D}(M, \mathbf{E}^*),$$

where $\varphi(\mathbf{f})(x) = \varphi(x)(\mathbf{f}(x))$.

Remark 10.2.11. The linear map $\mathbf{f} \mapsto \mathbf{T}_\mathbf{f}$ defines an operator from $L^1_{\mathrm{loc}}(M, \mathbf{E})$ to the space of distributions. We will later see that this operator is injective. Thus it is customary to identify the section $\mathbf{f}$ with the distribution it induces, writing simply $\mathbf{f}(\varphi)$ instead of $\mathbf{T}_\mathbf{f}(\varphi)$.

The appearance of $\mathbf{E}^*$ in the space of test sections is explained by the canonical pairing between a bundle and its dual:

Remark 10.2.12. The choice to define a distribution as a linear operator

$$\mathbf{T}\colon \mathcal{D}(M, \mathbf{E}^*) \longrightarrow W,$$

where W is a finite-dimensional normed vector space, is motivated by the existence of a canonical pairing between a vector bundle and its dual.
If $\mathbf{f} \in \Gamma(\mathbf{E})$ is a sufficiently regular section, then to each $\varphi \in \mathcal{D}(M, \mathbf{E}^*)$ we can naturally associate a scalar by fiberwise contraction

$$\varphi(\mathbf{f})(x) = \varphi(x)(\mathbf{f}(x)).$$

This allows us to define a linear operator

$$\mathbf{T}_\mathbf{f}\colon \mathcal{D}(M, \mathbf{E}^*) \longrightarrow \mathbb{K}, \qquad \mathbf{T}_\mathbf{f}(\varphi) = \int_M \varphi(x)(\mathbf{f}(x))\, d\lambda_\mathbf{g}(x),$$

generalizing the classical scalar case.
For example, if $\Omega \subseteq \mathbb{R}^n$ is open and $f \in L^1_{\mathrm{loc}}(\Omega)$, then the expression

$$\int_\Omega f(x)\,\varphi(x)\,dx, \qquad \varphi \in C_c^\infty(\Omega),$$

defines a scalar distribution. The preceding formulation is simply the intrinsic version of this construction in the setting of vector bundles.

Observe that this construction uses only the canonical pairing

$$\mathbf{E}_x^* \times \mathbf{E}_x \longrightarrow \mathbb{K},$$

which requires no additional structure. In particular, if we worked with sections of $\mathbf{E}$ instead of sections of $\mathbf{E}^*$, there would be no natural way to define an expression of the form

$$\int_M \psi(x)\,\mathbf{f}(x)\,d\lambda_{\mathbf{g}}(x),$$

for $\psi, \mathbf{f} \in \Gamma(\mathbf{E})$ without introducing a bundle metric identifying $\mathbf{E}$ with $\mathbf{E}^*$.
For this reason, the formulation in terms of $\mathbf{E}^*$ is intrinsic and independent of additional geometric choices.

The extension to the W-valued case arises naturally when considering finite families of distributions. If $W \cong \mathbb{K}^r$, a linear operator

$$\mathbf{T}\colon \mathcal{D}(M,\mathbf{E}^*) \longrightarrow W$$

can be written as

$$\mathbf{T}(\varphi) = \big(T_1(\varphi),\dots,T_r(\varphi)\big),$$

where each $T_i\colon \mathcal{D}(M,\mathbf{E}^*) \longrightarrow \mathbb{K}$ is a scalar distribution. In this sense, distributions with values in W introduce no new analytic difficulty, but allow finitely many scalar distributions to be treated simultaneously.

This formulation will be fundamental later when considering distributions on product manifolds and describing linear operators by distributional kernels.

10.2.1 Partial differential operators and distributions

We have seen that distributions are defined as linear functionals on the space of test sections $\mathcal{D}(M,\mathbf{E}^*)$. In particular, to extend the action of differential operators to distributions, we must understand how these operators interact with this space.

Let

$$P\colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{F})$$

be a differential operator. If $\mathbf{T}$ is a distribution, we would like to define a new distribution $P\mathbf{T}$ representing the action of P on $\mathbf{T}$. By analogy with the classical case, it is natural to expect this action to be determined by an identity of the form

$$(P\mathbf{T})(\varphi) = \mathbf{T}(\text{expression depending on } P \text{ and } \varphi).$$

Since $\mathbf{T}$ is defined only on $\mathcal{D}(M,\mathbf{E}^*)$, the preceding expression suggests that to each $\varphi \in \mathcal{D}(M,\mathbf{F}^*)$ we should

associate a section of $\mathcal{D}(M, \mathbf{E}^*)$. That is, we need to construct an operator

$$P' \colon \mathcal{D}(M, \mathbf{F}^*) \longrightarrow \mathcal{D}(M, \mathbf{E}^*),$$

that transfers the action of P to test sections.

Unlike the pointwise case, transferring differential operators requires the integral structure of the manifold in order to integrate by parts. This suggests that the operator P' should be characterized by an integral identity involving the natural evaluation between bundles and their duals.

Definition 10.2.13. (Formal transpose) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E}, \mathbf{F} \to M$ be complex vector bundles. If $P \in \mathbf{PDO}(\mathbf{E}, \mathbf{F})$, its *formal transpose* is an operator

$$P' \colon \Gamma(\mathbf{F}^*) \longrightarrow \Gamma(\mathbf{E}^*)$$

satisfying

$$\int_M \psi(P\mathbf{u})\, d\lambda_{\mathbf{g}} = \int_M (P'\psi)(\mathbf{u})\, d\lambda_{\mathbf{g}} \tag{10.1}$$

for every $\mathbf{u} \in \Gamma_c(\mathbf{E})$ and every $\psi \in \Gamma_c(\mathbf{F}^*)$. The pairing in this identity is complex-bilinear. In the real case, the same definition applies, with all conjugations below omitted.

Proposition 10.2.14. (Intrinsic construction of the formal transpose) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E}, \mathbf{F} \to M$ be complex vector bundles. Let $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$. The formal transpose exists, is unique, and belongs to $\mathbf{PDO}^{(m)}(\mathbf{F}^*, \mathbf{E}^*)$. For any auxiliary Hermitian metrics $\mathbf{h}_{\mathbf{E}}, \mathbf{h}_{\mathbf{F}}$, linear in the first variable, we have

$$P' = \mathcal{R}_{\mathbf{E}} \circ \overline{P_h^*} \circ \mathcal{R}_{\mathbf{F}}^{-1}. \tag{10.2}$$

The domains and codomains of the composition are displayed in the diagram

$$\mathbf{F}^* \xrightarrow{\mathcal{R}_{\mathbf{F}}^{-1}} \overline{\mathbf{F}} \xrightarrow{\overline{P_h^*}} \overline{\mathbf{E}} \xrightarrow{\mathcal{R}_{\mathbf{E}}} \mathbf{E}^*.$$

In particular, the right-hand side of (10.2) is independent of the auxiliary bundle metrics.

Proof. The Riesz isomorphisms $\mathcal{R}_{\mathbf{F}}^{-1} \colon \mathbf{F}^* \to \overline{\mathbf{F}}$ and $\mathcal{R}_{\mathbf{E}} \colon \overline{\mathbf{E}} \to \mathbf{E}^*$ are complex-linear and of order zero. By the theory of operator conjugation, $\overline{P_h^*} \colon \Gamma(\overline{\mathbf{F}}) \to \Gamma(\overline{\mathbf{E}})$ is complex-linear and has order at most m. By composition, the right-hand side of (10.2) is a complex-linear operator of order at most m.
Let $\mathbf{u} \in \Gamma_c(\mathbf{E})$ and $\psi \in \Gamma_c(\mathbf{F}^*)$, and write

$$\mathcal{R}_{\mathbf{F}}^{-1}\psi = \overline{\mathbf{v}}, \qquad \mathbf{v} \in \Gamma_c(\mathbf{F}).$$

By the definition $\mathcal{R}_{\mathbf{F}}(\overline{\mathbf{v}})(\mathbf{w}) = \mathbf{h}_{\mathbf{F}}(\mathbf{w}, \mathbf{v})$ and the Hermitian adjoint identity,

$$\begin{aligned} \int_M \psi(P\mathbf{u})\, d\lambda_{\mathbf{g}} &= \int_M \mathbf{h}_{\mathbf{F}}(P\mathbf{u}, \mathbf{v})\, d\lambda_{\mathbf{g}} \\ &= \int_M \mathbf{h}_{\mathbf{E}}(\mathbf{u}, P_h^*\mathbf{v})\, d\lambda_{\mathbf{g}} \end{aligned}$$

$$= \int_M \mathcal{R}_{\mathbf{E}}\left(\overline{P_h^*\mathbf{v}}\right)(\mathbf{u})\, d\lambda_{\mathbf{g}}$$
$$= \int_M \left(\mathcal{R}_{\mathbf{E}} \circ \overline{P_h^*} \circ \mathcal{R}_{\mathbf{F}}^{-1}\right)(\psi)(\mathbf{u})\, d\lambda_{\mathbf{g}}.$$

This proves (10.1).

For uniqueness, let $S_1, S_2 \in \mathbf{PDO}(\mathbf{F}^*, \mathbf{E}^*)$ be two operators satisfying this identity. Fix $\psi \in \Gamma_c(\mathbf{F}^*)$ and set $\eta = (S_1 - S_2)\psi \in \Gamma_c(\mathbf{E}^*)$. If $\mathcal{R}_{\mathbf{E}}^{-1}\eta = \overline{\mathbf{w}}$, then $\mathbf{w} \in \Gamma_c(\mathbf{E})$ and, taking $\mathbf{u} = \mathbf{w}$, we obtain

$$0 = \int_M \eta(\mathbf{w})\, d\lambda_{\mathbf{g}} = \int_M \mathbf{h}_{\mathbf{E}}(\mathbf{w}, \mathbf{w})\, d\lambda_{\mathbf{g}}.$$

Therefore $\mathbf{w} = 0$ and $S_1\psi = S_2\psi$. For a section ψ without compact support, choose a cutoff equal to one near a given point and use locality of S_1, S_2. Thus $S_1 = S_2$ on all sections. Since any choice of auxiliary metrics produces an operator satisfying the same integral identity, uniqueness proves independence of these metrics. □

Corollary 10.2.15. (Local formula for the formal transpose) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, let $\mathbf{E}, \mathbf{F} \to M$ be complex vector bundles, and let $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$. In a chart $\varphi\colon U \to \Omega \subseteq \mathbb{R}^n$, with coordinate functions $(x^1, \dots, x^n)$, let $(\mathbf{e}_1, \dots, \mathbf{e}_r)$ and $(\mathbf{f}_1, \dots, \mathbf{f}_s)$ be local frames of $\mathbf{E}$ and $\mathbf{F}$, and let $(\mathbf{e}^1, \dots, \mathbf{e}^r)$ and $(\mathbf{f}^1, \dots, \mathbf{f}^s)$ be their dual frames. Set

$$D_\varphi^\alpha a := \left[D^\alpha (a \circ \varphi^{-1})\right] \circ \varphi.$$

If

$$P\left(\sum_{i=1}^r u^i \mathbf{e}_i\right) = \sum_{j=1}^s \left(\sum_{i=1}^r \sum_{|\alpha| \le m} a_{\alpha i}^j D_\varphi^\alpha u^i\right) \mathbf{f}_j,$$

then, for $\psi = \sum_{j=1}^s \psi_j \mathbf{f}^j$,

$$P'\psi = \frac{1}{\sqrt{\det(\mathbf{g})}} \sum_{i=1}^r \left[\sum_{j=1}^s \sum_{|\alpha| \le m} (-1)^{|\alpha|} D_\varphi^\alpha \left(\sqrt{\det(\mathbf{g})}\, a_{\alpha i}^j \psi_j\right)\right] \mathbf{e}^i, \tag{10.3}$$

where $g_{ab} = \mathbf{g}(\partial_a, \partial_b)$.

Proof. Let $\mathbf{u} = \sum_{i=1}^r u^i \mathbf{e}_i \in \Gamma_c(\mathbf{E}|_U)$ and let $\psi = \sum_{j=1}^s \psi_j \mathbf{f}^j \in \Gamma(\mathbf{F}^*|_U)$. By the local formulas for P and the Riemannian measure,

$$\int_U \psi(P\mathbf{u})\, d\lambda_{\mathbf{g}} = \sum_{i=1}^r \sum_{j=1}^s \sum_{|\alpha| \le m} \int_\Omega \left(a_{\alpha i}^j \circ \varphi^{-1}\right)\left(\psi_j \circ \varphi^{-1}\right) D^\alpha \left(u^i \circ \varphi^{-1}\right)\left(\sqrt{\det(\mathbf{g})} \circ \varphi^{-1}\right) d\lambda_n.$$

The function $u^i \circ \varphi^{-1}$ has compact support in Ω. Integrating by parts $|\alpha|$ times, without boundary terms,

the summand corresponding to i, j, α becomes

$$(-1)^{|\alpha|}\int_{\Omega}\big(u^{i}\circ\varphi^{-1}\big)D^{\alpha}\Big[\Big(\sqrt{\det(\mathbf{g})}\,a^{j}_{\alpha i}\psi_{j}\Big)\circ\varphi^{-1}\Big]\,d\lambda_{n}.$$

Summing all terms and inserting $\big(\sqrt{\det(\mathbf{g})}\big)^{-1}\sqrt{\det(\mathbf{g})}$ gives

$$\int_{U}\boldsymbol{\psi}(P\mathbf{u})\,d\lambda_{\mathbf{g}}=\int_{U}(P'\boldsymbol{\psi})(\mathbf{u})\,d\lambda_{\mathbf{g}},$$

where $P'\boldsymbol{\psi}$ is precisely the right-hand side of (10.3). Uniqueness of the formal transpose identifies this local expression with the global operator already constructed. □

Proposition 10.2.16. (Rules for the formal transpose) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E},\mathbf{F},\mathbf{G}\to M$ be complex vector bundles. Let $P\in\mathbf{PDO}(\mathbf{E},\mathbf{F})$, $Q\in\mathbf{PDO}(\mathbf{F},\mathbf{G})$, and $R\in\mathbf{PDO}(\mathbf{E},\mathbf{F})$. Then:

(a) for every $\lambda\in\mathbb{C}$,
$$(P+\lambda R)'=P'+\lambda R';$$

(b)
$$(Q\circ P)'=P'\circ Q';$$

(c) if $U\subseteq M$ is open and P_{U} denotes the local restriction of P, then
$$(P_{U})'=(P')_{U};$$

(d) if P has order zero, then
$$(P'\boldsymbol{\psi})(\mathbf{u})=\boldsymbol{\psi}(P\mathbf{u})$$
pointwise; in particular, $(M_{f})'=M_{f}$;

(e) if
$$\kappa_{\mathbf{E}}\colon\overline{\mathbf{E}^{*}}\longrightarrow(\overline{\mathbf{E}})^{*},\qquad\kappa_{\mathbf{E}}(\overline{\boldsymbol{\eta}})(\overline{v}):=\overline{\boldsymbol{\eta}(v)},$$
and
$$\kappa_{\mathbf{F}}\colon\overline{\mathbf{F}^{*}}\longrightarrow(\overline{\mathbf{F}})^{*},\qquad\kappa_{\mathbf{F}}(\overline{\psi})(\overline{w}):=\overline{\psi(w)},$$
then
$$(\overline{P})'=\kappa_{\mathbf{E}}\circ\overline{P'}\circ\kappa_{\mathbf{F}}^{-1}.\tag{10.4}$$

Proof. The first identity follows from bilinearity of (10.1); unlike the Hermitian adjoint, no $\overline{\lambda}$ appears here. For $\mathbf{u}\in\Gamma_{c}(\mathbf{E})$ and $\boldsymbol{\theta}\in\Gamma_{c}(\mathbf{G}^{*})$,

$$\int_{M}\boldsymbol{\theta}(QP\mathbf{u})\,d\lambda_{\mathbf{g}}=\int_{M}(Q'\boldsymbol{\theta})(P\mathbf{u})\,d\lambda_{\mathbf{g}}=\int_{M}(P'Q'\boldsymbol{\theta})(\mathbf{u})\,d\lambda_{\mathbf{g}},$$

which proves the second identity by uniqueness. The same integral identity, applied entirely within U, proves the third. The fourth is the definition of the fiberwise algebraic transpose.

The map $\kappa_{\mathbf{E}}$ is a complex-linear isomorphism. For $\mathbf{u} \in \Gamma_c(\mathbf{E})$ and $\eta \in \Gamma_c(\mathbf{F}^*)$, we have

$$\kappa_{\mathbf{F}}(\overline{\eta})(\overline{P}\,\overline{\mathbf{u}}) = \overline{\eta(P\mathbf{u})}, \qquad \kappa_{\mathbf{E}}(\overline{P'\eta})(\overline{\mathbf{u}}) = \overline{(P'\eta)(\mathbf{u})}.$$

Conjugating the integral identity for P' yields the integral identity for the right-hand side of (10.4); uniqueness of the formal transpose finishes the proof. □

The preceding construction extends the action of differential operators to distributions. If $P\colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{F})$ is a differential operator and $P'\colon \Gamma(\mathbf{F}^*) \longrightarrow \Gamma(\mathbf{E}^*)$ denotes its formal transpose with respect to the bilinear evaluation pairing, then P' sends test sections of $\mathbf{F}^*$ to test sections of $\mathbf{E}^*$. This allows the action of P on a distribution to be defined by duality.

Lemma 10.2.17. (C^k estimate for differential operators) Let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be smooth vector bundles of ranks r and s, respectively, over a smooth manifold M with or without boundary, and let $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$. Then, for every compact set $K \subseteq M$ and every $k \in \mathbb{N}_0$, there exists a constant $C_{K,k} > 0$ such that

$$\|P\mathbf{u}\|_{C^k(K,\mathbf{F})} \leq C_{K,k}\|\mathbf{u}\|_{C^{k+m}(K,\mathbf{E})}, \qquad \mathbf{u} \in \Gamma_K^{k+m}(\mathbf{E}).$$

In particular, P induces a continuous map

$$P\colon \mathcal{D}_K(M,\mathbf{E}) \longrightarrow \mathcal{D}_K(M,\mathbf{F}).$$

Proof. Let $K \subseteq M$ be compact. Take a finite family of smooth charts (U_i, φ_i), with $i \in \{1,\dots,N\}$, such that each U_i is a regular coordinate ball, local trivializations

$$\boldsymbol{\tau}_{\mathbf{E},i}\colon \mathbf{E} \restriction_{U_i} \longrightarrow U_i \times \mathbb{K}^r, \qquad \boldsymbol{\tau}_{\mathbf{F},i}\colon \mathbf{F} \restriction_{U_i} \longrightarrow U_i \times \mathbb{K}^s,$$

exist, and $K \subseteq \bigcup_{i=1}^{N} U_i$ holds.

Consider a partition of unity $\{\psi_i\}_{i=1}^N$ subordinate to the cover $\{U_i\}_{i=1}^N$ of K, with sum one on a neighborhood of K, and define

$$K_i := K \cap \operatorname{supp}(\psi_i).$$

Since $\operatorname{supp}(\psi_i)$ is closed in M and contained in U_i, each K_i is a compact subset of U_i. Omit the indices for which $K_i = \varnothing$ and renumber the rest. If $\mathbf{u} \in \Gamma_K^{k+m}(\mathbf{E})$, then $\operatorname{supp}(\mathbf{u}) \subseteq K$ and

$$\mathbf{u} = \sum_{i=1}^{N} \psi_i \mathbf{u}.$$

Moreover, since $\operatorname{supp}(\psi_i) \subseteq U_i$, we have

$$\operatorname{supp}(\psi_i\mathbf{u}) \subseteq \operatorname{supp}(\mathbf{u}) \cap \operatorname{supp}(\psi_i) \subseteq K \cap \operatorname{supp}(\psi_i) = K_i.$$

Fix $i \in \{1,\dots,N\}$ and write $\mathbf{v}_i := \psi_i\mathbf{u}$. Define its local representation in the trivialization $\boldsymbol{\tau}_{\mathbf{E},i}$ by

$$\widetilde{v_i} := \pi_2 \circ \boldsymbol{\tau}_{\mathbf{E},i} \circ (\mathbf{v}_i \restriction_{U_i})\colon U_i \longrightarrow \mathbb{K}^r,$$

and similarly define the local representation of $P\mathbf{v}_i$ in the trivialization $\boldsymbol{\tau}_{\mathbf{F},i}$ by

$$\widetilde{P\mathbf{v}_i} := \pi_2 \circ \boldsymbol{\tau}_{\mathbf{F},i} \circ ((P\mathbf{v}_i) \restriction_{U_i}) \colon U_i \longrightarrow \mathbb{K}^s.$$

By Theorem 8.1.34, there exist smooth functions

$$a_{\alpha,i} \colon U_i \longrightarrow \operatorname{Hom}(\mathbb{K}^r, \mathbb{K}^s), \qquad |\alpha| \le m,$$

such that

$$\widetilde{P\mathbf{v}_i} = \sum_{|\alpha| \le m} a_{\alpha,i}\, D^\alpha \widetilde{v}_i.$$

Let β be a multi-index with $|\beta| \le k$. We apply the Leibniz rule to the bilinear map

$$\operatorname{Hom}(\mathbb{K}^r, \mathbb{K}^s) \times \mathbb{K}^r \longrightarrow \mathbb{K}^s, \qquad (A, w) \longmapsto A(w).$$

To make the notation precise, if $A \colon U_i \longrightarrow \operatorname{Hom}(\mathbb{K}^r, \mathbb{K}^s)$ and we write $A(x) = (A^b_a(x))$, with $1 \le a \le r$ and $1 \le b \le s$, then we define $D^\gamma A$ componentwise, that is,

$$D^\gamma A(x) := \big(D^\gamma A^b_a(x)\big).$$

With this convention, $D^\gamma A(x)$ remains an element of $\operatorname{Hom}(\mathbb{K}^r, \mathbb{K}^s)$.
Then, for each $|\beta| \le k$, we have

$$D^\beta(\widetilde{P\mathbf{v}_i}) = \sum_{|\alpha| \le m} \sum_{\gamma \le \beta} \binom{\beta}{\gamma} \big(D^\gamma a_{\alpha,i}\big)\big(D^{\alpha+\beta-\gamma} \widetilde{v}_i\big).$$

This identity follows by applying the Leibniz rule componentwise to the preceding matrix expression.
Since K_i is compact and the coefficients $a_{\alpha,i}$ are smooth, the functions $D^\gamma a_{\alpha,i}$ are bounded on K_i for every $|\gamma| \le k$. Moreover, if $|\alpha| \le m$, $\gamma \le \beta$, and $|\beta| \le k$, then $|\alpha + \beta - \gamma| \le m + k$. Thus there exists a constant $A_i > 0$ such that

$$\max_{|\beta| \le k} \|D^\beta(\widetilde{P\mathbf{v}_i})\|_{C^0(K_i, \mathbb{K}^s)} \le A_i \max_{|\eta| \le k+m} \|D^\eta \widetilde{v}_i\|_{C^0(K_i, \mathbb{K}^r)}.$$

Now relate this estimate to the C^j norms. On U_i, write $\varphi_i = (x_i^1, \dots, x_i^n)$ and denote the coordinate vector fields by $\partial_{x_i^1}, \dots, \partial_{x_i^n}$. Define a connection $\widetilde{\nabla}^{TM,i}$ on TU_i by declaring these coordinate vector fields parallel, that is,

$$\widetilde{\nabla}^{TM,i}_{\partial_{x_i^\ell}} \partial_{x_i^a} = 0, \qquad a, \ell \in \{1, \dots, n\}.$$

Likewise, if $\mathbf{e}_1^i, \dots, \mathbf{e}_r^i$ is the local frame of $\mathbf{E} \restriction_{U_i}$ induced by the trivialization $\boldsymbol{\tau}_{\mathbf{E},i}$, define a connection $\widetilde{\nabla}^{\mathbf{E},i}$ on $\mathbf{E} \restriction_{U_i}$ by declaring this frame parallel:

$$\widetilde{\nabla}^{\mathbf{E},i}_{\partial_{x_i^\ell}} \mathbf{e}_a^i = 0, \qquad a \in \{1, \dots, r\},\ \ell \in \{1, \dots, n\}.$$

Also take the Riemannian metric $\widetilde{\mathbf{g}}_i$ making the coordinate frame orthonormal and the bundle metric $\widetilde{\mathbf{h}}_{\mathbf{E},i}$ making the frame $\mathbf{e}_1^i, \dots, \mathbf{e}_r^i$ orthonormal.

With these choices, if $\mathbf{v}_i = \sum_{a=1}^{r} v_i^a \mathbf{e}_a^i$ on U_i, then $\widetilde{v}_i = (v_i^1, \dots, v_i^r)$ and the components of the iterated covariant derivatives of $\mathbf{v}_i$, computed using the connections $\widetilde{\nabla}^{TM,i}$ and $\widetilde{\nabla}^{\mathbf{E},i}$, are precisely the partial derivatives of the components of $\widetilde{v}_i$. Consequently, for each $j \le k+m$ there exists a constant $B_{i,j} > 0$ such that

$$\max_{|\eta|\le j} \|D^\eta \widetilde{v}_i\|_{C^0(K_i,\mathbb{K}^r)} \le B_{i,j} \|\mathbf{v}_i\|_{\widetilde{C^j}(K_i,\mathbf{E})}.$$

Here $\|\cdot\|_{\widetilde{C^j}(K_i,\mathbf{E})}$ denotes the C^j norm on sections of $\mathbf{E}$ constructed using the choices $\widetilde{\mathbf{g}}_i$, $\widetilde{\nabla}^{TM,i}$, $\widetilde{\mathbf{h}}_{\mathbf{E},i}$, and $\widetilde{\nabla}^{\mathbf{E},i}$. By Theorem 10.1.2, applied to the compact set K_i and the bundle $\mathbf{E}$, the norms $\|\cdot\|_{\widetilde{C^{k+m}}(K_i,\mathbf{E})}$ and $\|\cdot\|_{C^{k+m}(K_i,\mathbf{E})}$ are equivalent. In particular, there exists a constant $C_i > 0$ such that

$$\|\mathbf{v}_i\|_{\widetilde{C^{k+m}}(K_i,\mathbf{E})} \le C_i \|\mathbf{v}_i\|_{C^{k+m}(K_i,\mathbf{E})}.$$

Since $\mathbf{v}_i = \psi_i \mathbf{u}$, the Leibniz rule for covariant derivatives implies the existence of a constant $L_i > 0$ such that

$$\|\mathbf{v}_i\|_{C^{k+m}(K_i,\mathbf{E})} = \|\psi_i \mathbf{u}\|_{C^{k+m}(K_i,\mathbf{E})} \le L_i \|\mathbf{u}\|_{C^{k+m}(K,\mathbf{E})}.$$

Apply the same reasoning to the bundle $\mathbf{F}$. If $\mathbf{f}_1^i, \dots, \mathbf{f}_s^i$ is the local frame of $\mathbf{F}\restriction_{U_i}$ induced by $\boldsymbol{\tau}_{\mathbf{F},i}$, take the connection $\widetilde{\nabla}^{\mathbf{F},i}$ determined by

$$\widetilde{\nabla}^{\mathbf{F},i}_{\partial_{x_i^\ell}} \mathbf{f}_b^i = 0, \qquad b \in \{1,\dots,s\},\ \ell \in \{1,\dots,n\},$$

and the bundle metric $\widetilde{h}_{\mathbf{F},i}$ making that frame orthonormal. Then, using Theorem 10.1.2 again, there exists a constant $D_i > 0$ such that

$$\|P\mathbf{v}_i\|_{C^k(K_i,\mathbf{F})} \le D_i \max_{|\beta|\le k} \|D^\beta(\widetilde{P\mathbf{v}_i})\|_{C^0(K_i,\mathbb{K}^s)}.$$

Combining the preceding estimates gives

$$\|P\mathbf{v}_i\|_{C^k(K_i,\mathbf{F})} \le D_i A_i B_{i,k+m} C_i L_i \|\mathbf{u}\|_{C^{k+m}(K,\mathbf{E})}.$$

Thus, for each $i \in \{1,\dots,N\}$ there exists a constant $C_i' > 0$ such that

$$\|P(\psi_i \mathbf{u})\|_{C^k(K_i,\mathbf{F})} \le C_i' \|\mathbf{u}\|_{C^{k+m}(K,\mathbf{E})}.$$

Since $\mathbf{u} = \sum_{i=1}^{N} \psi_i \mathbf{u}$ and P is linear, we have $P\mathbf{u} = \sum_{i=1}^{N} P(\psi_i \mathbf{u})$. Moreover, locality of P implies $\operatorname{supp}(P(\psi_i \mathbf{u})) \subseteq \operatorname{supp}(\psi_i \mathbf{u}) \subseteq K_i$. Therefore $\|P(\psi_i \mathbf{u})\|_{C^k(K,\mathbf{F})} = \|P(\psi_i \mathbf{u})\|_{C^k(K_i,\mathbf{F})}$. Using the triangle inequality for the norm $C^k(K,\mathbf{F})$, we obtain

$$\|P\mathbf{u}\|_{C^k(K,\mathbf{F})} \le \sum_{i=1}^{N} \|P(\psi_i \mathbf{u})\|_{C^k(K,\mathbf{F})} = \sum_{i=1}^{N} \|P(\psi_i \mathbf{u})\|_{C^k(K_i,\mathbf{F})}.$$

The preceding estimates give

$$\|P\mathbf{u}\|_{C^k(K,\mathbf{F})} \le \left(\sum_{i=1}^{N} C_i' \right) \|\mathbf{u}\|_{C^{k+m}(K,\mathbf{E})}.$$

Setting $C_{K,k} := \sum_{i=1}^{N} C_i'$ yields the desired estimate.
Locality of P ensures that $\operatorname{supp}(P\mathbf{u}) \subseteq \operatorname{supp}(\mathbf{u})$, so the map is well defined, and the preceding argument also shows that it is continuous. □

Proposition 10.2.18. Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, let $\mathbf{E},\mathbf{F} \longrightarrow M$ be smooth vector bundles, let W be a finite-dimensional $\mathbb{K}$-vector space, and let $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$. Then P induces a continuous linear operator

$$P\colon \mathcal{D}'(M,\mathbf{E},W) \longrightarrow \mathcal{D}'(M,\mathbf{F},W)$$

given by

$$(P\mathbf{T})(\boldsymbol{\varphi}) := \mathbf{T}(P'\boldsymbol{\varphi}), \qquad \boldsymbol{\varphi} \in \mathcal{D}(M,\mathbf{F}^*),$$

where $P'\colon \Gamma(\mathbf{F}^*) \longrightarrow \Gamma(\mathbf{E}^*)$ is the bilinear formal transpose. Continuity is understood with respect to the weak-$*$ topologies on both distribution spaces.

Proof. First check that the definition makes sense. By Proposition 10.2.14, we have $P' \in \mathbf{PDO}^{(m)}(\mathbf{F}^*,\mathbf{E}^*)$. Thus, if $\boldsymbol{\varphi} \in \mathcal{D}(M,\mathbf{F}^*)$, then $P'\boldsymbol{\varphi}$ is a smooth section of $\mathbf{E}^*$.
Moreover, since differential operators are local, we have

$$\operatorname{supp}(P'\boldsymbol{\varphi}) \subseteq \operatorname{supp}(\boldsymbol{\varphi}).$$

In particular, if $\boldsymbol{\varphi}$ has compact support, then $P'\boldsymbol{\varphi}$ also has compact support. Thus $P'\boldsymbol{\varphi} \in \mathcal{D}(M,\mathbf{E}^*)$, and consequently the expression $\mathbf{T}(P'\boldsymbol{\varphi})$ is well defined.
Define $(P\mathbf{T})(\boldsymbol{\varphi}) := \mathbf{T}(P'\boldsymbol{\varphi})$ for $\boldsymbol{\varphi} \in \mathcal{D}(M,\mathbf{F}^*)$. Linearity of $P\mathbf{T}$ follows from linearity of $\mathbf{T}$ and P'.
Now prove that $P\mathbf{T} \in \mathcal{D}'(M,\mathbf{F},W)$. Let $K \subseteq M$ be compact. If $\boldsymbol{\varphi} \in \mathcal{D}_K(M,\mathbf{F}^*)$, then locality of P' gives $P'\boldsymbol{\varphi} \in \mathcal{D}_K(M,\mathbf{E}^*)$. Since $\mathbf{T} \in \mathcal{D}'(M,\mathbf{E},W)$, Theorem 10.2.5 provides $\ell \in \mathbb{N}_0$ and $c_K > 0$ such that

$$|\mathbf{T}(\boldsymbol{\psi})|_W \le c_K \|\boldsymbol{\psi}\|_{C^\ell(K,\mathbf{E}^*)} \qquad \forall \boldsymbol{\psi} \in \mathcal{D}_K(M,\mathbf{E}^*).$$

Applying this estimate to $\boldsymbol{\psi} = P'\boldsymbol{\varphi}$ gives

$$|(P\mathbf{T})(\boldsymbol{\varphi})|_W = |\mathbf{T}(P'\boldsymbol{\varphi})|_W \le c_K \|P'\boldsymbol{\varphi}\|_{C^\ell(K,\mathbf{E}^*)}.$$

Since P' is a differential operator of order m, Lemma 10.2.17 provides a constant $C_{K,\ell} > 0$ such that

$$\|P'\boldsymbol{\varphi}\|_{C^\ell(K,\mathbf{E}^*)} \le C_{K,\ell} \|\boldsymbol{\varphi}\|_{C^{\ell+m}(K,\mathbf{F}^*)}.$$

Therefore

$$|(P\mathbf{T})(\boldsymbol{\varphi})|_W \le c_K C_{K,\ell} \|\boldsymbol{\varphi}\|_{C^{\ell+m}(K,\mathbf{F}^*)} \qquad \forall \boldsymbol{\varphi} \in \mathcal{D}_K(M,\mathbf{F}^*).$$

Applying Theorem 10.2.5 again, now to the bundle $\mathbf{F}$, we conclude that $P\mathbf{T} \in \mathcal{D}'(M,\mathbf{F},W)$.
Next check linearity of the operator induced by P. If $\lambda,\mu \in \mathbb{K}$ and $\mathbf{T}_1,\mathbf{T}_2 \in \mathcal{D}'(M,\mathbf{E},W)$, then, for every $\boldsymbol{\varphi} \in \mathcal{D}(M,\mathbf{F}^*)$,

$$P(\lambda\mathbf{T}_1 + \mu\mathbf{T}_2)(\boldsymbol{\varphi}) = (\lambda\mathbf{T}_1 + \mu\mathbf{T}_2)(P'\boldsymbol{\varphi}) = \lambda\mathbf{T}_1(P'\boldsymbol{\varphi}) + \mu\mathbf{T}_2(P'\boldsymbol{\varphi}).$$

Therefore $P(\lambda \mathbf{T}_1 + \mu \mathbf{T}_2) = \lambda P\mathbf{T}_1 + \mu P\mathbf{T}_2$.
Finally, prove continuity of the induced operator in the weak-$*$ topologies. Let $(\mathbf{T}_\alpha)_\alpha$ be a net in $\mathcal{D}'(M, \mathbf{E}, W)$ such that $\mathbf{T}_\alpha \to \mathbf{T}$ in $\mathcal{D}'(M, \mathbf{E}, W)$. By Remark 10.2.2, this means that

$$\mathbf{T}_\alpha(\psi) \longrightarrow \mathbf{T}(\psi) \qquad \forall \psi \in \mathcal{D}(M, \mathbf{E}^*).$$

Now let $\varphi \in \mathcal{D}(M, \mathbf{F}^*)$. As already shown, $P'\varphi \in \mathcal{D}(M, \mathbf{E}^*)$. Therefore

$$(P\mathbf{T}_\alpha)(\varphi) = \mathbf{T}_\alpha(P'\varphi) \longrightarrow \mathbf{T}(P'\varphi) = (P\mathbf{T})(\varphi).$$

Since this holds for every $\varphi \in \mathcal{D}(M, \mathbf{F}^*)$, Remark 10.2.2 again gives $P\mathbf{T}_\alpha \to P\mathbf{T}$ in $\mathcal{D}'(M, \mathbf{F}, W)$. Thus the operator induced by P is continuous. □

Remark 10.2.19. If $\mathbf{u} \in \Gamma(\mathbf{E})$ is a smooth section, then $P\mathbf{u} \in \Gamma(\mathbf{F})$, and the regular distribution associated with $P\mathbf{u}$ agrees with the distribution obtained by applying P to the regular distribution associated with $\mathbf{u}$. If $\mathbf{T}_\mathbf{u}$ is given by

$$\mathbf{T}_\mathbf{u}(\psi) := \int_M \psi(\mathbf{u})\, d\lambda_\mathbf{g}, \qquad \psi \in \mathcal{D}(M, \mathbf{E}^*),$$

then, for every $\varphi \in \mathcal{D}(M, \mathbf{F}^*)$,

$$(P\mathbf{T}_\mathbf{u})(\varphi) = \mathbf{T}_\mathbf{u}(P'\varphi) = \int_M (P'\varphi)(\mathbf{u})\, d\lambda_\mathbf{g}.$$

By the definition of the bilinear formal transpose,

$$\int_M (P'\varphi)(\mathbf{u})\, d\lambda_\mathbf{g} = \int_M \varphi(P\mathbf{u})\, d\lambda_\mathbf{g}.$$

Therefore $P\mathbf{T}_\mathbf{u} = \mathbf{T}_{P\mathbf{u}}$.
In particular, if P has order 0, then P corresponds to a smooth section of $\operatorname{Hom}(\mathbf{E}, \mathbf{F})$ and P' corresponds to the pointwise transpose $\mathbf{F}^* \to \mathbf{E}^*$. In the special case where $\mathbf{E} = \mathbf{F}$ and P is multiplication by a function $f \in C^\infty(M)$, we obtain

$$(fT)(\varphi) = T(f\varphi).$$

The preceding proposition shows that the action of a differential operator on distributions is determined by the action of its bilinear formal transpose on test sections. This construction suffices to define distributional derivatives and, more generally, to transfer differential operators to the distributional setting. We now give some examples illustrating what has been developed so far.

Example 10.2.20. (Differential operators and their distributional extensions on bundles) Let $(M, \mathbf{g})$ be a closed Riemannian manifold, let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be smooth vector bundles, and let W be a finite-dimensional $\mathbb{K}$-vector space.
If $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$, the induced operator on distributions is defined by

$$(P\mathbf{T})(\varphi) := \mathbf{T}(P'\varphi), \qquad \mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W),\ \varphi \in \mathcal{D}(M, \mathbf{F}^*),$$

where $P' \colon \Gamma(\mathbf{F}^*) \longrightarrow \Gamma(\mathbf{E}^*)$ is the bilinear formal transpose. This definition is valid for arbitrary distributions with values in W.

To make the integral formulas concrete, we also consider the special case $W = \mathbb{K}$. If $\mathbf{u} \in \Gamma(\mathbf{E})$, denote by $\mathbf{T}_{\mathbf{u}}$ the regular distribution induced by $\mathbf{u}$, given by

$$\mathbf{T}_{\mathbf{u}}(\psi) := \int_M \psi(\mathbf{u})\, d\lambda_{\mathbf{g}}, \qquad \psi \in \mathcal{D}(M, \mathbf{E}^*).$$

(a) Let $\nabla^{\mathbf{E}} \colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(T^*M \otimes \mathbf{E})$ be a connection. The induced operator is

$$\nabla^{\mathbf{E}} \colon \mathcal{D}'(M, \mathbf{E}, W) \longrightarrow \mathcal{D}'(M, T^*M \otimes \mathbf{E}, W),$$

and is given by

$$(\nabla^{\mathbf{E}}\mathbf{T})(\varphi) = \mathbf{T}\big((\nabla^{\mathbf{E}})'\varphi\big), \qquad \varphi \in \mathcal{D}(M, TM \otimes \mathbf{E}^*).$$

In the regular case, that is, when $W = \mathbb{K}$ and $\mathbf{T} = \mathbf{T}_{\mathbf{u}}$, we have

$$(\nabla^{\mathbf{E}}\mathbf{T}_{\mathbf{u}})(\varphi) = \int_M \varphi(\nabla^{\mathbf{E}}\mathbf{u})\, d\lambda_{\mathbf{g}}.$$

If $\mathbf{E}$ is also equipped with a real bundle metric in the real case or a Hermitian metric in the complex case, the Riesz isomorphism of the bundle $\mathbf{H} := T^*M \otimes \mathbf{E}$ uniquely determines $\varphi^\sharp \in \Gamma_c(\mathbf{H})$ by

$$\overline{\varphi^\sharp} = \mathcal{R}_{\mathbf{H}}^{-1}\varphi, \qquad \varphi(w) = \mathbf{h}_{\mathbf{H}}(w, \varphi^\sharp).$$

In the complex case, $\varphi \mapsto \varphi^\sharp$ is antilinear; the map $\mathcal{R}_{\mathbf{H}}^{-1} : \mathbf{H}^* \to \overline{\mathbf{H}}$ is complex-linear. Then

$$(\nabla^{\mathbf{E}}\mathbf{T}_{\mathbf{u}})(\varphi) = \int_M \mathbf{h}_{\mathbf{H}}(\nabla^{\mathbf{E}}\mathbf{u}, \varphi^\sharp)\, d\lambda_{\mathbf{g}}.$$

By the definition of the formal Hermitian adjoint,

$$\int_M \mathbf{h}_{\mathbf{H}}(\nabla^{\mathbf{E}}\mathbf{u}, \varphi^\sharp)\, d\lambda_{\mathbf{g}} = \int_M \mathbf{h}_{\mathbf{E}}(\mathbf{u}, (\nabla^{\mathbf{E}})^*_h \varphi^\sharp)\, d\lambda_{\mathbf{g}}.$$

Thus, in the presence of bundle metrics, the same identity can be read as an integration-by-parts formula.

(b) For the covariant derivative of order k,

$$\nabla^k \colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(T^{(0,k)}(TM) \otimes \mathbf{E}),$$

the induced operator is given by

$$(\nabla^k\mathbf{T})(\varphi) = \mathbf{T}\big((\nabla^k)'\varphi\big), \qquad \varphi \in \mathcal{D}(M, T^{(k,0)}(TM) \otimes \mathbf{E}^*).$$

If $W = \mathbb{K}$ and $\mathbf{T} = \mathbf{T}_{\mathbf{u}}$, then

$$(\nabla^k\mathbf{T}_{\mathbf{u}})(\varphi) = \int_M \varphi(\nabla^k\mathbf{u})\, d\lambda_{\mathbf{g}}.$$

In the presence of a real or Hermitian bundle metric, set $\mathbf{H}_k := T^{(0,k)}(TM) \otimes \mathbf{E}$ and define $\varphi^\sharp$ by

$\overline{\varphi^\sharp} = \mathcal{R}_{\mathbf{H}_k}^{-1}\varphi$. We obtain

$$(\nabla^k \mathbf{T}_\mathbf{u})(\varphi) = \int_M \mathbf{h}_{\mathbf{H}_k}(\nabla^k \mathbf{u}, \varphi^\sharp)\, d\lambda_\mathbf{g} = \int_M \mathbf{h}_\mathbf{E}(\mathbf{u}, (\nabla^k)_h^* \varphi^\sharp)\, d\lambda_\mathbf{g}.$$

(c) Let $\operatorname{div}\colon \mathfrak{X}(M) \longrightarrow C^\infty(M)$ be the divergence operator associated with $\mathbf{g}$. Its distributional extension is given by

$$(\operatorname{div}\mathbf{T})(\varphi) = \mathbf{T}\big((\operatorname{div})'\varphi\big), \qquad \varphi \in \mathcal{D}(M).$$

In this case, $(\operatorname{div})'\varphi = -d\varphi$. Thus, if $W = \mathbb{K}$ and $\mathbf{T} = \mathbf{T}_\mathbf{X}$ for a smooth vector field $\mathbf{X} \in \mathfrak{X}(M)$, then

$$(\operatorname{div}\mathbf{T}_\mathbf{X})(\varphi) = \int_M \varphi \operatorname{div}\mathbf{X}\, d\lambda_\mathbf{g}.$$

Using the Riemannian metric,

$$\int_M \varphi \operatorname{div}\mathbf{X}\, d\lambda_\mathbf{g} = -\int_M d\varphi(\mathbf{X})\, d\lambda_\mathbf{g} = -\int_M \langle \operatorname{grad}\varphi, \mathbf{X}\rangle_\mathbf{g}\, d\lambda_\mathbf{g}.$$

Thus the bilinear formal transpose of divergence is written as $-d$, while the metric identifies it with the negative gradient.

(d) Suppose that $\mathbf{E}$ is equipped with a bundle metric $\mathbf{h}_\mathbf{E}$, real or Hermitian according to the scalar field, and that $\nabla^\mathbf{E}$ is compatible with it. On ∇^2, use the tensor connection induced by $\nabla^\mathbf{E}$ and the Levi–Civita connection of $\mathbf{g}$. Let $\Delta_B\colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{E})$ be the Bochner Laplacian associated with $\mathbf{g}$ and $\nabla^\mathbf{E}$, defined with the positive sign convention by $\Delta_B = (\nabla^\mathbf{E})_h^* \nabla^\mathbf{E} = -\operatorname{tr}_\mathbf{g}(\nabla^2)$. Its distributional extension is given by

$$(\Delta_B \mathbf{T})(\varphi) = \mathbf{T}\big((\Delta_B)'\varphi\big), \qquad \varphi \in \mathcal{D}(M, \mathbf{E}^*).$$

If $W = \mathbb{K}$ and $\mathbf{T} = \mathbf{T}_\mathbf{u}$, then

$$(\Delta_B \mathbf{T}_\mathbf{u})(\varphi) = \int_M \varphi(\Delta_B \mathbf{u})\, d\lambda_\mathbf{g}.$$

With this bundle metric $\mathbf{h}_\mathbf{E}$, define the test section $\varphi^\sharp \in \Gamma_c(\mathbf{E})$ by $\overline{\varphi^\sharp} := \mathcal{R}_\mathbf{E}^{-1}\varphi$. Then

$$(\Delta_B \mathbf{T}_\mathbf{u})(\varphi) = \int_M \mathbf{h}_\mathbf{E}(\Delta_B \mathbf{u}, \varphi^\sharp)\, d\lambda_\mathbf{g} = \int_M \mathbf{h}_\mathbf{E}(\mathbf{u}, (\Delta_B)_h^* \varphi^\sharp)\, d\lambda_\mathbf{g}.$$

Since $\Delta_B = (\nabla^\mathbf{E})_h^* \nabla^\mathbf{E}$, it is formally self-adjoint and satisfies $(\Delta_B)_h^* = \Delta_B$.

(e) *A Lorentzian digression, outside the Riemannian convention used throughout the rest of the chapter.* If $(M, \mathbf{g})$ is a closed Lorentzian manifold, the d'Alembert operator

$$\Box\colon C^\infty(M) \longrightarrow C^\infty(M), \qquad \Box := \operatorname{tr}_\mathbf{g}(\nabla^2),$$

also induces an operator on distributions

$$\Box\colon \mathcal{D}'(M, W) \longrightarrow \mathcal{D}'(M, W),$$

defined by

$$(\Box\mathbf{T})(\varphi) = \mathbf{T}(\Box'\varphi), \qquad \varphi \in \mathcal{D}(M).$$

In the regular scalar case, that is, if $W = \mathbb{K}$ and $\mathbf{T} = \mathbf{T_u}$, we obtain

$$(\Box\mathbf{T_u})(\varphi) = \int_M \varphi\, \Box\mathbf{u}\, d\lambda_{\mathbf{g}}.$$

In this case, $\lambda_{\mathbf{g}}$ denotes the positive Borel measure associated with the Lorentzian density: in coordinates, $d\lambda_{\mathbf{g}} = |\det(\mathbf{g})|^{1/2}\, dx$. No assertion is made that $\mathbf{g}$ defines a Riemannian distance, and none of the positive estimates specific to Riemannian geometry is used here.

(f) Finally, if $P \in \mathbf{PDO}^{(0)}(\mathbf{E},\mathbf{F})$ corresponds to a smooth section of $\operatorname{Hom}(\mathbf{E},\mathbf{F})$, then

$$(P\mathbf{T})(\varphi) = \mathbf{T}(P'\varphi), \qquad \varphi \in \mathcal{D}(M,\mathbf{F}^*).$$

If $W = \mathbb{K}$ and $\mathbf{T} = \mathbf{T_u}$, then

$$(P\mathbf{T_u})(\varphi) = \int_M \varphi(P\mathbf{u})\, d\lambda_{\mathbf{g}}.$$

In the presence of bundle metrics $\mathbf{h_E}$ and $\mathbf{h_F}$, define $\varphi^\sharp \in \Gamma_c(\mathbf{F})$ by $\overline{\varphi^\sharp} := \mathcal{R}_{\mathbf{F}}^{-1}\varphi$. This can then be written as

$$(P\mathbf{T_u})(\varphi) = \int_M \mathbf{h_F}(P\mathbf{u}, \varphi^\sharp)\, d\lambda_{\mathbf{g}} = \int_M \mathbf{h_E}(\mathbf{u}, P_h^*\varphi^\sharp)\, d\lambda_{\mathbf{g}}.$$

In general, the action on distributions is determined by the bilinear formal transpose P'. For regular distributions with fixed bundle metrics, the preceding formulas can be rewritten using the formal Hermitian adjoint P_h^*, recovering the usual integration-by-parts identities.

Example 10.2.21. (An example in which the space W plays a role) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, take the trivial bundle $\mathbf{E} = M \times \mathbb{K}$, and let $W = \mathbb{K}^2$. Fix a smooth function $u \in C^\infty(M)$ and a point $p \in M$. Define

$$T\colon \mathcal{D}(M) \longrightarrow \mathbb{K}^2$$

by

$$T(\varphi) := \left(\int_M \varphi u\, d\lambda_{\mathbf{g}},\ \varphi(p) \right).$$

Then $T \in \mathcal{D}'(M,\mathbb{K}^2)$. The first component is a regular distribution, while the second is the Dirac delta at p. If $P \in \mathbf{PDO}^{(m)}(M\times\mathbb{K}, M\times\mathbb{K})$, the distributional extension of P is given by

$$(PT)(\varphi) = T(P'\varphi).$$

Therefore

$$(PT)(\varphi) = \left(\int_M (P'\varphi) u\, d\lambda_{\mathbf{g}},\ (P'\varphi)(p) \right).$$

In particular, if $P = \Delta_{\mathbf{g}}$, which is formally self-adjoint, then

$$(\Delta_{\mathbf{g}} T)(\varphi) = \left(\int_M (\Delta_{\mathbf{g}}\varphi) u\, d\lambda_{\mathbf{g}},\ (\Delta_{\mathbf{g}}\varphi)(p) \right).$$

The first component represents the action of the Laplacian on the regular part, while the second represents its action on the Dirac delta. In this sense, taking $W = \mathbb{K}^2$ combines two different types of sources in a single distributional object: an extended source given by u and a point source concentrated at p.

In the preceding examples, we mainly considered the scalar case $W = \mathbb{K}$. We now extend these constructions to distributions with values in a finite-dimensional vector space.

Definition 10.2.22. (Regular distribution with values in W) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let W be a finite-dimensional $\mathbb{K}$-vector space. A distribution

$$\mathbf{T} \colon \mathcal{D}(M, \mathbf{E}^*) \longrightarrow W$$

is called *regular* if there exists $\mathbf{f} \in L^1_{\mathrm{loc}}(M, \mathbf{E} \otimes W)$ such that

$$\mathbf{T}(\boldsymbol{\varphi}) = \int_M (\boldsymbol{\varphi} \otimes \mathrm{id}_W)(\mathbf{f})\, d\lambda_{\mathbf{g}}, \qquad \forall \boldsymbol{\varphi} \in \mathcal{D}(M, \mathbf{E}^*).$$

Remark 10.2.23. When $W = \mathbb{K}$, this definition agrees with Definition 10.2.10.

Definition 10.2.24. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, let W be a finite-dimensional $\mathbb{K}$-vector space, and let $\mathbf{u} \in L^1_{\mathrm{loc}}(M, \mathbf{E} \otimes W)$. Define the regular distribution associated with $\mathbf{u}$ by

$$\mathbf{T}_{\mathbf{u}}(\boldsymbol{\varphi}) := \int_M (\boldsymbol{\varphi} \otimes \mathrm{id}_W)(\mathbf{u})\, d\lambda_{\mathbf{g}}, \qquad \boldsymbol{\varphi} \in \mathcal{D}(M, \mathbf{E}^*).$$

Remark 10.2.25. When $\mathbf{u} \in \Gamma(\mathbf{E} \otimes W)$ is a smooth section, the preceding expression defines a smooth regular distribution. In particular, this construction extends the classical association of smooth sections with regular distributions.

10.2.2 Local properties

A fundamental property of distributions is their local character. In particular, a distribution can be restricted to an open subset, reflecting the fact that its action is completely determined by the behavior of test functions on small neighborhoods. This construction is compatible with the vector bundle structure and will be used repeatedly below.

Definition 10.2.26. (Restriction of distributions on bundles) Let M be a smooth manifold with or without boundary, $\mathbf{E} \longrightarrow M$ a smooth vector bundle, and $U \subseteq M$ an open subset. Let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$. Define the restriction of $\mathbf{T}$ to U as the distribution

$$\mathbf{T} \restriction_U \in \mathcal{D}'(U, \mathbf{E}, W)$$

given by

$$\mathbf{T} \restriction_U (\boldsymbol{\varphi}) := \mathbf{T}(\widetilde{\boldsymbol{\varphi}}), \qquad \boldsymbol{\varphi} \in \mathcal{D}(U, \mathbf{E}^*),$$

where $\widetilde{\boldsymbol{\varphi}} \in \mathcal{D}(M, \mathbf{E}^*)$ is the extension of $\boldsymbol{\varphi}$ by zero outside U.

Lemma 10.2.27. (Well-definedness of restriction) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle, let W be a finite-dimensional $\mathbb{K}$-vector space, and let $U \subseteq M$ be open. If $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$, the formula

$$\mathbf{T} \restriction_U (\varphi) := \mathbf{T}(\widetilde{\varphi}), \qquad \varphi \in \mathcal{D}(U, \mathbf{E}^*),$$

where $\widetilde{\varphi}$ denotes the extension of φ by zero outside U, defines an element of $\mathcal{D}'(U, \mathbf{E}, W)$. If $V \subseteq U$ is open, then

$$(\mathbf{T} \restriction_U) \restriction_V = \mathbf{T} \restriction_V .$$

Proof. Denote extension by zero by

$$e_U : \mathcal{D}(U, \mathbf{E}^* \restriction_U) \longrightarrow \mathcal{D}(M, \mathbf{E}^*)$$

. This map is linear. If $K \Subset U$, every $\varphi \in \Gamma_K(\mathbf{E}^* \restriction_U)$ vanishes on a neighborhood of the boundary of U, so $e_U \varphi$ is smooth and supported in K. For each $m \in \mathbb{N}_0$, its covariant derivatives agree with those of φ on U and vanish outside U; in particular,

$$\|e_U \varphi\|_{C^m(K;M)} = \|\varphi\|_{C^m(K;U)}.$$

Thus the restriction of e_U to every fixed-support stage is continuous. The final property of the *LF* topology, given by Theorem 4.4.1, implies that e_U is continuous on the full test spaces.
Therefore $\mathbf{T} \restriction_U = \mathbf{T} \circ e_U$ is linear and continuous, that is, it belongs to $\mathcal{D}'(U, \mathbf{E}, W)$. Finally, if $V \subseteq U$, extending by zero first from V to U and then from U to M gives exactly the extension by zero from V to M. Composing with $\mathbf{T}$ yields the restriction identity. □

Restriction makes the local nature of distributions precise: the open subsets on which a distribution vanishes determine its support.

Definition 10.2.28. (Support of a distribution) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, let W be a finite-dimensional vector space, and let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$. Define the support of $\mathbf{T}$ as the set

$$\operatorname{supp}(\mathbf{T}) := M \setminus \bigcup \{U \subseteq M \text{ open} \mid \mathbf{T} \restriction_U = 0\}.$$

The following proposition gives an equivalent definition:

Proposition 10.2.29. Let M be a smooth manifold with or without boundary, let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle, and let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$. Then

$$\operatorname{supp}(\mathbf{T}) = \{x \in M \mid \text{for every open neighborhood } U \text{ of } x, \text{ there exists } \varphi \in \mathcal{D}(M, \mathbf{E}^*) \text{ with } \operatorname{supp}(\varphi) \subseteq U \text{ and } \mathbf{T}(\varphi) \neq 0\}.$$

Proof. Define

$$A := \bigcup \{U \subseteq M \text{ open} \mid \mathbf{T} \restriction_U = 0\}.$$

Observe that A is open, so its complement $M \setminus A$ is closed. We prove that $M \setminus A$ agrees with the set described

in the second definition.
Let $x \in M \setminus A$. Consider an open neighborhood U of x. We cannot have $\mathbf{T} \restriction_U = 0$, since this would give $U \subseteq A$ and, in particular, $x \in A$, a contradiction. Thus $\mathbf{T} \restriction_U \neq 0$. This means there exists a test section $\boldsymbol{\varphi} \in \mathcal{D}(U, \mathbf{E}^*)$ such that

$$\mathbf{T} \restriction_U (\boldsymbol{\varphi}) \neq 0.$$

If $\widetilde{\boldsymbol{\varphi}} \in \mathcal{D}(M, \mathbf{E}^*)$ denotes the extension of $\boldsymbol{\varphi}$ by zero outside U, then $\operatorname{supp}(\widetilde{\boldsymbol{\varphi}}) \subseteq U$ and

$$\mathbf{T}(\widetilde{\boldsymbol{\varphi}}) = \mathbf{T} \restriction_U (\boldsymbol{\varphi}) \neq 0.$$

We conclude that every open neighborhood of x contains the support of a test section on which $\mathbf{T}$ does not vanish, so x belongs to the second set.
Conversely, suppose x belongs to the second set. If $x \in A$, there is an open subset $U \subseteq M$ such that $x \in U$ and $\mathbf{T} \restriction_U = 0$. By hypothesis, however, there exists a test section $\boldsymbol{\varphi} \in \mathcal{D}(M, \mathbf{E}^*)$ with $\operatorname{supp}(\boldsymbol{\varphi}) \subseteq U$ such that

$$\mathbf{T}(\boldsymbol{\varphi}) \neq 0.$$

Since $\operatorname{supp}(\boldsymbol{\varphi}) \subseteq U$, the restriction $\boldsymbol{\varphi} \restriction_U$ belongs to $\mathcal{D}(U, \mathbf{E}^*)$, and its extension by zero to M agrees with $\boldsymbol{\varphi}$. Therefore

$$\mathbf{T}(\boldsymbol{\varphi}) = \mathbf{T} \restriction_U (\boldsymbol{\varphi} \restriction_U) = 0,$$

contradicting the choice of $\boldsymbol{\varphi}$. Consequently, $x \notin A$.
We have proved that the two sets agree, and hence that the definitions are equivalent. □

Support makes the local character of distributions precise. In particular, a distribution does not "detect" test sections supported in regions where it vanishes. This is expressed by the following fundamental result.

Proposition 10.2.30. Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let W be a finite-dimensional vector space. Let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$ and let $\boldsymbol{\varphi} \in \mathcal{D}(M, \mathbf{E}^*)$. If $\operatorname{supp}(\boldsymbol{\varphi}) \cap \operatorname{supp}(\mathbf{T}) = \varnothing$, then $\mathbf{T}(\boldsymbol{\varphi}) = 0$.

Proof. Let $K := \operatorname{supp}(\boldsymbol{\varphi})$, which is compact. For each $x \in K$, since $x \notin \operatorname{supp}(\mathbf{T})$, there is an open neighborhood U_x of x such that $\mathbf{T} \restriction_{U_x} = 0$. The family $\{U_x\}_{x \in K}$ is an open cover of K, so there exist open subsets $U_1, \dots, U_k$ still covering K.
Let $\{\chi_j\}_{j \in \{1,\dots,k\}}$ be a partition of unity subordinate to $\{U_j\}_{j \in \{1,\dots,k\}}$. For each $j \in \{1, \dots, k\}$, define $\boldsymbol{\varphi}_j := \chi_j \boldsymbol{\varphi}$. Then $\boldsymbol{\varphi} = \sum_{j=1}^{k} \boldsymbol{\varphi}_j$ and $\operatorname{supp}(\boldsymbol{\varphi}_j) \subseteq U_j$ for every $j \in \{1, \dots, k\}$.
Since $\mathbf{T} \restriction_{U_j} = 0$ and $\operatorname{supp}(\boldsymbol{\varphi}_j) \subseteq U_j$, it follows that $\mathbf{T}(\boldsymbol{\varphi}_j) = 0$ for every $j \in \{1, \dots, k\}$. Therefore $\mathbf{T}(\boldsymbol{\varphi}) = \sum_{j=1}^{k} \mathbf{T}(\boldsymbol{\varphi}_j) = 0$.

□

Remark 10.2.31. The condition $\operatorname{supp}(\varphi) \cap \operatorname{supp}(T) = \varnothing$ cannot be replaced by the condition that φ vanish on $\operatorname{supp}(T)$. For example, if $M = \mathbb{R}$, $\mathbf{E} = M \times \mathbb{K}$, and $T \in \mathcal{D}'(\mathbb{R}, M \times \mathbb{K}, \mathbb{K})$ is given by $T(\varphi) = \varphi'(0)$, then $\operatorname{supp}(T) = \{0\}$, but we may have $\varphi(0) = 0$ while $T(\varphi) \neq 0$.

The preceding property naturally extends the action of a distribution to certain sections without compact support.

Proposition 10.2.32. Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let W be a finite-dimensional vector space. Let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$ and let $\boldsymbol{\varphi} \in \Gamma(M, \mathbf{E}^*)$. If $\operatorname{supp}(\mathbf{T}) \cap \operatorname{supp}(\boldsymbol{\varphi})$ is compact, the quantity $\mathbf{T}(\boldsymbol{\varphi})$ can be defined consistently.

Proof. Let $K := \operatorname{supp}(\mathbf{T}) \cap \operatorname{supp}(\boldsymbol{\varphi})$, which is compact by hypothesis. Since M is a smooth manifold, there exists a relatively compact open subset $V \subseteq M$ such that $K \subseteq V$. For each $x \in K$, there is a relatively compact chart V_x containing x; compactness of K gives a finite subcover $V_{x_1}, \ldots, V_{x_N}$, and taking $V := \bigcup_{j=1}^{N} V_{x_j}$ gives an open subset with $\overline{V}$ compact and $K \subseteq V$.
Since $K \subseteq V$ and K is compact, choose an open subset $U \subseteq M$ such that

$$K \subseteq U \subseteq \overline{U} \subseteq V.$$

Now take a function $\sigma \in \mathcal{D}(M, \mathbb{K})$ such that $\sigma \equiv 1$ on $\overline{U}$ and $\operatorname{supp}(\sigma) \subseteq V$. Define

$$\mathbf{T}(\boldsymbol{\varphi}) := \mathbf{T}(\sigma \boldsymbol{\varphi}).$$

Observe that $\sigma\boldsymbol{\varphi} \in \mathcal{D}(M, \mathbf{E}^*)$, so the preceding expression makes sense.
To see that the definition is independent of the choice of σ, let σ and σ' be two functions with the preceding property. Then $\sigma - \sigma'$ vanishes on a neighborhood of K, and in particular

$$\operatorname{supp}\big((\sigma - \sigma')\boldsymbol{\varphi}\big) \cap \operatorname{supp}(\mathbf{T}) = \varnothing.$$

By Proposition 10.2.30, it follows that

$$\mathbf{T}\big((\sigma - \sigma')\boldsymbol{\varphi}\big) = 0.$$

Therefore

$$\mathbf{T}(\sigma\boldsymbol{\varphi}) - \mathbf{T}(\sigma'\boldsymbol{\varphi}) = \mathbf{T}\big((\sigma - \sigma')\boldsymbol{\varphi}\big) = 0,$$

proving that the definition is independent of the choice of σ. □

Remark 10.2.33. The preceding proposition shows that the action of a distribution extends to smooth sections without compact support, provided the intersection with the support of the distribution is compact. This reinforces the idea that the behavior of a distribution is completely determined by its support.

The localization used later to define function spaces requires coordinate representations of distributions. The following construction also fixes the volume factor; omitting it would change the components of a regular distribution.

Proposition 10.2.34. (Local representation of a distribution) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{E} \to M$ be a vector bundle of rank r, let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E})$, and let

$$\varphi \colon U \longrightarrow \Omega \subseteq \mathbb{R}^n, \qquad \mathbf{e} = (\mathbf{e}_1, \ldots, \mathbf{e}_r)$$

be a chart and a local frame of $\mathbf{E}$, with dual frame $\mathbf{e}^* = (\mathbf{e}^1, \dots, \mathbf{e}^r)$. If

$$J_\varphi(x) := \sqrt{\det\big(\mathbf{g}(\varphi^{-1}(x))\big)}, \qquad x \in \Omega,$$

define the coordinate component of $\mathbf{T}$ by

$$\big\langle T^a_{\varphi,\mathbf{e}}, \psi \big\rangle := (\mathbf{T} \restriction_U)\left(\left(\frac{\psi}{J_\varphi} \circ \varphi\right)\mathbf{e}^a\right), \qquad \psi \in \mathcal{D}(\Omega), \tag{10.5}$$

for $a \in \{1, \dots, r\}$. Then $T^a_{\varphi,\mathbf{e}} \in \mathcal{D}'(\Omega)$. If $\mathbf{u} = \sum_{a=1}^{r} u^a \mathbf{e}_a \in L^1_{\mathrm{loc}}(U, \mathbf{E})$ and $\mathbf{T} = \mathbf{T}_\mathbf{u}$, we have

$$T^a_{\varphi,\mathbf{e}} = T_{u^a \circ \varphi^{-1}} \quad \text{on } \Omega,$$

where the right-hand side is the Euclidean distribution defined using Lebesgue measure.
In the scalar case, we omit the frame and write $(\mathbf{T} \restriction_U) \circ \varphi^{-1}$ for this distribution. If $\kappa = \varphi^{-1} \colon \Omega \longrightarrow U$ is the corresponding parametrization, we also write $(\mathbf{T} \restriction_U) \circ \kappa$; both expressions denote the same object.
If $h \in C^\infty_c(U)$, each component of $h\mathbf{T}$ has compact support contained in Ω and admits a canonical extension by zero to $\mathbb{R}^n$. Specifically, if $K := \operatorname{supp}((h\mathbf{T})^a_{\varphi,\mathbf{e}}) \Subset \Omega$ and $\chi \in C^\infty_c(\Omega)$ satisfies $\chi = 1$ on a neighborhood of K, this extension is given by

$$\big\langle \widetilde{(h\mathbf{T})^a_{\varphi,\mathbf{e}}}, \psi \big\rangle := \big\langle (h\mathbf{T})^a_{\varphi,\mathbf{e}}, \chi(\psi \restriction_\Omega) \big\rangle, \qquad \psi \in \mathcal{D}(\mathbb{R}^n), \tag{10.6}$$

and is independent of χ.

Proof. The map

$$\psi \longmapsto \left(\frac{\psi}{J_\varphi} \circ \varphi\right)\mathbf{e}^a$$

is linear and continuous from $\mathcal{D}(\Omega)$ to $\mathcal{D}(U, \mathbf{E}^* \restriction_U)$: on each compact set, the Leibniz and chain rules control all its derivatives. Continuity of $\mathbf{T} \restriction_U$ proves that (10.5) defines a Euclidean distribution. For a regular distribution, use the change-of-variables formula

$$\int_U \eta \, d\lambda_\mathbf{g} = \int_\Omega (\eta \circ \varphi^{-1})(x) J_\varphi(x) \, d\lambda_n(x),$$

valid for every integrable function η supported in U. Thus

$$\int_U \left(\frac{\psi}{J_\varphi} \circ \varphi\right) u^a \, d\lambda_\mathbf{g} = \int_\Omega \psi(x) u^a(\varphi^{-1}(x)) \, dx,$$

proving the second assertion.
The identity $\operatorname{supp}(h\mathbf{T}) \subseteq \operatorname{supp}(h) \Subset U$ follows directly from the definition of the product of a distribution with a smooth function and Proposition 10.2.30. Thus the set K in the last assertion is compact in Ω. If χ_1 and χ_2 equal one near K, then $(\chi_1 - \chi_2)(\psi \restriction_\Omega)$ has support separated from K; Proposition 10.2.30 shows that the two formulas give the same value. Continuity of (10.6) is immediate on each space of test functions supported in a fixed compact set. □

Support describes where a distribution "lives." We can refine this idea by distinguishing points where the distribution is smooth from those where it has singularities.

Definition 10.2.35. (Singular support) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, let W be a finite-dimensional vector space, and let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$. Define the singular support of $\mathbf{T}$ as the set

$$\operatorname{sing\,supp}(\mathbf{T}) := \{x \in M \mid \text{for every neighborhood } U \text{ of } x,\ \mathbf{T} \restriction_U \neq \mathbf{T}_{\mathbf{u}} \text{ for every } \mathbf{u} \in \Gamma(U, \mathbf{E} \otimes W)\}.$$

Equivalently, $x \notin \operatorname{sing\,supp}(\mathbf{T})$ if and only if there exist an open neighborhood U of x and a smooth section $\mathbf{u} \in \Gamma(U, \mathbf{E} \otimes W)$ such that $\mathbf{T} \restriction_U = \mathbf{T}_{\mathbf{u}}$.

Proposition 10.2.36. Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, let W be a finite-dimensional vector space, and let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$. Then $\operatorname{sing\,supp}(\mathbf{T})$ is a closed subset of M, and

$$\operatorname{sing\,supp}(\mathbf{T}) \subseteq \operatorname{supp}(\mathbf{T}).$$

Proof. Let $x \notin \operatorname{sing\,supp}(\mathbf{T})$. Then there exist an open neighborhood U of x and a smooth section $\mathbf{u} \in \Gamma(U, \mathbf{E} \otimes W)$ such that $\mathbf{T} \restriction_U = \mathbf{T}_{\mathbf{u}}$. In particular, for every $y \in U$, $\mathbf{T} \restriction_U$ agrees with a distribution induced by a smooth section on a neighborhood of y, so $y \notin \operatorname{sing\,supp}(\mathbf{T})$. This shows that $U \subseteq M \setminus \operatorname{sing\,supp}(\mathbf{T})$, and hence $M \setminus \operatorname{sing\,supp}(\mathbf{T})$ is open. We conclude that $\operatorname{sing\,supp}(\mathbf{T})$ is closed.
For the second assertion, let $x \notin \operatorname{supp}(\mathbf{T})$. There is then an open neighborhood U of x such that $\mathbf{T} \restriction_U = 0$. Since $0 = \mathbf{T}_0$ with $0 \in \Gamma(U, \mathbf{E} \otimes W)$, $\mathbf{T} \restriction_U$ agrees with a distribution induced by a smooth section. Thus $x \notin \operatorname{sing\,supp}(\mathbf{T})$, implying $\operatorname{sing\,supp}(\mathbf{T}) \subseteq \operatorname{supp}(\mathbf{T})$. □

Example 10.2.37. Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let $p \in M$. Suppose that $\mathbf{E}_p^* \neq \{0\}$. Fix an auxiliary bundle metric $\mathbf{h}_{\mathbf{E}}$ on $\mathbf{E}$ and its dual metric $\mathbf{h}_{\mathbf{E}}^*$ on $\mathbf{E}^*$. Consider

$$\delta_p \colon \mathcal{D}(M, \mathbf{E}^*) \longrightarrow \mathbf{E}_p^*, \qquad \delta_p(\boldsymbol{\varphi}) := \boldsymbol{\varphi}(p),$$

the Dirac delta distribution at p. Recall that δ_p is a distribution with values in $\mathbf{E}_p^*$, that is,

$$\delta_p \in \mathcal{D}'(M, \mathbf{E}, \mathbf{E}_p^*).$$

We claim that

$$\operatorname{supp}(\delta_p) = \{p\}.$$

If $\dim M \geq 1$, we also have $\operatorname{sing\,supp}(\delta_p) = \{p\}$; if $\dim M = 0$, its singular support is empty.
Let $U \subseteq M$ be an open subset such that $p \notin U$. Then, for every test section $\boldsymbol{\varphi} \in \mathcal{D}(M, \mathbf{E}^*)$ with $\operatorname{supp}(\boldsymbol{\varphi}) \subseteq U$, we have $\boldsymbol{\varphi}(p) = 0$, and hence $\delta_p(\boldsymbol{\varphi}) = 0$. This shows that $\delta_p \restriction_U = 0$, giving

$$\operatorname{supp}(\delta_p) \subseteq \{p\}.$$

On the other hand, if U is any open subset containing p, there is a test section $\boldsymbol{\varphi} \in \mathcal{D}(M, \mathbf{E}^*)$ with $\operatorname{supp}(\boldsymbol{\varphi}) \subseteq U$ such that $\boldsymbol{\varphi}(p) \neq 0$. It suffices to take a nonzero element of $\mathbf{E}_p^*$ and use Lemma 1.7.28. Thus $\delta_p(\boldsymbol{\varphi}) = \boldsymbol{\varphi}(p) \neq$

0, implying $p \in \operatorname{supp}(\delta_p)$. We conclude that

$$\operatorname{supp}(\delta_p) = \{p\}.$$

If $\dim M = 0$, the manifold is discrete, and Riemannian measure is counting measure. Let $\mathbf{v}$ be the section of $\mathbf{E} \otimes \mathbf{E}_p^*$ that vanishes outside p and whose value at p is the canonical tensor $\sum_{a=1}^{r} e_a \otimes e^a$, where $\{e_a\}_{a=1}^r$ is any basis of $\mathbf{E}_p$ and $\{e^a\}_{a=1}^r$ its dual basis. This tensor is independent of the basis, and the section is smooth because every point is open. For every test section,

$$\mathbf{T}_{\mathbf{v}}(\boldsymbol{\varphi}) = \sum_{a=1}^{r} \boldsymbol{\varphi}(p)(e_a)e^a = \boldsymbol{\varphi}(p) = \delta_p(\boldsymbol{\varphi}).$$

Hence δ_p is regular and has empty singular support.
Now suppose that $d := \dim M \geq 1$. Let us show that $p \in \operatorname{sing\,supp}(\delta_p)$. Suppose, for a contradiction, that there exist an open subset U with $p \in U$ and a smooth section $\mathbf{u} \in \Gamma(U, \mathbf{E} \otimes \mathbf{E}_p^*)$ such that

$$\delta_p \restriction_U = \mathbf{T}_{\mathbf{u}}.$$

Then, for every test section $\boldsymbol{\varphi} \in \mathcal{D}(U, \mathbf{E}^*)$, we would have

$$\boldsymbol{\varphi}(p) = \delta_p(\boldsymbol{\varphi}) = \mathbf{T}_{\mathbf{u}}(\boldsymbol{\varphi}) = \int_U (\boldsymbol{\varphi} \otimes \mathrm{id}_{\mathbf{E}_p^*})(\mathbf{u})\, d\lambda_{\mathbf{g}}.$$

Consider an open subset $V \subseteq M$ such that $p \in V$, $\overline{V}$ is compact, and $\overline{V} \subseteq U$. We can choose it so that $\mathbf{E}^*$ admits a local trivialization over V and a chart (V, φ) exists. By Lemma 1.7.28, choose $\boldsymbol{\eta} \in \Gamma_c(V, \mathbf{E}^*)$ such that $\boldsymbol{\eta}(p) \neq 0$, and extend it by zero outside V.
Let $H = \mathbb{R}^d$ if the chart is interior and $H = \mathbb{H}^d$ if it is a boundary chart. Since $\varphi(V)$ is open in H, choose $r_n \downarrow 0$ so that $\overline{B_{\mathrm{euc}}(\varphi(p), r_1)} \cap H \subseteq \varphi(V)$. Restricting Euclidean cutoff functions centered at $\varphi(p)$ to H and transferring them by the chart gives $\rho_n \in C_c^\infty(V)$ with

$$0 \leq \rho_n \leq 1, \qquad \rho_n(p) = 1, \qquad \operatorname{supp}(\rho_n) \subseteq \varphi^{-1}\big(B_{\mathrm{euc}}(\varphi(p), r_n) \cap H\big).$$

The weight $\sqrt{\det(\mathbf{g})} \circ \varphi^{-1}$ is bounded on the compact coordinate set of radius r_1. Consequently, there exists $C_0 > 0$ independent of n such that

$$\lambda_{\mathbf{g}}(\operatorname{supp}\rho_n) \leq C_0 \lambda_d\big(B_{\mathrm{euc}}(\varphi(p), r_n)\big) \longrightarrow 0,$$

since $d \geq 1$. All these supports lie in $V \subseteq U$.
Now define

$$\boldsymbol{\varphi}_n := \rho_n \boldsymbol{\eta}.$$

Then $\boldsymbol{\varphi}_n \in \mathcal{D}(U, \mathbf{E}^*)$ and

$$\boldsymbol{\varphi}_n(p) = \boldsymbol{\eta}(p) \neq 0$$

for every n.
On the other hand, the section $\mathbf{s} := (\boldsymbol{\eta} \otimes \mathrm{id}_{\mathbf{E}_p^*})(\mathbf{u})$ is smooth on V and supported in the compact set $\operatorname{supp}\boldsymbol{\eta} \Subset$

V. It is therefore bounded on that compact set and zero outside it. Thus there exists a constant $C > 0$ such that $|\mathbf{s}(q)|_{\mathbf{h}^*_{\mathbf{E}}(p)} \le C$ for every $q \in V$.
Since $\boldsymbol{\varphi}_n = \rho_n \boldsymbol{\eta}$ and $\operatorname{supp}(\rho_n) \subseteq V$, we have

$$\int_U (\boldsymbol{\varphi}_n \otimes \mathrm{id}_{\mathbf{E}^*_p})(\mathbf{u})\, d\lambda_{\mathbf{g}} = \int_V \rho_n \mathbf{s}\, d\lambda_{\mathbf{g}}.$$

By the triangle inequality for integrals,

$$\left| \int_V \rho_n \mathbf{s}\, d\lambda_{\mathbf{g}} \right|_{\mathbf{h}^*_{\mathbf{E}}(p)} \le \int_V |\rho_n| |\mathbf{s}|_{\mathbf{h}^*_{\mathbf{E}}(p)}\, d\lambda_{\mathbf{g}}.$$

Since $0 \le \rho_n \le 1$ and $|\mathbf{s}|_{\mathbf{h}^*_{\mathbf{E}}(p)} \le C$ on $\operatorname{supp}(\rho_n)$, we obtain

$$\left| \int_U (\boldsymbol{\varphi}_n \otimes \mathrm{id}_{\mathbf{E}^*_p})(\mathbf{u})\, d\lambda_{\mathbf{g}} \right|_{\mathbf{h}^*_{\mathbf{E}}(p)} \le C\, \lambda_{\mathbf{g}}(\operatorname{supp}(\rho_n)).$$

Recall that $\lambda_{\mathbf{g}}(\operatorname{supp}(\rho_n)) \longrightarrow 0$; therefore

$$\int_U (\boldsymbol{\varphi}_n \otimes \mathrm{id}_{\mathbf{E}^*_p})(\mathbf{u})\, d\lambda_{\mathbf{g}} \longrightarrow 0.$$

This is a contradiction, since these integrals equal $\boldsymbol{\varphi}_n(p) = \boldsymbol{\eta}(p) \neq 0$. Thus no such smooth section $\mathbf{u}$ exists, and it follows that $p \in \operatorname{sing\,supp}(\delta_p)$.

We now examine further properties of support, including its relation to restrictions and partial differential operators.

Proposition 10.2.38. (Compatibility of restriction with support) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let W be a finite-dimensional vector space. Let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$ and let $U \subseteq M$ be open. Then

$$\operatorname{supp}(\mathbf{T} \restriction_U) = \operatorname{supp}(\mathbf{T}) \cap U.$$

Proof. First prove that $\operatorname{supp}(\mathbf{T} \restriction_U) \subseteq \operatorname{supp}(\mathbf{T}) \cap U$. Let $x \in U$ be such that $x \notin \operatorname{supp}(\mathbf{T})$. There is then an open neighborhood $V \subseteq M$ of x such that $\mathbf{T} \restriction_V = 0$. Since $U \cap V$ is an open neighborhood of x in U, we have

$$(\mathbf{T} \restriction_U) \restriction_{U \cap V} = \mathbf{T} \restriction_{U \cap V} = 0.$$

Therefore $x \notin \operatorname{supp}(\mathbf{T} \restriction_U)$.
Conversely, let $x \in \operatorname{supp}(\mathbf{T}) \cap U$. Consider an open neighborhood $V \subseteq U$ of x. Since U is open in M, we may also view V as an open subset of M. Since $x \in \operatorname{supp}(\mathbf{T})$, we cannot have $\mathbf{T} \restriction_V = 0$. Thus there is a test section $\boldsymbol{\varphi} \in \mathcal{D}(V, \mathbf{E}^*)$ such that $\mathbf{T} \restriction_V (\boldsymbol{\varphi}) \neq 0$. But $\mathbf{T} \restriction_V = (\mathbf{T} \restriction_U) \restriction_V$, so $(\mathbf{T} \restriction_U) \restriction_V \neq 0$. Since this holds for every open neighborhood V of x in U, it follows that $x \in \operatorname{supp}(\mathbf{T} \restriction_U)$.
We conclude that $\operatorname{supp}(\mathbf{T} \restriction_U) = \operatorname{supp}(\mathbf{T}) \cap U$. □

Proposition 10.2.39. (Compatibility of restriction with differential operators) Let M be a smooth manifold without boundary, let $\mathbf{E}, \mathbf{F} \to M$ be smooth vector bundles, and let W be a finite-dimensional vector space. Let $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$, let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$, and let $U \subseteq M$ be open. If P_U is the restriction of P to U, then

$$(P\mathbf{T})|_U = P_U(\mathbf{T}|_U) \qquad \text{on } \mathcal{D}'(U, \mathbf{F}|_U, W). \tag{10.7}$$

Proof. Compatibility of the formal transpose with restrictions gives $(P_U)' = (P')_U$. Let $\boldsymbol{\varphi} \in \mathcal{D}(U, \mathbf{F}^*|_U)$ and denote its extension by zero by $\widetilde{\boldsymbol{\varphi}}$; it is smooth because $\operatorname{supp} \boldsymbol{\varphi} \Subset U$. Locality of P' implies that $P'\widetilde{\boldsymbol{\varphi}}$ is the extension by zero of $(P_U)'\boldsymbol{\varphi}$. Therefore

$$\begin{aligned}((P\mathbf{T})|_U)(\boldsymbol{\varphi}) &= (P\mathbf{T})(\widetilde{\boldsymbol{\varphi}}) = \mathbf{T}(P'\widetilde{\boldsymbol{\varphi}}) \\ &= (\mathbf{T}|_U)((P_U)'\boldsymbol{\varphi}) = (P_U(\mathbf{T}|_U))(\boldsymbol{\varphi}),\end{aligned}$$

which is (10.7). □

Proposition 10.2.40. (Locality of differential operators on distributions) Let M be a smooth manifold without boundary, let $\mathbf{E}, \mathbf{F} \to M$ be smooth vector bundles, and let W be a finite-dimensional vector space. Let $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$ and let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$. Then

$$\operatorname{supp}(P\mathbf{T}) \subseteq \operatorname{supp}(\mathbf{T}).$$

Proof. Let $x \notin \operatorname{supp}(\mathbf{T})$. There is then an open neighborhood U of x such that $\mathbf{T} \restriction_U = 0$.
Let $\boldsymbol{\varphi} \in \mathcal{D}(U, \mathbf{F}^*)$ and let $\widetilde{\boldsymbol{\varphi}} \in \mathcal{D}(M, \mathbf{F}^*)$ be its extension by zero outside U. By Proposition 10.2.39, we have

$$(P\mathbf{T}) \restriction_U (\boldsymbol{\varphi}) = \mathbf{T} \restriction_U \left((P'\widetilde{\boldsymbol{\varphi}}) \restriction_U\right).$$

Since $\mathbf{T} \restriction_U = 0$, we obtain

$$(P\mathbf{T}) \restriction_U (\boldsymbol{\varphi}) = 0.$$

This holds for every $\boldsymbol{\varphi} \in \mathcal{D}(U, \mathbf{F}^*)$, so $(P\mathbf{T}) \restriction_U = 0$. Consequently, $x \notin \operatorname{supp}(P\mathbf{T})$.
Therefore

$$\operatorname{supp}(P\mathbf{T}) \subseteq \operatorname{supp}(\mathbf{T}).$$

□

Lemma 10.2.41. (Restriction of regular distributions) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let W be a finite-dimensional vector space. Let $\mathbf{u} \in \Gamma(\mathbf{E} \otimes W)$ and let $U \subseteq M$ be open. Then

$$(\mathbf{T}_{\mathbf{u}}) \restriction_U = \mathbf{T}_{\mathbf{u} \restriction_U}$$

as elements of $\mathcal{D}'(U, \mathbf{E} \restriction_U, W)$.

Proof. Let $\boldsymbol{\varphi} \in \mathcal{D}(U, \mathbf{E}^* \restriction_U)$. By the definition of restriction of a distribution,

$$(\mathbf{T}_{\mathbf{u}}) \restriction_U (\boldsymbol{\varphi}) = \mathbf{T}_{\mathbf{u}}(\widetilde{\boldsymbol{\varphi}}),$$

where $\widetilde{\varphi} \in \mathcal{D}(M, \mathbf{E}^*)$ denotes the extension of φ by zero outside U.
By the definition of $\mathbf{T}_{\mathbf{u}}$, we have

$$\mathbf{T}_{\mathbf{u}}(\widetilde{\varphi}) = \int_M (\widetilde{\varphi} \otimes \mathrm{id}_W)(\mathbf{u})\, d\lambda_{\mathbf{g}}.$$

Since $\widetilde{\varphi}$ vanishes outside U, this integral reduces to

$$\int_U (\varphi \otimes \mathrm{id}_W)(\mathbf{u} \restriction_U)\, d\lambda_{\mathbf{g}}.$$

But the last expression is precisely

$$\mathbf{T}_{\mathbf{u}\restriction_U}(\varphi).$$

Therefore $(\mathbf{T}_{\mathbf{u}}) \restriction_U (\varphi) = \mathbf{T}_{\mathbf{u}\restriction_U}(\varphi)$ for every $\varphi \in \mathcal{D}(U, \mathbf{E}^* \restriction_U)$, proving the equality. □

Proposition 10.2.42. (Smooth regular distributions and support) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let W be a finite-dimensional vector space. Let $\mathbf{u} \in \Gamma(\mathbf{E} \otimes W)$ and let $\mathbf{T}_{\mathbf{u}} \in \mathcal{D}'(M, \mathbf{E}, W)$ be the smooth regular distribution induced by $\mathbf{u}$. Then

$$\operatorname{supp}(\mathbf{T}_{\mathbf{u}}) = \operatorname{supp}(\mathbf{u}).$$

Proof. Let $x \notin \operatorname{supp}(\mathbf{u})$. There is then an open neighborhood U of x such that $\mathbf{u} \restriction_U = 0$. If $\varphi \in \mathcal{D}(U, \mathbf{E}^*)$, we have

$$(\mathbf{T}_{\mathbf{u}} \restriction_U)(\varphi) = \mathbf{T}_{\mathbf{u}\restriction_U}(\varphi) = \int_U (\varphi \otimes \mathrm{id}_W)(\mathbf{u} \restriction_U)\, d\lambda_{\mathbf{g}} = 0.$$

It follows that $\mathbf{T}_{\mathbf{u}} \restriction_U = 0$, and hence $x \notin \operatorname{supp}(\mathbf{T}_{\mathbf{u}})$. This proves that $\operatorname{supp}(\mathbf{T}_{\mathbf{u}}) \subseteq \operatorname{supp}(\mathbf{u})$.
Conversely, let $x \in \operatorname{supp}(\mathbf{u})$. We show that $x \in \operatorname{supp}(\mathbf{T}_{\mathbf{u}})$. Let U be an arbitrary open neighborhood of x. Since $x \in \operatorname{supp}(\mathbf{u})$, there exists $y \in U$ such that $\mathbf{u}(y) \neq 0$.
Since $\mathbf{u}(y) \in \mathbf{E}_y \otimes W$ is nonzero, there exist $\ell_0 \in \mathbf{E}_y^*$ and $\omega \in W^*$ such that

$$\omega\big((\ell_0 \otimes \mathrm{id}_W)(\mathbf{u}(y))\big) \neq 0.$$

Applying Lemma 1.7.28 to the bundle $\mathbf{E}^* \to M$, choose a smooth section $\boldsymbol{\ell} \in \Gamma(\mathbf{E}^*)$ with $\operatorname{supp}(\boldsymbol{\ell}) \subseteq U$ and $\boldsymbol{\ell}(y) = \ell_0$.
Multiplying $\boldsymbol{\ell}$ by a nonzero scalar if necessary, we may assume that

$$\operatorname{Re}\, \omega\big((\boldsymbol{\ell}(y) \otimes \mathrm{id}_W)(\mathbf{u}(y))\big) > 0,$$

where, if $\mathbb{K} = \mathbb{R}$, Re is understood as the identity. By continuity, there is a relatively compact open subset $V \subseteq U$, with $y \in V$, such that

$$\operatorname{Re}\, \omega\big((\boldsymbol{\ell}(z) \otimes \mathrm{id}_W)(\mathbf{u}(z))\big) > 0 \qquad \forall z \in V.$$

Now let $\rho \in \mathcal{D}(U, \mathbb{K})$ be a cutoff function such that $\rho \geq 0$, $\rho \not\equiv 0$, and $\operatorname{supp}(\rho) \subseteq V$. Define

$$\varphi := \rho\, \boldsymbol{\ell} \restriction_U \in \mathcal{D}(U, \mathbf{E}^*).$$

Then

$$\omega\big(\mathbf{T}_{\mathbf{u}} \restriction_U (\boldsymbol{\varphi})\big) = \omega\left(\int_U (\boldsymbol{\varphi} \otimes \mathrm{id}_W)(\mathbf{u})\, d\lambda_{\mathbf{g}}\right).$$

Since W is finite dimensional, we may move ω inside the integral, obtaining

$$\omega\big(\mathbf{T}_{\mathbf{u}} \restriction_U (\boldsymbol{\varphi})\big) = \int_U \omega\big((\boldsymbol{\varphi} \otimes \mathrm{id}_W)(\mathbf{u})\big)\, d\lambda_{\mathbf{g}}.$$

Using the definition of $\boldsymbol{\varphi}$ and the fact that $\operatorname{supp}(\rho) \subseteq V$, this reduces to

$$\omega\big(\mathbf{T}_{\mathbf{u}} \restriction_U (\boldsymbol{\varphi})\big) = \int_V \rho\, \omega\big((\boldsymbol{\ell} \otimes \mathrm{id}_W)(\mathbf{u})\big)\, d\lambda_{\mathbf{g}}.$$

Taking real parts,

$$\operatorname{Re}\, \omega\big(\mathbf{T}_{\mathbf{u}} \restriction_U (\boldsymbol{\varphi})\big) = \int_V \rho\, \operatorname{Re}\, \omega\big((\boldsymbol{\ell} \otimes \mathrm{id}_W)(\mathbf{u})\big)\, d\lambda_{\mathbf{g}}.$$

The integrand is nonnegative and does not vanish identically, since $\rho \geq 0$, $\rho \not\equiv 0$, and

$$\operatorname{Re}\, \omega\big((\boldsymbol{\ell}(z) \otimes \mathrm{id}_W)(\mathbf{u}(z))\big) > 0 \qquad \forall z \in V.$$

Consequently,

$$\operatorname{Re}\, \omega\big(\mathbf{T}_{\mathbf{u}} \restriction_U (\boldsymbol{\varphi})\big) > 0,$$

and in particular $\mathbf{T}_{\mathbf{u}} \restriction_U (\boldsymbol{\varphi}) \neq 0$. Therefore $\mathbf{T}_{\mathbf{u}} \restriction_U \neq 0$.
Since U was an arbitrary neighborhood of x, we conclude that $x \in \operatorname{supp}(\mathbf{T}_{\mathbf{u}})$. Consequently,

$$\operatorname{supp}(\mathbf{T}_{\mathbf{u}}) = \operatorname{supp}(\mathbf{u}).$$

□

Proposition 10.2.43. (Compatibility of restriction with singular support) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let W be a finite-dimensional vector space. Let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$ and let $U \subseteq M$ be open. Then

$$\operatorname{sing\,supp}(\mathbf{T} \restriction_U) = \operatorname{sing\,supp}(\mathbf{T}) \cap U.$$

Proof. Let $x \in U$ be such that $x \notin \operatorname{sing\,supp}(\mathbf{T})$. There then exist an open neighborhood $V \subseteq M$ of x and a smooth section $\mathbf{u} \in \Gamma(V, \mathbf{E} \otimes W)$ such that

$$\mathbf{T} \restriction_V = \mathbf{T}_{\mathbf{u}}.$$

Restricting to $U \cap V$ gives

$$(\mathbf{T} \restriction_U) \restriction_{U\cap V} = \mathbf{T} \restriction_{U\cap V} = (\mathbf{T}_{\mathbf{u}}) \restriction_{U\cap V} = \mathbf{T}_{\mathbf{u}\restriction_{U\cap V}}.$$

Therefore $x \notin \operatorname{sing\,supp}(\mathbf{T} \restriction_U)$. This proves that

$$\operatorname{sing\,supp}(\mathbf{T} \restriction_U) \subseteq \operatorname{sing\,supp}(\mathbf{T}) \cap U.$$

Conversely, let $x \in U$ be such that $x \notin \operatorname{sing\,supp}(\mathbf{T} \restriction_U)$. There then exist an open neighborhood $V \subseteq U$ of x

and a smooth section $\mathbf{u} \in \Gamma(V, \mathbf{E} \otimes W)$ such that

$$(\mathbf{T} \restriction_U) \restriction_V = \mathbf{T}_{\mathbf{u}}.$$

Since V is also open in M, we have $\mathbf{T} \restriction_V = (\mathbf{T} \restriction_U) \restriction_V = \mathbf{T}_{\mathbf{u}}$. Therefore $x \notin \operatorname{sing\,supp}(\mathbf{T})$. This proves the reverse containment.
We conclude that

$$\operatorname{sing\,supp}(\mathbf{T} \restriction_U) = \operatorname{sing\,supp}(\mathbf{T}) \cap U.$$

□

Proposition 10.2.44. (Locality of differential operators and singular support) Let M be a smooth manifold without boundary, let $\mathbf{E}, \mathbf{F} \to M$ be smooth vector bundles, and let W be a finite-dimensional vector space. Let $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$ and let $\mathbf{T} \in \mathcal{D}'(M, \mathbf{E}, W)$. Then

$$\operatorname{sing\,supp}(P\mathbf{T}) \subseteq \operatorname{sing\,supp}(\mathbf{T}).$$

Proof. Let $x \notin \operatorname{sing\,supp}(\mathbf{T})$. There then exist an open neighborhood U of x and a smooth section $\mathbf{u} \in \Gamma(U, \mathbf{E} \otimes W)$ such that

$$\mathbf{T} \restriction_U = \mathbf{T}_{\mathbf{u}}.$$

We show that $(P\mathbf{T}) \restriction_U$ is also a smooth regular distribution.
Let $\boldsymbol{\varphi} \in \mathcal{D}(U, \mathbf{F}^*)$ and let $\widetilde{\boldsymbol{\varphi}} \in \mathcal{D}(M, \mathbf{F}^*)$ be its extension by zero outside U. By Proposition 10.2.39, we have

$$(P\mathbf{T}) \restriction_U (\boldsymbol{\varphi}) = \mathbf{T} \restriction_U \big((P'\widetilde{\boldsymbol{\varphi}}) \restriction_U\big).$$

Using $\mathbf{T} \restriction_U = \mathbf{T}_{\mathbf{u}}$, we obtain

$$(P\mathbf{T}) \restriction_U (\boldsymbol{\varphi}) = \mathbf{T}_{\mathbf{u}}\big((P'\widetilde{\boldsymbol{\varphi}}) \restriction_U\big) = \int_U \big((P'\widetilde{\boldsymbol{\varphi}}) \restriction_U \otimes \mathrm{id}_W\big)(\mathbf{u})\, d\lambda_{\mathbf{g}}.$$

Now observe that $\widetilde{\boldsymbol{\varphi}}$ agrees with $\boldsymbol{\varphi}$ on U, so $\widetilde{\boldsymbol{\varphi}} - \boldsymbol{\varphi} = 0$ on U. Since P' is a differential operator, it is local, and therefore

$$P'(\widetilde{\boldsymbol{\varphi}} - \boldsymbol{\varphi}) = 0 \qquad \text{on } U.$$

Consequently,

$$(P'\widetilde{\boldsymbol{\varphi}}) \restriction_U = P'\boldsymbol{\varphi},$$

where $P'\boldsymbol{\varphi}$ is computed in U.
Substitute this into the preceding integral. To justify the resulting identity, work locally: write

$$\mathbf{u} = \sum_{a=1}^{N} \mathbf{u}_a \otimes w_a,$$

where $\{w_1, \dots, w_N\}$ is a basis of W and each $\mathbf{u}_a$ is a smooth local section of $\mathbf{E}$. Then

$$\big((P'\widetilde{\boldsymbol{\varphi}}) \restriction_U \otimes \mathrm{id}_W\big)(\mathbf{u}) = \sum_{a=1}^{N} (P'\boldsymbol{\varphi})(\mathbf{u}_a)\, w_a.$$

Applying the definition of the bilinear formal transpose (on U), we have

$$\int_U (P'\varphi)(\mathbf{u}_a)\,d\lambda_{\mathbf{g}} = \int_U \varphi(P\mathbf{u}_a)\,d\lambda_{\mathbf{g}} \qquad \text{for every } a \in \{1,\dots,N\}.$$

Therefore

$$\int_U \big((P'\widetilde{\varphi}) \restriction_U \otimes \mathrm{id}_W\big)(\mathbf{u})\,d\lambda_{\mathbf{g}} = \sum_{a=1}^{N} \left(\int_U \varphi(P\mathbf{u}_a)\,d\lambda_{\mathbf{g}}\right) w_a.$$

On the other hand, since P acts only on the component in $\mathbf{E}$, we have

$$(P\otimes \mathrm{id}_W)\mathbf{u} = \sum_{a=1}^{N} P\mathbf{u}_a \otimes w_a \in \Gamma(U, \mathbf{F}\otimes W).$$

It follows that

$$\sum_{a=1}^{N} \left(\int_U \varphi(P\mathbf{u}_a)\,d\lambda_{\mathbf{g}}\right) w_a = \int_U \big(\varphi\otimes \mathrm{id}_W\big)\big((P\otimes \mathrm{id}_W)\mathbf{u}\big)\,d\lambda_{\mathbf{g}}.$$

Consequently,

$$(P\mathbf{T}) \restriction_U (\varphi) = \int_U \big(\varphi\otimes \mathrm{id}_W\big)\big((P\otimes \mathrm{id}_W)\mathbf{u}\big)\,d\lambda_{\mathbf{g}} = \mathbf{T}_{(P\otimes \mathrm{id}_W)\mathbf{u}}(\varphi).$$

Since this holds for every $\varphi \in \mathcal{D}(U, \mathbf{F}^*)$, we conclude that

$$(P\mathbf{T}) \restriction_U = \mathbf{T}_{(P\otimes \mathrm{id}_W)\mathbf{u}}.$$

In particular, $(P\mathbf{T}) \restriction_U$ is a smooth regular distribution on a neighborhood of x, implying

$$x \notin \operatorname{sing\,supp}(P\mathbf{T}).$$

Since x was arbitrary, we obtain

$$\operatorname{sing\,supp}(P\mathbf{T}) \subseteq \operatorname{sing\,supp}(\mathbf{T}).$$

□

10.2.3 External products and parameter-dependent sections

To study operators from a more global viewpoint, it is useful to consider sections depending on two variables. In the Euclidean case, these arise when operators are written using functions of two variables, usually called kernels. For manifolds and vector bundles, the corresponding expression must be formulated intrinsically.

Remark 10.2.45. (Products with boundary and corners) If both factors have boundary, $M\times N$ is a manifold with corners. Its product charts take values in relatively open subsets of $\mathbb{R}^{m+n-r}\times[0,\infty)^r$, with $r \in \{0,1,2\}$. A section is smooth up to the faces if all ordinary derivatives of its interior components extend continuously to them. Lemma B.12.19, applied locally after multiplication by a cutoff function, shows that this condition is equivalent to admitting local smooth extensions to Euclidean space. The chain rule ensures independence of the product charts.

Bundles over the product, their compactly supported sections, and their distributions will be understood in this sense. On each compact set, covariant derivative norms are equivalent to ordinary derivative norms in

finitely many product charts: this follows by applying the triangular expressions for covariant derivatives and boundedness of their coefficients, which are smooth up to the faces. The fixed-support spaces are Fréchet. Indeed, a uniform limit of all derivatives in these charts preserves the differentiation identities by the fundamental theorem of calculus along interior segments; continuity extends these identities to the faces, and the support remains in the fixed compact set. Inclusions of supports are closed and preserve their seminorms, so an exhaustion by compact sets defines the same strict inductive limit LF as in the preceding section. Its arguments for completeness and stagewise continuity apply unchanged to these products. In particular, test functions may be nonzero on any of the faces.

If $\mathbf{E} \longrightarrow M$ and $\mathbf{F} \longrightarrow N$ are smooth vector bundles, a section depending on two variables and taking values in $\mathbf{E}_x \otimes \mathbf{F}_y^*$ for each $(x, y) \in M \times N$ must be understood as a section of a vector bundle over $M \times N$.

Pullback by the canonical projections of the product gives vector bundles over $M \times N$ from bundles defined over each factor. This allows us to introduce the external product.

Definition 10.2.46. (External product of vector bundles) Let M and N be smooth manifolds with or without boundary, and let $\mathbf{E} \longrightarrow M$ and $\mathbf{F} \longrightarrow N$ be smooth vector bundles. Denote the canonical projections by $\pi_M : M \times N \longrightarrow M$ and $\pi_N : M \times N \longrightarrow N$.
Define the *external product* of $\mathbf{E}$ and $\mathbf{F}$ as the smooth vector bundle over $M \times N$ given by

$$\mathbf{E} \boxtimes \mathbf{F} := \pi_M^* \mathbf{E} \otimes \pi_N^* \mathbf{F}.$$

In particular, for each $(x, y) \in M \times N$, its fiber is $(\mathbf{E} \boxtimes \mathbf{F})_{(x,y)} = \mathbf{E}_x \otimes \mathbf{F}_y$.

Remark 10.2.47. There is a canonical isomorphism

$$(\mathbf{E} \boxtimes \mathbf{F})^* \cong \mathbf{E}^* \boxtimes \mathbf{F}^*.$$

Fiberwise, we have $(\mathbf{E}_x \otimes \mathbf{F}_y)^* \cong \mathbf{E}_x^* \otimes \mathbf{F}_y^*$, since the vector spaces involved are finite dimensional. These fiberwise isomorphisms are compatible with local trivializations and therefore define a smooth bundle isomorphism.

The external product allows an expression of the form $\varphi(x, y) \in \mathbf{E}_x \otimes \mathbf{F}_y^*$ to be interpreted intrinsically as a section of $\mathbf{E} \boxtimes \mathbf{F}^*$ over $M \times N$. Before applying distributions in one variable, we specify an elementary isomorphism that will be used repeatedly.

Remark 10.2.48. (Convention) If V is a finite-dimensional $\mathbb{K}$-vector space and N is a smooth manifold with or without boundary, we identify V with the trivial vector bundle $N \times V \to N$. Consequently, if $\mathbf{F} \to N$ is a vector bundle, we write simply $V \otimes \mathbf{F}$ for the tensor product of the trivial bundle $N \times V$ with $\mathbf{F}$. With this convention,

$$(V \otimes \mathbf{F})_y \cong V \otimes \mathbf{F}_y, \qquad y \in N.$$

Proposition 10.2.49. Let N be a smooth manifold with or without boundary, let $\mathbf{F} \longrightarrow N$ be a smooth vector bundle, let V be a finite-dimensional $\mathbb{K}$-vector space, and let $K \subseteq N$ be compact. Then, for every

$k \in \mathbb{N}_0$, the linear map

$$\Theta_K : V \otimes_\pi \Gamma_K^k(\mathbf{F}) \longrightarrow \Gamma_K^k(V \otimes \mathbf{F}), \qquad \Theta_K(v \otimes \mathbf{s})(y) := v \otimes \mathbf{s}(y),$$

extended by linearity, is a linear isomorphism.
Moreover, if we fix a norm on V, a Riemannian metric $\mathbf{g}$ on N, and a bundle metric and connection on $\mathbf{F}$, then Θ_K is a topological isomorphism from $V \otimes_\pi \Gamma_K^k(\mathbf{F})$, equipped with the projective tensor norm induced by $\|\cdot\|_V$ and $\|\cdot\|_{C^k(K,\mathbf{F})}$, onto $\Gamma_K^k(V \otimes \mathbf{F})$ with the norm $\|\cdot\|_{C^k(K,V\otimes\mathbf{F})}$.

Proof. First prove that Θ_K is well defined. If $v \in V$ and $\mathbf{s} \in \Gamma_K^k(\mathbf{F})$, then, for each $y \in N$, $v \otimes \mathbf{s}(y) \in (V \otimes \mathbf{F})_y$, so the map $y \longmapsto v \otimes \mathbf{s}(y)$ defines a section of class C^k of the bundle $V \otimes \mathbf{F}$. Moreover, $\operatorname{supp}(\Theta_K(v \otimes \mathbf{s})) \subseteq \operatorname{supp}(\mathbf{s}) \subseteq K$. Therefore $\Theta_K(v \otimes \mathbf{s}) \in \Gamma_K^k(V \otimes \mathbf{F})$. Extending by linearity gives a linear map

$$\Theta_K : V \otimes \Gamma_K^k(\mathbf{F}) \longrightarrow \Gamma_K^k(V \otimes \mathbf{F}).$$

Let us check surjectivity. Take a basis $\{e_1, \dots, e_r\}$ of V, and let $\{\varepsilon^1, \dots, \varepsilon^r\}$ be the dual basis of V^*. If $\sigma \in \Gamma_K^k(V \otimes \mathbf{F})$, define $\sigma_i(y) := (\varepsilon^i \otimes \mathrm{id}_{\mathbf{F}_y})(\sigma(y))$ for $i \in \{1, \dots, r\}$.
Since $\varepsilon^i \otimes \mathrm{id}_{\mathbf{F}}$ defines a smooth bundle homomorphism $V \otimes \mathbf{F} \longrightarrow \mathbf{F}$, it follows that σ_i is of class C^k. Moreover, if $y \notin K$, then $\sigma(y) = 0$ and hence $\sigma_i(y) = 0$. Thus $\sigma_i \in \Gamma_K^k(\mathbf{F})$.
For each $y \in N$, using the basis $\{e_i\}$ gives $\sigma(y) = \sum_{i=1}^r e_i \otimes \sigma_i(y)$. Therefore $\sigma = \Theta_K\left(\sum_{i=1}^r e_i \otimes \sigma_i\right)$. This proves that Θ_K is surjective.
Now prove injectivity. Suppose that

$$\Theta_K\left(\sum_{i=1}^r e_i \otimes \mathbf{s}_i\right) = 0, \qquad \mathbf{s}_i \in \Gamma_K^k(\mathbf{F}).$$

Then, for every $y \in N$, $\sum_{i=1}^r e_i \otimes \mathbf{s}_i(y) = 0$ in $V \otimes \mathbf{F}_y$. Composing with $\varepsilon^j \otimes \mathrm{id}_{\mathbf{F}_y}$ gives $\mathbf{s}_j(y) = 0$ for every $y \in N$.
Since this holds for every $j \in \{1, \dots, r\}$, it follows that $\mathbf{s}_j = 0$ for every j. Therefore $\sum_{i=1}^r e_i \otimes \mathbf{s}_i = 0$ in $V \otimes \Gamma_K^k(\mathbf{F})$, and Θ_K is injective.
Finally, prove the topological assertion. The connection on $\mathbf{F}$ and the trivial connection on $N \times V$ induce a connection on $V \otimes \mathbf{F}$. If $\sigma = \sum_{i=1}^r e_i \otimes \mathbf{s}_i$, then, for $0 \le j \le k$, $\nabla^j \sigma = \sum_{i=1}^r e_i \otimes \nabla^j \mathbf{s}_i$. Since V is finite dimensional, there exist constants $A, B > 0$, depending on the basis and fixed metrics but independent of the sections, such that for every $y \in K$ and $0 \le j \le k$,

$$A \max_{1\le i\le r} |\nabla^j \mathbf{s}_i(y)|_{\mathbf{g},\mathbf{h}_\mathbf{F}} \le \left|\sum_{i=1}^r e_i \otimes \nabla^j \mathbf{s}_i(y)\right|_{\mathbf{g},\mathbf{h}_{V\otimes\mathbf{F}}} \le B \max_{1\le i\le r} |\nabla^j \mathbf{s}_i(y)|_{\mathbf{g},\mathbf{h}_\mathbf{F}}.$$

Taking the supremum over $y \in K$ and the maximum over $0 \le j \le k$ gives constants $C_1, C_2 > 0$ such that

$$C_1 \max_{1\le i\le r} \|\mathbf{s}_i\|_{C^k(K,\mathbf{F})} \le \left\| \Theta_K \left(\sum_{i=1}^{r} e_i \otimes \mathbf{s}_i \right) \right\|_{C^k(K, V\otimes\mathbf{F})} \le C_2 \max_{1\le i\le r} \|\mathbf{s}_i\|_{C^k(K,\mathbf{F})}.$$

For the fixed basis (e_i), the quantity $\max_{1\le i\le r} \|\mathbf{s}_i\|_{C^k(K,\mathbf{F})}$ is equivalent to the projective norm of $\sum_{i=1}^{r} e_i \otimes \mathbf{s}_i$. These inequalities show that Θ_K and Θ_K^{-1} are continuous. □

Corollary 10.2.50. Let N be a smooth manifold with or without boundary, let $\mathbf{F} \longrightarrow N$ be a smooth vector bundle, and let V be a finite-dimensional $\mathbb{K}$-vector space. Then, for every $k \in \mathbb{N}_0$, the linear map

$$\Theta : V \otimes \mathcal{D}^k(N,\mathbf{F}) \longrightarrow \mathcal{D}^k(N, V\otimes\mathbf{F}), \qquad \Theta(v\otimes\mathbf{s})(y) := v \otimes \mathbf{s}(y),$$

extended by linearity, is a continuous linear isomorphism with continuous inverse.

Proof. Recall that $\mathcal{D}^k(N,\mathbf{F}) = \Gamma_c^k(\mathbf{F})$ and that this space is equipped with the inductive topology

$$\mathcal{D}^k(N,\mathbf{F}) = \varinjlim_{\ell\in\mathbb{N}} \Gamma^k_{K_\ell}(\mathbf{F}),$$

where $(K_\ell)_{\ell\in\mathbb{N}}$ is an increasing exhaustion of N by compact sets. Likewise,

$$\mathcal{D}^k(N, V\otimes\mathbf{F}) = \varinjlim_{\ell\in\mathbb{N}} \Gamma^k_{K_\ell}(V\otimes\mathbf{F}).$$

For each ℓ, Proposition 10.2.49 provides a continuous linear isomorphism with continuous inverse

$$\Theta_{K_\ell} : V \otimes \Gamma^k_{K_\ell}(\mathbf{F}) \longrightarrow \Gamma^k_{K_\ell}(V\otimes\mathbf{F}).$$

Moreover, if $K_\ell \subseteq K_{\ell'}$, the corresponding maps are compatible with the natural inclusions, since all are defined by the same formula $v\otimes\mathbf{s} \mapsto (y \mapsto v\otimes\mathbf{s}(y))$.
Thus the isomorphisms Θ_{K_ℓ} induce a linear map

$$\Theta : V \otimes \mathcal{D}^k(N,\mathbf{F}) \longrightarrow \mathcal{D}^k(N, V\otimes\mathbf{F}).$$

Let us prove that this map is bijective. If $\mathbf{s} \in \mathcal{D}^k(N,\mathbf{F})$, there exists ℓ such that $\mathbf{s} \in \Gamma^k_{K_\ell}(\mathbf{F})$; by the preceding proposition, $\Theta(v\otimes\mathbf{s}) \in \Gamma^k_{K_\ell}(V\otimes\mathbf{F}) \subseteq \mathcal{D}^k(N, V\otimes\mathbf{F})$. This shows that Θ is well defined.
Now let $\sigma \in \mathcal{D}^k(N, V\otimes\mathbf{F})$. There exists ℓ such that $\sigma \in \Gamma^k_{K_\ell}(V\otimes\mathbf{F})$. By Proposition 10.2.49, there exist $\mathbf{s}_1, \dots, \mathbf{s}_r \in \Gamma^k_{K_\ell}(\mathbf{F})$ such that

$$\sigma = \sum_{i=1}^{r} e_i \otimes \mathbf{s}_i.$$

Since $\mathbf{s}_i \in \mathcal{D}^k(N,\mathbf{F})$, we obtain

$$\sigma = \Theta\left(\sum_{i=1}^{r} e_i \otimes \mathbf{s}_i \right).$$

This proves surjectivity. Injectivity follows in the same way by choosing a compact set containing the supports of all sections involved and applying injectivity of Θ_K on that compact set.
Finally, continuity of Θ and its inverse follows from the definition of the inductive topology, since it suffices to check continuity on each space $\Gamma^k_{K_\ell}$, where it was already proved in Proposition 10.2.49. This proves that Θ is a topological isomorphism. □

We apply this corollary with $V = \mathbf{E}_x$ and the bundle $\mathbf{F}^*$ over N. Thus, for each $x \in M$, there is a canonical isomorphism

$$\mathbf{E}_x \otimes \mathcal{D}^k(N, \mathbf{F}^*) \cong \mathcal{D}^k(N, \mathbf{E}_x \otimes \mathbf{F}^*).$$

This justifies the action of a distribution in the variable y on sections of $\mathbf{E}_x \otimes \mathbf{F}^*$.

Lemma 10.2.51. Let $(M, \mathbf{g})$ and $(N, \widetilde{\mathbf{g}})$ be Riemannian manifolds with or without boundary, equipped with their respective Riemann–Lebesgue measures $\lambda_{\mathbf{g}}$ and $\lambda_{\widetilde{\mathbf{g}}}$. Let $\mathbf{E} \longrightarrow M$ and $\mathbf{F} \longrightarrow N$ be smooth vector bundles, let $K \subseteq N$ be compact, and let $\varphi \in \Gamma^k(M \times N, \mathbf{E} \boxtimes \mathbf{F}^*)$ be a section such that $\operatorname{supp}(\varphi) \subseteq M \times K$.
Let $m < k$ and let $\mathbf{T} \in \mathcal{D}'(N, \mathbf{F}, \mathbb{K})$ be a distribution of order m. Then the map $\mathbf{f}\colon M \longrightarrow \mathbf{E}$ given by $\mathbf{f}(x) := \mathbf{T}(\varphi(x, \cdot))$ defines a section in $\Gamma^{k-m}(M, \mathbf{E})$ supported in the projection of $\operatorname{supp}(\varphi)$ onto the first factor, that is,

$$\operatorname{supp}(\mathbf{f}) \subseteq \{x \in M \mid \exists y \in K \text{ such that } (x, y) \in \operatorname{supp}(\varphi)\}.$$

Moreover, if P is a linear differential operator of order $\leq k - m$ acting on sections of $\mathbf{E}$, then

$$P\mathbf{f} = \mathbf{T}(P_x \varphi(x, \cdot)),$$

where P_x indicates that P acts in the variable x.
In particular, if φ is smooth and compactly supported and $\mathbf{T} \in \mathcal{D}'(N, \mathbf{F}, \mathbb{K})$ is an arbitrary distribution, then $\mathbf{f}$ is a compactly supported smooth section of $\mathbf{E}$.

Proof. First explain the meaning of $\mathbf{T}(\varphi(x, \cdot))$. Fix $x \in M$. Since $\varphi(x, y) \in \mathbf{E}_x \otimes \mathbf{F}^*_y$, the section $\varphi(x, \cdot)$ belongs to $\mathcal{D}^k(N, \mathbf{E}_x \otimes \mathbf{F}^*)$. Moreover, since $\operatorname{supp}(\varphi) \subseteq M \times K$, we have $\operatorname{supp}(\varphi(x, \cdot)) \subseteq K$.
By Corollary 10.2.50, applied to $V = \mathbf{E}_x$ and the bundle $\mathbf{F}^*$, there is a canonical isomorphism

$$\mathbf{E}_x \otimes \mathcal{D}^k(N, \mathbf{F}^*) \cong \mathcal{D}^k(N, \mathbf{E}_x \otimes \mathbf{F}^*).$$

Thus we may regard $\varphi(x, \cdot)$ as an element of $\mathbf{E}_x \otimes \mathcal{D}^k(N, \mathbf{F}^*)$. Writing

$$\varphi(x, \cdot) = \sum_{i=1}^{r} v_i \otimes \varphi_i(x, \cdot),$$

with $v_i \in \mathbf{E}_x$ and $\varphi_i(x, \cdot) \in \mathcal{D}^k(N, \mathbf{F}^*)$, define

$$\mathbf{T}(\varphi(x, \cdot)) := (\mathrm{id}_{\mathbf{E}_x} \otimes \mathbf{T})(\varphi(x, \cdot)) = \sum_{i=1}^{r} v_i \, \mathbf{T}(\varphi_i(x, \cdot)).$$

This definition is independent of the chosen decomposition because it comes from the linear map $\mathrm{id}_{\mathbf{E}_x} \otimes \mathbf{T}$.
For simplicity, we write $\mathbf{T}(\varphi(x, \cdot))$ instead of $(\mathrm{id}_{\mathbf{E}_x} \otimes \mathbf{T})(\varphi(x, \cdot))$.

Now prove that $\mathbf{f}$ is of class C^{k-m}. Since the issue is local in M, take a coordinate chart and a local trivialization of $\mathbf{E}$. Identifying the chart with an open subset $U \subseteq \mathbb{R}^n$, we may assume locally that $\mathbf{E} \restriction_U \cong U \times \mathbb{K}^r$. Independence of the C^m norms from the metric and connection on compact sets allows us to work locally with the trivial connection and Euclidean norm in the factor $\mathbb{K}^r$. Also fix an auxiliary bundle metric $\mathbf{h}_{\mathbf{F}}$ and a connection on $\mathbf{F}$; on $\mathbb{K}^r \otimes \mathbf{F}^*$, use the product metric h_{prod} induced by the Euclidean norm and $\mathbf{h}_{\mathbf{F}}^*$. Varying the chart and trivialization gives the global assertion.

Fix $x_0 \in U$ and take a compact convex neighborhood $U' \subseteq U$ of x_0. Since $\boldsymbol{\varphi}$ is of class C^k and has support in the variable y contained in K, for every multi-index α with $|\alpha| \le k-m$ we have

$$D_x^\alpha \boldsymbol{\varphi}(x,\cdot) \in \mathcal{D}^m(N, \mathbb{K}^r \otimes \mathbf{F}^*)$$

for every $x \in U'$.

Use Taylor's formula with integral remainder in the variable x, centered at x_0, through order $k-m$. For $x \in U'$ and $y \in N$, we have

$$\boldsymbol{\varphi}(x,y) = \sum_{|\alpha| \le k-m} \frac{1}{\alpha!} D_x^\alpha \boldsymbol{\varphi}(x_0,y)(x-x_0)^\alpha$$

$$+ \sum_{|\alpha| = k-m} \frac{k-m}{\alpha!} \int_0^1 (1-t)^{k-m-1} \left[D_x^\alpha \boldsymbol{\varphi}((1-t)x_0 + tx, y) - D_x^\alpha \boldsymbol{\varphi}(x_0,y) \right] dt\, (x-x_0)^\alpha.$$

For $|\alpha| = k-m$, define

$$R_\alpha(x,\cdot) := \int_0^1 (1-t)^{k-m-1} \left[D_x^\alpha \boldsymbol{\varphi}((1-t)x_0 + tx, \cdot) - D_x^\alpha \boldsymbol{\varphi}(x_0,\cdot) \right] dt.$$

Then

$$\boldsymbol{\varphi}(x,\cdot) = \sum_{|\alpha| \le k-m} \frac{1}{\alpha!} D_x^\alpha \boldsymbol{\varphi}(x_0,\cdot)(x-x_0)^\alpha + \sum_{|\alpha| = k-m} \frac{k-m}{\alpha!} R_\alpha(x,\cdot)(x-x_0)^\alpha.$$

Since $D_x^\alpha \boldsymbol{\varphi}(x_0,\cdot) \in \mathcal{D}^m(N, \mathbb{K}^r \otimes \mathbf{F}^*)$ for $|\alpha| \le k-m$, and since $\mathbf{T}$ has order m on K, we may apply $\mathrm{id}_{\mathbb{K}^r} \otimes \mathbf{T}$ to each term. We obtain

$$\mathbf{T}(\boldsymbol{\varphi}(x,\cdot)) = \sum_{|\alpha| \le k-m} \frac{1}{\alpha!} \mathbf{T}\big(D_x^\alpha \boldsymbol{\varphi}(x_0,\cdot)\big)(x-x_0)^\alpha + \sum_{|\alpha| = k-m} \frac{k-m}{\alpha!} \mathbf{T}(R_\alpha(x,\cdot))(x-x_0)^\alpha.$$

Let us prove that $\mathbf{T}(R_\alpha(x,\cdot)) \to 0$ as $x \to x_0$. Here ∇_y^j denotes the iterated connection acting only on the factor N of the bundle $\mathbb{K}^r \otimes \mathbf{F}^*$. Since $D_x^\alpha \boldsymbol{\varphi}$ is of class C^m in the variable y and continuous in x, the sections $\nabla_y^j D_x^\alpha \boldsymbol{\varphi}(x,y)$, with $0 \le j \le m$, are continuous on $U' \times K$. Since $U' \times K$ is compact, they are uniformly continuous. Thus, given $\varepsilon > 0$, there exists $\delta > 0$ such that, if $\|x - x_0\|_{\mathbb{R}^n} < \delta$, then for every $t \in [0,1]$, every $y \in K$, and every $0 \le j \le m$,

$$\left| \nabla_y^j D_x^\alpha \boldsymbol{\varphi}((1-t)x_0 + tx, y) - \nabla_y^j D_x^\alpha \boldsymbol{\varphi}(x_0,y) \right|_{\widetilde{g}, h_{\mathrm{prod}}} < \varepsilon.$$

It follows that

$$\|R_\alpha(x,\cdot)\|_{C^m(K, \mathbb{K}^r \otimes \mathbf{F}^*)} \le \varepsilon \int_0^1 (1-t)^{k-m-1}\, dt = \frac{\varepsilon}{k-m}.$$

Consequently, $\|R_\alpha(x,\cdot)\|_{C^m(K, \mathbb{K}^r \otimes \mathbf{F}^*)} \to 0$ as $x \to x_0$.

Since $\mathbf{T}$ has order m, there exists a constant $C_K > 0$ such that

$$|\mathbf{T}(\psi)| \le C_K \|\psi\|_{C^m(K,\mathbf{F}^*)}$$

for every test section ψ of $\mathbf{F}^*$ supported in K. Using this estimate componentwise in $\mathbb{K}^r \otimes \mathbf{F}^*$ and increasing C_K if necessary gives

$$|\mathbf{T}(R_\alpha(x,\cdot))|_{\mathbb{K}^r} \le C_K \|R_\alpha(x,\cdot)\|_{C^m(K,\mathbb{K}^r\otimes\mathbf{F}^*)} \longrightarrow 0.$$

Thus the preceding expression for $\mathbf{T}(\varphi(x,\cdot))$ shows that $\mathbf{f}$ admits a Taylor expansion at x_0 of order $k-m$ with coefficients $\mathbf{T}(D_x^\alpha \varphi(x_0,\cdot))$. Therefore

$$D_x^\alpha \mathbf{f}(x_0) = \mathbf{T}(D_x^\alpha \varphi(x_0,\cdot)), \qquad |\alpha| \le k-m.$$

It remains to check continuity of these derivatives. Let $|\alpha| \le k-m$. For $x, x_0 \in U'$, using again that $\mathbf{T}$ has order m on K, we have

$$\begin{aligned} |D_x^\alpha \mathbf{f}(x) - D_x^\alpha \mathbf{f}(x_0)|_{\mathbb{K}^r} &= \left|\mathbf{T}(D_x^\alpha \varphi(x,\cdot) - D_x^\alpha \varphi(x_0,\cdot))\right|_{\mathbb{K}^r} \\ &\le C_K \|D_x^\alpha \varphi(x,\cdot) - D_x^\alpha \varphi(x_0,\cdot)\|_{C^m(K,\mathbb{K}^r\otimes\mathbf{F}^*)}. \end{aligned}$$

The last term tends to 0 as $x \to x_0$, by uniform continuity of the derivatives on $U' \times K$. Thus $D_x^\alpha \mathbf{f}$ is continuous. Since x_0 was arbitrary, we conclude that $\mathbf{f} \in \Gamma^{k-m}(M,\mathbf{E})$.

Now prove the support assertion. Since $\operatorname{supp}(\varphi)$ is closed in $M\times N$ and contained in $M\times K$, with K compact, its projection onto M is closed. If x does not belong to this projection, there is a neighborhood U_x of x such that $(U_x \times K) \cap \operatorname{supp}(\varphi) = \varnothing$. Therefore $\varphi(x,\cdot) = 0$ and consequently $\mathbf{f}(x) = 0$. This proves the support inclusion.

Now let P be a linear differential operator of order $\le k-m$ acting on sections of $\mathbf{E}$. In local coordinates, P is a finite combination of derivatives in the variable x of order at most $k-m$, with smooth coefficients and bundle homomorphisms. Since we have already proved that

$$D_x^\alpha \mathbf{f}(x) = \mathbf{T}(D_x^\alpha \varphi(x,\cdot)) \qquad |\alpha| \le k-m,$$

combining these identities linearly with the coefficients of P gives

$$(P\mathbf{f})(x) = \mathbf{T}(P_x \varphi(x,\cdot)).$$

By locality, this identity is independent of the chart and trivialization.

Finally, suppose φ is smooth and compactly supported and $\mathbf{T} \in \mathcal{D}'(N,\mathbf{F},\mathbb{K})$ is an arbitrary distribution. Since $\operatorname{supp}(\varphi)$ is compact in $M\times N$, there exists a compact set $K \subseteq N$ such that $\operatorname{supp}(\varphi) \subseteq M \times K$. Moreover, the projection of $\operatorname{supp}(\varphi)$ onto M is compact. By the definition of a distribution, for this compact set K there is an integer m_K such that $\mathbf{T}$ has order $\le m_K$ on K. Since φ is smooth, the result already proved applies with any $k > m_K$. Thus $\mathbf{f}$ is of class C^ℓ for every $\ell \in \mathbb{N}_0$, and is therefore smooth. The compact support assertion follows from the support inclusion already proved and compactness of the projection of a compact set under $M \times N \to M$. □

The preceding result allows a distribution to be evaluated in one variable of a section defined on a product. The resulting section in the remaining variable loses at most as many derivatives as the order of the distribution.

10.2.4 Tensor products of test spaces

The topological description of test sections on $M \times N$ is obtained first with fixed supports, then by passage to the inductive limit. The first stage involves projective products of nuclear Fréchet spaces. The second involves the inductive product, which linearizes separately continuous bilinear maps on LF spaces. Definitions and abstract results concerning these topologies are given in Section B.12.

Lemma 10.2.52. (Localization in models with faces) Let $U \subseteq G_{m,r} := \mathbb{R}^{m-r} \times [0,\infty)^r$ and $V \subseteq G_{n,s}$ be relatively open subsets. For every compact set $C \subseteq U$, the space $\mathcal{D}_C(U)$ of functions smooth up to the faces and supported in C is nuclear Fréchet. If

$$C_0 \subseteq \mathrm{Int}_{G_{m,r}}(C_1) \subseteq U, \qquad D_0 \subseteq \mathrm{Int}_{G_{n,s}}(D_1) \subseteq V$$

are compact, there exists a continuous linear operator

$$\mathscr{R} : \mathcal{D}_{C_0 \times D_0}(U \times V) \longrightarrow \mathcal{D}_{C_1}(U) \widehat{\otimes}_\pi \mathcal{D}_{D_1}(V)$$

whose composition with multiplication of functions is the identity.

Proof. For $f \in \mathcal{D}_C(U)$, its extension by zero to the complement of U in $G_{m,r}$ is smooth: the support C lies in the relatively open subset U. This operation crosses only the boundary of the open subset within the model. Next apply the operator $E_{m,r}$ from Lemma B.12.19. We obtain a continuous map

$$J_C : \mathcal{D}_C(U) \longrightarrow \mathcal{D}_{\widehat{C}}(\mathbb{R}^m), \qquad J_C f = E_{m,r}\widetilde{f},$$

for a fixed compact set $\widehat{C}$. Restriction to U is the inverse of J_C on its image and is continuous for every derivative seminorm. This image is closed. Indeed, if $J_C f_j \to h$ in $\mathcal{D}_{\widehat{C}}(\mathbb{R}^m)$, the restrictions converge with all derivatives to $f = h|_U$, which is supported in C; continuity of extension gives $J_C f = h$. Thus $\mathcal{D}_C(U)$ is isomorphic to a closed subspace of a nuclear Fréchet space, and the first assertion follows from Corollary B.12.20 and Proposition B.12.15.

To construct $\mathscr{R}$, first extend $\Phi \in \mathcal{D}_{C_0 \times D_0}(U \times V)$ by zero to $G_{m,r} \times G_{n,s}$, then extend in each group of variables:

$$\widehat{\Phi} := E^x_{m,r} E^y_{n,s} \widetilde{\Phi}.$$

The extension depends continuously on Φ in every seminorm and is supported in $A_0 \times B_0$, for fixed compact sets $A_0 \subseteq \mathbb{R}^m$ and $B_0 \subseteq \mathbb{R}^n$. This follows by applying support control in each group while treating the other as a parameter. Choose compact sets A_1, B_1 containing A_0, B_0 in their respective interiors. Lemma B.12.22 provides a continuous operator

$$R_{\mathrm{eucl}} : \mathcal{D}_{A_0 \times B_0}(\mathbb{R}^{m+n}) \longrightarrow \mathcal{D}_{A_1}(\mathbb{R}^m) \widehat{\otimes}_\pi \mathcal{D}_{B_1}(\mathbb{R}^n)$$

recovering each function upon application of the external product. Its construction by Fourier series on tori applies to $\widehat{\Phi}$, which is smooth across all faces.

Take $\chi \in \mathcal{D}_{C_1}(U)$ and $\eta \in \mathcal{D}_{D_1}(V)$ equal to one near C_0 and D_0. These functions are obtained by restricting Euclidean cutoffs: compactness allows each smaller compact set to be covered by finitely many balls whose

intersections with the model lie in the relative interior of the larger compact set. The maps

$$P(f) := \chi(f|_U), \qquad Q(g) := \eta(g|_V)$$

are continuous into $\mathcal{D}_{C_1}(U)$ and $\mathcal{D}_{D_1}(V)$ by the Leibniz rule. Define

$$\mathscr{R}\Phi := (P\widehat{\otimes}Q)R_{\mathrm{eucl}}\widehat{\Phi}.$$

All operations are continuous and, by the restriction identity for the extensions, the product of their factors is

$$\chi(x)\eta(y)\widehat{\Phi}|_{U\times V} = \chi(x)\eta(y)\Phi = \Phi.$$

This proves the second assertion. □

Proposition 10.2.53. (Nuclearity of sections with fixed support) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank, and let $K \subseteq M$ be compact. Then $\Gamma_K(\mathbf{E})$ is a nuclear Fréchet space.

Proof. By Proposition 10.1.7, only nuclearity remains to be proved. Choose coordinate and trivializing open subsets $U_1,\dots,U_s$ covering K, with U_j relatively compact, and functions $\chi_j \in C_c^\infty(U_j)$ such that $\sum_{j=1}^{s}\chi_j = 1$ on a neighborhood of K. Fix a chart $\kappa_j\colon U_j \longrightarrow \kappa_j(U_j)$ whose image is a relatively open subset of $\mathbb{R}^{\dim M}$ or of the closed half-space, and a local frame $(\mathbf{e}_{j,1},\dots,\mathbf{e}_{j,r})$ of $\mathbf{E}$ on U_j, where $r = \operatorname{rank}(\mathbf{E})$.
For $\mathbf{u} \in \Gamma_K(\mathbf{E})$, write

$$(\chi_j\mathbf{u})|_{U_j} = \sum_{a=1}^{r} u_j^a \mathbf{e}_{j,a}$$

and set $K_j := \kappa_j(K \cap \operatorname{supp}\chi_j)$. The map

$$I\colon \Gamma_K(\mathbf{E}) \longrightarrow \prod_{j=1}^{s} \mathcal{D}_{K_j}(\kappa_j(U_j))^r, \qquad I(\mathbf{u}) := \left(u_j^a \circ \kappa_j^{-1}\right)_{j,a},$$

is linear and continuous. Define a map in the opposite direction by

$$S\left((v_j^a)_{j,a}\right) := \sum_{j=1}^{s}\left(\sum_{a=1}^{r}\widetilde{(v_j^a \circ \kappa_j)}\mathbf{e}_{j,a}\right)^M.$$

The tilde with superscript M denotes extension by zero from U_j to M. Each section in the sum is supported in the compact set $\kappa_j^{-1}(K_j) \Subset U_j$, so this extension is smooth. Moreover, $\kappa_j^{-1}(K_j) \subseteq K$, so S takes values in $\Gamma_K(\mathbf{E})$. Local derivative expressions show that S is continuous: each C^k seminorm of a summand is bounded by a finite sum of C^k seminorms of its component functions.
Since $\sum_{j=1}^{s}\chi_j = 1$ on a neighborhood of K and $\mathbf{u}$ vanishes outside K, we have $S(I(\mathbf{u})) = \mathbf{u}$ for every $\mathbf{u} \in \Gamma_K(\mathbf{E})$.
Consequently, I is a topological embedding, and $I \circ S$ is a continuous projection onto its image. This image is therefore a complemented subspace of the finite product.

Each space $\mathcal{D}_{K_j}(\kappa_j(U_j))$ is nuclear by Lemma 10.2.52. Proposition B.12.15 shows that the finite product and its complemented subspace $I(\Gamma_K(\mathbf{E}))$ are nuclear. Since I is a topological isomorphism onto its image, $\Gamma_K(\mathbf{E})$ is nuclear. The same argument with quadrant charts proves the assertion for the products with corners in Remark 10.2.45. □

Theorem 10.2.54. (Localized tensor product representation of sections) Let M and N be smooth manifolds with or without boundary, and let $\mathbf{E} \to M$ and $\mathbf{F} \to N$ be smooth vector bundles of finite rank. Let the following sets be compact:

$$K_0 \subseteq \operatorname{Int}(K_1) \subseteq M, \qquad L_0 \subseteq \operatorname{Int}(L_1) \subseteq N.$$

The external product induces a topological embedding

$$T_{K_1,L_1} : \Gamma_{K_1}(\mathbf{E}) \widehat{\otimes}_\pi \Gamma_{L_1}(\mathbf{F}) \longrightarrow \Gamma_{K_1\times L_1}(\mathbf{E} \boxtimes \mathbf{F}).$$

Its image contains $\Gamma_{K_0\times L_0}(\mathbf{E} \boxtimes \mathbf{F})$, and the restriction of $T^{-1}_{K_1,L_1}$ to this subspace is continuous.

Proof. Local derivative estimates for $u \boxtimes v$ show that the bilinear map

$$\Gamma_{K_1}(\mathbf{E}) \times \Gamma_{L_1}(\mathbf{F}) \longrightarrow \Gamma_{K_1\times L_1}(\mathbf{E} \boxtimes \mathbf{F})$$

is continuous. The universal property of the projective product and completeness of the target give the continuous operator T_{K_1,L_1}.

We first construct a continuous preimage for sections supported in $K_0 \times L_0$. Choose coordinate and trivializing open subsets

$$U_1, \dots, U_A \Subset \operatorname{Int}(K_1), \qquad V_1, \dots, V_B \Subset \operatorname{Int}(L_1),$$

covering K_0 and L_0. Let $(\mathbf{e}_{i,1}, \dots, \mathbf{e}_{i,r})$ and $(\mathbf{f}_{j,1}, \dots, \mathbf{f}_{j,s})$ be the local frames. Take cutoff functions $\chi_i \in C^\infty_c(U_i)$ and $\eta_j \in C^\infty_c(V_j)$ such that

$$\sum_{i=1}^{A} \chi_i = 1 \quad \text{on a neighborhood of } K_0, \qquad \sum_{j=1}^{B} \eta_j = 1 \quad \text{on a neighborhood of } L_0.$$

Denote the charts by $\kappa_i \colon U_i \longrightarrow \kappa_i(U_i)$ and $\lambda_j \colon V_j \longrightarrow \lambda_j(V_j)$. Choose compact sets $\widetilde{C}_i \Subset \kappa_i(U_i)$ and $\widetilde{D}_j \Subset \lambda_j(V_j)$ whose interiors contain, respectively,

$$C_i := \kappa_i(K_0 \cap \operatorname{supp}(\chi_i)), \qquad D_j := \lambda_j(L_0 \cap \operatorname{supp}(\eta_j)).$$

Let $\mathbf{\Phi} \in \Gamma_{K_0\times L_0}(\mathbf{E} \boxtimes \mathbf{F})$. On $U_i \times V_j$, write

$$(\chi_i \boxtimes \eta_j)\mathbf{\Phi} = \sum_{a=1}^{r} \sum_{b=1}^{s} \big(\Phi^{ab}_{ij} \circ (\kappa_i \times \lambda_j)\big) \mathbf{e}_{i,a} \boxtimes \mathbf{f}_{j,b},$$

where

$$\Phi^{ab}_{ij} \in \mathcal{D}_{C_i\times D_j}\big(\kappa_i(U_i) \times \lambda_j(V_j)\big).$$

Extraction of each coefficient is continuous in the fixed-support topologies. Lemma 10.2.52 gives a contin-

uous operator

$$\mathscr{R}_{ij} : \mathcal{D}_{C_i \times D_j}\big(\kappa_i(U_i) \times \lambda_j(V_j)\big) \longrightarrow \mathcal{D}_{\widetilde{C}_i}(\kappa_i(U_i)) \widehat{\otimes}_\pi \mathcal{D}_{\widetilde{D}_j}(\lambda_j(V_j))$$

whose composition with multiplication of functions is the identity.
For $h \in \mathcal{D}_{\widetilde{C}_i}(\kappa_i(U_i))$, the section $(h \circ \kappa_i)\mathbf{e}_{i,a}$ is supported in $\kappa_i^{-1}(\widetilde{C}_i) \Subset U_i$. Denote by

$$\widetilde{(h \circ \kappa_i)\mathbf{e}_{i,a}}^{M}$$

its extension by zero from U_i to M. If $k \in \mathcal{D}_{\widetilde{D}_j}(\lambda_j(V_j))$, write

$$\widetilde{(k \circ \lambda_j)\mathbf{f}_{j,b}}^{N}$$

for the extension by zero from V_j to N. Define

$$P_{i,a}(h) := \widetilde{(h \circ \kappa_i)\mathbf{e}_{i,a}}^{M}, \qquad Q_{j,b}(k) := \widetilde{(k \circ \lambda_j)\mathbf{f}_{j,b}}^{N}.$$

These extensions are smooth, and the maps $P_{i,a}$ and $Q_{j,b}$ are continuous. Moreover, they take values in $\Gamma_{K_1}(\mathbf{E})$ and $\Gamma_{L_1}(\mathbf{F})$ because their supports lie in $\operatorname{Int}(K_1)$ and $\operatorname{Int}(L_1)$. By the universal property of the projective product, $P_{i,a} \widehat{\otimes} Q_{j,b}$ is continuous. Set

$$R^{K_1,L_1}_{K_0,L_0}\mathbf{\Phi} := \sum_{i=1}^{A}\sum_{j=1}^{B}\sum_{a=1}^{r}\sum_{b=1}^{s}(P_{i,a}\widehat{\otimes}Q_{j,b})\mathscr{R}_{ij}(\Phi_{ij}^{ab}).$$

The sum is finite, so $R^{K_1,L_1}_{K_0,L_0}$ is continuous. Applying T_{K_1,L_1}, each term recovers the corresponding coefficient of $(\chi_i \boxtimes \eta_j)\mathbf{\Phi}$. The partition-of-unity identities give

$$T_{K_1,L_1} R^{K_1,L_1}_{K_0,L_0}\mathbf{\Phi} = \sum_{i=1}^{A}\sum_{j=1}^{B}(\chi_i \boxtimes \eta_j)\mathbf{\Phi} = \mathbf{\Phi}.$$

It remains to prove that T_{K_1,L_1} is a topological embedding. Cover K_1 and L_1 by finitely many trivializing charts $(U_\alpha, \kappa_\alpha)$ and (V_β, λ_β). Choose cutoff functions $\zeta_\alpha \in C_c^\infty(U_\alpha)$ and $\theta_\beta \in C_c^\infty(V_\beta)$ whose sums equal one on neighborhoods of K_1 and L_1. Taking the components of $\zeta_\alpha u$ and $\theta_\beta v$ in the local frames, first extend them by zero within their coordinate models and then, by Lemma B.12.19, to the full Euclidean space. In interior charts, the latter operator is the identity. We obtain topological embeddings

$$I_{\mathbf{E}} : \Gamma_{K_1}(\mathbf{E}) \hookrightarrow \prod_{c=1}^{C}\mathcal{D}_{A_c}(\mathbb{R}^{\dim M}), \qquad I_{\mathbf{F}} : \Gamma_{L_1}(\mathbf{F}) \hookrightarrow \prod_{d=1}^{D}\mathcal{D}_{B_d}(\mathbb{R}^{\dim N}).$$

The index c ranges over pairs consisting of a chart of the first factor and a frame component, and d ranges over the analogous pairs for the second factor. Let the compact supports before extension be

$$A_c^0 = \kappa_\alpha(K_1 \cap \operatorname{supp}(\zeta_\alpha)), \qquad B_d^0 = \lambda_\beta(L_1 \cap \operatorname{supp}(\theta_\beta)),$$

repeated once for each component. Choose A_c and B_d containing the fixed supports of their smooth ex-

tensions. For example, if u_α^a is the component of $\zeta_\alpha u$ in U_α, the corresponding coordinate of $I_{\mathbf{E}}u$ is $E_\alpha\big(\widetilde{u_\alpha^a \circ \kappa_\alpha^{-1}}\big)$, where the tilde denotes extension by zero from $\kappa_\alpha(U_\alpha)$ to its model $G_{\dim M, r_\alpha}$, and $E_\alpha = E_{\dim M, r_\alpha}$, with $r_\alpha \in \{0,1\}$. The extension with a tilde is smooth because $\operatorname{supp}(\zeta_\alpha) \Subset U_\alpha$, and E_α smoothly extends its jets across the geometric boundary. The same convention, with operators E_β, is used for $I_{\mathbf{F}}$.

That $I_{\mathbf{E}}$ and $I_{\mathbf{F}}$ are embeddings is checked with the C^k seminorms: components are bounded by seminorms of the section, while the cutoff identity bounds the section seminorms by a finite sum of seminorms of its components. The same construction, using $\zeta_\alpha \boxtimes \theta_\beta$ and the extension $E_\alpha^x E_\beta^y$ of each localized component, gives an embedding

$$I_{\mathbf{E}\boxtimes\mathbf{F}} : \Gamma_{K_1\times L_1}(\mathbf{E}\boxtimes\mathbf{F}) \hookrightarrow \prod_{c,d} \mathcal{D}_{A_c\times B_d}(\mathbb{R}^{\dim M+\dim N}).$$

Support control in each group of variables allows us to use precisely the compact sets $A_c \times B_d$. The product identity in the extension lemma ensures, for elementary sections, that extending a component of $u \boxtimes v$ is the same as multiplying the extended components of u and v. By continuity, the same identity holds in the completed tensor products.

By Proposition 10.2.53, the two domain spaces are nuclear. The finite products in the codomain are nuclear as well. Theorem B.12.14 identifies the topologies π and ε, and Proposition B.12.18 shows that $I_{\mathbf{E}}\widehat{\otimes}I_{\mathbf{F}}$ is a topological embedding. After applying Proposition B.12.3, the external product becomes, in each coordinate (c,d), the scalar map

$$\mathcal{D}_{A_c}(\mathbb{R}^{\dim M})\widehat{\otimes}_\pi \mathcal{D}_{B_d}(\mathbb{R}^{\dim N}) \longrightarrow \mathcal{D}_{A_c\times B_d}(\mathbb{R}^{\dim M+\dim N}),$$

which is an embedding by Lemma B.12.22.

Let (z_γ) be a net in $\Gamma_{K_1}(\mathbf{E})\widehat{\otimes}_\pi\Gamma_{L_1}(\mathbf{F})$, and suppose that $T_{K_1,L_1}z_\gamma \to 0$. Commutativity of the localization maps implies that the image of $(I_{\mathbf{E}}\widehat{\otimes}I_{\mathbf{F}})z_\gamma$ under all the preceding scalar embeddings converges to zero. Since their finite product is an embedding, $(I_{\mathbf{E}}\widehat{\otimes}I_{\mathbf{F}})z_\gamma \to 0$. The map $I_{\mathbf{E}}\widehat{\otimes}I_{\mathbf{F}}$ is also an embedding, so $z_\gamma \to 0$. Applying the same argument to a constant net proves injectivity of T_{K_1,L_1}. Thus its inverse on the image is continuous. By injectivity, the operator constructed at the outset is the restriction of this inverse to $\Gamma_{K_0\times L_0}(\mathbf{E}\boxtimes\mathbf{F})$. □

Theorem 10.2.55. (Tensor product representation of test spaces) Let M and N be smooth manifolds with or without boundary, and let $\mathbf{E} \to M$ and $\mathbf{F} \to N$ be smooth vector bundles of finite rank. The external product induces a canonical topological isomorphism

$$\mathcal{D}(M,\mathbf{E})\widehat{\otimes}_\iota\mathcal{D}(N,\mathbf{F}) \cong \mathcal{D}(M\times N, \mathbf{E}\boxtimes\mathbf{F}).$$

In particular, finite linear combinations of sections $\mathbf{u}\boxtimes\mathbf{v}$ are dense in $\mathcal{D}(M\times N,\mathbf{E}\boxtimes\mathbf{F})$.

Proof. Choose exhaustions by compact sets $(K_j)_{j\in\mathbb{N}}$ and $(L_j)_{j\in\mathbb{N}}$ such that $K_j \subseteq \operatorname{Int}(K_{j+1})$ and $L_j \subseteq \operatorname{Int}(L_{j+1})$. Then $(K_j\times L_j)_{j\in\mathbb{N}}$ is an exhaustion of $M\times N$ with the same property.

First identify the topology on the algebraic tensor product. The ι topology on $\mathcal{D}(M,\mathbf{E})\otimes\mathcal{D}(N,\mathbf{F})$ agrees with the final locally convex topology for the maps

$$\Gamma_{K_p}(\mathbf{E})\otimes_\pi\Gamma_{L_q}(\mathbf{F}) \longrightarrow \mathcal{D}(M,\mathbf{E})\otimes\mathcal{D}(N,\mathbf{F}), \qquad p,q\in\mathbb{N}.$$

To check this, let $b\colon \mathcal{D}(M,\mathbf{E})\times\mathcal{D}(N,\mathbf{F}) \longrightarrow Z$ be a bilinear map. If b is separately continuous, its restriction

to $\Gamma_{K_p}(\mathbf{E}) \times \Gamma_{L_q}(\mathbf{F})$ is separately continuous as well. These two spaces are Fréchet, so Proposition B.12.10 makes the restriction continuous. Conversely, suppose all restrictions are continuous. If $\mathbf{u} \in \mathcal{D}(M,\mathbf{E})$, there exists p such that $\mathbf{u} \in \Gamma_{K_p}(\mathbf{E})$. For each q, the map $\mathbf{v} \mapsto b(\mathbf{u},\mathbf{v})$ is continuous on $\Gamma_{L_q}(\mathbf{F})$. The final property of the LF topology on $\mathcal{D}(N,\mathbf{F})$ implies continuity on the entire space. The same argument with the factors interchanged proves continuity in the first variable. The universal property of the inductive product, Proposition B.12.8, gives equality of the topologies.

The external product is separately continuous. Indeed, if $\mathbf{v} \in \Gamma_{L_q}(\mathbf{F})$ is fixed, for each p the local estimates C^k show that $\mathbf{u} \longmapsto \mathbf{u} \boxtimes \mathbf{v}$ is continuous from $\Gamma_{K_p}(\mathbf{E})$ to $\Gamma_{K_p \times L_q}(\mathbf{E} \boxtimes \mathbf{F})$. The final property of the LF topology gives continuity on $\mathcal{D}(M,\mathbf{E})$. The other factor is treated in the same way. Thus the external product linearizes to a continuous operator on $\mathcal{D}(M,\mathbf{E}) \otimes_\iota \mathcal{D}(N,\mathbf{F})$. Since $\mathcal{D}(M \times N, \mathbf{E} \boxtimes \mathbf{F})$ is complete by Theorem 4.4.6, this operator extends uniquely to

$$T : \mathcal{D}(M,\mathbf{E}) \widehat{\otimes}_\iota \mathcal{D}(N,\mathbf{F}) \longrightarrow \mathcal{D}(M \times N, \mathbf{E} \boxtimes \mathbf{F}).$$

We construct the inverse of T. For $\mathbf{\Phi} \in \Gamma_{K_j \times L_j}(\mathbf{E} \boxtimes \mathbf{F})$, Theorem 10.2.54 gives a unique element

$$R_j \mathbf{\Phi} \in \Gamma_{K_{j+1}}(\mathbf{E}) \widehat{\otimes}_\pi \Gamma_{L_{j+1}}(\mathbf{F})$$

whose image under the external product is $\mathbf{\Phi}$. The map R_j is continuous. Inclusion of the two fixed-support stages into the test spaces induces a continuous operator from this completed projective product to $\mathcal{D}(M,\mathbf{E}) \widehat{\otimes}_\iota \mathcal{D}(N,\mathbf{F})$.

We must check independence of the stage. Suppose that $j < q$ and $\mathbf{\Phi} \in \Gamma_{K_j \times L_j}(\mathbf{E} \boxtimes \mathbf{F})$. Include $R_j \mathbf{\Phi}$ and $R_q \mathbf{\Phi}$ in

$$\Gamma_{K_{q+1}}(\mathbf{E}) \widehat{\otimes}_\pi \Gamma_{L_{q+1}}(\mathbf{F}).$$

The inclusions used here are topological embeddings. Indeed, fixed-support spaces are nuclear by Proposition 10.2.53, so $\pi = \varepsilon$, and the assertion follows from Proposition B.12.18. Both preimages have external-product image $\mathbf{\Phi}$. Injectivity in Theorem 10.2.54, applied at stage $K_{q+1} \times L_{q+1}$, shows that they agree.

We may therefore define

$$R : \mathcal{D}(M \times N, \mathbf{E} \boxtimes \mathbf{F}) \longrightarrow \mathcal{D}(M,\mathbf{E}) \widehat{\otimes}_\iota \mathcal{D}(N,\mathbf{F}), \qquad R\mathbf{\Phi} := R_j \mathbf{\Phi}$$

when $\operatorname{supp} \mathbf{\Phi} \subseteq K_j \times L_j$. Each restriction of R to $\Gamma_{K_j \times L_j}(\mathbf{E} \boxtimes \mathbf{F})$ is continuous. The LF topology on the domain is final with respect to these stages, so R is continuous. By construction, $T \circ R$ is the identity.

Now let $\mathbf{u} \in \mathcal{D}(M,\mathbf{E})$ and $\mathbf{v} \in \mathcal{D}(N,\mathbf{F})$. Choose j so that $\operatorname{supp} \mathbf{u} \subseteq K_j$ and $\operatorname{supp} \mathbf{v} \subseteq L_j$. The elements $R(\mathbf{u} \boxtimes \mathbf{v})$ and $\mathbf{u} \otimes \mathbf{v}$, viewed at the corresponding stage, have the same image under the external product. Localized injectivity gives

$$R(\mathbf{u} \boxtimes \mathbf{v}) = \mathbf{u} \otimes \mathbf{v}.$$

Thus $R \circ T$ is the identity on the algebraic tensor product. This subspace is dense in its completion, and continuity of $R \circ T$ extends the identity to all of $\mathcal{D}(M,\mathbf{E}) \widehat{\otimes}_\iota \mathcal{D}(N,\mathbf{F})$. Therefore T and R are inverse topological isomorphisms. The image of the algebraic tensor product under T is the space of finite linear combinations of sections $\mathbf{u} \boxtimes \mathbf{v}$, so this space is dense in the test space of the product. $\square$

Corollary 10.2.56. (Tensor decomposition with support control) Let M and N be smooth manifolds with or without boundary, let $\mathbf{E} \to M$ and $\mathbf{F} \to N$ be smooth vector bundles of finite rank, and let $K_0 \subseteq \operatorname{Int}(K_1) \subseteq M$ and $L_0 \subseteq \operatorname{Int}(L_1) \subseteq N$ be compact. Every section

$$\mathbf{\Phi} \in \Gamma_{K_0 \times L_0}(\mathbf{E}^* \boxtimes \mathbf{F}^*)$$

has a unique preimage

$$u_{\mathbf{\Phi}} \in \Gamma_{K_1}(\mathbf{E}^*) \widehat{\otimes}_\pi \Gamma_{L_1}(\mathbf{F}^*)$$

under the external-product map. Moreover, $\mathbf{\Phi} \mapsto u_{\mathbf{\Phi}}$ is continuous.

Proof. Apply Theorem 10.2.54 to the bundles $\mathbf{E}^*$ and $\mathbf{F}^*$. The external-product map at stage $K_1 \times L_1$ is injective and its image contains $\Gamma_{K_0 \times L_0}(\mathbf{E}^* \boxtimes \mathbf{F}^*)$. Thus each $\mathbf{\Phi}$ has a unique preimage $u_{\mathbf{\Phi}}$. Continuity of $\mathbf{\Phi} \mapsto u_{\mathbf{\Phi}}$ is precisely continuity of the inverse restricted to this subspace. □

10.2.5 The Schwartz kernel theorem

A continuous operator can be studied as a distribution on the product of its source and target manifolds. In the presence of bundles, the kernel takes values in the appropriate tensor product; the following formulation makes this identification explicit.

Theorem 10.2.57. (Schwartz kernel theorem for vector bundles) Let M and N be smooth manifolds with or without boundary, let $\mathbf{E} \to M$ and $\mathbf{F} \to N$ be smooth vector bundles, and let W be a finite-dimensional $\mathbb{K}$-vector space.
Let

$$A \colon \mathcal{D}(N, \mathbf{F}^*) \longrightarrow \mathcal{D}'(M, \mathbf{E}, W)$$

be a linear map, where the target is equipped with the weak-$*$ topology, or equivalently the pointwise convergence topology of Definition 10.2.1. The following conditions are equivalent:

(a) A is continuous;

(b) the bilinear map

$$B_A \colon \mathcal{D}(M, \mathbf{E}^*) \times \mathcal{D}(N, \mathbf{F}^*) \longrightarrow W, \qquad B_A(\varphi, \psi) := (A\psi)(\varphi),$$

is separately continuous;

(c) for any compact sets $K \subseteq M$ and $L \subseteq N$, the restriction of B_A to $\Gamma_K(\mathbf{E}^*) \times \Gamma_L(\mathbf{F}^*)$ is continuous.

When these conditions hold, there exists a unique distribution

$$\mathbf{K}_A \in \mathcal{D}'(M \times N, \mathbf{E} \boxtimes \mathbf{F}, W)$$

such that

$$\mathbf{K}_A(\varphi \boxtimes \psi) = (A\psi)(\varphi)$$

for every $\varphi \in \mathcal{D}(M, \mathbf{E}^*)$ and every $\psi \in \mathcal{D}(N, \mathbf{F}^*)$.

Conversely, every distribution $\mathbf{K} \in \mathcal{D}'(M \times N, \mathbf{E} \boxtimes \mathbf{F}, W)$ defines a linear map

$$A_{\mathbf{K}} \colon \mathcal{D}(N, \mathbf{F}^*) \longrightarrow \mathcal{D}'(M, \mathbf{E}, W)$$

by

$$(A_{\mathbf{K}}\psi)(\varphi) := \mathbf{K}(\varphi \boxtimes \psi),$$

and this map is continuous in the weak-$*$ topology. Moreover, the correspondences $A \mapsto \mathbf{K}_A$ and $\mathbf{K} \mapsto A_{\mathbf{K}}$ are linear and mutually inverse. In other words, there is a canonical linear bijection

$$\mathcal{D}'(M \times N, \mathbf{E} \boxtimes \mathbf{F}, W) \cong \mathcal{L}\big(\mathcal{D}(N, \mathbf{F}^*), \mathcal{D}'(M, \mathbf{E}, W)_\sigma\big),$$

where the subscript σ indicates the weak-$*$ topology.

Proof. If A is continuous in the topology of pointwise convergence, then, for each $\varphi \in \mathcal{D}(M, \mathbf{E}^*)$, the map

$$\psi \longmapsto (A\psi)(\varphi) = \mathrm{ev}_\varphi(A\psi)$$

is continuous. For each ψ, the map $\varphi \mapsto (A\psi)(\varphi)$ is continuous because $A\psi$ is a distribution. This proves $(a) \Rightarrow (b)$.

Suppose (b). The restriction of B_A to $\Gamma_K(\mathbf{E}^*) \times \Gamma_L(\mathbf{F}^*)$ is separately continuous. Both factors are Fréchet spaces by Proposition 10.1.7, and Proposition B.12.10 shows that the restriction is continuous. Therefore $(b) \Rightarrow (c)$.

Finally, suppose (c) and fix $\varphi \in \mathcal{D}(M, \mathbf{E}^*)$. There exists a compact set $K \subseteq M$ such that $\varphi \in \Gamma_K(\mathbf{E}^*)$. For every compact set $L \subseteq N$, condition (c) implies that $\psi \mapsto B_A(\varphi, \psi)$ is continuous on $\Gamma_L(\mathbf{F}^*)$. Since the topology on $\mathcal{D}(N, \mathbf{F}^*)$ is final with respect to these fixed-support spaces, the same map is continuous on $\mathcal{D}(N, \mathbf{F}^*)$. Thus $\mathrm{ev}_\varphi \circ A$ is continuous for every φ. The weak-$*$ topology on $\mathcal{D}'(M, \mathbf{E}, W)$ is the initial topology for evaluations, so Proposition B.10.40 proves continuity of A. This gives $(c) \Rightarrow (a)$.

Now suppose these conditions hold. By (b) and the universal property of the inductive product, Proposition B.12.8, there exists a unique continuous operator

$$\widetilde{B}_A : \mathcal{D}(M, \mathbf{E}^*) \otimes_\iota \mathcal{D}(N, \mathbf{F}^*) \longrightarrow W$$

such that $\widetilde{B}_A(\varphi \otimes \psi) = B_A(\varphi, \psi)$. The space W is complete because it is finite dimensional. The universal property of completion extends $\widetilde{B}_A$ uniquely to a continuous operator

$$\widehat{B}_A : \mathcal{D}(M, \mathbf{E}^*) \widehat{\otimes}_\iota \mathcal{D}(N, \mathbf{F}^*) \longrightarrow W.$$

Let

$$T : \mathcal{D}(M, \mathbf{E}^*) \widehat{\otimes}_\iota \mathcal{D}(N, \mathbf{F}^*) \longrightarrow \mathcal{D}(M \times N, \mathbf{E}^* \boxtimes \mathbf{F}^*)$$

be the isomorphism in Theorem 10.2.55. Define

$$\mathbf{K}_A := \widehat{B}_A \circ T^{-1}.$$

This is a continuous linear operator on $\mathcal{D}(M \times N, \mathbf{E}^* \boxtimes \mathbf{F}^*)$. Through the isomorphism $(\mathbf{E} \boxtimes \mathbf{F})^* \cong \mathbf{E}^* \boxtimes \mathbf{F}^*$ in

Remark 10.2.47, it is identified with an element of $\mathcal{D}'(M\times N,\mathbf{E}\boxtimes\mathbf{F},W)$. Moreover,

$$\mathbf{K}_A(\varphi\boxtimes\psi)=\widehat{B}_A(\varphi\otimes\psi)=B_A(\varphi,\psi)=(A\psi)(\varphi).$$

For uniqueness, let $\mathbf{S}$ be another distribution satisfying the same identity. Then $\mathbf{S}-\mathbf{K}_A$ vanishes on every section $\varphi\boxtimes\psi$ and, by linearity, on all finite linear combinations of them. These combinations are dense by Theorem 10.2.55. Since $\mathbf{S}-\mathbf{K}_A$ is continuous, it vanishes on all of $\mathcal{D}(M\times N,\mathbf{E}^*\boxtimes\mathbf{F}^*)$. Therefore $\mathbf{S}=\mathbf{K}_A$.
Conversely, let $\mathbf{K}\in\mathcal{D}'(M\times N,\mathbf{E}\boxtimes\mathbf{F},W)$. For $\psi\in\mathcal{D}(N,\mathbf{F}^*)$, define

$$(A_{\mathbf{K}}\psi)(\varphi):=\mathbf{K}(\varphi\boxtimes\psi).$$

For fixed ψ, the map $\varphi\mapsto\varphi\boxtimes\psi$ is continuous, as proved in constructing the isomorphism of Theorem 10.2.55. Its composition with $\mathbf{K}$ is therefore a continuous operator from $\mathcal{D}(M,\mathbf{E}^*)$ to W. This proves that $A_{\mathbf{K}}\psi\in\mathcal{D}'(M,\mathbf{E},W)$. Linearity of $A_{\mathbf{K}}$ follows from linearity of $\mathbf{K}$.
To prove continuity of $A_{\mathbf{K}}$ into the weak-$*$ dual, fix $\varphi\in\mathcal{D}(M,\mathbf{E}^*)$. The map

$$\mathrm{ev}_\varphi\circ A_{\mathbf{K}}:\psi\longmapsto\mathbf{K}(\varphi\boxtimes\psi)$$

is continuous because $\psi\mapsto\varphi\boxtimes\psi$ is continuous. Every evaluation is continuous. By the universal property of the initial topology, $A_{\mathbf{K}}$ is continuous in the weak-$*$ topology.
Finally,

$$(A_{\mathbf{K}_A}\psi)(\varphi)=\mathbf{K}_A(\varphi\boxtimes\psi)=(A\psi)(\varphi),$$

so $A_{\mathbf{K}_A}=A$. Starting with $\mathbf{K}$, the distributions $\mathbf{K}_{A_{\mathbf{K}}}$ and $\mathbf{K}$ agree on every elementary product. Density proved in Theorem 10.2.55 and continuity of both distributions imply that they agree on the entire test space. Therefore $\mathbf{K}_{A_{\mathbf{K}}}=\mathbf{K}$. The definitions also show that the two correspondences are linear. □

Remark 10.2.58. (Variants of the kernel theorem) The scalar Euclidean formulation can be found in [149, Theorem 51.7]. A proof by regularization and a formulation on manifolds appear in [64, Theorem 3.1]. Taylor proves the compact-manifold version using Sobolev estimates and Hilbert–Schmidt operators in [142, Chapter 4, §6]. For the geometric formulation with vector bundles over closed manifolds, see also [90, Chapter 13, §3.5]. The result here holds for noncompact manifolds and different bundles on the two factors. Control through the stages $K_j\times L_j$ replaces a global compactness hypothesis.

11

Principal symbol and elliptic operators

Chapters 8 and 10 construct differential operators between sections, their formal adjoints, and their distributional extensions. Building on this foundation, this chapter isolates the highest-order part, formulates ellipticity intrinsically, and derives the regularity estimates that will be used to study the heat semigroup and fractional Sobolev spaces.

The principal part of an operator contains less information than the full operator, but it governs several of its fundamental analytic properties. On a compact manifold, invertibility of the principal symbol allows us to recover all derivatives of a section from the operator applied to that section and a zeroth-order term. Elliptic regularity and the equivalence of the Sobolev norm and the graph norm follow from this observation. The same symbol will later be the geometric object that enters index theory.

Throughout this chapter, M will be a smooth manifold of dimension n, without boundary unless otherwise specified, and $\mathbf{E}, \mathbf{F}, \mathbf{G} \to M$ will be smooth real or complex vector bundles of finite rank. Whenever L^2 or Sobolev norms are involved, we fix a Riemannian metric $\mathbf{g}$ on M, bundle metrics $\mathbf{h}_{\mathbf{E}}$, $\mathbf{h}_{\mathbf{F}}$, and $\mathbf{h}_{\mathbf{G}}$ on the corresponding bundles, Hermitian in the complex case, and compatible connections $\nabla^{\mathbf{E}}$, $\nabla^{\mathbf{F}}$, and $\nabla^{\mathbf{G}}$. On tensor factors constructed from TM and T^*M, we use the Levi–Civita connection of $\mathbf{g}$.

Ellipticity: a local condition with global consequences

Elliptic theory took its modern form with the recognition that the highest-order terms control regularity, whereas lower-order terms can be treated as perturbations. The principal symbol encodes this dominant part on the cotangent bundle. Its invertibility away from the zero section is a pointwise condition, yet it leads to global estimates, finite-dimensional kernels, and stability of the index. This contrast between a microlocal hypothesis and global consequences will recur throughout the remainder of the book.

11.1 The principal symbol

Recall that $\mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$ denotes the space of partial differential operators of order at most m introduced in Definition 8.1.3. For $f \in C^\infty(M)$, we write $\mathrm{ad}(f)(P) = [P, f]$, where $[P, f](u) = P(fu) - fP(u)$. Proposition 8.1.25 shows that the pointwise evaluation of an iterated commutator of length m depends only on the differentials of the functions involved.

Definition 11.1.1. (Principal symbol) Let M be a smooth manifold without boundary, let $\mathbf{E},\mathbf{F}\to M$ be smooth vector bundles of finite rank, and let $P\in\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$, with $m\geq 1$. For $x\in M$, $\xi_1,\dots,\xi_m\in T_x^*M$, and $v\in\mathbf{E}_x$, choose functions $f_1,\dots,f_m\in C^\infty(M)$ such that $df_j(x)=\xi_j$ and define

$$\widetilde{\sigma}_m(P)_x(\xi_1,\dots,\xi_m)v:=\frac{1}{m!}\operatorname{ad}(f_1)\cdots\operatorname{ad}(f_m)(P)|_x(v).$$

The **polarized form of the principal symbol** is the map $\widetilde{\sigma}_m(P)_x\colon (T_x^*M)^m\longrightarrow\operatorname{Hom}(\mathbf{E}_x,\mathbf{F}_x)$, and the **principal symbol** of P is the map

$$\sigma_m(P)\colon T^*M\longrightarrow\operatorname{Hom}(\mathbf{E},\mathbf{F}),\qquad \sigma_m(P)(x,\xi):=\widetilde{\sigma}_m(P)_x(\xi,\dots,\xi).$$

If $m=0$, the operator P is $C^\infty(M)$-linear and corresponds to a bundle homomorphism; in this case we set $\sigma_0(P)(x):=P_x$.

The normalization by $m!$ ensures that, in coordinates, the symbol is exactly the homogeneous polynomial formed from the coefficients of order m.

Proposition 11.1.2. (Well-definedness and elementary properties) Let M be a smooth manifold without boundary, let $\mathbf{E},\mathbf{F}\to M$ be smooth vector bundles of finite rank, and let $P\in\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$. The form $\widetilde{\sigma}_m(P)_x$ is well defined, symmetric, and multilinear in the covariables. Moreover, $\sigma_m(P)$ is smooth and satisfies

$$\sigma_m(P)(x,t\xi)=t^m\sigma_m(P)(x,\xi)$$

for all $x\in M$, $\xi\in T_x^*M$, and $t\in\mathbb{R}$.

Proof. Independence of the chosen functions is precisely the content of Proposition 8.1.25. We prove linearity in the first covariable; the other arguments are treated in the same way. Let $\xi,\eta,\xi_2,\dots,\xi_m\in T_x^*M$ and $a,b\in\mathbb{R}$. Choose smooth functions $f,g,f_2,\dots,f_m$ such that $df(x)=\xi$, $dg(x)=\eta$, and $df_j(x)=\xi_j$. Since $d(af+bg)(x)=a\xi+b\eta$, the cited proposition allows us to use $af+bg$ to represent this covariable. Linearity of $f\mapsto\operatorname{ad}(f)$ then gives

$$\widetilde{\sigma}_m(P)_x(a\xi+b\eta,\xi_2,\dots,\xi_m)=a\widetilde{\sigma}_m(P)_x(\xi,\xi_2,\dots,\xi_m)+b\widetilde{\sigma}_m(P)_x(\eta,\xi_2,\dots,\xi_m).$$

Lemma 8.1.21 allows us to interchange two consecutive commutators; hence the form is symmetric, and the linearity just proved in the first entry implies linearity in every entry.
It remains to check smoothness. In a chart (U,φ), with $\varphi=(x^1,\dots,x^n)$, and local frames $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ of $\mathbf{E}$ and $(\mathbf{f}_1,\dots,\mathbf{f}_s)$ of $\mathbf{F}$, Corollary 8.1.35 allows us to write

$$P\left(\sum_{a=1}^{r}u^a\mathbf{e}_a\right)=\sum_{b=1}^{s}\left(\sum_{|\alpha|\leq m}\sum_{a=1}^{r}(A_\alpha)_{ba}D^\alpha u^a\right)\mathbf{f}_b,$$

where $A_\alpha\colon U\longrightarrow M_{s\times r}(\mathbb{K})$ is smooth. For $x\in U$ and $\xi=\sum_{i=1}^{n}\xi_i\,\mathbf{d}x^i|_x$, consider near x the linear coordinate

function $\ell_\xi := \sum_{i=1}^{n} \xi_i x^i$. Multiplying it by a smooth function equal to one on a neighborhood of x produces a function in $C^\infty(M)$ with the same differential at x. Proposition 8.1.25 therefore allows us to use ℓ_ξ in the m entries defining $\sigma_m(P)(x,\xi)$.

Since $[\partial_i, \ell_\xi] = \xi_i \operatorname{Id}$ and $[AB, \ell_\xi] = A[B,\ell_\xi] + [A,\ell_\xi]B$, each commutator replaces one of the $|\alpha|$ differential factors of D^α with the corresponding component of ξ. If $|\alpha| < m$, the result vanishes after m commutators. If $|\alpha| = m$, a term survives only if each of the m factors is replaced exactly once, and the commutators can select these factors in $m!$ orders. Consequently,

$$\operatorname{ad}(\ell_\xi)^m(D^\alpha) = \begin{cases} m!\,\xi^\alpha \operatorname{Id}, & |\alpha| = m, \\ 0, & |\alpha| < m. \end{cases}$$

The matrices A_α act by multiplication and commute with scalar functions. Dividing by the normalization $m!$ in the definition yields

$$\sigma_m(P)(x,\xi) = \sum_{|\alpha|=m} A_\alpha(x)\xi^\alpha.$$

The coefficients A_α are smooth, and the right-hand side is a homogeneous polynomial of degree m in ξ; therefore $\sigma_m(P)$ is smooth and $\sigma_m(P)(x,t\xi) = t^m \sigma_m(P)(x,\xi)$. □

Proposition 11.1.3. (Local expression) Let M be a smooth manifold without boundary, let $\mathbf{E},\mathbf{F} \to M$ be smooth vector bundles of finite rank, and let $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$. In a chart and local frames in which $P = \sum_{|\alpha|\le m} A_\alpha D^\alpha$, if $\xi = \sum_{j=1}^{n} \xi_j dx^j|_x$, then

$$\sigma_m(P)(x,\xi) = \sum_{|\alpha|=m} A_\alpha(x)\xi^\alpha, \qquad \xi^\alpha := \prod_{j=1}^{n} \xi_j^{\alpha_j}.$$

Consequently, P has order at most $m-1$ if and only if $\sigma_m(P) = 0$.

Proof. This formula is the diagonal computation carried out in the proof of Proposition 11.1.2. If P has order at most $m-1$, no coefficients A_α with $|\alpha| = m$ occur, and the symbol vanishes. Conversely, if $\sigma_m(P) = 0$, every entry of the polynomial matrix $\sum_{|\alpha|=m} A_\alpha(x)\xi^\alpha$ vanishes for all $\xi \in \mathbb{R}^n$. Uniqueness of polynomial coefficients implies $A_\alpha(x) = 0$ for every $|\alpha| = m$ and every x in the chart. Corollary 8.1.35 then shows that $P \in \mathbf{PDO}^{(m-1)}(\mathbf{E},\mathbf{F})$. □

Remark 11.1.4. The preceding definition does not include powers of i. With this convention, the symbol of $-\partial_j^2$ is $-\xi_j^2$. Applying the Fourier transform instead introduces the multiplier $(i\xi)^\alpha$. We will explicitly account for this distinction in the proof of the elliptic estimates.

11.1.1 Elementary symbol calculus

The principal symbol records the highest-order part of an operator. Before using it to formulate ellipticity, we need to check how it behaves under composition and passage to adjoints.

Proposition 11.1.5. (Symbol of a composition) Let M be a smooth manifold without boundary, and let $\mathbf{E},\mathbf{F},\mathbf{G} \to M$ be smooth vector bundles of finite rank. Let $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$ and $Q \in \mathbf{PDO}^{(\ell)}(\mathbf{F},\mathbf{G})$. Then $Q \circ P \in \mathbf{PDO}^{(m+\ell)}(\mathbf{E},\mathbf{G})$ and

$$\sigma_{m+\ell}(Q \circ P)(x,\xi) = \sigma_{\ell}(Q)(x,\xi) \circ \sigma_{m}(P)(x,\xi).$$

Proof. Membership in $\mathbf{PDO}^{(m+\ell)}(\mathbf{E},\mathbf{G})$ was proved in Proposition 8.1.19. In a chart and local frames, write

$$P = \sum_{|\alpha| \le m} A_\alpha D^\alpha, \qquad Q = \sum_{|\beta| \le \ell} B_\beta D^\beta.$$

Upon expanding $Q(Pu)$, terms of order $m+\ell$ arise only when all the derivatives D^β act on $D^\alpha u$ and none acts on A_α. Thus the highest-order part is

$$\sum_{|\beta|=\ell} \sum_{|\alpha|=m} B_\beta A_\alpha D^{\alpha+\beta} u.$$

Evaluating the symbol at ξ gives

$$\sum_{|\beta|=\ell} \sum_{|\alpha|=m} B_\beta(x) A_\alpha(x) \xi^{\alpha+\beta} = \left(\sum_{|\beta|=\ell} B_\beta(x) \xi^\beta \right) \left(\sum_{|\alpha|=m} A_\alpha(x) \xi^\alpha \right),$$

which is the asserted identity. □

The formal Hermitian adjoint was already constructed in Theorem 8.2.3. We need only record the effect of that construction on the principal part.

Proposition 11.1.6. (Symbol of the formal Hermitian adjoint) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E},\mathbf{F} \to M$ be smooth vector bundles of finite rank equipped with real or Hermitian bundle metrics $\mathbf{h}_{\mathbf{E}}$ and $\mathbf{h}_{\mathbf{F}}$. If $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$ and P_h^* is its formal Hermitian adjoint, then

$$\sigma_m(P_h^*)(x,\xi) = (-1)^m \sigma_m(P)(x,\xi)^*,$$

where the adjoint on the right is taken between the fibers $(\mathbf{E}_x,\mathbf{h}_{\mathbf{E}})$ and $(\mathbf{F}_x,\mathbf{h}_{\mathbf{F}})$.

Proof. In orthonormal or unitary local frames, write

$$P\left(\sum_{i=1}^{r} u^i \mathbf{e}_i \right) = \sum_{j=1}^{s} \left(\sum_{i=1}^{r} \sum_{|\alpha| \le m} a_{\alpha i}^{j} D_\varphi^\alpha u^i \right) \mathbf{f}_j.$$

Theorem 8.2.3 shows that the component along $\mathbf{e}_i$ of $P_h^*(\sum_{j=1}^{s} v^j \mathbf{f}_j)$ is

$$\frac{1}{\sqrt{\det(\mathbf{g})}} \sum_{j=1}^{s} \sum_{|\alpha| \le m} (-1)^{|\alpha|} D_\varphi^\alpha \Big(\sqrt{\det(\mathbf{g})}\, \overline{a_{\alpha i}^{j}}\, v^j \Big).$$

Terms of order m arise only when all $|\alpha|$ derivatives act on v^j. If

$$A_\alpha = (a^j_{\alpha i})\colon U \longrightarrow M_{s\times r}(\mathbb{K}),$$

their coefficients form, pointwise, the matrix $(-1)^m A^*_\alpha$ for $|\alpha| = m$. Proposition 11.1.3 gives

$$\sigma_m(P^*_h)(x,\xi) = (-1)^m \sum_{|\alpha|=m} A_\alpha(x)^* \xi^\alpha = (-1)^m \sigma_m(P)(x,\xi)^*.$$

□

Corollary 11.1.7. (Symbol under conjugation) Let M be a smooth manifold without boundary, let $\mathbf{E},\mathbf{F} \to M$ be smooth complex vector bundles of finite rank, and let $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$. Then

$$\sigma_m(\overline{P})(x,\xi) = \overline{\sigma_m(P)(x,\xi)}\colon \overline{\mathbf{E}_x} \longrightarrow \overline{\mathbf{F}_x}.$$

In particular, P is elliptic if and only if $\overline{P}$ is elliptic.

Proof. In conjugate frames, the principal coefficients of $\overline{P}$ are $\overline{A_\alpha}$ by Proposition 8.1.36. Proposition 11.1.3 gives the formula; conjugation preserves invertibility. □

Corollary 11.1.8. (Symbol of the formal transpose) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, let $\mathbf{E},\mathbf{F} \to M$ be smooth vector bundles of finite rank, and let $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$. If P' is its bilinear formal transpose, then

$$\sigma_m(P')(x,\xi) = (-1)^m \sigma_m(P)(x,\xi)^T\colon \mathbf{F}^*_x \longrightarrow \mathbf{E}^*_x, \tag{11.1}$$

where T is the algebraic transpose, without conjugation. Thus P is elliptic if and only if P' is elliptic.

Proof. Corollary 10.2.15 shows that the coefficient of D^α of order m is $(-1)^m A^T_\alpha$; every derivative falling on the coordinate weight of the measure or on A_α has lower order. The local formula for the symbol yields (11.1). The transpose of a finite-dimensional map is invertible exactly when the map itself is invertible. □

Example 11.1.9. (The connection) Let M be a smooth manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$. By Proposition 8.1.12, $\nabla^{\mathbf{E}}$ is a first-order differential operator from $\mathbf{E}$ to $T^*M \otimes \mathbf{E}$. The Leibniz rule gives

$$[\nabla^{\mathbf{E}}, f]\mathbf{u} = df \otimes \mathbf{u},$$

and consequently

$$\sigma_1(\nabla^{\mathbf{E}})(x,\xi)v = \xi \otimes v.$$

This symbol is injective for $\xi \neq 0$, although it is not surjective when $n > 1$.

Example 11.1.10. (The Bochner Laplacian) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle with a real or Hermitian bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection

$\nabla^{\mathbf{E}}$. The Bochner Laplacian $\Delta_B = (\nabla^{\mathbf{E}})_h^* \nabla^{\mathbf{E}}$, defined in Definition 8.2.10, satisfies

$$\sigma_2(\Delta_B)(x,\xi) = -\|\xi\|_{\mathbf{g}}^2 \operatorname{Id}_{\mathbf{E}_x}.$$

This identity follows from Propositions 11.1.5 and 11.1.6, since

$$\sigma_1((\nabla^{\mathbf{E}})_h^*)(x,\xi)(\eta \otimes v) = -\langle \xi, \eta \rangle_{\mathbf{g}} v.$$

11.2 Elliptic operators

Ellipticity expresses the invertibility of the principal symbol in every nonzero cotangent direction. This condition allows derivatives of the solution to be recovered from the equation and leads to regularity estimates.

Definition 11.2.1. (Ellipticity) Let M be a smooth manifold without boundary, let $\mathbf{E}, \mathbf{F} \to M$ be smooth vector bundles of finite rank, and let $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$, with $m \geq 1$. We say that P is **elliptic** if, for every $x \in M$ and every $\xi \in T_x^* M \setminus \{0\}$, the map

$$\sigma_m(P)(x,\xi) \colon \mathbf{E}_x \longrightarrow \mathbf{F}_x$$

is a linear isomorphism.

The definition requires $\mathbf{E}$ and $\mathbf{F}$ to have the same rank. When the symbol is only injective or only surjective, one speaks of an overdetermined or underdetermined elliptic operator, respectively. These variants will be useful in index theory, but are not needed for the estimates in this chapter.

Proposition 11.2.2. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, let $\mathbf{E}, \mathbf{F}, \mathbf{G} \to M$ be smooth vector bundles of finite rank equipped with bundle metrics, and let $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$.

(a) P is elliptic if and only if P_h^* is elliptic;

(b) if P is elliptic, then $P_h^* P$ and $P P_h^*$ are elliptic of order $2m$;

(c) if $Q \in \mathbf{PDO}^{(\ell)}(\mathbf{F}, \mathbf{G})$ and both P and Q are elliptic, then $Q \circ P$ is elliptic.

Proof. Part (a) follows from Proposition 11.1.6, because a linear map between finite-dimensional spaces is invertible if and only if its adjoint is invertible. For (b), Propositions 11.1.5 and 11.1.6 give

$$\sigma_{2m}(P_h^* P)(x,\xi) = (-1)^m \sigma_m(P)(x,\xi)^* \sigma_m(P)(x,\xi),$$

which is invertible for $\xi \neq 0$. The argument for $P P_h^*$ is identical. Part (c) follows because a composition of isomorphisms is an isomorphism. □

Example 11.2.3. The Bochner Laplacian is elliptic by Example 11.1.10. The Weitzenböck identity, Theorem 8.2.33, shows that the bundle-valued Hodge Laplacian differs from the Bochner Laplacian by a zeroth-order endomorphism. They therefore have the same principal symbol and are both elliptic.

Proposition 11.2.4. (Differential symbol of a Dirac-type operator) Let $(\mathbf{S}, c, \nabla^{\mathbf{S}})$ be a Clifford module with connection, and let $D = c \circ \nabla^{\mathbf{S}}$ be the operator in Definition 8.3.1. Its differential principal symbol is

$$\sigma_1(D)(x,\xi) = c(\xi)\colon \mathbf{S}_x \longrightarrow \mathbf{S}_x. \tag{11.2}$$

In particular, D is elliptic and, for $\xi \neq 0$,

$$\sigma_1(D)(x,\xi)^{-1} = -\frac{c(\xi)}{|\xi|_{\mathbf{g}}^2}.$$

If the module is graded, the block $D^+\colon \Gamma(\mathbf{S}^+) \to \Gamma(\mathbf{S}^-)$ is elliptic and its symbol is the restriction $c(\xi)\colon \mathbf{S}^+_x \to \mathbf{S}^-_x$.

Proof. By (8.26), for any function f with $df_x = \xi$,

$$\sigma_1(D)(x,\xi) = [D, f]_x = c(df_x) = c(\xi).$$

The Clifford relation $c(\xi)^2 = -|\xi|_{\mathbf{g}}^2 I$ gives the stated inverse. In the graded case, $c(\xi)$ is odd and its square satisfies the same identity on each summand, so both restrictions are isomorphisms for $\xi \neq 0$. □

11.3 Elliptic estimates on vector bundles

We first prove the estimate for systems with constant coefficients, then freeze the coefficients at a point, and finally globalize the result by means of a partition of unity. The only ingredient from Fourier analysis is Plancherel's identity.

11.3.1 An interpolation inequality

Local estimates involve lower-order terms that must be absorbed. The following inequality quantifies this absorption in terms of a small portion of the higher-order norm and a lower-order norm.

Lemma 11.3.1. (Interpolation between integer orders) Let $m \in \mathbb{N}$ and $0 \leq j < m$. For every $\varepsilon > 0$, there exists $C_\varepsilon > 0$ such that

$$\|u\|_{H^j(\mathbb{R}^n,\mathbb{K}^r)} \leq \varepsilon \|u\|_{H^m(\mathbb{R}^n,\mathbb{K}^r)} + C_\varepsilon \|u\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)}$$

for every $u \in H^m(\mathbb{R}^n, \mathbb{K}^r)$.

Proof. We use the Fourier transform with unitary normalization, write $\langle \xi \rangle := (1 + \|\xi\|^2)^{\frac{1}{2}}$, and set

$$\|u\|_{s,\mathbf{F}} := \|\langle \xi \rangle^s \widehat{u}\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)}.$$

For each $s \in \mathbb{N}_0$, the Leibniz formula for $(1 + \|\xi\|^2)^s$ and Plancherel's identity give constants $a_s, b_s > 0$, depending only on n, r, s, and the chosen normalization of the Sobolev norm, such that

$$a_s \|u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} \leq \|u\|_{s,\mathbf{F}} \leq b_s \|u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)}.$$

Let $R \geq 1$ and set $\mathbf{E}_R := \{\xi \in \mathbb{R}^n \mid \langle \xi \rangle \leq R\}$. On $\mathbf{E}_R$ we have $\langle \xi \rangle^j \leq R^j$, whereas on $\mathbf{E}_R^c$ we have $\langle \xi \rangle^{j-m} \leq R^{j-m}$. By the triangle inequality in $L^2(\mathbb{R}^n, \mathbb{K}^r)$, applied componentwise, and Plancherel's identity,

$$\begin{aligned} \|u\|_{j,\mathbf{F}} &= \|\langle \xi \rangle^j \widehat{u}\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)} \\ &\leq \|\mathbf{1}_{\mathbf{E}_R} \langle \xi \rangle^j \widehat{u}\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)} + \|\mathbf{1}_{\mathbf{E}_R^c} \langle \xi \rangle^j \widehat{u}\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)} \\ &\leq R^j \|\widehat{u}\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)} + R^{j-m} \|\langle \xi \rangle^m \widehat{u}\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)} \\ &= R^j \|u\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)} + R^{j-m} \|u\|_{m,\mathbf{F}}. \end{aligned}$$

Let $\delta := \frac{a_j \varepsilon}{b_m}$ and choose $R_\varepsilon := \max\left\{1, \delta^{-\frac{1}{m-j}}\right\}$. Then $R_\varepsilon^{j-m} \leq \delta$ and, using the two preceding inequalities,

$$\|u\|_{H^j(\mathbb{R}^n,\mathbb{K}^r)} \leq a_j^{-1} \|u\|_{j,\mathbf{F}} \leq \varepsilon \|u\|_{H^m(\mathbb{R}^n,\mathbb{K}^r)} + a_j^{-1} R_\varepsilon^j \|u\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)}.$$

Thus it suffices to take $C_\varepsilon := a_j^{-1} R_\varepsilon^j$. □

11.3.2 Systems with constant coefficients

Freezing the coefficients first reduces the problem to a translation-invariant system. In this model, the Fourier transform converts ellipticity into an algebraic estimate for the symbol.

Lemma 11.3.2. (Estimate for a constant-coefficient elliptic system) Let $n, r, m \in \mathbb{N}$, let $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, and let $A_\alpha \in \mathrm{End}(\mathbb{K}^r)$ for $|\alpha| \leq m$. Consider the operator

$$P_0(D) \colon C_c^\infty(\mathbb{R}^n, \mathbb{K}^r) \longrightarrow C_c^\infty(\mathbb{R}^n, \mathbb{K}^r), \qquad P_0(D)u = \sum_{|\alpha| \leq m} A_\alpha D^\alpha u,$$

with constant coefficients, and suppose that

$$p_m(\xi) := \sum_{|\alpha| = m} A_\alpha \xi^\alpha$$

is invertible for $\xi \neq 0$. There exists $C > 0$ such that

$$\|u\|_{H^m(\mathbb{R}^n,\mathbb{K}^r)} \leq C\left(\|P_0(D)u\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)} + \|u\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)}\right)$$

for every $u \in C_c^\infty(\mathbb{R}^n, \mathbb{K}^r)$.

Proof. If $\mathbb{K} = \mathbb{R}$, we complexify the system to use the Fourier transform; the resulting estimate is then restricted to real-valued functions. The function $(\xi, v) \mapsto \|p_m(\xi)v\|_{\mathbb{C}^r}$ is continuous on the compact set $S^{n-1} \times S^{2r-1}$ and does not vanish. Thus there exists $c > 0$ such that

$$\|p_m(\xi)v\|_{\mathbb{C}^r} \geq c\|\xi\|^m \|v\|_{\mathbb{C}^r}$$

for all $\xi \in \mathbb{R}^n$ and $v \in \mathbb{C}^r$.

We must distinguish the preceding principal symbol from the Fourier multiplier. Set

$$p^{\#}(\xi) := \sum_{|\alpha|\le m} A_\alpha (i\xi)^\alpha, \qquad p_m^{\#}(\xi) := \sum_{|\alpha|=m} A_\alpha (i\xi)^\alpha = i^m p_m(\xi).$$

Since $|i^m| = 1$, the preceding estimate gives $\|p_m^{\#}(\xi)v\|_{\mathbb{C}^r} \ge c\|\xi\|^m \|v\|_{\mathbb{C}^r}$. If

$$r^{\#}(\xi) := p^{\#}(\xi) - p_m^{\#}(\xi),$$

then there exists $C_0 > 0$ such that $\|r^{\#}(\xi)v\|_{\mathbb{C}^r} \le C_0(1+\|\xi\|)^{m-1}\|v\|_{\mathbb{C}^r}$. Consequently,

$$\|p^{\#}(\xi)v\|_{\mathbb{C}^r} \ge c\|\xi\|^m\|v\|_{\mathbb{C}^r} - C_0(1+\|\xi\|)^{m-1}\|v\|_{\mathbb{C}^r}.$$

Choose $R > 1$ so that $C_0(1+\|\xi\|)^{m-1} \le \dfrac{c}{2}\|\xi\|^m$ for $\|\xi\| \ge R$. In this region,

$$(1+\|\xi\|^2)^{\frac{m}{2}}\|v\|_{\mathbb{C}^r} \le C_1\|p^{\#}(\xi)v\|_{\mathbb{C}^r}.$$

For $\|\xi\| < R$, we have $(1+\|\xi\|^2)^{\frac{m}{2}}\|v\|_{\mathbb{C}^r} \le C_R\|v\|_{\mathbb{C}^r}$. Therefore

$$(1+\|\xi\|^2)^{\frac{m}{2}}\|\widehat{u}(\xi)\|_{\mathbb{C}^r} \le C\big(\|p^{\#}(\xi)\widehat{u}(\xi)\|_{\mathbb{C}^r} + \|\widehat{u}(\xi)\|_{\mathbb{C}^r}\big).$$

We square, integrate, and apply Plancherel's identity. Since

$$\widehat{P_0(D)u}(\xi) = p^{\#}(\xi)\widehat{u}(\xi),$$

the asserted estimate follows. □

Lemma 11.3.3. (Constant-coefficient estimate at an arbitrary Sobolev order) Let $n, r, m \in \mathbb{N}$, let $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, and let $A_\alpha \in \mathrm{End}(\mathbb{K}^r)$ for $|\alpha| = m$. Let the operator

$$P_m(D)\colon \mathcal{S}(\mathbb{R}^n, \mathbb{K}^r) \longrightarrow \mathcal{S}(\mathbb{R}^n, \mathbb{K}^r), \qquad P_m(D)v = \sum_{|\alpha|=m} A_\alpha D^\alpha v,$$

be a homogeneous system with constant coefficients, and suppose that its symbol

$$p_m(\xi) := \sum_{|\alpha|=m} A_\alpha \xi^\alpha$$

is invertible for $\xi \neq 0$. For every $s \in \mathbb{R}$, there exists $C_s > 0$ such that

$$\|v\|_{H^{s+m}(\mathbb{R}^n,\mathbb{K}^r)} \le C_s\big(\|P_m(D)v\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} + \|v\|_{H^{s+m-1}(\mathbb{R}^n,\mathbb{K}^r)}\big)$$

for every $v \in \mathcal{S}(\mathbb{R}^n, \mathbb{K}^r)$.

Proof. As in the proof of Lemma 11.3.2, ellipticity and compactness of the sphere give $c > 0$ such that

$$\|p_m^{\#}(\xi)z\|_{\mathbb{C}^r} \ge c\|\xi\|^m\|z\|_{\mathbb{C}^r}, \qquad p_m^{\#}(\xi) := \sum_{|\alpha|=m} A_\alpha (i\xi)^\alpha,$$

for all $\xi \in \mathbb{R}^n$ and $z \in \mathbb{C}^r$. Choose $R \geq 1$. If $\|\xi\| \geq R$, the preceding inequality implies

$$\langle \xi \rangle^{s+m} \|z\|_{\mathbb{C}^r} \leq C_{s,R} \langle \xi \rangle^s \|p_m^{\#}(\xi) z\|_{\mathbb{C}^r}.$$

If $\|\xi\| < R$, then

$$\langle \xi \rangle^{s+m} \|z\|_{\mathbb{C}^r} \leq C_{s,R} \langle \xi \rangle^{s+m-1} \|z\|_{\mathbb{C}^r}.$$

Combining the two regions gives, for every ξ and every z,

$$\langle \xi \rangle^{s+m} \|z\|_{\mathbb{C}^r} \leq C_s \left(\langle \xi \rangle^s \|p_m^{\#}(\xi) z\|_{\mathbb{C}^r} + \langle \xi \rangle^{s+m-1} \|z\|_{\mathbb{C}^r} \right).$$

We apply this inequality to $z = \widehat{v}(\xi)$, square, and integrate. Since $\widehat{P_m(D)v} = p_m^{\#} \widehat{v}$, Plancherel's identity completes the proof. □

11.3.3 Freezing coefficients

On a small ball, a variable-coefficient operator is compared with the constant-coefficient operator obtained by fixing at the center only the coefficients of its principal part. This part determines ellipticity. The principal error retains order m, but its coefficients become small; the remaining terms need not be small because they have order at most $m-1$.

Lemma 11.3.4. (Local estimate for elliptic systems) Let $n, r, m \in \mathbb{N}$, let $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, let $U \subseteq \mathbb{R}^n$ be open, and let $A_\alpha \in C^\infty(U; \mathrm{End}(\mathbb{K}^r))$. Let

$$P \colon C_c^\infty(U, \mathbb{K}^r) \longrightarrow C_c^\infty(U, \mathbb{K}^r), \qquad Pu = \sum_{|\alpha| \leq m} A_\alpha(x) D^\alpha u,$$

be an elliptic system with smooth coefficients. For every $x_0 \in U$, there exist an open subset V, with $x_0 \in V \Subset U$, and a constant $C > 0$ such that

$$\|u\|_{H^m(\mathbb{R}^n, \mathbb{K}^r)} \leq C \left(\|Pu\|_{L^2(\mathbb{R}^n, \mathbb{K}^r)} + \|u\|_{L^2(\mathbb{R}^n, \mathbb{K}^r)} \right)$$

for every $u \in C_c^\infty(V, \mathbb{K}^r)$, extended by zero outside V.

Proof. We freeze only the principal coefficients at x_0 and write

$$P = P_{x_0}^{(m)} + R_1 + R_0,$$

where

$$P_{x_0}^{(m)} := \sum_{|\alpha| = m} A_\alpha(x_0) D^\alpha, \qquad R_1 := \sum_{|\alpha| = m} \big(A_\alpha(x) - A_\alpha(x_0) \big) D^\alpha,$$

and R_0 collects the terms of order at most $m-1$. For every $W \Subset U$, the operators $P_{x_0}^{(m)}$, R_1, and R_0 send $C_c^\infty(W, \mathbb{K}^r)$ into $C_c^\infty(U, \mathbb{K}^r)$. Lemma 11.3.2 applied to $P_{x_0}^{(m)}$ gives

$$\|u\|_{H^m(\mathbb{R}^n, \mathbb{K}^r)} \leq C_0 \left(\|P_{x_0}^{(m)} u\|_{L^2(\mathbb{R}^n, \mathbb{K}^r)} + \|u\|_{L^2(\mathbb{R}^n, \mathbb{K}^r)} \right).$$

Choose $r_0 > 0$ so that $\overline{B(x_0, r_0)} \subseteq U$. For $|\alpha| = m$, set

$$C_\alpha(r_0) := \sup_{z \in \overline{B(x_0,r_0)}} \sum_{j=1}^{n} \left\| \frac{\partial A_\alpha}{\partial x^j}(z) \right\|, \qquad C_*(r_0) := \sum_{|\alpha|=m} C_\alpha(r_0).$$

Hadamard's lemma 1.4.10, applied to the matrix entries of A_α, gives, for $x \in B(x_0, r_0)$,

$$A_\alpha(x) - A_\alpha(x_0) = \sum_{j=1}^{n} (x^j - x_0^j) \int_0^1 \frac{\partial A_\alpha}{\partial x^j}\big(x_0 + t(x - x_0)\big)\, dt. \tag{11.3}$$

Since the segment lies in the ball, for $0 < r \le r_0$ we obtain the quantitative bound

$$\sup_{x \in B(x_0,r)} \|A_\alpha(x) - A_\alpha(x_0)\| \le r C_\alpha(r_0). \tag{11.4}$$

Choose $r \in (0, r_0)$ small enough that

$$r C_*(r_0) \le \frac{1}{4 C_0 C_1}$$

, and take $V = B(x_0, r)$. If $C_*(r_0) = 0$, any $r < r_0$ satisfies this condition. Then

$$\sup_{x \in V} \sum_{|\alpha|=m} \|A_\alpha(x) - A_\alpha(x_0)\| \le \frac{1}{4 C_0 C_1},$$

where C_1 satisfies $\sum_{|\alpha|=m} \|D^\alpha u\|_{L^2(\mathbb{R}^n, \mathbb{K}^r)} \le C_1 \|u\|_{H^m(\mathbb{R}^n, \mathbb{K}^r)}$. Thus

$$\|R_1 u\|_{L^2(\mathbb{R}^n, \mathbb{K}^r)} \le \frac{1}{4 C_0} \|u\|_{H^m(\mathbb{R}^n, \mathbb{K}^r)}.$$

Since R_0 has order at most $m - 1$, there exists $C_2 > 0$ such that $\|R_0 u\|_{L^2(\mathbb{R}^n, \mathbb{K}^r)} \le C_2 \|u\|_{H^{m-1}(\mathbb{R}^n, \mathbb{K}^r)}$. Applying Lemma 11.3.1 with $\varepsilon = (4 C_0 C_2)^{-1}$ yields

$$\|R_0 u\|_{L^2(\mathbb{R}^n, \mathbb{K}^r)} \le \frac{1}{4 C_0} \|u\|_{H^m(\mathbb{R}^n, \mathbb{K}^r)} + C_3 \|u\|_{L^2(\mathbb{R}^n, \mathbb{K}^r)}.$$

Since $P^{(m)}_{x_0} u = Pu - R_1 u - R_0 u$,

$$\|u\|_{H^m(\mathbb{R}^n, \mathbb{K}^r)} \le C_0 \|Pu\|_{L^2(\mathbb{R}^n, \mathbb{K}^r)} + \frac{1}{2} \|u\|_{H^m(\mathbb{R}^n, \mathbb{K}^r)} + C_4 \|u\|_{L^2(\mathbb{R}^n, \mathbb{K}^r)}.$$

Moving the middle term to the left-hand side completes the proof. □

Proposition 11.3.5. (Local estimate at an arbitrary Sobolev order) Let $n, r, m \in \mathbb{N}$, let $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, let $U \subseteq \mathbb{R}^n$ be open, and let $A_\alpha \in C^\infty(U; \mathrm{End}(\mathbb{K}^r))$. Let

$$P \colon C_c^\infty(U, \mathbb{K}^r) \longrightarrow C_c^\infty(U, \mathbb{K}^r), \qquad Pv = \sum_{|\alpha| \le m} A_\alpha(x) D^\alpha v,$$

be an elliptic system with smooth coefficients. Given $x_0 \in U$ and $s \in \mathbb{R}$, there exist an open subset V, with

$x_0 \in V \Subset U$, and a constant $C_s > 0$ such that

$$\|v\|_{H^{s+m}(\mathbb{R}^n,\mathbb{K}^r)} \le C_s\big(\|Pv\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} + \|v\|_{H^{s+m-1}(\mathbb{R}^n,\mathbb{K}^r)}\big)$$

for every $v \in C_c^\infty(V,\mathbb{K}^r)$, extended by zero outside V.

Proof. We freeze only the principal coefficients at x_0 and set

$$P_{x_0}^{(m)} := \sum_{|\alpha|=m} A_\alpha(x_0) D^\alpha.$$

Lemma 11.3.3 provides a constant $C_0 > 0$ such that

$$\|v\|_{H^{s+m}(\mathbb{R}^n,\mathbb{K}^r)} \le C_0\big(\|P_{x_0}^{(m)} v\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} + \|v\|_{H^{s+m-1}(\mathbb{R}^n,\mathbb{K}^r)}\big).$$

Write

$$P = P_{x_0}^{(m)} + R_1 + R_0,$$

where

$$R_1 := \sum_{|\alpha|=m} \big(A_\alpha(x) - A_\alpha(x_0)\big) D^\alpha$$

and R_0 collects the terms of order at most $m-1$. For every $W \Subset U$, the operators $P_{x_0}^{(m)}$, R_1, and R_0 send $C_c^\infty(W,\mathbb{K}^r)$ into $C_c^\infty(U,\mathbb{K}^r)$.

We will apply the refined multiplication estimate, Lemma 6.1.8, after extending the coefficients to all of $\mathbb{R}^n$. Let us make this localization precise. Choose $r_0 > 0$ with $\overline{B(x_0,r_0)} \subseteq U$, and define $C_\alpha(r_0)$ and $C_*(r_0)$ as in the preceding proof. Identities (11.3) and (11.4) show that, for $0 < r < r_0$,

$$\sum_{|\alpha|=m} \sup_{x \in B(x_0,r)} \|A_\alpha(x) - A_\alpha(x_0)\| \le r C_*(r_0). \tag{11.5}$$

Let $C_1 > 0$ be a constant bounding the product of the matrix constant in Lemma 6.1.8 and the norms of the operators $D^\alpha : H^{s+m}(\mathbb{R}^n,\mathbb{K}^r) \longrightarrow H^s(\mathbb{R}^n,\mathbb{K}^r)$, $|\alpha| = m$. This constant depends on n, s, m and the ranks, but not on r, θ, or the coefficients. Choose $r \in (0, r_0)$ so that $C_0 C_1 r C_*(r_0) \le \frac{1}{2}$, and take $V = B(x_0, r/2)$. Choose $\theta \in C_c^\infty(B(x_0,r))$ with $0 \le \theta \le 1$ and $\theta = 1$ on a neighborhood of $\overline{V}$. If $v \in C_c^\infty(V,\mathbb{K}^r)$, we may replace each coefficient of R_1 by

$$B_\alpha(x) := \theta(x)\big(A_\alpha(x) - A_\alpha(x_0)\big),$$

interpreted as zero outside $B(x_0,r)$. This coefficient is smooth and agrees with $A_\alpha - A_\alpha(x_0)$ on a neighborhood of the support of v. Moreover, since $0 \le \theta \le 1$ and its support is contained in $B(x_0,r)$, estimate (11.5) gives

$$\sum_{|\alpha|=m} \|B_\alpha\|_{L^\infty(\mathbb{R}^n)} \le r C_*(r_0).$$

Lemma 6.1.8, applied componentwise, and continuity of $D^\alpha : H^{s+m}(\mathbb{R}^n,\mathbb{K}^r) \longrightarrow H^s(\mathbb{R}^n,\mathbb{K}^r)$ give

$$\|R_1 v\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} \le C_1 r C_*(r_0) \|v\|_{H^{s+m}(\mathbb{R}^n,\mathbb{K}^r)} + C_2 \|v\|_{H^{s+m-1}(\mathbb{R}^n,\mathbb{K}^r)}.$$

Here the second term collects the remainders that lose one derivative; their constants may depend on derivatives of the coefficients and on θ, but not on v.
To handle R_0, we extend its coefficients in the same way using θ and then by zero to $\mathbb{R}^n$. Since each summand has the form $B_\alpha D^\alpha v$ with $|\alpha| \le m-1$, Lemma 6.1.8, together with Proposition 6.1.6, gives

$$\|R_0 v\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} \le C_3 \|v\|_{H^{s+m-1}(\mathbb{R}^n,\mathbb{K}^r)}.$$

The identity $P_{x_0}^{(m)} v = Pv - R_1 v - R_0 v$ implies

$$\|v\|_{H^{s+m}(\mathbb{R}^n,\mathbb{K}^r)} \le C_0 \|Pv\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} + C_0 C_1 r C_*(r_0) \|v\|_{H^{s+m}(\mathbb{R}^n,\mathbb{K}^r)} + C_4 \|v\|_{H^{s+m-1}(\mathbb{R}^n,\mathbb{K}^r)}.$$

Our choice of radius satisfies $C_0 C_1 r C_*(r_0) \le \frac{1}{2}$; if $C_*(r_0) = 0$, any radius for which the preceding localizations are defined suffices. This condition explains quantitatively why the term R_1, although it retains order m, can be absorbed into the left-hand side. The coefficients of R_0 have not been made small: the loss of one order is what allows them to remain in the last term. This gives the asserted estimate. □

Proposition 11.3.6. (Higher-order local estimate) Under the hypotheses of Lemma 11.3.4, for each $k \in \mathbb{N}_0$ the open subset V can be shrunk, if necessary, so that there exists $C_k > 0$ such that

$$\|u\|_{H^{k+m}(\mathbb{R}^n,\mathbb{K}^r)} \le C_k \left(\|Pu\|_{H^k(\mathbb{R}^n,\mathbb{K}^r)} + \|u\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)} \right)$$

for every $u \in C_c^\infty(V,\mathbb{K}^r)$, extended by zero outside V.

Proof. Apply Proposition 11.3.5 with $s = k$. After shrinking V if necessary, we obtain

$$\|u\|_{H^{k+m}(\mathbb{R}^n,\mathbb{K}^r)} \le C_1 \left(\|Pu\|_{H^k(\mathbb{R}^n,\mathbb{K}^r)} + \|u\|_{H^{k+m-1}(\mathbb{R}^n,\mathbb{K}^r)} \right).$$

Lemma 11.3.1, applied with orders $k+m-1$ and $k+m$, provides, for every $\varepsilon > 0$, a constant $C_\varepsilon > 0$ such that

$$\|u\|_{H^{k+m-1}(\mathbb{R}^n,\mathbb{K}^r)} \le \varepsilon \|u\|_{H^{k+m}(\mathbb{R}^n,\mathbb{K}^r)} + C_\varepsilon \|u\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)}.$$

Choose ε so that $C_1 \varepsilon < 1$ and absorb the corresponding term into the left-hand side. We obtain

$$\|u\|_{H^{k+m}(\mathbb{R}^n,\mathbb{K}^r)} \le C_k \left(\|Pu\|_{H^k(\mathbb{R}^n,\mathbb{K}^r)} + \|u\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)} \right),$$

as desired. □

11.3.4 Globalization on a closed manifold

The local estimates give a global estimate by means of a finite partition of unity. Commutators with cutoff functions have lower order, so the interpolation inequality controls the terms introduced by patching.

Theorem 11.3.7. (Global elliptic estimate) Let $(M,\mathbf{g})$ be a closed Riemannian manifold, let $\mathbf{E},\mathbf{F} \to M$ be smooth vector bundles with bundle metrics $\mathbf{h_E},\mathbf{h_F}$, and let $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$ be elliptic. For every $k \in \mathbb{N}_0$,

there exists $C_k > 0$ such that

$$\|\mathbf{u}\|_{H^{k+m}(M,\mathbf{E})} \leq C_k\big(\|P\mathbf{u}\|_{H^k(M,\mathbf{F})} + \|\mathbf{u}\|_{L^2(M,\mathbf{E})}\big)$$

for every $\mathbf{u} \in \Gamma(\mathbf{E})$. Moreover, P extends uniquely to a continuous linear operator

$$P\colon H^{k+m}(M,\mathbf{E}) \longrightarrow H^k(M,\mathbf{F}).$$

Proof. Continuity of $P\colon H^{k+m}(M,\mathbf{E}) \longrightarrow H^k(M,\mathbf{F})$ follows from the local expression in Corollary 8.1.35. Each derivative of order at most k of $P\mathbf{u}$ is a finite sum of smooth coefficients multiplied by derivatives of the components of $\mathbf{u}$ of order at most $k+m$. Lemma 9.1.44, applied with $p = 2$, locally identifies the norm defined using covariant derivatives with the sum of the Sobolev norms of the components. This allows us to sum the estimates over a finite cover.

If $m = 0$, the operator P is a smooth bundle homomorphism, and ellipticity means that each P_x is invertible. In local frames, the inverse matrix formula shows that P^{-1} is smooth. The same Leibniz estimate, applied to P^{-1} on a finite cover, gives $\|\mathbf{u}\|_{H^k(M,\mathbf{E})} \leq C_k\|P\mathbf{u}\|_{H^k(M,\mathbf{F})}$. This also proves the reverse inequality at order zero.

Now suppose that $m \geq 1$. For the reverse inequality, choose a finite cover $(U_a)_{a=1}^N$ by charts over which $\mathbf{E}$ and $\mathbf{F}$ admit smooth frames, and a subordinate partition of unity $(\chi_a)_{a=1}^N$. Refine the cover so that $\operatorname{supp}(\chi_a)$ lies in an open subset on which Proposition 11.3.6 applies. In coordinates and components,

$$\|\chi_a\mathbf{u}\|_{H^{k+m}(M,\mathbf{E})} \leq C_a\big(\|P(\chi_a\mathbf{u})\|_{H^k(M,\mathbf{F})} + \|\chi_a\mathbf{u}\|_{L^2(M,\mathbf{E})}\big).$$

Since

$$P(\chi_a\mathbf{u}) = \chi_a Pu + [P,\chi_a]\mathbf{u}$$

and $[P,\chi_a]$ has order at most $m-1$,

$$\|[P,\chi_a]\mathbf{u}\|_{H^k(M,\mathbf{F})} \leq C_a'\|\mathbf{u}\|_{H^{k+m-1}(M,\mathbf{E})}.$$

Summing over a and using Lemma 9.1.44 once again,

$$\|\mathbf{u}\|_{H^{k+m}(M,\mathbf{E})} \leq C\big(\|P\mathbf{u}\|_{H^k(M,\mathbf{F})} + \|\mathbf{u}\|_{H^{k+m-1}(M,\mathbf{E})} + \|\mathbf{u}\|_{L^2(M,\mathbf{E})}\big).$$

The global version of Lemma 11.3.1, obtained by applying it in the finitely many charts, gives

$$\|\mathbf{u}\|_{H^{k+m-1}(M,\mathbf{E})} \leq \varepsilon\|\mathbf{u}\|_{H^{k+m}(M,\mathbf{E})} + C_\varepsilon\|\mathbf{u}\|_{L^2(M,\mathbf{E})}.$$

Choose ε so that the first term can be absorbed into the left-hand side. This proves the estimate for smooth sections. Continuity of P and density of $\Gamma(\mathbf{E})$ in $H^{k+m}(M,\mathbf{E})$ yield the indicated extension and extend the inequality to all of $H^{k+m}(M,\mathbf{E})$. □

Corollary 11.3.8. (Equivalence with the graph norm) Let $(M,\mathbf{g})$ be a closed Riemannian manifold, let $\mathbf{E},\mathbf{F} \to M$ be smooth vector bundles with bundle metrics $\mathbf{h_E},\mathbf{h_F}$, and let $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$ be elliptic. For

each $k \in \mathbb{N}_0$, there exist constants $c_P, C_P > 0$, depending on P, k, and the fixed geometric data, such that

$$c_P \|\mathbf{u}\|_{H^{k+m}(M,\mathbf{E})} \le \|\mathbf{u}\|_{L^2(M,\mathbf{E})} + \|P\mathbf{u}\|_{H^k(M,\mathbf{F})} \le C_P \|\mathbf{u}\|_{H^{k+m}(M,\mathbf{E})}$$

for every $\mathbf{u} \in H^{k+m}(M,\mathbf{E})$.

Proof. Theorem 11.3.7 gives one inequality. The other follows from continuity of $P\colon H^{k+m}(M,\mathbf{E}) \longrightarrow H^k(M,\mathbf{F})$ and the continuous inclusion $H^{k+m}(M,\mathbf{E}) \hookrightarrow L^2(M,\mathbf{E})$. □

In the language of operators on bundles, the preceding estimate agrees with the fundamental elliptic inequality in [21, Exercise 9.12(b)]. An alternative construction of elliptic regularity, based on microlocal tools that have not yet been defined, will be developed in Chapter 15.

11.4 Elliptic regularity

The operator P acts on distributions through the construction in Chapter 10; see Proposition 10.2.18. Thus the equation $P\mathbf{u} = \mathbf{f}$ makes sense for $\mathbf{u} \in \mathcal{D}'(M,\mathbf{E})$ under the definition of distributional derivative already established.

Lemma 11.4.1. (Local gain of one derivative) Let $\Omega \subseteq \mathbb{R}^n$ be open, let

$$P = \sum_{|\alpha| \le m} A_\alpha(x) D^\alpha$$

be an elliptic system with smooth coefficients, and let $t \in \mathbb{Z}$. If

$$v \in H^t_{\mathrm{loc}}(\Omega, \mathbb{K}^r) \qquad \text{and} \qquad Pv \in H^{t-m+1}_{\mathrm{loc}}(\Omega, \mathbb{K}^r),$$

then

$$v \in H^{t+1}_{\mathrm{loc}}(\Omega, \mathbb{K}^r).$$

Proof. Fix $x_0 \in \Omega$. Apply Proposition 11.3.5 with the index

$$s := t - m + 1.$$

We obtain an open subset V_0, with $x_0 \in V_0 \Subset \Omega$, and a constant $C > 0$ such that

$$\|z\|_{H^{t+1}(\mathbb{R}^n,\mathbb{K}^r)} \le C\big(\|Pz\|_{H^{t-m+1}(\mathbb{R}^n,\mathbb{K}^r)} + \|z\|_{H^t(\mathbb{R}^n,\mathbb{K}^r)}\big)$$

for every $z \in C^\infty_c(V_0, \mathbb{K}^r)$.
Choose open subsets W, V such that

$$x_0 \in W \Subset V \Subset V_0$$

and a function $\chi \in C^\infty_c(V)$ equal to one on a neighborhood of $\overline{W}$. Define

$$w := \chi v,$$

extended by zero outside Ω. Since $v \in H^t_{\mathrm{loc}}$, Definition 6.1.7 gives $w \in H^t(\mathbb{R}^n, \mathbb{K}^r)$ and $\operatorname{supp}(w) \subseteq \operatorname{supp}(\chi) \Subset V$.

In the distributional sense,

$$Pw = \chi Pv + [P, \chi]v.$$

Let us justify the regularity of both summands. The hypothesis on Pv gives $\chi Pv \in H^{t-m+1}(\mathbb{R}^n, \mathbb{K}^r)$. On the other hand, $[P, \chi]$ is a differential system of order at most $m-1$. Choose $\eta \in C^\infty_c(V_0)$ such that $\eta = 1$ on a neighborhood of $\operatorname{supp}(\chi)$. Locality of differential operators allows us to write

$$[P, \chi]v = [P, \chi](\eta v).$$

Since $\eta v \in H^t(\mathbb{R}^n, \mathbb{K}^r)$, continuity of differentiation and multiplication by smooth coefficients, Proposition 6.1.6 and Lemma 6.1.8, gives

$$[P, \chi]v \in H^{t-m+1}(\mathbb{R}^n, \mathbb{K}^r).$$

Therefore

$$Pw \in H^{t-m+1}(\mathbb{R}^n, \mathbb{K}^r).$$

Let J_ε be the mollifier in Proposition 6.1.11 and set $w_\varepsilon := J_\varepsilon w$. Since $\operatorname{supp}(w) \Subset V$, there exists $\varepsilon_0 > 0$ such that

$$\operatorname{supp}(w_\varepsilon) \subseteq V_0 \qquad \text{for } 0 < \varepsilon < \varepsilon_0.$$

Moreover, $w_\varepsilon \in C^\infty_c(V_0, \mathbb{K}^r)$, so the preceding elliptic estimate applies:

$$\|w_\varepsilon\|_{H^{t+1}(\mathbb{R}^n, \mathbb{K}^r)} \leq C\big(\|Pw_\varepsilon\|_{H^{t-m+1}(\mathbb{R}^n, \mathbb{K}^r)} + \|w_\varepsilon\|_{H^t(\mathbb{R}^n, \mathbb{K}^r)}\big).$$

To control the first term, we extend the coefficients of P outside V_0. Choose $\vartheta \in C^\infty_c(\Omega)$ equal to one on a neighborhood of $\overline{V_0}$ and replace A_α with the extension by zero of ϑA_α to $\mathbb{R}^n$. This replacement does not change Pw, Pw_ε, or the commutator on their supports. Then

$$Pw_\varepsilon = P(J_\varepsilon w) = J_\varepsilon(Pw) + [P, J_\varepsilon]w.$$

Proposition 6.1.11 and Corollary 6.1.13 give, uniformly for $0 < \varepsilon < \varepsilon_0$,

$$\|Pw_\varepsilon\|_{H^{t-m+1}(\mathbb{R}^n, \mathbb{K}^r)} \leq \|Pw\|_{H^{t-m+1}(\mathbb{R}^n, \mathbb{K}^r)} + C_1\|w\|_{H^t(\mathbb{R}^n, \mathbb{K}^r)}.$$

Also, $\|w_\varepsilon\|_{H^t(\mathbb{R}^n, \mathbb{K}^r)} \leq \|w\|_{H^t(\mathbb{R}^n, \mathbb{K}^r)}$. Consequently,

$$\|w_\varepsilon\|_{H^{t+1}(\mathbb{R}^n, \mathbb{K}^r)} \leq C_2\big(\|Pw\|_{H^{t-m+1}(\mathbb{R}^n, \mathbb{K}^r)} + \|w\|_{H^t(\mathbb{R}^n, \mathbb{K}^r)}\big),$$

and the right-hand side is independent of ε.

The space $H^{t+1}(\mathbb{R}^n, \mathbb{K}^r)$ is a Hilbert space. Thus there exist a sequence $\varepsilon_j \to 0$ and an element $z \in H^{t+1}(\mathbb{R}^n, \mathbb{K}^r)$ such that $w_{\varepsilon_j} \rightharpoonup z$ weakly in $H^{t+1}(\mathbb{R}^n, \mathbb{K}^r)$. The continuous inclusion $H^{t+1}(\mathbb{R}^n, \mathbb{K}^r) \hookrightarrow H^t(\mathbb{R}^n, \mathbb{K}^r)$ implies that the same sequence converges weakly to z in $H^t(\mathbb{R}^n, \mathbb{K}^r)$. However, Proposition 6.1.11 gives $w_{\varepsilon_j} \to w$ strongly in $H^t(\mathbb{R}^n, \mathbb{K}^r)$. Uniqueness of the weak limit shows that $z = w$. Consequently, $w \in H^{t+1}(\mathbb{R}^n, \mathbb{K}^r)$.

Since $\chi = 1$ on a neighborhood of $\overline{W}$, we have $v = w$ on W. Thus $v \in H^{t+1}_{\mathrm{loc}}(W, \mathbb{K}^r)$ on a neighborhood of x_0.

Since x_0 was arbitrary, the localization criterion in Lemma 6.1.9 yields $v \in H^{t+1}_{\mathrm{loc}}(\Omega, \mathbb{K}^r)$. □

Theorem 11.4.2. (Local elliptic regularity) Let M be a smooth manifold without boundary, let $\mathbf{E}, \mathbf{F} \to M$ be smooth vector bundles of finite rank, let $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$ be elliptic, and let $k \in \mathbb{N}_0$. If $\mathbf{u} \in \mathcal{D}'(M, \mathbf{E})$ and $P\mathbf{u} \in H^k_{\mathrm{loc}}(M, \mathbf{F})$, then $\mathbf{u} \in H^{k+m}_{\mathrm{loc}}(M, \mathbf{E})$. In particular, if $P\mathbf{u}$ is smooth, then $\mathbf{u}$ is smooth.

Proof. If $m = 0$, ellipticity gives a smooth inverse homomorphism P^{-1}. Multiplication of distributions by its smooth coefficients is compatible with composition, so $\mathbf{u} = P^{-1}(P\mathbf{u})$. The Leibniz rule in each chart proves the local continuity of P^{-1} on H^k and its preservation of smoothness. Both conclusions follow directly in this case.

Suppose that $m \geq 1$ and fix $x_0 \in M$. Choose a regular coordinate ball (U, φ) around x_0, with $\Omega := \varphi(U) \subseteq \mathbb{R}^n$, and smooth frames

$$\mathbf{e}_1, \dots, \mathbf{e}_r \qquad \text{and} \qquad \mathbf{f}_1, \dots, \mathbf{f}_r$$

for $\mathbf{E}|_U$ and $\mathbf{F}|_U$, respectively. The ranks agree because the principal symbol of an elliptic operator is an isomorphism between fibers. Shrinking U if necessary, we may assume that U is relatively compact and that x_0 corresponds to the point $y_0 := \varphi(x_0)$.

Let $q \in C^\infty(\Omega)$ be the positive coordinate weight of the Riemannian measure, characterized by the change-of-variables formula

$$\int_U \eta \, d\lambda_{\mathbf{g}} = \int_\Omega (\eta \circ \varphi^{-1})(y) q(y) \, d\lambda_n(y)$$

for every integrable function η supported in U. Let $\mathbf{e}^1, \dots, \mathbf{e}^r$ and $\mathbf{f}^1, \dots, \mathbf{f}^r$ be the dual frames of $\mathbf{E}^*|_U$ and $\mathbf{F}^*|_U$, respectively. The local representation of $\mathbf{u}$ is the vector-valued distribution

$$\widehat{u} = (u^1, \dots, u^r) \in \mathcal{D}'(\Omega, \mathbb{K}^r)$$

defined by

$$\langle u^a, \psi \rangle := \mathbf{u}\left(((q^{-1}\psi) \circ \varphi) \mathbf{e}^a \right), \qquad \psi \in C^\infty_c(\Omega),$$

where the test section is extended by zero outside U. Define $\widehat{Pu} = ((Pu)^1, \dots, (Pu)^r)$ by

$$\langle (Pu)^b, \psi \rangle := P\mathbf{u}\left(((q^{-1}\psi) \circ \varphi) \mathbf{f}^b \right), \qquad \psi \in C^\infty_c(\Omega), \quad 1 \leq b \leq r,$$

again extending the test section by zero. This normalization by q^{-1} makes the components correspond to Lebesgue measure on Ω.

In the chosen frames, the operator has the form

$$P_U = \sum_{|\alpha| \leq m} A_\alpha(y) D^\alpha.$$

The distributional extension of P is compatible with this local representation. Let us verify this assertion. If $\Psi = (\Psi_1, \dots, \Psi_r) \in C^\infty_c(\Omega, (\mathbb{K}^r)^*)$, identify $q^{-1}\Psi$ with the section of $\mathbf{F}^*|_U$ given by $\sum_{b=1}^r ((q^{-1}\Psi_b) \circ \varphi) \mathbf{f}^b$. Let P^{t}_U be the bilinear formal transpose of the system with respect to Lebesgue measure; its matrices are transposed,

not conjugated. Corollary 10.2.15 gives

$$P'\big(q^{-1}\Psi\big) = q^{-1}P_U^{\mathrm{t}}\Psi.$$

By the definition of the distributional action,

$$\langle\widehat{Pu},\Psi\rangle = (P\mathbf{u})(q^{-1}\Psi) = \mathbf{u}\big(P'(q^{-1}\Psi)\big) = \langle\widehat{u},P_U^{\mathrm{t}}\Psi\rangle = \langle P_U\widehat{u},\Psi\rangle.$$

Thus

$$\widehat{Pu} = P_U\widehat{u} \qquad \text{on } \mathcal{D}'(\Omega,\mathbb{K}^r).$$

By Proposition 11.1.3, the principal symbol of the system is

$$p_m(y,\xi) = \sum_{|\alpha|=m} A_\alpha(y)\xi^\alpha.$$

Ellipticity of P means that $p_m(y,\xi)$ is invertible for every $y\in\Omega$ and every $\xi\neq 0$. Thus P_U is an elliptic system with smooth coefficients.
The hypothesis $P\mathbf{u}\in H^k_{\mathrm{loc}}(M,\mathbf{F})$ and Lemma 9.1.44 imply that the components of $P\mathbf{u}$ in the frame $\mathbf{f}_1,\dots,\mathbf{f}_r$ belong to $H^k_{\mathrm{loc}}(\Omega,\mathbb{K}^r)$. The preceding normalization merely multiplies test functions by the positive smooth function q^{-1}, so the local representation satisfies

$$P_U\widehat{u} = \widehat{Pu} \in H^k_{\mathrm{loc}}(\Omega,\mathbb{K}^r).$$

We now need a starting point for the iteration. Choose $\chi_0\in C_c^\infty(\Omega)$ such that $\chi_0 = 1$ on a neighborhood of y_0. By Proposition 6.1.10, there exists $N\in\mathbb{N}$ such that

$$\chi_0\widehat{u}\in H^{-N}(\mathbb{R}^n,\mathbb{K}^r).$$

The localization criterion, Lemma 6.1.9, shows that

$$\widehat{u}\in H^{-N}_{\mathrm{loc}}(\Omega_0,\mathbb{K}^r)$$

on some open neighborhood $\Omega_0\Subset\Omega$ of y_0 on which $\chi_0 = 1$.
Apply Lemma 11.4.1 repeatedly. In the first step, take $t = -N$. Since

$$-N-m+1\le k,$$

the continuous inclusion in Proposition 6.1.6 gives

$$P_U\widehat{u}\in H^k_{\mathrm{loc}}(\Omega_0)\hookrightarrow H^{-N-m+1}_{\mathrm{loc}}(\Omega_0).$$

The derivative-gain lemma yields

$$\widehat{u}\in H^{-N+1}_{\mathrm{loc}}(\Omega_0).$$

Suppose inductively that, for some integer t with

$$-N \le t < k+m,$$

we have obtained $\widehat{u} \in H^t_{\mathrm{loc}}(\Omega_0)$. Since $t \le k+m-1$, we have $t-m+1 \le k$, and again

$$P_U \widehat{u} \in H^k_{\mathrm{loc}}(\Omega_0) \hookrightarrow H^{t-m+1}_{\mathrm{loc}}(\Omega_0).$$

Lemma 11.4.1 implies

$$\widehat{u} \in H^{t+1}_{\mathrm{loc}}(\Omega_0).$$

After finitely many steps, we reach

$$\widehat{u} \in H^{k+m}_{\mathrm{loc}}(\Omega_0, \mathbb{K}^r).$$

Lemma 9.1.44, applied in the frame $\mathbf{e}_1, \dots, \mathbf{e}_r$, identifies the Sobolev regularity of a section with that of its local components. Thus

$$\mathbf{u} \in H^{k+m}_{\mathrm{loc}}(M, \mathbf{E})$$

on a neighborhood of x_0. Since x_0 was arbitrary, the first assertion is proved.
Finally, suppose that $P\mathbf{u}$ is smooth. Then $P\mathbf{u} \in H^k_{\mathrm{loc}}(M, \mathbf{F})$ for every $k \in \mathbb{N}_0$, and the first part gives

$$\mathbf{u} \in H^{k+m}_{\mathrm{loc}}(M, \mathbf{E}) \qquad \text{for every } k \in \mathbb{N}_0.$$

Fix $\ell \in \mathbb{N}_0$ and choose k so that $k+m > \ell + \dfrac{n}{2}$. In a chart and a local frame, the Euclidean Sobolev embedding gives

$$H^{k+m}_{\mathrm{loc}}(\mathbb{R}^n, \mathbb{K}^r) \hookrightarrow C^{\ell}_{\mathrm{loc}}(\mathbb{R}^n, \mathbb{K}^r).$$

Thus $\mathbf{u} \in C^{\ell}(\mathbf{E})$. Since ℓ was arbitrary, we conclude that $\mathbf{u}$ is smooth. □

Remark 11.4.3. The geometric part of the proof consists of using a chart and local frames to identify the symbol of the system with the intrinsic symbol of the operator. Once this identification is made, the analytic argument is the same for functions and sections: the matrices A_α couple the components, but uniform invertibility of the symbol on the covector sphere gives the same Fourier estimate.

11.4.1 Minimal and maximal realizations on a closed manifold

Let $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$ and suppose that M is closed. Define the initial realization

$$P_0 \colon \Gamma(\mathbf{E}) \subseteq L^2(M, \mathbf{E}) \longrightarrow L^2(M, \mathbf{F}), \qquad P_0\mathbf{u} := P\mathbf{u}.$$

Since $\Gamma(\mathbf{E})$ is dense, P_0 is densely defined. Its closure, when it exists, is called the minimal realization and is denoted by $P_{\min}$. The maximal realization is defined through the distributional extension of P:

$$\mathcal{D}(P_{\max}) := \{\mathbf{u} \in L^2(M, \mathbf{E}) \mid P\mathbf{u} \in L^2(M, \mathbf{F}) \text{ in the distributional sense}\}, \qquad P_{\max}\mathbf{u} := P\mathbf{u}.$$

Theorem 11.4.4. (Domain of an elliptic operator on a closed manifold) Let $(M,\mathbf{g})$ be a closed Riemannian manifold, let $\mathbf{E},\mathbf{F}\to M$ be smooth vector bundles equipped with bundle metrics, and let $P\in\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$ be elliptic. Then P_0 is closable,

$$P_{\min}=P_{\max},\qquad \mathcal{D}(P_{\min})=\mathcal{D}(P_{\max})=H^m(M,\mathbf{E}),$$

and there exist constants $c_P,C_P>0$, depending on P and the fixed geometric data, such that

$$c_P\|\mathbf{u}\|_{H^m(M,\mathbf{E})}\le\|\mathbf{u}\|_{L^2(M,\mathbf{E})}+\|P_{\max}\mathbf{u}\|_{L^2(M,\mathbf{F})}\le C_P\|\mathbf{u}\|_{H^m(M,\mathbf{E})}$$

for every $\mathbf{u}\in H^m(M,\mathbf{E})$. In particular, every closed realization of P lying between the minimal and maximal realizations agrees with them.

Proof. Let $\mathbf{u}\in\mathcal{D}(P_{\max})$. Then $\mathbf{u}\in L^2(M,\mathbf{E})$ and $P\mathbf{u}\in L^2(M,\mathbf{F})$ distributionally. Theorem 11.4.2 with $k=0$ gives $\mathbf{u}\in H^m_{\mathrm{loc}}(M,\mathbf{E})$. Since M is compact, a finite cover by charts turns this local regularity into $\mathbf{u}\in H^m(M,\mathbf{E})$. Thus

$$\mathcal{D}(P_{\max})\subseteq H^m(M,\mathbf{E}).$$

The reverse inclusion follows from the continuity $P\colon H^m(M,\mathbf{E})\longrightarrow L^2(M,\mathbf{F})$ in Theorem 11.3.7. Therefore $\mathcal{D}(P_{\max})=H^m(M,\mathbf{E})$. Corollary 11.3.8 shows that this domain is complete in the graph norm; hence $P_{\max}$ is closed. Since $P_0\subseteq P_{\max}$, the initial operator is closable.

Now take $\mathbf{u}\in H^m(M,\mathbf{E})$. By density, there exists a sequence $(\mathbf{u}_j)\subseteq\Gamma(\mathbf{E})$ such that $\mathbf{u}_j\to\mathbf{u}$ in $H^m(M,\mathbf{E})$. Continuity of P gives $P\mathbf{u}_j\to P\mathbf{u}$ in $L^2(M,\mathbf{F})$. Thus $(\mathbf{u}_j,P\mathbf{u}_j)$ converges to $(\mathbf{u},P\mathbf{u})$ in $L^2(M,\mathbf{E})\times L^2(M,\mathbf{F})$, which shows that $\mathbf{u}\in\mathcal{D}(P_{\min})$ and $P_{\min}\mathbf{u}=P\mathbf{u}$. We obtain $H^m(M,\mathbf{E})\subseteq\mathcal{D}(P_{\min})$. Since we always have $P_{\min}\subseteq P_{\max}$, the two realizations agree.

Equivalence of the graph norm and the $H^m(M,\mathbf{E})$ norm is Corollary 11.3.8 with $k=0$. If $\widetilde{P}$ is any closed realization of P satisfying

$$P_{\min}\subseteq\widetilde{P}\subseteq P_{\max},$$

then the equalities already proved imply $P_{\min}=\widetilde{P}=P_{\max}$. This proves the last assertion. □

Corollary 11.4.5. (Closed realization of the connection Laplacian) Let $(M,\mathbf{g})$ be a closed Riemannian manifold, and let $(\mathbf{E},\mathbf{h}_{\mathbf{E}},\nabla^{\mathbf{E}})$ be a real vector bundle with a bundle metric or a Hermitian bundle with a compatible connection. Consider

$$L_{\mathbf{E},0}:=(\nabla^{\mathbf{E}})^*_h\nabla^{\mathbf{E}}\colon\Gamma(\mathbf{E})\subset L^2(M,\mathbf{E})\longrightarrow L^2(M,\mathbf{E}).$$

Then

$$\overline{L_{\mathbf{E},0}}=L_{\mathbf{E},\min}=L_{\mathbf{E},\max}=L^*_{\mathbf{E},0},\qquad \mathcal{D}(\overline{L_{\mathbf{E},0}})=H^2(M,\mathbf{E}).\tag{11.6}$$

This realization is self-adjoint, nonnegative, and agrees with the Friedrichs realization. In particular, $L_{\mathbf{E},0}$ is essentially self-adjoint.

Proof. The differential operator $L_{\mathbf{E},0}$ is elliptic of order two and formally self-adjoint. Theorem 11.4.4 gives $L_{\mathbf{E},\min}=L_{\mathbf{E},\max}$ with domain $H^2(M,\mathbf{E})$. By the definition of the adjoint of a densely defined operator and

the formal adjoint identity,

$$\mathbf{v} \in \mathcal{D}(L^*_{\mathbf{E},0}) \iff L_{\mathbf{E},0}\mathbf{v} \in L^2(M,\mathbf{E}) \text{ distributionally}, \qquad L^*_{\mathbf{E},0}\mathbf{v} = L_{\mathbf{E},0}\mathbf{v};$$

hence $L^*_{\mathbf{E},0} = L_{\mathbf{E},\max}$. Since the minimal realization is the closure of the initial operator, we obtain (11.6), and equality with its adjoint proves self-adjointness.
For $\mathbf{u} \in \Gamma(\mathbf{E})$,

$$\langle L_{\mathbf{E},0}\mathbf{u}, \mathbf{u}\rangle_{L^2(M,\mathbf{E})} = \|\nabla^{\mathbf{E}}\mathbf{u}\|^2_{L^2(M,T^*M\otimes\mathbf{E})} \geq 0.$$

Taking the closure preserves nonnegativity. The Friedrichs realization is a self-adjoint extension of $L_{\mathbf{E},0}$ contained in $L^*_{\mathbf{E},0}$; since the minimal and maximal realizations agree, there is no distinct intermediate closed extension, and the Friedrichs realization is the one in (11.6). The equality $\overline{L_{\mathbf{E},0}} = L^*_{\mathbf{E},0}$ is precisely essential self-adjointness of the initial operator. □

11.5 Powers of the Bochner Laplacian

The equivalence in Theorem 9.1.42 was obtained by integration by parts and commutation identities for covariant derivatives. Elliptic theory allows us to interpret it as an equivalence of graph norms.

Corollary 11.5.1. (Powers of the Laplacian and Sobolev norms) Let $(M,\mathbf{g})$ be a closed Riemannian manifold, and let $\mathbf{E} \to M$ be a smooth vector bundle with a real or Hermitian bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. Let $L_{\mathbf{E}} = (\nabla^{\mathbf{E}})^*_h\nabla^{\mathbf{E}}$ be the realization in (11.6). For every $q \in \mathbb{N}$,

$$\mathcal{D}(L^q_{\mathbf{E}}) = H^{2q}(M,\mathbf{E}),$$

and there exist constants $c_q, C_q > 0$ such that

$$c_q\|\mathbf{u}\|_{H^{2q}(M,\mathbf{E})} \leq \|\mathbf{u}\|_{L^2(M,\mathbf{E})} + \|L^q_{\mathbf{E}}\mathbf{u}\|_{L^2(M,\mathbf{E})} \leq C_q\|\mathbf{u}\|_{H^{2q}(M,\mathbf{E})}.$$

Moreover,

$$\bigcap_{q=1}^{\infty} \mathcal{D}(L^q_{\mathbf{E}}) = \Gamma(\mathbf{E}).$$

Proof. Proposition 11.1.5 and Example 11.1.10 show that the differential operator $((\nabla^{\mathbf{E}})^*_h\nabla^{\mathbf{E}})^q$ is elliptic of order $2q$. Theorem 11.4.4 gives its maximal domain $H^{2q}(M,\mathbf{E})$ and constants $c_q, C_q > 0$ such that

$$c_q\|\mathbf{u}\|_{H^{2q}(M,\mathbf{E})} \leq \|\mathbf{u}\|_{L^2(M,\mathbf{E})} + \|L^q_{\mathbf{E}}\mathbf{u}\|_{L^2(M,\mathbf{E})} \leq C_q\|\mathbf{u}\|_{H^{2q}(M,\mathbf{E})}.$$

The operator $L_{\mathbf{E}}$ is nonnegative and self-adjoint. By the spectral theorem B.4.6, the power $L^q_{\mathbf{E}}$ is closed. On $\Gamma(\mathbf{E})$, it agrees with the differential power $L^q_{\mathbf{E},0}$ and therefore extends that initial operator. Moreover, if $\mathbf{u} \in \mathcal{D}(L^q_{\mathbf{E}})$, then $L^q_{\mathbf{E},0}\mathbf{u} = L^q_{\mathbf{E}}\mathbf{u} \in L^2(M,\mathbf{E})$ in the distributional sense; thus $L^q_{\mathbf{E}}$ is contained in the maximal realization of $L^q_{\mathbf{E},0}$. Theorem 11.4.4, applied to the elliptic operator $L^q_{\mathbf{E},0}$, states that its minimal and maximal realizations agree. Consequently,

$$(L^q_{\mathbf{E},0})_{\min} \subseteq L^q_{\mathbf{E}} \subseteq (L^q_{\mathbf{E},0})_{\max} = (L^q_{\mathbf{E},0})_{\min},$$

and the three realizations are equal. The domain identity and both estimates follow. The direct inequality can also be read from Theorem 9.1.42, where the $H^{2q}(M,\mathbf{E})$ norm is expressed in terms of powers of the Laplacian and intermediate covariant derivatives.
If $\mathbf{u}$ belongs to all the domains, then $\mathbf{u} \in H^{2q}(M,\mathbf{E})$ for every q. The local Sobolev embeddings imply $\mathbf{u} \in C^k(M,\mathbf{E})$ for each k, so $\mathbf{u}$ is smooth. The reverse inclusion is immediate. □

Remark 11.5.2. On a complete, noncompact manifold without boundary, local elliptic regularity remains valid, but a global estimate with a single constant requires uniform control of the geometry and the coefficients. Analogous estimates hold under bounded geometry hypotheses; we will return to this point in the corresponding chapter.

The principal symbol constructed here is also the symbol that enters index theory. If $\pi\colon T^*M \longrightarrow M$ is the projection, an elliptic operator determines an isomorphism over $T^*M \setminus 0_M$

$$\pi^*\mathbf{E} \longrightarrow \pi^*\mathbf{F}, \qquad (x,\xi,v) \longmapsto (x,\xi,\boldsymbol{\sigma}_m(P)(x,\xi)v).$$

The restriction of this isomorphism to the cosphere bundle contains the topological information that will be used later. This covariant formulation agrees with the one developed in [21, Definition 6.36 and Chapter 9].

12

Fractional Sobolev spaces on vector bundles and the heat kernel: an intrinsic approach

The integer-order Sobolev spaces studied in the preceding chapters are constructed using the covariant derivatives $\nabla^j \mathbf{u}$. When the order is no longer an integer, no finite family of derivatives by itself gives an intrinsic definition. One alternative is to choose a nonnegative elliptic operator, construct the semigroup it generates, and define its negative powers through a Laplace integral. This is the viewpoint of Bessel potentials.

The semigroup arises in solving the evolution problem

$$\partial_t \mathbf{u} + L_{\mathbf{E}} \mathbf{u} = 0, \qquad \mathbf{u}(0) = \mathbf{u}_0.$$

Formally, its solution is $\mathbf{u}(t) = e^{-tL_{\mathbf{E}}} \mathbf{u}_0$. Integrating these operators with respect to t with the appropriate weight produces negative powers of $I + L_{\mathbf{E}}$ and, with them, a scale of fractional regularity. Heat thus links a parabolic PDE to the functional calculus of an elliptic operator.

The development proceeds on two levels. In $L^2(M, \mathbf{E})$, we have the Hilbert space structure, closed sesquilinear forms, and spectral calculus for self-adjoint operators. Once the heat semigroup has been constructed on this space, the Kato–Simon inequality allows us to compare it with the scalar semigroup and extend it consistently to $L^p(M, \mathbf{E})$. Bessel potentials are then defined by Bochner integrals. For scalar functions on complete manifolds, this program was developed by Strichartz; see [137, Theorems 3.5 and 4.2]. Here we formulate it directly for sections and prove the covariant steps involved in the construction.

Throughout this chapter, $(M, \mathbf{g})$ will be a connected, complete Riemannian manifold without boundary. The bundle $\mathbf{E} \to M$ will be a smooth real or complex vector bundle of finite rank, equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$, Hermitian in the complex case, and $\nabla^{\mathbf{E}}$ will be a connection compatible with $\mathbf{h}_{\mathbf{E}}$. In the real case, spectral theory is applied to the complexification of $\mathbf{E}$; the Laplacian, semigroup, and Bessel potentials of real order preserve real sections. We write $L^p(M, \mathbf{E})$ for the spaces defined with respect to the Riemann–Lebesgue measure $\lambda_{\mathbf{g}}$. On Sobolev classes, $\nabla^j \mathbf{u}$ denotes the weak covariant derivative $\nabla^j_w \mathbf{u}$.

Heat as a tool for regularity

Since Fourier, the heat equation has served to separate and damp frequencies. On a manifold, the semigroup generated by a Laplacian retains this role, even though global translations are no longer available. Spectral theory constructs heat from the operator; its estimates reveal the geometry of the manifold; and integrals of the semigroup produce Bessel potentials and fractional orders. The same object thus connects evolution, regularization, and functional analysis.

12.1 The connection Laplacian on $L^2(M,\mathbf{E})$

It is useful to establish at the outset the relation between the two signs used in this book. For functions,

$$\Delta_{\mathbf{g}} = \operatorname{div}_{\mathbf{g}} \operatorname{grad}_{\mathbf{g}} = \operatorname{tr}_{\mathbf{g}}(\nabla^2)$$

has Fourier symbol $-|\xi|^2_{\mathbf{g}}$, whereas $d^*d = -\Delta_{\mathbf{g}}$ is nonnegative. For a compatible connection, we similarly define the covariant trace

$$\Delta_{\mathbf{E}}\mathbf{u} := \operatorname{tr}_{\mathbf{g}}(\nabla^2\mathbf{u}), \qquad (\nabla^{\mathbf{E}})^*_h\nabla^{\mathbf{E}} = -\Delta_{\mathbf{E}}$$

on compactly supported smooth sections; the trace contracts the first two derivative indices of $\nabla^2\mathbf{u}$. The operator $L_{\mathbf{E}}$ constructed below is the nonnegative realization of $(\nabla^{\mathbf{E}})^*_h\nabla^{\mathbf{E}}$; thus the equation $\partial_t\mathbf{u} + L_{\mathbf{E}}\mathbf{u} = 0$ is equivalent, in the smooth setting, to $\partial_t\mathbf{u} = \Delta_{\mathbf{E}}\mathbf{u}$.

12.1.1 The realization determined by the energy form

The Bochner Laplacian was defined in Definition 8.2.10. In this chapter, we use the notation

$$L_{\mathbf{E},0} := \Delta_B \restriction_{\Gamma_c(\mathbf{E})} = (\nabla^{\mathbf{E}})^*_h\nabla^{\mathbf{E}} = -\operatorname{tr}_{\mathbf{g}}(\nabla^2), \qquad \mathcal{D}(L_{\mathbf{E},0}) = \Gamma_c(\mathbf{E}),$$

for its initial restriction to compactly supported smooth sections. Its distributional action requires no new definition: it is obtained by applying Proposition 10.2.18 to the differential operator $L_{\mathbf{E},0}$. In particular, if $\mathbf{u} \in \mathcal{D}'(M,\mathbf{E})$, the expression $L_{\mathbf{E},0}\mathbf{u}$ has the meaning established in the chapter on distributions on vector bundles.

The local formula for the Bochner Laplacian, proved in the chapter on partial differential operators, gives

$$L_{\mathbf{E},0}\mathbf{u} = -\sum_{i=1}^{n}\left(\nabla^{\mathbf{E}}_{\mathbf{e}_i}\nabla^{\mathbf{E}}_{\mathbf{e}_i}\mathbf{u} - \nabla^{\mathbf{E}}_{\nabla^{TM}_{\mathbf{e}_i}\mathbf{e}_i}\mathbf{u}\right)$$

in any local orthonormal frame $(\mathbf{e}_1,\dots,\mathbf{e}_n)$ of TM. Example 11.1.10 shows that its principal symbol is $-|\xi|^2_{\mathbf{g}}\operatorname{Id}_{\mathbf{E}_x}$; it is therefore elliptic.

Notation 12.1.1. (Connection Laplacian) In what follows, we call the preceding operator $L_{\mathbf{E},0}$ the **initial connection Laplacian**. The letter $L_{\mathbf{E}}$ is reserved for its self-adjoint realization on $L^2(M,\mathbf{E})$.

Corollary 12.1.2. (The closed case) If, in addition, M is closed, the elliptic results already proved give

$$\overline{L_{\mathbf{E},0}} = L_{\mathbf{E},\min} = L_{\mathbf{E},\max} = L^*_{\mathbf{E},0}, \qquad \mathcal{D}(\overline{L_{\mathbf{E},0}}) = H^2(M,\mathbf{E}).$$

The common realization is self-adjoint, nonnegative, and agrees with the Friedrichs realization. In particular, the initial operator $L_{\mathbf{E},0}$ is essentially self-adjoint.

Proof. This is Corollary 11.4.5, obtained from elliptic regularity, equality of the minimal and maximal realizations, and formal adjunction. □

Proposition 12.1.3. Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. The operator $L_{\mathbf{E},0}$ is densely defined, symmetric, and nonnegative. For any $\mathbf{u},\mathbf{v}\in\Gamma_c(\mathbf{E})$, we have

$$\langle L_{\mathbf{E},0}\mathbf{u},\mathbf{v}\rangle_{L^2(M,\mathbf{E})}=\int_M\langle\nabla^{\mathbf{E}}\mathbf{u},\nabla^{\mathbf{E}}\mathbf{v}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\,d\lambda_{\mathbf{g}}=\langle\mathbf{u},L_{\mathbf{E},0}\mathbf{v}\rangle_{L^2(M,\mathbf{E})}.$$

In particular,

$$\langle L_{\mathbf{E},0}\mathbf{u},\mathbf{u}\rangle_{L^2(M,\mathbf{E})}=\|\nabla^{\mathbf{E}}\mathbf{u}\|^2_{L^2(M,T^*M\otimes\mathbf{E})}.$$

Proof. Density of $\Gamma_c(\mathbf{E})$ in $L^2(M,\mathbf{E})$ was proved in the chapter on Sobolev spaces on bundles. The first equality is the integration-by-parts formula characterizing $(\nabla^{\mathbf{E}})^*_h$; the second follows by interchanging $\mathbf{u}$ and $\mathbf{v}$ and using the Hermitian symmetry of the inner product. Taking $\mathbf{v}=\mathbf{u}$ gives the last identity and hence nonnegativity. □

Define on $\Gamma_c(\mathbf{E})$ the form

$$\mathfrak{q}_{\mathbf{E}}(\mathbf{u},\mathbf{v}):=\int_M\langle\nabla^{\mathbf{E}}\mathbf{u},\nabla^{\mathbf{E}}\mathbf{v}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\,d\lambda_{\mathbf{g}}.$$

Its closure has domain $W^{1,2}_0(M,\mathbf{E})$. To identify this space with $W^{1,2}(M,\mathbf{E})$, we need cutoff functions whose gradients tend uniformly to zero. Before constructing them, we give a detailed proof of the existence of a smooth exhaustion function with bounded gradient.

Lemma 12.1.4. (Smoothing Lipschitz functions) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary. Let $f\colon M\longrightarrow\mathbb{R}$ be an L-Lipschitz function with respect to the Riemannian distance, and let $\varepsilon>0$. There exists $h\in C^\infty(M)$ such that

$$|h-f|<\varepsilon\qquad\text{and}\qquad|dh|_{\mathbf{g}}\le L+\varepsilon$$

throughout M.

Proof. If $L=0$, connectedness of M implies that f is constant, and it suffices to take $h=f$. Suppose that $L>0$ and fix

$$\theta:=\min\left\{\frac{1}{4},\frac{\varepsilon}{16L}\right\}.$$

For each $p\in M$, Proposition 2.8.10, applied with this value of θ, provides a regular normal coordinate ball U_p and a normal chart $\kappa_p\colon U_p\longrightarrow B_{\mathrm{euc}}(0,r_p)$ such that, for every $z\in B_{\mathrm{euc}}(0,r_p)$ and $w\in\mathbb{R}^n$,

$$(1-\theta)\|w\|\le\left|d(\kappa_p^{-1})_z w\right|_{\mathbf{g}}\le(1+\theta)\|w\|.$$

These balls cover M. Consider the family $\mathcal{B}$ of regular coordinate balls V for which $\overline{V} \subseteq U_p$ for some $p \in M$. This family is a basis: if $q \in O$ and O is open, choose p with $q \in U_p$ and, inside the Euclidean open subset $\kappa_p(O \cap U_p)$, two concentric balls centered at $\kappa_p(q)$ whose radii satisfy $0 < s < s'$ and whose closed ball of radius s' is contained in $\kappa_p(O \cap U_p)$. The preimage of the ball of radius s is a regular coordinate ball V such that $q \in V$ and $\overline{V} \subseteq O \cap U_p$, in accordance with Definition 1.2.9. Theorem 1.2.8 allows us to choose from $\mathcal{B}$ a countable, locally finite refinement $(V_j)_{j\in\mathbb{N}}$ of the cover $(U_p)_{p\in M}$. For each j, fix a normal ball U_j from the original cover such that $\overline{V}_j \subseteq U_j$, and denote its normal chart by $\kappa_j \colon U_j \longrightarrow B_{\mathrm{euc}}(0, r_j)$. Let $(\varphi_j)_{j\in\mathbb{N}}$ be a smooth partition of unity subordinate to $(V_j)_{j\in\mathbb{N}}$, whose existence is guaranteed by Theorem 1.3.5. Since $\operatorname{supp}(\varphi_j)$ is closed in M and contained in the compact set $\overline{V}_j$, the numbers

$$C_j := \|d\varphi_j\|_{L^\infty(M,T^*M)}, \qquad \delta_j := \min\left\{\frac{\varepsilon}{4}, \frac{\varepsilon}{2^{j+4}(1+C_j)}\right\}$$

are well defined, with $C_j \geq 0$ and $\delta_j > 0$.

Fix $j \in \mathbb{N}$ and write $F_j := f \circ \kappa_j^{-1}$. If $z, z' \in B_{\mathrm{euc}}(0, r_j)$, the segment joining them remains in this Euclidean ball. The curve $\gamma(t) := \kappa_j^{-1}((1-t)z + tz')$ lies in U_j and satisfies

$$d_{\mathbf{g}}\big(\kappa_j^{-1}(z), \kappa_j^{-1}(z')\big) \leq L_{\mathbf{g}}(\gamma) \leq (1+\theta)\|z - z'\|.$$

Since f is L-Lipschitz with respect to $d_{\mathbf{g}}$, it follows that

$$|F_j(z) - F_j(z')| \leq L(1+\theta)\|z - z'\|.$$

Thus F_j is L_j-Lipschitz, where $L_j := L(1+\theta)$. McShane's extension theorem, Theorem B.1.6, gives an extension $\widetilde{F}_j \colon \mathbb{R}^n \longrightarrow \mathbb{R}$ with the same constant L_j. Take the mollifier ρ from Theorem B.9.1 and set

$$\tau_j := \min\left\{1, \frac{\delta_j}{2L_j m_1(\rho)}\right\}, \qquad f_j := \big(\widetilde{F}_j * \rho_{\tau_j}\big) \circ \kappa_j \quad \text{in } U_j.$$

The estimates in that theorem imply $|f_j - f| \leq \dfrac{\delta_j}{2}$ on U_j and $\|D(\widetilde{F}_j * \rho_{\tau_j})\| \leq L_j$. If $q \in U_j$, $z = \kappa_j(q)$, and $v \in T_qM$ satisfies $|v|_{\mathbf{g}} = 1$, the first metric inequality gives $\|d\kappa_j(v)\| \leq \dfrac{1}{1-\theta}$. Therefore

$$|df_j|_{\mathbf{g}} \leq \sup_{\substack{v\in T_qM \\ |v|_{\mathbf{g}}=1}} \Big|D(\widetilde{F}_j * \rho_{\tau_j})_z\big(d\kappa_j(v)\big)\Big| \leq \frac{L_j}{1-\theta} = L\frac{1+\theta}{1-\theta}.$$

Moreover,

$$L\frac{1+\theta}{1-\theta} - L = \frac{2L\theta}{1-\theta} \leq \frac{\varepsilon}{6}.$$

Indeed, if $\theta = \dfrac{\varepsilon}{16L}$, use $\theta \leq \dfrac{1}{4}$; if $\theta = \dfrac{1}{4}$, then $\varepsilon \geq 4L$ and the same bound follows.

Each product $\varphi_j f_j$, defined to be zero outside U_j, is smooth because $\operatorname{supp}(\varphi_j) \subseteq V_j \Subset U_j$. Define $h := \displaystyle\sum_{j=1}^{\infty} \varphi_j f_j$.

The sum is locally finite, so $h \in C^\infty(M)$. Since $\sum_{j=1}^{\infty} \varphi_j = 1$ and $\varphi_j \geq 0$,

$$|h - f| \leq \sum_{j=1}^{\infty} \varphi_j |f_j - f| \leq \frac{1}{2} \sum_{j=1}^{\infty} \varphi_j \delta_j \leq \frac{\varepsilon}{8} < \varepsilon.$$

The identity $\sum_{j=1}^{\infty} d\varphi_j = 0$ allows us to write, without differentiating the Lipschitz function f,

$$dh = \sum_{j=1}^{\infty} \varphi_j \, df_j + \sum_{j=1}^{\infty} (f_j - f) \, d\varphi_j.$$

By the preceding bounds and local finiteness,

$$|dh|_{\mathbf{g}} \leq L + \frac{\varepsilon}{6} + \frac{1}{2} \sum_{j=1}^{\infty} \delta_j C_j \leq L + \frac{\varepsilon}{6} + \frac{\varepsilon}{2} \sum_{j=1}^{\infty} 2^{-j-4} < L + \varepsilon.$$

This proves both assertions. □

Remark 12.1.5. The preceding proof does not require the balls U_j to be strongly geodesically convex. The convexity used is that of $\kappa_j(U_j) = B_{\mathrm{euc}}(0, r_j)$: the Euclidean segment determines a curve contained in U_j, and its length gives an upper bound for the Riemannian distance. Thus the local control in Proposition 2.8.10 is exactly the geometric result needed.

Proposition 12.1.6. (Exhaustion function with bounded gradient) Let $(M, \mathbf{g})$ be a connected, complete Riemannian manifold without boundary. There exists a strictly positive proper function $\rho \in C^\infty(M)$ such that

$$|d\rho|_{\mathbf{g}} \leq 2$$

throughout M.

Proof. Fix $o \in M$ and consider $r(x) := d_{\mathbf{g}}(o, x)$. The triangle inequality shows that r is 1-Lipschitz. Since M is complete, the Hopf–Rinow theorem, Theorem 2.9.9, implies that the closed balls $\overline{B}_{\mathbf{g}}(o, R)$ are compact; hence r is proper.

Apply Lemma 12.1.4 to r with $\varepsilon = 1$. We obtain $h \in C^\infty(M)$ such that $|h - r| < 1$ and $|dh|_{\mathbf{g}} \leq 2$. In particular, $|h(o)| < 1$ because $r(o) = 0$. Set $\rho := h - h(o) + 2$. This function is strictly positive because

$$\rho(x) \geq r(x) - 1 - h(o) + 2 \geq 1 - h(o) > 0,$$

, and it is proper: if $\rho(x) \leq R$, then $r(x) \leq R + h(o) - 1$, so the sublevel set $\{\rho \leq R\}$ is contained in a closed ball and is closed; by Theorem 2.9.9, it is compact. Finally, $d\rho = dh$, so $|d\rho|_{\mathbf{g}} \leq 2$. □

Lemma 12.1.7. (Cutoff functions on complete manifolds) Let $(M, \mathbf{g})$ be a connected, complete Riemannian manifold without boundary. There exists a sequence $(\chi_j)_{j \in \mathbb{N}} \subseteq C_c^\infty(M)$ such that $0 \leq \chi_j \leq 1$, $\chi_j \to 1$

uniformly on every compact set, and

$$\|d\chi_j\|_{L^\infty(M,T^*M)} \longrightarrow 0.$$

Proof. Let ρ be the function in Proposition 12.1.6. Choose a nonincreasing function $\eta \in C^\infty(\mathbb{R})$ such that $0 \le \eta \le 1$, $\eta(s) = 1$ for $s \le 1$, and $\eta(s) = 0$ for $s \ge 2$, and define

$$\chi_j(x) := \eta\left(\frac{\rho(x)}{j}\right).$$

The support of χ_j is contained in the sublevel set $\{\rho \le 2j\}$, which is compact because ρ is proper. Since $\rho > 0$ and η is nonincreasing, the sequence (χ_j) is increasing. If $K \subseteq M$ is compact and $R_K := \max_{x\in K} \rho(x)$, then $\chi_j = 1$ on K for every integer $j \ge \max\{1, \lceil R_K \rceil\}$. In particular, χ_j converges pointwise to 1. Finally,

$$|d\chi_j|_{\mathbf{g}} = \frac{1}{j}\left|\eta'\left(\frac{\rho}{j}\right)\right| |d\rho|_{\mathbf{g}} \le \frac{2\|\eta'\|_{L^\infty(\mathbb{R})}}{j},$$

which proves the asserted convergence. □

Proposition 12.1.8. Let $(M, \mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Then $W_0^{1,2}(M, \mathbf{E}) = W^{1,2}(M, \mathbf{E})$.

Proof. Let $\mathbf{u} \in W^{1,2}(M, \mathbf{E})$, and let (χ_j) be the functions in the preceding lemma. The weak Leibniz rule gives

$$\nabla^{\mathbf{E}}(\chi_j \mathbf{u}) = d\chi_j \otimes \mathbf{u} + \chi_j \nabla^{\mathbf{E}} \mathbf{u}.$$

Since $0 \le \chi_j \le 1$ and $\chi_j \to 1$ pointwise, we have

$$|(1-\chi_j)\mathbf{u}|^2_{\mathbf{h}_{\mathbf{E}}} \le |\mathbf{u}|^2_{\mathbf{h}_{\mathbf{E}}}, \qquad |(1-\chi_j)\nabla^{\mathbf{E}}\mathbf{u}|^2_{\mathbf{g},\mathbf{h}_{\mathbf{E}}} \le |\nabla^{\mathbf{E}}\mathbf{u}|^2_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}.$$

Both dominating functions are integrable. Lebesgue's dominated convergence theorem B.6.14 implies

$$(1-\chi_j)\mathbf{u} \longrightarrow 0 \quad \text{in } L^2(M, \mathbf{E})$$

and

$$(1-\chi_j)\nabla^{\mathbf{E}}\mathbf{u} \longrightarrow 0 \quad \text{in } L^2(M, T^*M \otimes \mathbf{E}).$$

Moreover,

$$\|d\chi_j \otimes \mathbf{u}\|_{L^2(M,T^*M\otimes\mathbf{E})} \le \|d\chi_j\|_{L^\infty(M,T^*M)} \|\mathbf{u}\|_{L^2(M,\mathbf{E})} \longrightarrow 0.$$

Therefore $\chi_j \mathbf{u} \to \mathbf{u}$ in $W^{1,2}(M, \mathbf{E})$. For each j, the Meyers–Serrin theorem for bundles, Theorem 9.1.48, approximates $\chi_j \mathbf{u}$ in $W^{1,2}(M, \mathbf{E})$ by smooth sections $\mathbf{u}_{j,k}$. Choose $\zeta_j \in C_c^\infty(M)$ equal to 1 on a neighborhood of $\operatorname{supp}(\chi_j \mathbf{u})$. Since multiplication by ζ_j is continuous on $W^{1,2}(M, \mathbf{E})$, we have $\zeta_j \mathbf{u}_{j,k} \to \chi_j \mathbf{u}$, and now $\zeta_j \mathbf{u}_{j,k} \in \Gamma_c(\mathbf{E})$. Thus $\mathbf{u} \in W_0^{1,2}(M, \mathbf{E})$. □

The closure of $\mathfrak{q}_{\mathbf{E}}$ is therefore a densely defined, symmetric, nonnegative, closed sesquilinear form with domain $W^{1,2}(M, \mathbf{E})$.

Theorem 12.1.9. (Friedrichs realization of the connection Laplacian) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. There exists a unique nonnegative self-adjoint operator

$$L_{\mathbf{E}}\colon \mathcal{D}(L_{\mathbf{E}})\subseteq L^2(M,\mathbf{E})\longrightarrow L^2(M,\mathbf{E})$$

such that $\mathcal{D}(L_{\mathbf{E}})\subseteq W^{1,2}(M,\mathbf{E})$ and

$$\mathfrak{q}_{\mathbf{E}}(\mathbf{u},\mathbf{v})=\langle L_{\mathbf{E}}\mathbf{u},\mathbf{v}\rangle_{L^2(M,\mathbf{E})},\qquad \mathbf{u}\in\mathcal{D}(L_{\mathbf{E}}),\quad \mathbf{v}\in W^{1,2}(M,\mathbf{E}).$$

Its domain is

$$\mathcal{D}(L_{\mathbf{E}})=\left\{\mathbf{u}\in W^{1,2}(M,\mathbf{E})\;\middle|\;\begin{array}{l}\text{there exists } \mathbf{f}\in L^2(M,\mathbf{E}) \text{ such that}\\ \mathfrak{q}_{\mathbf{E}}(\mathbf{u},\mathbf{v})=\langle \mathbf{f},\mathbf{v}\rangle_{L^2(M,\mathbf{E})} \text{ for every } \mathbf{v}\in W^{1,2}(M,\mathbf{E})\end{array}\right\},$$

and, in this case, $L_{\mathbf{E}}\mathbf{u}=\mathbf{f}$. Moreover, $L_{\mathbf{E}}$ extends $L_{\mathbf{E},0}$.

Proof. Existence, uniqueness, and the characterization of the domain follow from Theorem B.4.2. If $\mathbf{u}\in\Gamma_c(\mathbf{E})$, Proposition 12.1.3 gives

$$\mathfrak{q}_{\mathbf{E}}(\mathbf{u},\mathbf{v})=\langle L_{\mathbf{E},0}\mathbf{u},\mathbf{v}\rangle_{L^2(M,\mathbf{E})}$$

for $\mathbf{v}\in\Gamma_c(\mathbf{E})$. Both sides depend continuously on $\mathbf{v}$ in the $W^{1,2}(M,\mathbf{E})$ norm, and $\Gamma_c(\mathbf{E})$ is dense in that space by Proposition 12.1.8. The identity extends to all of $\mathbf{v}\in W^{1,2}(M,\mathbf{E})$, which proves that $\mathbf{u}\in\mathcal{D}(L_{\mathbf{E}})$ and $L_{\mathbf{E}}\mathbf{u}=L_{\mathbf{E},0}\mathbf{u}$. □

Theorem 12.1.10. (Essential self-adjointness) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. The operator $L_{\mathbf{E},0}$ is essentially self-adjoint on $L^2(M,\mathbf{E})$, and its closure agrees with $L_{\mathbf{E}}$.

Proof. Since $L_{\mathbf{E},0}$ is symmetric and nonnegative, Proposition B.4.5 reduces the proof to verifying that $\ker(L_{\mathbf{E},0}^{*}+I)=\{0\}$. Let $\mathbf{u}$ belong to this kernel. Then

$$L_{\mathbf{E},0}\mathbf{u}=-\mathbf{u}$$

in the distributional sense. Theorem 11.4.2, applied to the elliptic operator $L_{\mathbf{E},0}+I$, implies that $\mathbf{u}$ is smooth. Take the cutoff functions (χ_j) from Lemma 12.1.7. The Leibniz identities

$$\nabla^{\mathbf{E}}(\chi_j\mathbf{u})=d\chi_j\otimes\mathbf{u}+\chi_j\nabla^{\mathbf{E}}\mathbf{u}$$

and

$$\nabla^{\mathbf{E}}(\chi_j^2\mathbf{u})=2\chi_j d\chi_j\otimes\mathbf{u}+\chi_j^2\nabla^{\mathbf{E}}\mathbf{u}$$

give, after expanding and taking real parts,

$$|\nabla^{\mathbf{E}}(\chi_j\mathbf{u})|^2_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}=\operatorname{Re}\langle\nabla^{\mathbf{E}}\mathbf{u},\nabla^{\mathbf{E}}(\chi_j^2\mathbf{u})\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}+|d\chi_j\otimes\mathbf{u}|^2_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}.$$

The section $\chi_j^2\mathbf{u}$ is smooth and compactly supported. Integrating and using the definition of the distributional adjoint,

$$\|\nabla^{\mathbf{E}}(\chi_j\mathbf{u})\|^2_{L^2(M,T^*M\otimes\mathbf{E})} = \mathrm{Re}\langle L^*_{\mathbf{E},0}\mathbf{u}, \chi_j^2\mathbf{u}\rangle_{L^2(M,\mathbf{E})} + \|d\chi_j\otimes\mathbf{u}\|^2_{L^2(M,T^*M\otimes\mathbf{E})}.$$

Since $L^*_{\mathbf{E},0}\mathbf{u} = -\mathbf{u}$,

$$0 \le \|\nabla^{\mathbf{E}}(\chi_j\mathbf{u})\|^2_{L^2(M,T^*M\otimes\mathbf{E})} = -\|\chi_j\mathbf{u}\|^2_{L^2(M,\mathbf{E})} + \|d\chi_j\otimes\mathbf{u}\|^2_{L^2(M,T^*M\otimes\mathbf{E})}.$$

Therefore

$$\|\chi_j\mathbf{u}\|^2_{L^2(M,\mathbf{E})} \le \|d\chi_j\|^2_{L^\infty(M,T^*M)}\|\mathbf{u}\|^2_{L^2(M,\mathbf{E})} \longrightarrow 0.$$

On the other hand, $|\chi_j\mathbf{u}-\mathbf{u}|^2_{\mathbf{h}_\mathbf{E}} = |1-\chi_j|^2|\mathbf{u}|^2_{\mathbf{h}_\mathbf{E}} \le |\mathbf{u}|^2_{\mathbf{h}_\mathbf{E}}$, the dominating function belongs to $L^1(M)$, and $\chi_j\mathbf{u}\to\mathbf{u}$ pointwise. Lebesgue's dominated convergence theorem B.6.14 then gives $\|\chi_j\mathbf{u}-\mathbf{u}\|_{L^2(M,\mathbf{E})}\to 0$. Since at the same time $\|\chi_j\mathbf{u}\|_{L^2(M,\mathbf{E})}\to 0$, it follows that $\mathbf{u}=0$. □

12.1.2 The spectral semigroup and the scalar semigroup

For $t\ge 0$, define

$$P_t^{\mathbf{E}} := e^{-tL_{\mathbf{E}}}$$

by spectral calculus. On the trivial bundle of rank one, we write $L = \Delta_B = -\Delta$ for the positive scalar realization and $P_t = e^{-tL}$.

Theorem 12.1.11. (Covariant heat semigroup on L^2) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. The family $(P_t^{\mathbf{E}})_{t\ge0}$ satisfies:

(a) $P_0^{\mathbf{E}} = I$ and $P_{t+s}^{\mathbf{E}} = P_t^{\mathbf{E}}P_s^{\mathbf{E}}$ for $s,t\ge 0$;

(b) each $P_t^{\mathbf{E}}$ is self-adjoint and $\|P_t^{\mathbf{E}}\|_{\mathcal{L}(L^2(M,\mathbf{E}))}\le 1$;

(c) $P_t^{\mathbf{E}}\mathbf{u}\to\mathbf{u}$ in $L^2(M,\mathbf{E})$ as $t\to 0^+$;

(d) if $t>0$, then $P_t^{\mathbf{E}}\mathbf{u}\in\mathcal{D}(L_{\mathbf{E}}^m)$ for every $m\in\mathbb{N}$;

(e) for $\mathbf{u}\in L^2(M,\mathbf{E})$, the map $t\mapsto P_t^{\mathbf{E}}\mathbf{u}$ is differentiable in $(0,\infty)$ and

$$\frac{d}{dt}P_t^{\mathbf{E}}\mathbf{u} = -L_{\mathbf{E}}P_t^{\mathbf{E}}\mathbf{u};$$

if $\mathbf{u}\in\mathcal{D}(L_{\mathbf{E}})$, the right derivative at $t=0$ exists and equals $-L_{\mathbf{E}}\mathbf{u}$.

Proof. This is Proposition B.4.9 applied to $A = L_{\mathbf{E}}$. For regularization, it suffices to observe that, if $t>0$, the function $\lambda\mapsto\lambda^m e^{-t\lambda}$ is bounded on $[0,\infty)$. □

Before comparing the scalar and covariant semigroups, we need positivity of the scalar resolvent.

Lemma 12.1.12. (Positivity and uniform bound for the scalar resolvent) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary. Let $\lambda>0$ and let $R_\lambda = (\lambda I + L)^{-1}$. Then:

(a) if $f\in L^2(M)$ is real and $f\ge 0$, then $R_\lambda f\ge 0$ almost everywhere;

(b) if $f \in L^2(M)\cap L^\infty(M)$, then

$$\|R_\lambda f\|_{L^\infty(M)} \le \frac{1}{\lambda}\|f\|_{L^\infty(M)}.$$

Proof. Let $u = R_\lambda f$. The variational characterization of the resolvent, Corollary B.4.3, gives

$$\int_M \langle du, d\varphi\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}} + \lambda \int_M u\varphi\, d\lambda_{\mathbf{g}} = \int_M f\varphi\, d\lambda_{\mathbf{g}}$$

for every $\varphi \in W^{1,2}(M)$.

First suppose that $f \ge 0$ and take $u_- := \max\{-u, 0\}$. Theorem 9.1.49, applied to the negative part, gives $u_- \in W^{1,2}(M)$ and

$$du_- = -\mathbf{1}_{\{u<0\}}\, du$$

almost everywhere. Choosing $\varphi = u_-$ yields

$$-\|du_-\|^2_{L^2(M,T^*M)} - \lambda\|u_-\|^2_{L^2(M)} = \int_M f u_-\, d\lambda_{\mathbf{g}} \ge 0.$$

The left-hand side is nonpositive; therefore $u_- = 0$.

For the uniform bound, we may first assume that f is real. The resolvent preserves real-valued functions because its defining form has real coefficients. Let $c = \frac{\|f\|_{L^\infty(M)}}{\lambda}$. If $c = 0$, the first part applied to u and $-u$ gives $u = 0$. Thus suppose that $c > 0$ and set $z = (u-c)_+$. The function z belongs to $W^{1,2}(M)$; moreover, the set $\{u > c\}$ has finite measure because $u \in L^2(M)$, and the Cauchy–Schwarz inequality in Theorem B.3.2 gives $z \in L^1(M)$. On $\{u > c\}$, we have $u = z + c$, whereas $dz = du$. Taking $\varphi = z$,

$$\|dz\|^2_{L^2(M,T^*M)} + \lambda\|z\|^2_{L^2(M)} + \lambda c\int_M z\, d\lambda_{\mathbf{g}} = \int_M fz\, d\lambda_{\mathbf{g}} \le \lambda c\int_M z\, d\lambda_{\mathbf{g}}.$$

Thus $z = 0$ and $u \le c$. Applying the same argument to $-u$ gives $|u| \le c$. Now let f be complex-valued, and write again $u = R_\lambda f$. The resolvent preserves real-valued functions and is positive. For each $\theta \in \mathbb{R}$,

$$\mathrm{Re}(e^{-i\theta}u) = R_\lambda\big(\mathrm{Re}(e^{-i\theta}f)\big) \le R_\lambda|f|.$$

The identity $|z| = \sup_{\theta\in 2\pi\mathbb{Q}} \mathrm{Re}(e^{-i\theta}z)$, valid for every $z \in \mathbb{C}$, and countability of $2\pi\mathbb{Q}$ allow us to take the supremum outside a single null set. Thus $|R_\lambda f| \le R_\lambda|f|$ almost everywhere. Applying the real-valued bound already proved to $|f|$ yields $|u| \le \frac{1}{\lambda}\|f\|_{L^\infty(M)}$. □

Corollary 12.1.13. (Sub-Markov property of the scalar semigroup) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary. The semigroup $(P_t)_{t\ge 0}$ preserves positivity. Moreover, for $f \in L^2(M)\cap L^\infty(M)$,

$$\|P_t f\|_{L^\infty(M)} \le \|f\|_{L^\infty(M)}.$$

Proof. The exponential formula in Proposition B.4.16, applied to the generator $-L$, gives

$$P_t f = \lim_{n\to\infty}\left(I + \frac{t}{n}L\right)^{-n} f$$

in $L^2(M)$. Each factor is

$$\left(I + \frac{t}{n}L\right)^{-1} = \frac{n}{t}\left(\frac{n}{t}I + L\right)^{-1}$$

and, by the preceding lemma, preserves positivity and is a contraction on $L^\infty(M)$. The iterates have the same properties. From convergence in $L^2(M)$, extract a subsequence converging almost everywhere; passage to the limit preserves positivity and the pointwise bound. □

12.1.3 The Kato–Simon inequality

The weak Kato inequality, Corollary 9.5.7, asserts that if $\mathbf{u} \in W^{1,2}(M,\mathbf{E})$, then $|\mathbf{u}|_{\mathbf{h_E}} \in W^{1,2}(M)$ and

$$|d|\mathbf{u}|_{\mathbf{h_E}}|_{\mathbf{g}} \le |\nabla^{\mathbf{E}}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$$

almost everywhere. To obtain semigroup domination, we first prove a resolvent inequality.

Lemma 12.1.14. (Resolvent domination) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. For $\lambda > 0$ and $\mathbf{f} \in L^2(M,\mathbf{E})$,

$$\left|(\lambda I + L_{\mathbf{E}})^{-1}\mathbf{f}\right|_{\mathbf{h_E}} \le (\lambda I + L)^{-1}|\mathbf{f}|_{\mathbf{h_E}}$$

almost everywhere.

Proof. Set

$$\mathbf{u} := (\lambda I + L_{\mathbf{E}})^{-1}\mathbf{f}$$

and, for $\varepsilon > 0$,

$$a_\varepsilon := \left(|\mathbf{u}|^2_{\mathbf{h_E}} + \varepsilon^2\right)^{\frac{1}{2}}.$$

The function a_ε belongs to $W^{1,2}_{\mathrm{loc}}(M)$, and

$$da_\varepsilon(\mathbf{X}) = \frac{\mathrm{Re}\langle\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u},\mathbf{u}\rangle_{\mathbf{h_E}}}{a_\varepsilon}$$

for almost every point and every vector field $\mathbf{X}$. In particular,

$$|da_\varepsilon|_{\mathbf{g}} \le |\nabla^{\mathbf{E}}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}.$$

Let $0 \le \varphi \in C^\infty_c(M)$. The section

$$\mathbf{v}_\varepsilon := \frac{\varphi}{a_\varepsilon}\mathbf{u}$$

belongs to $W^{1,2}(M,\mathbf{E})$ and has compact support. The variational resolvent equation is the one in Corollary B.4.3 applied to the form $\mathfrak{q}_{\mathbf{E}}$:

$$\mathfrak{q}_{\mathbf{E}}(\mathbf{u},\mathbf{v}_\varepsilon) + \lambda\langle\mathbf{u},\mathbf{v}_\varepsilon\rangle_{L^2(M,\mathbf{E})} = \langle\mathbf{f},\mathbf{v}_\varepsilon\rangle_{L^2(M,\mathbf{E})}.$$

The Leibniz rule gives

$$\nabla^{\mathbf{E}} \mathbf{v}_\varepsilon = \frac{d\varphi}{a_\varepsilon} \otimes \mathbf{u} + \frac{\varphi}{a_\varepsilon} \nabla^{\mathbf{E}} \mathbf{u} - \frac{\varphi}{a_\varepsilon^2} da_\varepsilon \otimes \mathbf{u}.$$

Contracting with $\nabla^{\mathbf{E}} \mathbf{u}$ and taking real parts, the first term produces $\langle da_\varepsilon, d\varphi \rangle_{\mathbf{g}}$. For the other two terms, we obtain

$$\operatorname{Re} \left\langle \nabla^{\mathbf{E}} \mathbf{u}, \frac{\varphi}{a_\varepsilon} \nabla^{\mathbf{E}} \mathbf{u} - \frac{\varphi}{a_\varepsilon^2} da_\varepsilon \otimes \mathbf{u} \right\rangle_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}} = \frac{\varphi}{a_\varepsilon} \left(|\nabla^{\mathbf{E}} \mathbf{u}|^2_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}} - |da_\varepsilon|^2_{\mathbf{g}} \right) \geq 0.$$

Therefore

$$\operatorname{Re} \mathfrak{q}_{\mathbf{E}}(\mathbf{u}, \mathbf{v}_\varepsilon) \geq \int_M \langle da_\varepsilon, d\varphi \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}}.$$

Moreover,

$$\operatorname{Re} \langle \mathbf{u}, \mathbf{v}_\varepsilon \rangle_{\mathbf{h}_{\mathbf{E}}} = \varphi \frac{|\mathbf{u}|^2_{\mathbf{h}_{\mathbf{E}}}}{a_\varepsilon} = \varphi \left(a_\varepsilon - \frac{\varepsilon^2}{a_\varepsilon} \right),$$

and

$$\operatorname{Re} \langle \mathbf{f}, \mathbf{v}_\varepsilon \rangle_{\mathbf{h}_{\mathbf{E}}} \leq \varphi |\mathbf{f}|_{\mathbf{h}_{\mathbf{E}}} \frac{|\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}}}{a_\varepsilon} \leq \varphi |\mathbf{f}|_{\mathbf{h}_{\mathbf{E}}}.$$

Substituting these estimates into the variational equation,

$$\int_M \langle da_\varepsilon, d\varphi \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} + \lambda \int_M a_\varepsilon \varphi \, d\lambda_{\mathbf{g}} \leq \int_M |\mathbf{f}|_{\mathbf{h}_{\mathbf{E}}} \varphi \, d\lambda_{\mathbf{g}} + \lambda \varepsilon \int_M \varphi \, d\lambda_{\mathbf{g}},$$

since $\frac{\varepsilon^2}{a_\varepsilon} \leq \varepsilon$.

Now let $\varepsilon \to 0^+$. We have $a_\varepsilon \to |\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}}$ pointwise and $|a_\varepsilon - |\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}}| \leq \varepsilon$, so the zeroth-order term converges. Likewise,

$$da_\varepsilon = \frac{\operatorname{Re} \langle \nabla^{\mathbf{E}} \mathbf{u}, \mathbf{u} \rangle_{\mathbf{h}_{\mathbf{E}}}}{a_\varepsilon} \longrightarrow d|\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}}$$

almost everywhere; on the set where $\mathbf{u} = 0$, the weak differential of $|\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}}$ vanishes almost everywhere. Since $|da_\varepsilon|_{\mathbf{g}} \leq |\nabla^{\mathbf{E}} \mathbf{u}|_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}}$ and $d\varphi$ is bounded and compactly supported, Lebesgue's dominated convergence theorem B.6.14 gives

$$\int_M \langle d|\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}}, d\varphi \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} + \lambda \int_M |\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}} \varphi \, d\lambda_{\mathbf{g}} \leq \int_M |\mathbf{f}|_{\mathbf{h}_{\mathbf{E}}} \varphi \, d\lambda_{\mathbf{g}}.$$

Let

$$w := (\lambda I + L)^{-1} |\mathbf{f}|_{\mathbf{h}_{\mathbf{E}}}.$$

Subtracting the weak equation for w, we wish to use the test function

$$z := (|\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}} - w)_+.$$

Theorem 9.1.49, applied to $|\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}} - w$ and the function $t \mapsto t_+$, shows that $z \in W^{1,2}(M)$ and that

$$dz = \mathbf{1}_{\{|\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}} > w\}} (d|\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}} - dw)$$

almost everywhere. By Proposition 12.1.8, $W^{1,2}(M) = W^{1,2}_0(M)$. To use z as a test function, we combine smooth approximation with nonnegative truncations. Choose $\varphi_j \in C^\infty_c(M)$ with $\varphi_j \to z$ in $W^{1,2}(M)$ and, after passing to a subsequence, assume that $\varphi_j \to z$ almost everywhere. For $\delta > 0$, let $\vartheta_\delta \in C^\infty(\mathbb{R})$ be a

convex function such that

$$\vartheta_\delta(t) = 0 \quad \text{if } t \le 0, \qquad 0 \le \vartheta_\delta'(t) \le 1, \qquad |\vartheta_\delta(t) - t_+| \le \delta.$$

These functions are obtained by integrating a smooth nondecreasing approximation to the indicator function of $(0, +\infty)$. Choose $\delta_j \to 0^+$ so that

$$\delta_j \, \lambda_{\mathbf{g}}(\operatorname{supp} \varphi_j)^{\frac{1}{2}} \longrightarrow 0$$

and define $z_j := \vartheta_{\delta_j}(\varphi_j)$. Then $z_j \in C_c^\infty(M)$, $z_j \ge 0$, and

$$\|z_j - z\|_{L^2(M)} \le \|\varphi_j - z\|_{L^2(M)} + \delta_j \lambda_{\mathbf{g}}(\operatorname{supp} \varphi_j)^{\frac{1}{2}} \longrightarrow 0.$$

The chain rule gives $dz_j = \vartheta_{\delta_j}'(\varphi_j) d\varphi_j$. Therefore

$$|dz_j - dz|_{\mathbf{g}} \le |d\varphi_j - dz|_{\mathbf{g}} + |\vartheta_{\delta_j}'(\varphi_j) - \mathbf{1}_{\{z>0\}}| |dz|_{\mathbf{g}}.$$

The first term converges to zero in $L^2(M, T^*M)$. In the second, the factor multiplying $|dz|_{\mathbf{g}}$ converges to zero almost everywhere: this is immediate on $\{z > 0\}$, whereas $dz = 0$ almost everywhere on the level set $\{z = 0\}$. Since this factor is bounded by 1, Lebesgue's dominated convergence theorem B.6.14 shows that $dz_j \to dz$ in $L^2(M, T^*M)$. Thus $z_j \to z$ in $W^{1,2}(M)$.

The preceding weak inequality is continuous with respect to this norm, since $d|\mathbf{u}|_{\mathbf{h_E}} - dw \in L^2(M, T^*M)$ and $\lambda(|\mathbf{u}|_{\mathbf{h_E}} - w) \in L^2(M)$. We may therefore apply it to z_j and pass to the limit. On the set $\{z > 0\}$, we have $|\mathbf{u}|_{\mathbf{h_E}} - w = z$, and obtain

$$\int_M |dz|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}} + \lambda \int_M z^2 \, d\lambda_{\mathbf{g}} \le 0.$$

Both terms are nonnegative, so $z = 0$ almost everywhere. This is equivalent to $|\mathbf{u}|_{\mathbf{h_E}} \le w$. □

Theorem 12.1.15. (Kato–Simon inequality) Let $(M, \mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. For every $t \ge 0$ and every $\mathbf{u} \in L^2(M, \mathbf{E})$,

$$|P_t^{\mathbf{E}} \mathbf{u}|_{\mathbf{h_E}} \le P_t(|\mathbf{u}|_{\mathbf{h_E}})$$

almost everywhere.

Proof. For $\tau > 0$, the preceding lemma with $\lambda = \frac{1}{\tau}$ is equivalent to

$$\left| (I + \tau L_{\mathbf{E}})^{-1} v \right|_{\mathbf{h_E}} \le (I + \tau L)^{-1} |v|_{\mathbf{h_E}}.$$

Fix $\tau > 0$ and write $R_{\mathbf{E}} = (I + \tau L_{\mathbf{E}})^{-1}$ and $R = (I + \tau L)^{-1}$. The preceding inequality is the case $k = 1$ of $|R_{\mathbf{E}}^k \mathbf{u}| \le R^k |\mathbf{u}|$. If it holds for $k \in \mathbb{N}$, apply it first to $R_{\mathbf{E}}^k \mathbf{u}$ and then use the fact that R preserves positivity:

$$|R_{\mathbf{E}}^{k+1} \mathbf{u}| \le R\big(|R_{\mathbf{E}}^k \mathbf{u}|\big) \le R\big(R^k |\mathbf{u}|\big) = R^{k+1} |\mathbf{u}|.$$

This proves the inequality for each $k \in \mathbb{N}$. Given $t > 0$, take $\tau = t/N$ and $k = N$, with $N \in \mathbb{N}$, to obtain

$$\left| \left(I + \frac{t}{N} L_{\mathbf{E}} \right)^{-N} \mathbf{u} \right|_{\mathbf{h_E}} \leq \left(I + \frac{t}{N} L \right)^{-N} |\mathbf{u}|_{\mathbf{h_E}}.$$

Proposition B.4.16 shows that the left-hand side converges in $L^2(M, \mathbf{E})$ to $P_t^{\mathbf{E}} \mathbf{u}$ and the right-hand side in $L^2(M)$ to $P_t |\mathbf{u}|_{\mathbf{h_E}}$. Choose a common subsequence converging almost everywhere and pass to the limit in the pointwise inequality. The resulting inequality is the assertion for $t > 0$; at $t = 0$, both sides agree. □

12.2 The covariant heat kernel

The kernel $\mathbf{K}_t^{\mathbf{E}}$ is a section of $\mathbf{E} \boxtimes \mathbf{E}^* \to M_x \times M_y$, equipped with the product connection. In every differential calculation, we distinguish the variables by writing

$$\nabla_x^r \nabla_y^s \mathbf{K}_t^{\mathbf{E}}.$$

After fixing charts or frames, we write its components as

$$\left(\nabla_x^r \nabla_y^s \mathbf{K}_t^{\mathbf{E}} \right)_{i_1 \cdots i_r \, ; \, j_1 \cdots j_s},$$

where the semicolon separates the indices of x from those of y. Each group follows the recursive convention in Chapter 9; in particular, these derivatives will not be mixed with undeclared indexed compositions. We denote by

$$\Delta_{B,\mathbf{E}}^{(x)} \quad \text{and} \quad \Delta_{B,\mathbf{E}^*}^{(y)}$$

the positive Bochner Laplacians acting, respectively, on the factor $\mathbf{E}_x$ and the dual factor $\mathbf{E}_y^*$ of the product connection.

12.2.1 Regularization and continuity of evaluations

The essential step in constructing the kernel is that $P_t^{\mathbf{E}}$ transforms sections in $L^2(M, \mathbf{E})$ into smooth sections when $t > 0$. This property follows directly from spectral calculus and the elliptic regularity developed in the preceding chapter.

Lemma 12.2.1. (Semigroup regularization) Let $(M, \mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Let $t > 0$, $k \in \mathbb{N}_0$, and let $K \subseteq M$ be compact. The operator $P_t^{\mathbf{E}}$ induces a continuous linear map

$$P_t^{\mathbf{E}} \colon L^2(M, \mathbf{E}) \longrightarrow C^k(K, \mathbf{E}).$$

In particular, $P_t^{\mathbf{E}} \mathbf{u}$ has a smooth representative for every $\mathbf{u} \in L^2(M, \mathbf{E})$.

Proof. Set $\mathbf{v} = P_t^{\mathbf{E}} \mathbf{u}$. Spectral calculus gives $\mathbf{v} \in \mathcal{D}(L_{\mathbf{E}}^m)$ for every $m \in \mathbb{N}$ and

$$L_{\mathbf{E},0}^j \mathbf{v} = L_{\mathbf{E}}^j \mathbf{v} \in L^2(M, \mathbf{E}), \qquad j \in \mathbb{N}_0,$$

where the first equality is distributional. Let us see how local regularity follows. If $\mathbf{v}, L_{\mathbf{E},0}\mathbf{v} \in L^2$, Theorem 11.4.2 gives $\mathbf{v} \in H^2_{\mathrm{loc}}$. Suppose that membership of the powers up to order m in L^2 already implies regularity H^{2m}_{loc}. If powers up to order $m+1$ also exist, apply this assertion to $L_{\mathbf{E},0}\mathbf{v}$ to obtain $L_{\mathbf{E},0}\mathbf{v} \in H^{2m}_{\mathrm{loc}}$. The same elliptic regularity theorem, now with right-hand side in H^{2m}_{loc}, gives $\mathbf{v} \in H^{2m+2}_{\mathrm{loc}}$. This proves the assertion for every $m \in \mathbb{N}$. The local embeddings in Chapter 9 provide a smooth representative.

Continuity can be expressed by a bound that also controls time. Choose relatively compact neighborhoods of K, each with closure contained in the next. Apply the local elliptic estimate to the operator $L^m_{\mathbf{E},0}$, of order $2m$, and then the Sobolev embedding with $2m > k + n/2$. This yields

$$\|\mathbf{v}\|_{C^k(K,\mathbf{E})} \le C_{K,k,m}\big(\|L^m_{\mathbf{E}}\mathbf{v}\|_{L^2(M,\mathbf{E})} + \|\mathbf{v}\|_{L^2(M,\mathbf{E})}\big).$$

The constant uses only the charts, frames, and coefficients on the chosen compact neighborhoods. By spectral calculus,

$$\|L^m_{\mathbf{E}} P^{\mathbf{E}}_t\|_{\mathcal{L}(L^2)} \le \sup_{\lambda\in[0,\infty)} \lambda^m e^{-t\lambda} = \left(\frac{m}{et}\right)^m.$$

Together with contractivity of $P^{\mathbf{E}}_t$, this gives

$$\|P^{\mathbf{E}}_t \mathbf{u}\|_{C^k(K,\mathbf{E})} \le C_{K,k,m}\left(1 + \left(\frac{m}{et}\right)^m\right)\|\mathbf{u}\|_{L^2(M,\mathbf{E})}. \tag{12.1}$$

In particular, the bound is uniform for $t \ge t_0 > 0$. Here the constant may depend on the compact set K; completeness alone does not impose uniformity with respect to its location in M. □

For $t > 0$ and $x \in M$, denote the regularized evaluation operator by

$$R_{t,x} \colon L^2(M,\mathbf{E}) \longrightarrow \mathbf{E}_x, \qquad R_{t,x}\mathbf{u} := P^{\mathbf{E}}_t \mathbf{u}(x),$$

. The preceding lemma shows that $R_{t,x}$ is continuous.

Theorem 12.2.2. (Covariant heat kernel) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. There exists a unique smooth map

$$\mathbf{K}^{\mathbf{E}} \colon (0,\infty)\times M \times M \longrightarrow \mathbf{E} \boxtimes \mathbf{E}^*, \qquad (t,x,y) \longmapsto \mathbf{K}^{\mathbf{E}}_t(x,y) \in \mathrm{Hom}(\mathbf{E}_y, \mathbf{E}_x),$$

such that, for every $t > 0$, $\mathbf{u} \in L^2(M,\mathbf{E})$, and $x \in M$,

$$P^{\mathbf{E}}_t \mathbf{u}(x) = \int_M \mathbf{K}^{\mathbf{E}}_t(x,y)\mathbf{u}(y)\, d\lambda_{\mathbf{g}}(y).$$

The integral converges absolutely in the finite-dimensional fiber $\mathbf{E}_x$. Moreover:

(a) $\mathbf{K}^{\mathbf{E}}_t(y,x) = \mathbf{K}^{\mathbf{E}}_t(x,y)^*$;

(b) for $s,t > 0$,

$$\mathbf{K}^{\mathbf{E}}_{t+s}(x,y) = \int_M \mathbf{K}^{\mathbf{E}}_t(x,z)\mathbf{K}^{\mathbf{E}}_s(z,y)\, d\lambda_{\mathbf{g}}(z);$$

(c) the kernel satisfies, smoothly in both variables,

$$\frac{\partial}{\partial t}\mathbf{K}_t^{\mathbf{E}} = -\Delta_{B,\mathbf{E}}^{(x)}\mathbf{K}_t^{\mathbf{E}} = -\Delta_{B,\mathbf{E}^*}^{(y)}\mathbf{K}_t^{\mathbf{E}}.$$

In particular, for $y \in M$ and $\eta \in \mathbf{E}_y$, the first equality follows by evaluating the kernel on η;

(d) if $p_t(x,y)$ is the kernel obtained by the same construction for the trivial bundle of rank one, then

$$\|\mathbf{K}_t^{\mathbf{E}}(x,y)\|_{\mathcal{L}((\mathbf{E}_y,\mathbf{h}_{\mathbf{E}}(y)),(\mathbf{E}_x,\mathbf{h}_{\mathbf{E}}(x)))} \le p_t(x,y).$$

Proof. Fix $t > 0$ and set $s = \frac{t}{2}$. Since $R_{s,x}$ is continuous, it has an adjoint

$$R_{s,x}^*\colon \mathbf{E}_x \longrightarrow L^2(M,\mathbf{E}).$$

Define

$$\mathbf{K}_t^{\mathbf{E}}(x,y) := R_{s,x}R_{s,y}^*.$$

This formula already shows that $\mathbf{K}_t^{\mathbf{E}}(x,y)$ is a linear map from $\mathbf{E}_y$ to $\mathbf{E}_x$.
Smoothness. Let $U, V \subseteq M$ be open subsets over which smooth orthonormal frames $(\mathbf{e}_a)_{a=1}^r$ and $(\mathbf{f}_b)_{b=1}^r$ of $\mathbf{E}$ exist. For $s > 0$ and $y \in V$, define

$$\mathbf{\Psi}_b(s,y) := R_{s,y}^*\mathbf{f}_b(y) \in L^2(M,\mathbf{E}).$$

Fix $\mathbf{u} \in L^2(M,\mathbf{E})$. By the definition of the adjoint,

$$\langle \mathbf{u}, \mathbf{\Psi}_b(s,y)\rangle_{L^2(M,\mathbf{E})} = \langle P_s^{\mathbf{E}}\mathbf{u}(y), \mathbf{f}_b(y)\rangle_{\mathbf{h}_{\mathbf{E}}}. \tag{12.2}$$

Let us check the joint regularity that we will use. Let $(s_0,y_0) \in (0,\infty)\times V$ and choose a compact interval $J \Subset (0,\infty)$ containing s_0 in its interior. For $a \in \mathbb{N}_0$, we have, in $L^2(M,\mathbf{E})$,

$$\partial_s^a P_s^{\mathbf{E}}\mathbf{u} = (-L_{\mathbf{E}})^a P_s^{\mathbf{E}}\mathbf{u}, \qquad s \in J.$$

The function $s \mapsto (-L_{\mathbf{E}})^a P_s^{\mathbf{E}}\mathbf{u}$ is continuous in $L^2(M,\mathbf{E})$. Let $\delta > 0$ be such that $2\delta < \inf_{s\in J} s$. For $s \in J$, write

$$(-L_{\mathbf{E}})^a P_s^{\mathbf{E}}\mathbf{u} = P_\delta^{\mathbf{E}}\big((-L_{\mathbf{E}})^a P_{s-\delta}^{\mathbf{E}}\mathbf{u}\big).$$

The map $s \mapsto (-L_{\mathbf{E}})^a P_{s-\delta}^{\mathbf{E}}\mathbf{u}$ is continuous in $L^2(M,\mathbf{E})$, whereas, by Lemma 12.2.1, $P_\delta^{\mathbf{E}}\colon L^2(M,\mathbf{E}) \longrightarrow C^q(K,\mathbf{E})$ is continuous for every $q \in \mathbb{N}_0$ and every compact set $K \Subset V$. Thus

$$s \longmapsto (-L_{\mathbf{E}})^a P_s^{\mathbf{E}}\mathbf{u}$$

is continuous on J with values in each of these spaces $C^q(K,\mathbf{E})$. In a trivialization over V, for each multi-index β, the derivative

$$\partial_s^a\partial_y^\beta\langle P_s^{\mathbf{E}}\mathbf{u}(y), \mathbf{f}_b(y)\rangle_{\mathbf{h}_{\mathbf{E}}}$$

is, by the Leibniz rule, a finite sum of pairings between coordinate derivatives of $(-L_{\mathbf{E}})^a P_s^{\mathbf{E}}\mathbf{u}$ and derivatives of the frame $\mathbf{f}_b$. Each summand is continuous in (s,y). Consequently, the right-hand side of (12.2) is jointly

smooth in (s,y).

We have proved that $(s,y)\mapsto \mathbf{\Psi}_b(s,y)$ is weakly smooth with values in the Hilbert space $L^2(M,\mathbf{E})$. Theorem B.3.26, applied in charts on $(0,\infty)\times V$, shows that this map is smooth in the norm of $L^2(M,\mathbf{E})$.

If $s=\frac{t}{2}$, then

$$\left\langle \mathbf{K}_t^{\mathbf{E}}(x,y)\mathbf{f}_b(y),\mathbf{e}_a(x)\right\rangle_{\mathbf{h_E}} = \left\langle \mathbf{\Psi}_b(s,y),\mathbf{\Psi}_a(s,x)\right\rangle_{L^2(M,\mathbf{E})}.$$

The inner product is a continuous sesquilinear map; hence the last expression is smooth in (t,x,y). Since this holds for every component in local frames, $\mathbf{K}^{\mathbf{E}}$ is a smooth section of $\mathbf{E}\boxtimes\mathbf{E}^*$.

Integral representation. Fix $x\in M$ and $\xi\in\mathbf{E}_x$. For $\mathbf{u}\in L^2(M,\mathbf{E})$, the section

$$y\longmapsto \mathbf{K}_t^{\mathbf{E}}(x,y)^*\xi = R_{s,y}R_{s,x}^*\xi = P_s^{\mathbf{E}}(R_{s,x}^*\xi)(y)$$

belongs to $L^2(M,\mathbf{E})$. The Cauchy–Schwarz inequality in Theorem B.3.2 shows that its scalar product with $\mathbf{u}$ is integrable. Using the definition of the adjoint and self-adjointness of $P_s^{\mathbf{E}}$,

$$\begin{aligned}\int_M \left\langle \mathbf{K}_t^{\mathbf{E}}(x,y)\mathbf{u}(y),\xi\right\rangle_{\mathbf{h_E}} d\lambda_{\mathbf{g}}(y) &= \left\langle \mathbf{u},P_s^{\mathbf{E}}R_{s,x}^*\xi\right\rangle_{L^2(M,\mathbf{E})}\\ &= \left\langle P_s^{\mathbf{E}}\mathbf{u},R_{s,x}^*\xi\right\rangle_{L^2(M,\mathbf{E})}\\ &= \left\langle R_{s,x}P_s^{\mathbf{E}}\mathbf{u},\xi\right\rangle_{\mathbf{h_E}}\\ &= \left\langle P_t^{\mathbf{E}}\mathbf{u}(x),\xi\right\rangle_{\mathbf{h_E}}.\end{aligned}$$

Convergence is also absolute in the fiber norm. If $(\xi_a)_{a=1}^{r_{\mathbf{E}}}$ is an orthonormal basis of $\mathbf{E}_x$, then

$$\int_M |\mathbf{K}_t^{\mathbf{E}}(x,y)\mathbf{u}(y)|\,d\lambda_{\mathbf{g}}(y)\le \sum_{a=1}^{r_{\mathbf{E}}}\|\mathbf{K}_t^{\mathbf{E}}(x,\cdot)^*\xi_a\|_{L^2(M,\mathbf{E})}\|\mathbf{u}\|_{L^2(M,\mathbf{E})}<\infty.$$

Since $\xi\in\mathbf{E}_x$ was arbitrary, the integral formula follows.

If another smooth kernel satisfies the same formula, their difference, paired with local frames, integrates to zero against every compactly supported smooth section. The fundamental lemma of distribution theory implies that each component vanishes; hence the kernel is unique.

Symmetry and the semigroup property. The definition gives

$$\mathbf{K}_t^{\mathbf{E}}(y,x)^* = (R_{s,y}R_{s,x}^*)^* = R_{s,x}R_{s,y}^* = \mathbf{K}_t^{\mathbf{E}}(x,y).$$

For the semigroup property, fix $\eta\in\mathbf{E}_y$. The section $z\mapsto \mathbf{K}_s^{\mathbf{E}}(z,y)\eta$ belongs to $L^2(M,\mathbf{E})$ because it can be written as $P_{\frac{s}{2}}^{\mathbf{E}}R_{\frac{s}{2},y}^*\eta$. Applying the integral formula and $P_t^{\mathbf{E}}P_s^{\mathbf{E}}=P_{t+s}^{\mathbf{E}}$,

$$\int_M \mathbf{K}_t^{\mathbf{E}}(x,z)\mathbf{K}_s^{\mathbf{E}}(z,y)\eta\,d\lambda_{\mathbf{g}}(z) = P_t^{\mathbf{E}}\big(\mathbf{K}_s^{\mathbf{E}}(\cdot,y)\eta\big)(x) = \mathbf{K}_{t+s}^{\mathbf{E}}(x,y)\eta.$$

The heat equation. Fix $t>0$, $y\in M$, and $\eta\in\mathbf{E}_y$. Choose $t_0\in(0,t)$ and set

$$\mathbf{w} := \mathbf{K}_{t_0}^{\mathbf{E}}(\cdot,y)\eta\in L^2(M,\mathbf{E}).$$

The semigroup property gives

$$\mathbf{K}^{\mathbf{E}}_{\tau}(\cdot,y)\eta = P^{\mathbf{E}}_{\tau-t_0}\mathbf{w}, \qquad \tau > t_0.$$

Since $\mathbf{w} = P^{\mathbf{E}}_{\frac{t_0}{2}} R^{*}_{\frac{t_0}{2},y}\eta$, spectral calculus shows that $\mathbf{w} \in \mathcal{D}(L^r_{\mathbf{E}})$ for every $r \in \mathbb{N}$. Differentiability of the semigroup gives, for $h \to 0^+$,

$$\frac{P^{\mathbf{E}}_{\tau-t_0+h}\mathbf{w} - P^{\mathbf{E}}_{\tau-t_0}\mathbf{w}}{h} \longrightarrow -L_{\mathbf{E}}P^{\mathbf{E}}_{\tau-t_0}\mathbf{w}$$

in $L^2(M,\mathbf{E})$. Since smoothness of the kernel in the time variable has already been proved, this one-sided derivative identifies the ordinary derivative. Convergence also holds in the graph norm of $L^r_{\mathbf{E}}$. Indeed, powers of $L_{\mathbf{E}}$ commute with the semigroup and

$$L^r_{\mathbf{E}}\left(\frac{P^{\mathbf{E}}_h - I}{h}P^{\mathbf{E}}_{\tau-t_0}\mathbf{w} + L_{\mathbf{E}}P^{\mathbf{E}}_{\tau-t_0}\mathbf{w}\right) = \left(\frac{P^{\mathbf{E}}_h - I}{h} + L_{\mathbf{E}}\right)L^r_{\mathbf{E}}P^{\mathbf{E}}_{\tau-t_0}\mathbf{w} \longrightarrow 0$$

in $L^2(M,\mathbf{E})$.

Let $K \subseteq M$ be compact and choose r with $2r > k + \frac{n}{2}$. Local elliptic estimates for the expression $(\Delta^{(x)}_{B,\mathbf{E}})^r$ turn convergence in the graph norm into convergence in $H^{2r}_{\mathrm{loc}}(M,\mathbf{E})$ and, in particular, on a neighborhood of K. The local Sobolev embedding for bundles then turns this into convergence in $C^k(K,\mathbf{E})$. Thus the time derivative exists as a smooth section and

$$\frac{\partial}{\partial t}\mathbf{K}^{\mathbf{E}}_t(\cdot,y)\eta = -\Delta^{(x)}_{B,\mathbf{E}}\mathbf{K}^{\mathbf{E}}_t(\cdot,y)\eta.$$

Since k and K were arbitrary, the equality holds on $\Gamma(\mathbf{E})$. Applying this equality to the dual bundle and using $\mathbf{K}^{\mathbf{E}}_t(y,x) = \mathbf{K}^{\mathbf{E}}_t(x,y)^*$ gives, upon interchanging x and y,

$$\partial_t\mathbf{K}^{\mathbf{E}}_t = -\Delta^{(y)}_{B,\mathbf{E}^*}\mathbf{K}^{\mathbf{E}}_t.$$

Pointwise domination of the kernel. Fix $y \in M$ and $\eta \in \mathbf{E}_y$. Let $r_{\mathbf{E}} = \operatorname{rank}\mathbf{E}$. Choose an open neighborhood V of y with a smooth orthonormal frame $(\mathbf{e}_a)_{a=1}^{r_{\mathbf{E}}}$ and write $\eta = \sum_{a=1}^{r_{\mathbf{E}}}\eta_a\mathbf{e}_a(y)$. Define the local section of constant norm, with $\eta_a \in \mathbb{K}$ for $a \in \{1,\dots,r_{\mathbf{E}}\}$,

$$\widetilde{\eta}(z) := \sum_{a=1}^{r_{\mathbf{E}}}\eta_a\mathbf{e}_a(z).$$

We construct the required approximate identity explicitly. Take a chart $\kappa\colon V \longrightarrow \Omega \subseteq \mathbb{R}^n$ with $\kappa(y) = 0$ and choose $\rho > 0$ so that $\overline{B}_{\mathrm{euc}}(0,\rho) \subseteq \Omega$. Let $a \in C^\infty(\Omega)$ be the positive coordinate weight of the Riemannian measure, determined by

$$\int_V \varphi\, d\lambda_{\mathbf{g}} = \int_\Omega (\varphi\circ\kappa^{-1})(z)a(z)\,d\lambda_n(z)$$

for every integrable function φ supported in V. Denote by ω the mollifier in Theorem B.9.1; for $j \in \mathbb{N}$, define

$$\varepsilon_j := \frac{\rho}{j+1}, \qquad c_j := \left(\int_\Omega \varepsilon_j^{-n}\omega\left(\frac{z}{\varepsilon_j}\right)a(z)\,dz\right)^{-1},$$

where the integrand vanishes outside $\overline{B}_{\mathrm{euc}}(0,\varepsilon_j) \subseteq \Omega$. The number c_j is well defined and positive. Set

$$\rho_j(q) := \begin{cases} c_j \varepsilon_j^{-n} \omega\left(\dfrac{\kappa(q)}{\varepsilon_j}\right), & q \in V, \\ 0, & q \notin V. \end{cases}$$

Since the support of the first expression is compact and contained in V, its extension by zero is smooth. Moreover, $\rho_j \geq 0$, $\displaystyle\int_M \rho_j \, d\lambda_{\mathbf{g}} = 1$, and $\operatorname{supp}(\rho_j) \subseteq \kappa^{-1}(\overline{B}_{\mathrm{euc}}(0,\varepsilon_j))$. If W is a neighborhood of y, choose $0 < r_W \leq \rho$ such that $\kappa^{-1}(B_{\mathrm{euc}}(0,r_W)) \subseteq W$; then $\operatorname{supp}(\rho_j) \subseteq W$ for every j satisfying $j+1 > \dfrac{\rho}{r_W}$. Set $\mathbf{u}_j = \rho_j \widetilde{\eta}$. Then

$$|\mathbf{u}_j|_{\mathbf{h}_{\mathbf{E}}} = |\eta|_{\mathbf{h}_{\mathbf{E}}} \rho_j.$$

The Kato–Simon inequality initially gives, for almost every $x \in M$,

$$|P_t^{\mathbf{E}} \mathbf{u}_j(x)|_{\mathbf{h}_{\mathbf{E}}} \leq |\eta|_{\mathbf{h}_{\mathbf{E}}} P_t \rho_j(x).$$

For $t > 0$, both functions in this inequality are continuous, since the scalar and covariant semigroups are regularizing. If the inequality failed at a point, it would fail on a nonempty open subset and hence on a set of positive measure. It therefore holds for every $x \in M$. By the integral formula,

$$P_t^{\mathbf{E}} \mathbf{u}_j(x) = \int_M \mathbf{K}_t^{\mathbf{E}}(x,z) \widetilde{\eta}(z) \rho_j(z) \, d\lambda_{\mathbf{g}}(z).$$

The function $z \mapsto \mathbf{K}_t^{\mathbf{E}}(x,z)\widetilde{\eta}(z)$ is continuous. Given $\delta > 0$, there exists a neighborhood W of y on which its difference from $\mathbf{K}_t^{\mathbf{E}}(x,y)\eta$ has norm less than δ throughout W. The explicit choice above gives an index beyond which $\operatorname{supp}(\rho_j) \subseteq W$, and then

$$\left| P_t^{\mathbf{E}} \mathbf{u}_j(x) - \mathbf{K}_t^{\mathbf{E}}(x,y)\eta \right|_{\mathbf{h}_{\mathbf{E}}} \leq \int_M \delta \rho_j \, d\lambda_{\mathbf{g}} = \delta.$$

Therefore $P_t^{\mathbf{E}} \mathbf{u}_j(x) \to \mathbf{K}_t^{\mathbf{E}}(x,y)\eta$. The same argument applied to the scalar kernel gives $P_t \rho_j(x) \to p_t(x,y)$. Passing to the limit,

$$|\mathbf{K}_t^{\mathbf{E}}(x,y)\eta|_{\mathbf{h}_{\mathbf{E}}} \leq p_t(x,y) |\eta|_{\mathbf{h}_{\mathbf{E}}}.$$

Taking the supremum over unit vectors in $\mathbf{E}_y$ gives the operator bound. □

Remark 12.2.3. (Scope of the kernel construction) The preceding construction gives a smooth kernel for every $t > 0$ and the domination estimate $\|\mathbf{K}_t^{\mathbf{E}}(x,y)\| \leq p_t(x,y)$. Estimate (12.1) describes regularization on compact sets and is uniform when time stays bounded away from zero. Asymptotic expansions as $t \to 0^+$ additionally require the local analysis in Chapter 15. For the scalar construction of these expansions, see [34, Chapter VI, §§3–4].

The following scalar properties will be needed to extend the semigroup to the entire L^p scale.

Proposition 12.2.4. (Properties of the scalar kernel) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary. The scalar kernel $p_t(x,y)$ is smooth, symmetric, and nonnegative. It satisfies

$$p_{t+s}(x,y) = \int_M p_t(x,z)p_s(z,y)\,d\lambda_{\mathbf{g}}(z)$$

and

$$\int_M p_t(x,y)\,d\lambda_{\mathbf{g}}(y) \le 1.$$

Proof. Smoothness, symmetry, and the composition identity are the trivial-bundle case of the preceding theorem. Suppose that $p_t(x_0,y_0) < 0$. By continuity, there exist a neighborhood W of y_0 and a constant $c > 0$ such that $p_t(x_0,y) \le -c$ for every $y \in W$. Choose a nonzero function $f \in C_c^\infty(W)$ with $f \ge 0$. Then

$$P_t f(x_0) = \int_W p_t(x_0,y)f(y)\,d\lambda_{\mathbf{g}}(y) \le -c\int_W f\,d\lambda_{\mathbf{g}} < 0,$$

contradicting positivity of the scalar semigroup proved in Corollary 12.1.13. Therefore $p_t \ge 0$.
Take the functions (χ_j) from Lemma 12.1.7. We chose this sequence so that $0 \le \chi_j \le 1$, it is increasing, and it converges pointwise to 1. Contractivity on $L^\infty(M)$ gives $0 \le P_t\chi_j(x) \le 1$. Since $p_t(x,y) \ge 0$, the sequence $p_t(x,\cdot)\chi_j$ is also increasing and converges pointwise to $p_t(x,\cdot)$. The monotone convergence theorem B.6.11 gives

$$\int_M p_t(x,y)\,d\lambda_{\mathbf{g}}(y) = \lim_{j\to\infty}\int_M p_t(x,y)\chi_j(y)\,d\lambda_{\mathbf{g}}(y) = \lim_{j\to\infty} P_t\chi_j(x) \le 1.$$

□

12.3 Extension of the semigroup to $L^p(M,\mathbf{E})$

12.3.1 The scalar semigroup on the L^p scale

Proposition 12.3.1. (Scalar semigroup on L^p) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary. For each $1 \le p \le \infty$ and $t \ge 0$, the operator P_t extends to a positive contraction P_t^p on $L^p(M)$. The extensions are consistent. If $1 \le p < \infty$, $(P_t^p)_{t\ge 0}$ is a C_0-semigroup.

Proof. The bound on L^∞ was proved in Corollary 12.1.13. For $f \in L^1(M) \cap L^2(M)$, self-adjointness and the bound on L^∞ give

$$\|P_t f\|_{L^1(M)} = \sup_{\substack{\varphi\in L^2(M)\cap L^\infty(M)\\ \|\varphi\|_{L^\infty(M)}\le 1}} \left|\int_M (P_t f)\varphi\,d\lambda_{\mathbf{g}}\right| = \sup_{\substack{\varphi\in L^2(M)\cap L^\infty(M)\\ \|\varphi\|_{L^\infty(M)}\le 1}} \left|\int_M f(P_t\varphi)\,d\lambda_{\mathbf{g}}\right| \le \|f\|_{L^1(M)}.$$

In the first line, the norm is initially understood to take values in $[0,\infty]$; the last bound proves a posteriori that $P_t f \in L^1$. Let us justify the supremum formula without assuming this conclusion. If $h \in L^2(M)$, choose an increasing exhaustion $(K_j)_{j\in\mathbb{N}}$ by compact sets; each K_j has finite measure. In the real case, set $\varphi_j =$

$\mathbf{1}_{K_j}\operatorname{sgn}(h)$ and, in the complex case,

$$\varphi_j(x) := \begin{cases} \mathbf{1}_{K_j}(x)\,\dfrac{\overline{h(x)}}{|h(x)|}, & h(x) \neq 0, \\ 0, & h(x) = 0. \end{cases}$$

Then $\varphi_j \in L^2(M) \cap L^\infty(M)$, $\|\varphi_j\|_{L^\infty(M)} \leq 1$, and

$$\left| \int_M h\varphi_j \, d\lambda_{\mathbf{g}} \right| = \int_{K_j} |h| \, d\lambda_{\mathbf{g}} \longrightarrow \int_M |h| \, d\lambda_{\mathbf{g}}$$

by monotone convergence, even if the value is infinite. The reverse inequality holds for every φ by the definition of the extended integral. The Riesz–Thorin theorem 5.7.7 gives contractivity on $L^p(M)$ for $1 < p < \infty$. Density of $L^2(M) \cap L^p(M)$ in $L^p(M)$ when $p < \infty$ gives the unique extension. For $p = \infty$, the integral formula with $p_t \geq 0$ and mass at most one defines the extension on $L^\infty(M)$.

The integral formula also represents the extensions for finite exponents. Indeed, if $f \in L^p(M)$ and $1 \leq p < \infty$, Jensen's inequality for the subprobability measure $p_t(x,y)\,d\lambda_{\mathbf{g}}(y)$ gives

$$\left(\int_M p_t(x,y)|f(y)| \, d\lambda_{\mathbf{g}}(y) \right)^p \leq \int_M p_t(x,y)|f(y)|^p \, d\lambda_{\mathbf{g}}(y).$$

For $p = 1$, this inequality is an equality. Tonelli's theorem, symmetry of the kernel, and its mass bound show that the integral of the right-hand side with respect to x does not exceed $\|f\|^p_{L^p(M)}$. Thus the kernel integral converges absolutely for almost every x and defines a contraction on $L^p(M)$. It agrees with P_t on the intersection with L^2, and density identifies this contraction with P^p_t.

For consistency, let $p, q < \infty$ and $f \in L^p(M) \cap L^q(M)$. Using the preceding exhaustion (K_j), set

$$f_j = \mathbf{1}_{K_j}\mathbf{1}_{\{|f| \leq j\}} f.$$

Each f_j is bounded and has support of finite measure; hence it belongs simultaneously to $L^2(M)$, $L^p(M)$, and $L^q(M)$. Dominated convergence applied to $|f_j - f|^p$ and $|f_j - f|^q$ gives convergence in both spaces. By contractivity, $P^p_t f_j \to P^p_t f$ in $L^p(M)$ and $P^q_t f_j \to P^q_t f$ in $L^q(M)$. The terms of the two sequences agree for every j because they arise from the same operator on $L^2(M)$. Pairing with a compactly supported smooth test function, Hölder's inequality identifies their distributional limits; thus $P^p_t f = P^q_t f$ almost everywhere. If one exponent is infinite, the integral formula already proved for each exponent directly gives the same function.

For $p < \infty$, now take $f_j \to f$ in $L^p(M)$ with $f_j \in L^2(M) \cap L^p(M)$. Consistency allows us to apply the semigroup identity on $L^2(M)$ to each f_j, and

$$\|P^p_t P^p_s f - P^p_{t+s} f\|_{L^p(M)} \leq \|P^p_t P^p_s (f - f_j)\|_{L^p(M)} + \|P^p_{t+s}(f_j - f)\|_{L^p(M)} \leq 2\|f - f_j\|_{L^p(M)} \longrightarrow 0.$$

For $p = \infty$ and $s, t > 0$, the double integral arising in the composition of kernels converges absolutely, since

$$\int_M \int_M p_t(x,z) p_s(z,y) |f(y)| \, d\lambda_{\mathbf{g}}(y) \, d\lambda_{\mathbf{g}}(z) \leq \|f\|_{L^\infty(M)}.$$

Fubini's theorem and the Chapman–Kolmogorov identity for the kernel give $P^\infty_t P^\infty_s f = P^\infty_{t+s} f$. When one

time is zero, the equality follows from $P_0^p = I$.

Let us prove strong continuity for $p < \infty$. If $f \in C_c^\infty(M)$, then $Lf \in L^p(M) \cap L^2(M)$. In $L^2(M)$, spectral differentiability gives

$$P_t f - f = -\int_0^t P_s(Lf)\,ds.$$

Let us justify strong measurability of the integrand before using the strong continuity we are proving. Set $g = Lf$ and use the cutoffs χ_j from Lemma 12.1.7. For $s > 0$, the map $s \mapsto \chi_j P_s g$ is continuous with values in $L^p(M)$: heat regularization gives uniform continuity on the compact support of χ_j on each compact time interval in $(0,\infty)$. For every $s > 0$, dominated convergence in M gives $\chi_j P_s g \to P_s^p g$ in $L^p(M)$. Thus $s \mapsto P_s^p g$ is the pointwise limit of strongly measurable maps; assigning its value at $s = 0$ does not change this property. Moreover, its norm does not exceed $\|g\|_{L^p(M)}$. The Bochner integral exists in $L^p(M)$. Pairing the integrals in L^2 and L^p with compactly supported smooth test functions, consistency gives the same result; their distributional realizations agree. Therefore the same identity holds in $L^p(M)$:

$$P_t^p f - f = -\int_0^t P_s^p(Lf)\,ds.$$

Thus

$$\|P_t^p f - f\|_{L^p(M)} \le \int_0^t \|P_s^p(Lf)\|_{L^p(M)}\,ds \le t\|Lf\|_{L^p(M)} \longrightarrow 0$$

as $t \to 0^+$. For $f \in L^p(M)$, take $g_j \in C_c^\infty(M)$ with $g_j \to f$ in $L^p(M)$. Then

$$\|P_t^p f - f\|_{L^p(M)} \le 2\|f - g_j\|_{L^p(M)} + t\|Lg_j\|_{L^p(M)}.$$

First fix j to control the first term, and then let $t \to 0^+$. This proves strong continuity at zero for each f. The semigroup property and contractivity transfer it to any time: for $h > 0$, both the right and left differences at a positive time are bounded by $\|P_h^p f - f\|_{L^p(M)}$. □

12.3.2 The covariant semigroup on $L^p(M,\mathbf{E})$

Theorem 12.3.2. (Covariant semigroup on L^p) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Let $1 \le p \le \infty$. For each $t \ge 0$, $P_t^{\mathbf{E}}$ admits a contractive extension

$$P_t^{\mathbf{E},p} \colon L^p(M,\mathbf{E}) \longrightarrow L^p(M,\mathbf{E}).$$

The extensions are consistent and satisfy:

(a) $P_{t+s}^{\mathbf{E},p} = P_t^{\mathbf{E},p} P_s^{\mathbf{E},p}$;

(b) if $1 \le p < \infty$, $(P_t^{\mathbf{E},p})_{t\ge 0}$ is a C_0-semigroup;

(c) if $t > 0$ and $\mathbf{u} \in L^p(M,\mathbf{E})$,

$$P_t^{\mathbf{E},p}\mathbf{u}(x) = \int_M \mathbf{K}_t^{\mathbf{E}}(x,y)\mathbf{u}(y)\,d\lambda_{\mathbf{g}}(y)$$

for almost every x;

(d) for $t \geq 0$,

$$|P_t^{\mathbf{E},p}\mathbf{u}|_{\mathbf{h_E}} \leq P_t^p(|\mathbf{u}|_{\mathbf{h_E}})$$

almost everywhere.

For $p = \infty$, the preceding conclusions do not include strong continuity on $t = 0$.

Proof. If $\mathbf{u} \in L^2(M,\mathbf{E}) \cap L^p(M,\mathbf{E})$, the Kato–Simon inequality and scalar contractivity give

$$\|P_t^{\mathbf{E}}\mathbf{u}\|_{L^p(M,\mathbf{E})} \leq \|P_t^p(|\mathbf{u}|_{\mathbf{h_E}})\|_{L^p(M)} \leq \|\mathbf{u}\|_{L^p(M,\mathbf{E})}.$$

For $p < \infty$, the subspace $L^2(M,\mathbf{E}) \cap L^p(M,\mathbf{E})$ is dense in $L^p(M,\mathbf{E})$, and Theorem B.2.36 provides the unique extension. The pointwise inequality passes to the limit: if $\mathbf{u}_j \to \mathbf{u}$ in $L^p(M,\mathbf{E})$, then, after passing to a subsequence, $P_t^{\mathbf{E},p}\mathbf{u}_j \to P_t^{\mathbf{E},p}\mathbf{u}$ and $P_t^p(|\mathbf{u}_j|_{\mathbf{h_E}}) \to P_t^p(|\mathbf{u}|_{\mathbf{h_E}})$ almost everywhere.
For $p = \infty$ and $t > 0$, define

$$P_t^{\mathbf{E},\infty}\mathbf{u}(x) := \int_M \mathbf{K}_t^{\mathbf{E}}(x,y)\mathbf{u}(y)\, d\lambda_{\mathbf{g}}(y),$$

and set $P_0^{\mathbf{E},\infty} := I$. The kernel bound and Proposition 12.2.4 give

$$|P_t^{\mathbf{E},\infty}\mathbf{u}(x)|_{\mathbf{h_E}} \leq \|\mathbf{u}\|_{L^\infty(M,\mathbf{E})} \int_M p_t(x,y)\, d\lambda_{\mathbf{g}}(y) \leq \|\mathbf{u}\|_{L^\infty(M,\mathbf{E})}.$$

The same estimate proves absolute convergence of the integral and pointwise domination.
For $p < \infty$ and $\mathbf{u} \in L^p(M,\mathbf{E})$, kernel domination and the Jensen–Tonelli argument in the scalar proposition show that

$$\int_M \|\mathbf{K}_t^{\mathbf{E}}(x,y)\mathbf{u}(y)\|_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}}(y) \leq P_t^p(|\mathbf{u}|_{\mathbf{h_E}})(x) < \infty$$

for almost every x. This integral defines a contractive operator on $L^p(M,\mathbf{E})$ agreeing with $P_t^{\mathbf{E}}$ on $L^2(M,\mathbf{E}) \cap L^p(M,\mathbf{E})$. The approximation is obtained by taking

$$\mathbf{u}_j = \mathbf{1}_{K_j}\mathbf{1}_{\{|\mathbf{u}|_{\mathbf{h_E}} \leq j\}}\mathbf{u}.$$

Then $\mathbf{u}_j \in L^2(M,\mathbf{E}) \cap L^p(M,\mathbf{E})$ and $\|\mathbf{u}_j - \mathbf{u}\|_{L^p(M,\mathbf{E})} \to 0$. Both the integral operator and $P_t^{\mathbf{E},p}$ send this difference to a section whose norm does not exceed $\|\mathbf{u}_j - \mathbf{u}\|_{L^p(M,\mathbf{E})}$. Their limits agree, proving the integral formula for every $\mathbf{u}$.
Since all exponents are represented by the same kernel, the extensions are consistent, including the infinite exponent. For $s, t > 0$, the norm of the integrand in the composition of operators is dominated by

$$p_t(x,z)p_s(z,y)|\mathbf{u}(y)|_{\mathbf{h_E}}.$$

The double integral of this function is $P_{t+s}^p(|\mathbf{u}|_{\mathbf{h_E}})(x)$, by Tonelli's theorem and the scalar Chapman–Kolmogorov identity. It is finite for almost every x when $p < \infty$, and for every x when $p = \infty$. Fubini's theorem in the finite-dimensional fiber $\mathbf{E}_x$ therefore allows the integrals to be interchanged. The composition identity for the covariant kernel gives $P_t^{\mathbf{E},p}P_s^{\mathbf{E},p}\mathbf{u} = P_{t+s}^{\mathbf{E},p}\mathbf{u}$ almost everywhere. Zero times are included by setting $P_0^{\mathbf{E},p} = I$.

Finally, if $\mathbf{u}\in\Gamma_c(\mathbf{E})$, then $L_{\mathbf{E},0}\mathbf{u}\in L^p(M,\mathbf{E})\cap L^2(M,\mathbf{E})$. The identity

$$P_t^{\mathbf{E}}\mathbf{u}-\mathbf{u}=-\int_0^t P_s^{\mathbf{E}}(L_{\mathbf{E},0}\mathbf{u})\,ds$$

is obtained first in $L^2(M,\mathbf{E})$. Strong measurability in $L^p(M,\mathbf{E})$ is checked as in Proposition 12.3.1: for each compact cutoff χ_j, covariant regularization makes $s\mapsto \chi_j P_s^{\mathbf{E}}(L_{\mathbf{E},0}\mathbf{u})$ continuous when $s>0$, and these maps converge pointwise in L^p to the integrand. Contractivity bounds its norm by $\|L_{\mathbf{E},0}\mathbf{u}\|_{L^p(M,\mathbf{E})}$, so it is Bochner integrable. Consistency, checked against test sections, identifies this integral with the one obtained in L^2. Therefore

$$P_t^{\mathbf{E},p}\mathbf{u}-\mathbf{u}=-\int_0^t P_s^{\mathbf{E},p}(L_{\mathbf{E},0}\mathbf{u})\,ds.$$

Thus

$$\|P_t^{\mathbf{E},p}\mathbf{u}-\mathbf{u}\|_{L^p(M,\mathbf{E})}\le t\|L_{\mathbf{E},0}\mathbf{u}\|_{L^p(M,\mathbf{E})}\longrightarrow 0$$

as $t\to 0^+$. For an arbitrary section $\mathbf{u}\in L^p(M,\mathbf{E})$, choose $\mathbf{v}_j\in\Gamma_c(\mathbf{E})$ with $\mathbf{v}_j\to\mathbf{u}$ in $L^p(M,\mathbf{E})$ and use

$$\|P_t^{\mathbf{E},p}\mathbf{u}-\mathbf{u}\|_{L^p(M,\mathbf{E})}\le 2\|\mathbf{u}-\mathbf{v}_j\|_{L^p(M,\mathbf{E})}+t\|L_{\mathbf{E},0}\mathbf{v}_j\|_{L^p(M,\mathbf{E})}.$$

First fix j and then let $t\to 0^+$; finally, let $j\to\infty$. The semigroup property transfers strong continuity to all times, just as in the scalar case. □

Definition 12.3.3. (Generator on L^p) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Let $1\le p<\infty$. Define

$$\mathcal{D}(L_{\mathbf{E},p}):=\left\{\mathbf{u}\in L^p(M,\mathbf{E})\,\middle|\,\lim_{t\to 0^+}\frac{\mathbf{u}-P_t^{\mathbf{E},p}\mathbf{u}}{t}\text{ exists in }L^p(M,\mathbf{E})\right\}$$

and

$$L_{\mathbf{E},p}\mathbf{u}:=\lim_{t\to 0^+}\frac{\mathbf{u}-P_t^{\mathbf{E},p}\mathbf{u}}{t}.$$

Then $-L_{\mathbf{E},p}$ is the generator of $(P_t^{\mathbf{E},p})_{t\ge 0}$.

Proposition 12.3.4. Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. For $1\le p<\infty$, $L_{\mathbf{E},p}$ is closed, densely defined, and maximally accretive. Moreover,

$$\Gamma_c(\mathbf{E})\subseteq\mathcal{D}(L_{\mathbf{E},p}),\qquad L_{\mathbf{E},p}\mathbf{u}=L_{\mathbf{E},0}\mathbf{u}\quad\text{for }\mathbf{u}\in\Gamma_c(\mathbf{E}),$$

and $L_{\mathbf{E},2}=L_{\mathbf{E}}$.

Proof. Closedness and density of the domain follow from Proposition B.4.12; maximal accretivity is the

Lumer–Phillips theorem, Theorem B.4.15, applied to the generator $-L_{\mathbf{E},p}$. If $\mathbf{u} \in \Gamma_c(\mathbf{E})$, then

$$\frac{\mathbf{u} - P_t^{\mathbf{E},p}\mathbf{u}}{t} = \frac{1}{t}\int_0^t P_s^{\mathbf{E},p}(L_{\mathbf{E},0}\mathbf{u})\,ds.$$

Strong continuity of the semigroup implies that the right-hand side converges to $L_{\mathbf{E},0}\mathbf{u}$ in $L^p(M,\mathbf{E})$ as $t \to 0^+$. For $p = 2$, the semigroups defined by extension and by spectral calculus agree; uniqueness of the generator gives $L_{\mathbf{E},2} = L_{\mathbf{E}}$. □

12.4 Bessel potentials and spaces of real order

12.4.1 Bessel potentials

The functional calculus of the Laplacian transfers the Euclidean multiplier $(1 + \|\xi\|^2)^{-\frac{s}{2}}$ to the manifold. The resulting Bessel potentials encode a gain of regularity without choosing coordinates.

Definition 12.4.1. (Bessel potential) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Let $s > 0$ and $1 \le p < \infty$. Define

$$J_{s,p}^{\mathbf{E}}\mathbf{u} := \frac{1}{\Gamma(\frac{s}{2})}\int_0^\infty t^{\frac{s}{2}-1}e^{-t}P_t^{\mathbf{E},p}\mathbf{u}\,dt, \qquad \mathbf{u} \in L^p(M,\mathbf{E}),$$

where the integral is a Bochner integral in $L^p(M,\mathbf{E})$.

Proposition 12.4.2. (Properties of Bessel potentials) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Let $r, s > 0$ and $1 \le p, q < \infty$.

(a) $J_{s,p}^{\mathbf{E}} \in \mathcal{L}(L^p(M,\mathbf{E}))$ and $\|J_{s,p}^{\mathbf{E}}\|_{\mathcal{L}(L^p(M,\mathbf{E}))} \le 1$;

(b) $J_{s,p}^{\mathbf{E}} J_{r,p}^{\mathbf{E}} = J_{s+r,p}^{\mathbf{E}}$;

(c) $J_{2,p}^{\mathbf{E}} = (I + L_{\mathbf{E},p})^{-1}$ and

$$J_{2m,p}^{\mathbf{E}} = (I + L_{\mathbf{E},p})^{-m}$$

for $m \in \mathbb{N}$;

(d) $J_{s,p}^{\mathbf{E}}$ is injective and its range is dense in $L^p(M,\mathbf{E})$;

(e) if $\mathbf{u} \in L^p(M,\mathbf{E}) \cap L^q(M,\mathbf{E})$, then $J_{s,p}^{\mathbf{E}}\mathbf{u} = J_{s,q}^{\mathbf{E}}\mathbf{u}$ almost everywhere.

Proof. Contractivity of the semigroup gives

$$\int_0^\infty \left\| \frac{t^{\frac{s}{2}-1}e^{-t}}{\Gamma(\frac{s}{2})} P_t^{\mathbf{E},p}\mathbf{u} \right\|_{L^p(M,\mathbf{E})} dt \le \frac{\|\mathbf{u}\|_{L^p(M,\mathbf{E})}}{\Gamma(\frac{s}{2})}\int_0^\infty t^{\frac{s}{2}-1}e^{-t}\,dt = \|\mathbf{u}\|_{L^p(M,\mathbf{E})}.$$

This proves convergence of the Bochner integral and $\|J_{s,p}^{\mathbf{E}}\|_{\mathcal{L}(L^p(M,\mathbf{E}))} \le 1$.

For the semigroup law, the norm of the double integrand is bounded by

$$\frac{t^{\frac{s}{2}-1}\tau^{\frac{r}{2}-1}e^{-(t+\tau)}}{\Gamma(\frac{s}{2})\Gamma(\frac{r}{2})}\|\mathbf{u}\|_{L^p(M,\mathbf{E})}.$$

The integral of this function over $(0,\infty)^2$ is $\|\mathbf{u}\|_{L^p(M,\mathbf{E})}$. Thus Fubini's theorem for Bochner integrals B.6.26 applies and

$$J^{\mathbf{E}}_{s,p}J^{\mathbf{E}}_{r,p}\mathbf{u} = \frac{1}{\Gamma(\frac{s}{2})\Gamma(\frac{r}{2})}\int_0^\infty\int_0^\infty t^{\frac{s}{2}-1}\tau^{\frac{r}{2}-1}e^{-(t+\tau)}P^{\mathbf{E},p}_{t+\tau}\mathbf{u}\,d\tau\,dt.$$

Make the change of variables

$$a = t+\tau, \qquad \theta = \frac{t}{t+\tau}.$$

Its Jacobian is a, and the beta–gamma identity in Lemma B.4.18 gives

$$\int_0^1 \theta^{\frac{s}{2}-1}(1-\theta)^{\frac{r}{2}-1}\,d\theta = \frac{\Gamma(\frac{s}{2})\Gamma(\frac{r}{2})}{\Gamma\left(\frac{s+r}{2}\right)}.$$

We obtain $J^{\mathbf{E}}_{s+r,p}\mathbf{u}$.
The resolvent formula, Proposition B.4.14, applied to the generator $-L_{\mathbf{E},p}$ with $\lambda = 1$, gives $J^{\mathbf{E}}_{2,p} = (I+L_{\mathbf{E},p})^{-1}$. The semigroup law gives the formula for $J^{\mathbf{E}}_{2m,p}$.
If $J^{\mathbf{E}}_{s,p}\mathbf{u} = 0$, choose $m\in\mathbb{N}$ with $2m > s$. Then

$$J^{\mathbf{E}}_{2m,p}\mathbf{u} = J^{\mathbf{E}}_{2m-s,p}J^{\mathbf{E}}_{s,p}\mathbf{u} = 0.$$

The operator $(I+L_{\mathbf{E},p})^{-m}$ is injective, so $\mathbf{u}=0$. For density, observe that

$$J^{\mathbf{E}}_{2m,p} = J^{\mathbf{E}}_{s,p}J^{\mathbf{E}}_{2m-s,p}.$$

Therefore

$$\operatorname{Ran}(J^{\mathbf{E}}_{2m,p}) \subseteq \operatorname{Ran}(J^{\mathbf{E}}_{s,p}).$$

Moreover,

$$\operatorname{Ran}(J^{\mathbf{E}}_{2m,p}) = \operatorname{Ran}\big((I+L_{\mathbf{E},p})^{-m}\big) = \mathcal{D}\big((I+L_{\mathbf{E},p})^{m}\big),$$

where the last space is viewed with its inclusion into $L^p(M,\mathbf{E})$. The domain of a power of the generator is dense by Proposition B.4.12. Consequently, $\operatorname{Ran}(J^{\mathbf{E}}_{s,p})$ is dense in $L^p(M,\mathbf{E})$.
Finally, consistency of the semigroups implies that, for $\mathbf{u}\in L^p(M,\mathbf{E})\cap L^q(M,\mathbf{E})$, the truncated integrals

$$J^{\mathbf{E},[a,b]}_{s}\mathbf{u} := \frac{1}{\Gamma(\frac{s}{2})}\int_a^b t^{\frac{s}{2}-1}e^{-t}P^{\mathbf{E}}_t\mathbf{u}\,dt$$

are the same sections for all $0<a<b<\infty$. As $a\to 0^+$ and $b\to+\infty$, these sections converge to $J^{\mathbf{E}}_{s,p}\mathbf{u}$ in $L^p(M,\mathbf{E})$ and to $J^{\mathbf{E}}_{s,q}\mathbf{u}$ in $L^q(M,\mathbf{E})$. From any sequence of intervals exhausting $(0,+\infty)$, one can extract a subsequence converging almost everywhere in both spaces: first extract one for convergence in $L^p(M,\mathbf{E})$, and then a further subsequence for convergence in $L^q(M,\mathbf{E})$. The two pointwise limits agree, and hence $J^{\mathbf{E}}_{s,p}\mathbf{u} = J^{\mathbf{E}}_{s,q}\mathbf{u}$ almost everywhere. □

12.4.2 The Bessel kernel

The spectral representation of the potential can be converted into an integral representation. Its kernel separates the singularity near the diagonal from the decay at large distances and makes the regularization properties visible.

Definition 12.4.3. (Covariant Bessel kernel) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. For $s>0$, define

$$G_s^{\mathbf{E}}(x,y):=\frac{1}{\Gamma(\frac{s}{2})}\int_0^\infty t^{\frac{s}{2}-1}e^{-t}\mathbf{K}_t^{\mathbf{E}}(x,y)\,dt$$

whenever the integral converges. Also define

$$g_s(x,y):=\frac{1}{\Gamma(\frac{s}{2})}\int_0^\infty t^{\frac{s}{2}-1}e^{-t}p_t(x,y)\,dt,$$

initially allowing the value $+\infty$.

Proposition 12.4.4. Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. For almost every $(x,y)\in M\times M$, $g_s(x,y)<\infty$, the integral defining $G_s^{\mathbf{E}}(x,y)$ converges and

$$\|G_s^{\mathbf{E}}(x,y)\|_{\mathcal{L}((\mathbf{E}_y,\mathbf{h}_{\mathbf{E}}(y)),(\mathbf{E}_x,\mathbf{h}_{\mathbf{E}}(x)))}\le g_s(x,y).$$

Moreover,

$$\int_M g_s(x,y)\,d\lambda_{\mathbf{g}}(y)\le 1$$

for every x, and, if $\mathbf{u}\in L^p(M,\mathbf{E})$ with $1\le p<\infty$,

$$J_{s,p}^{\mathbf{E}}\mathbf{u}(x)=\int_M G_s^{\mathbf{E}}(x,y)\mathbf{u}(y)\,d\lambda_{\mathbf{g}}(y)$$

for almost every x.

Proof. The function $(t,x,y)\mapsto p_t(x,y)$ is nonnegative and measurable. Thus g_s is measurable as the integral of a nonnegative function. For each $x\in M$, Tonelli's theorem B.6.17 and the mass bound for p_t give

$$\begin{aligned}\int_M g_s(x,y)\,d\lambda_{\mathbf{g}}(y)&=\frac{1}{\Gamma(\frac{s}{2})}\int_0^\infty t^{\frac{s}{2}-1}e^{-t}\left(\int_M p_t(x,y)\,d\lambda_{\mathbf{g}}(y)\right)dt\\&\le\frac{1}{\Gamma(\frac{s}{2})}\int_0^\infty t^{\frac{s}{2}-1}e^{-t}\,dt=1.\end{aligned}$$

Since $p_t(x,y)=p_t(y,x)$, also

$$g_s(x,y)=g_s(y,x). \tag{12.3}$$

In particular, $g_s(x,\cdot)$ is finite almost everywhere for each x. Since the set

$$N_s:=\{(x,y)\in M\times M\mid g_s(x,y)=+\infty\}$$

is measurable, Tonelli's theorem applied to $\mathbf{1}_{N_s}$ shows that $(\lambda_{\mathbf{g}} \otimes \lambda_{\mathbf{g}})(N_s) = 0$.
If $(x, y) \notin N_s$, the bound

$$\|\mathbf{K}_t^{\mathbf{E}}(x, y)\|_{\mathcal{L}((\mathbf{E}_y, \mathbf{h}_{\mathbf{E}}(y)),(\mathbf{E}_x, \mathbf{h}_{\mathbf{E}}(x)))} \le p_t(x, y)$$

proves that the function with values in the finite-dimensional space $\operatorname{Hom}(\mathbf{E}_y, \mathbf{E}_x)$ appearing in the definition of $G_s^{\mathbf{E}}(x, y)$ is absolutely integrable. Thus the integral converges and

$$\|G_s^{\mathbf{E}}(x, y)\|_{\mathcal{L}((\mathbf{E}_y, \mathbf{h}_{\mathbf{E}}(y)),(\mathbf{E}_x, \mathbf{h}_{\mathbf{E}}(x)))} \le g_s(x, y).$$

On N_s, we henceforth assign the value $G_s^{\mathbf{E}}(x, y) = 0$. This choice gives a measurable kernel. Indeed, on the product of two trivializing open subsets, the components of

$$\frac{1}{\Gamma(\frac{s}{2})} \int_{\frac{1}{\nu}}^{\nu} t^{\frac{s}{2}-1} e^{-t} \mathbf{K}_t^{\mathbf{E}}(x, y)\, dt, \qquad \nu \in \mathbb{N},$$

are measurable, in fact smooth, functions. Outside N_s, they converge componentwise to those of $G_s^{\mathbf{E}}$, while N_s is measurable. Thus the limit defined on $M \times M \setminus N_s$ and extended by zero to N_s is measurable in every pair of local frames. This proves the first assertions.
Before treating the covariant kernel, we record boundedness of the scalar integral operator. For a measurable function $f \ge 0$, set

$$(\mathcal{T}_s f)(x) := \int_M g_s(x, y) f(y)\, d\lambda_{\mathbf{g}}(y),$$

initially allowing the value $+\infty$. If $1 \le p < \infty$, Jensen's inequality for the subprobability measure $g_s(x, y)\, d\lambda_{\mathbf{g}}(y)$ gives

$$|\mathcal{T}_s f(x)|^p \le \int_M g_s(x, y) |f(y)|^p\, d\lambda_{\mathbf{g}}(y).$$

For $p = 1$, the same inequality is immediate. Integrate in x and use Tonelli's theorem, the symmetry (12.3), and the mass bound already proved. We obtain

$$\|\mathcal{T}_s f\|_{L^p(M)} \le \|f\|_{L^p(M)}. \tag{12.4}$$

Decomposition into positive and negative parts gives the same conclusion for arbitrary scalar functions. In particular, the integral defining $\mathcal{T}_s f$ is finite for almost every x when $f \in L^p(M)$. For $f \in C_c^\infty(M)$, Fubini's theorem and the semigroup representation show that $\mathcal{T}_s f = J_{s,p} f$. Density and (12.4) extend this identity to all of $L^p(M)$.
First let $\mathbf{u} \in \Gamma_c(\mathbf{E})$. For almost every x,

$$\begin{aligned} &\frac{1}{\Gamma(\frac{s}{2})} \int_0^\infty \int_M t^{\frac{s}{2}-1} e^{-t} |\mathbf{K}_t^{\mathbf{E}}(x, y)\mathbf{u}(y)|_{\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}}(y)\, dt \\ &\qquad \le \int_M g_s(x, y) |\mathbf{u}(y)|_{\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}}(y). \end{aligned}$$

Tonelli's theorem and the representation of the scalar semigroup by p_t show, for almost every x, that

$$\begin{aligned}\int_M g_s(x,y)|\mathbf{u}(y)|_{\mathbf{h_E}}\,d\lambda_{\mathbf{g}}(y) &= \frac{1}{\Gamma(\frac{s}{2})}\int_0^\infty t^{\frac{s}{2}-1}e^{-t}P_t(|\mathbf{u}|_{\mathbf{h_E}})(x)\,dt\\ &= \big(\mathcal{T}_s(|\mathbf{u}|_{\mathbf{h_E}})\big)(x) = J_{s,p}(|\mathbf{u}|_{\mathbf{h_E}})(x).\end{aligned}$$

Here $J_{s,p}$ denotes the scalar Bessel potential. The last expression belongs to $L^p(M)$ and is therefore finite for almost every x. Fubini's theorem for Bochner integrals B.6.26 then allows us to interchange the integrals and gives

$$\begin{aligned}J^{\mathbf{E}}_{s,p}\mathbf{u}(x) &= \frac{1}{\Gamma(\frac{s}{2})}\int_0^\infty t^{\frac{s}{2}-1}e^{-t}\left(\int_M \mathbf{K}^{\mathbf{E}}_t(x,y)\mathbf{u}(y)\,d\lambda_{\mathbf{g}}(y)\right)dt\\ &= \int_M G^{\mathbf{E}}_s(x,y)\mathbf{u}(y)\,d\lambda_{\mathbf{g}}(y)\end{aligned}$$

for almost every x.
Whenever the integral converges absolutely, define

$$\mathcal{G}^{\mathbf{E}}_s\mathbf{u}(x) := \int_M G^{\mathbf{E}}_s(x,y)\mathbf{u}(y)\,d\lambda_{\mathbf{g}}(y).$$

The preceding bound gives

$$|\mathcal{G}^{\mathbf{E}}_s\mathbf{u}(x)|_{\mathbf{h_E}} \le \int_M g_s(x,y)|\mathbf{u}(y)|_{\mathbf{h_E}}\,d\lambda_{\mathbf{g}}(y) = J_{s,p}(|\mathbf{u}|_{\mathbf{h_E}})(x) \tag{12.5}$$

for almost every x. The right-hand side is finite almost everywhere, and its L^p norm does not exceed $\|\mathbf{u}\|_{L^p(M,\mathbf{E})}$. Thus $\mathcal{G}^{\mathbf{E}}_s$ defines a contractive operator on the subspace $\Gamma_c(\mathbf{E})$.
Now take $\mathbf{u}\in L^p(M,\mathbf{E})$ and choose $\mathbf{u}_j\in\Gamma_c(\mathbf{E})$ with $\mathbf{u}_j\to\mathbf{u}$ in $L^p(M,\mathbf{E})$. Inequality (12.5), applied to $\mathbf{u}_j-\mathbf{u}_k$, shows that $(\mathcal{G}^{\mathbf{E}}_s\mathbf{u}_j)_j$ is Cauchy in $L^p(M,\mathbf{E})$. Therefore $\mathcal{G}^{\mathbf{E}}_s$ extends uniquely to a contractive operator on $L^p(M,\mathbf{E})$. Since $\mathcal{G}^{\mathbf{E}}_s\mathbf{u}_j = J^{\mathbf{E}}_{s,p}\mathbf{u}_j$ and both operators are continuous, we obtain

$$\mathcal{G}^{\mathbf{E}}_s\mathbf{u} = J^{\mathbf{E}}_{s,p}\mathbf{u}$$

in $L^p(M,\mathbf{E})$.
Finally, the preceding scalar identity, now applied to $|\mathbf{u}|_{\mathbf{h_E}}$, shows that

$$\big(\mathcal{T}_s(|\mathbf{u}|_{\mathbf{h_E}})\big)(x) = \int_M g_s(x,y)|\mathbf{u}(y)|_{\mathbf{h_E}}\,d\lambda_{\mathbf{g}}(y) < \infty$$

for almost every x. At these points, the integral

$$\int_M G^{\mathbf{E}}_s(x,y)\mathbf{u}(y)\,d\lambda_{\mathbf{g}}(y)$$

converges absolutely. Since $\mathcal{T}_s$ is contractive on $L^p(M)$, $\mathcal{T}_s(|\mathbf{u}_j-\mathbf{u}|_{\mathbf{h_E}})\to 0$ in $L^p(M)$. Choose a subsequence, without relabeling, for which

$$\mathcal{T}_s(|\mathbf{u}_j-\mathbf{u}|_{\mathbf{h_E}})(x)\longrightarrow 0 \quad\text{and}\quad \mathcal{G}^{\mathbf{E}}_s\mathbf{u}_j(x)\longrightarrow\mathcal{G}^{\mathbf{E}}_s\mathbf{u}(x)$$

for almost every x. For each j, let X_j be a set of full measure on which the integral representation already proved for $\mathbf{u}_j$ holds. Intersecting the sets X_j, the set on which the preceding scalar integrals are finite, and the two sets of pointwise convergence gives a single set $X \subseteq M$ of full measure on which all these properties hold simultaneously. If $x \in X$,

$$\begin{aligned}&\left|\mathcal{G}_s^{\mathbf{E}}\mathbf{u}_j(x) - \int_M G_s^{\mathbf{E}}(x,y)\mathbf{u}(y)\,d\lambda_{\mathbf{g}}(y)\right|_{\mathbf{h}_{\mathbf{E}}}\\ &\qquad \le \int_M g_s(x,y)|\mathbf{u}_j(y)-\mathbf{u}(y)|_{\mathbf{h}_{\mathbf{E}}}\,d\lambda_{\mathbf{g}}(y) = \mathcal{T}_s(|\mathbf{u}_j-\mathbf{u}|_{\mathbf{h}_{\mathbf{E}}})(x),\end{aligned}$$

so the left-hand side tends to zero. By uniqueness of the limit, the extension $\mathcal{G}_s^{\mathbf{E}}\mathbf{u}$ agrees almost everywhere with the kernel integral. Since $\mathcal{G}_s^{\mathbf{E}} = J_{s,p}^{\mathbf{E}}$ in $L^p(M,\mathbf{E})$, the asserted representation follows. □

12.4.3 Definition of the fractional scale

With the potential and its kernel available, we can define real orders of regularity intrinsically. The definition is arranged to agree with integer orders and to be stable under spectral calculus.

Definition 12.4.5. (Bessel Sobolev spaces of positive order) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Let $s > 0$ and $1 \le p < \infty$. Define

$$H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E}) := J^{\mathbf{E}}_{s,p}(L^p(M,\mathbf{E})).$$

If $\mathbf{u} = J^{\mathbf{E}}_{s,p}\mathbf{f}$, set

$$\|\mathbf{u}\|_{H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})} := \|\mathbf{f}\|_{L^p(M,\mathbf{E})}.$$

Injectivity of $J^{\mathbf{E}}_{s,p}$ ensures that this norm is well defined. For $s = 0$, set $H^{0,p}_{L_{\mathbf{E}}}(M,\mathbf{E}) := L^p(M,\mathbf{E})$.

Definition 12.4.6. (Spaces of negative order) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Let $s < 0$ and $1 \le p < \infty$. Define $H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})$ as the completion of $L^p(M,\mathbf{E})$ with respect to the norm

$$\|\mathbf{u}\|_{H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})} := \|J^{\mathbf{E}}_{-s,p}\mathbf{u}\|_{L^p(M,\mathbf{E})}.$$

Notation 12.4.7. (Scalar Bessel scale) On the trivial bundle of rank one, equipped with the trivial connection, the connection Laplacian is the positive realization $L = \Delta_B = -\Delta$ introduced in the section on the scalar semigroup. For every $s \in \mathbb{R}$ and $1 \le p < \infty$, we write

$$H^{s,p}_{L}(M) := H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})$$

in this case. Thus $H^{s,p}_{L}(M)$ always denotes the intrinsic scale constructed through the heat semigroup and the potentials $(I+L)^{-\frac{s}{2}}$, while the notation without a subscript is reserved for the spaces defined by localization when these are introduced.

Proposition 12.4.8. (Conjugation of the Bessel scale) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a smooth complex vector bundle of finite rank with a Hermitian metric and a compatible connection. The conjugate connection $\nabla^{\overline{\mathbf{E}}}$ is compatible with $\mathbf{h}_{\overline{\mathbf{E}}}$, and its Laplacian satisfies

$$L_{\overline{\mathbf{E}},0}(\overline{\mathbf{u}}) = \overline{L_{\mathbf{E},0}\mathbf{u}}, \qquad \mathbf{u}\in\Gamma_c(\mathbf{E}).$$

For every $1\le p<\infty$, $t\ge 0$, and $r>0$,

$$P_t^{\overline{\mathbf{E}},p}(\overline{\mathbf{u}}) = \overline{P_t^{\mathbf{E},p}\mathbf{u}},$$
$$J_{r,p}^{\overline{\mathbf{E}}}(\overline{\mathbf{u}}) = \overline{J_{r,p}^{\mathbf{E}}\mathbf{u}}.$$

Consequently, for each $s\in\mathbb{R}$, the map

$$\mathfrak{C}_{s,p,\mathbf{E}}\colon \overline{H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})}\longrightarrow H^{s,p}_{L_{\overline{\mathbf{E}}}}(M,\overline{\mathbf{E}}), \qquad \mathfrak{C}_{s,p,\mathbf{E}}(\overline{\mathbf{u}})=\overline{\mathbf{u}}, \tag{12.6}$$

is a complex-linear isometric isomorphism.

Proof. Compatibility of $\nabla^{\overline{\mathbf{E}}}$ and parallelism of $\mathcal{R}_{\mathbf{E}}$ were proved in Proposition 2.5.7. Conjugating the local formula $L_{\mathbf{E},0}\mathbf{u}=-\operatorname{tr}_{\mathbf{g}}(\nabla^2\mathbf{u})$ gives the first identity. Conjugation of sections is an antilinear isometry between the L^2 spaces and between the domains of the energy forms; uniqueness of the associated self-adjoint realization gives $L_{\overline{\mathbf{E}}}\mathfrak{C}=\mathfrak{C}L_{\mathbf{E}}$. Spectral calculus, followed by uniqueness of the consistent extensions to L^p, gives the semigroup identity. Integrating this identity in the Laplace formula for $J_{r,p}$ gives the potential identity. For $s>0$, the norm of the image of $J^{\mathbf{E}}_{s,p}\mathbf{u}$ is the norm of $\overline{\mathbf{u}}$ in $L^p(M,\overline{\mathbf{E}})$, equal to that of $\mathbf{u}$. For $s<0$, the same conclusion follows from the norm defining the completion. Surjectivity follows by conjugating again. Finally, the scalar structure of the conjugate space shows that (12.6) is complex-linear. □

Theorem 12.4.9. (Properties of the Bessel scale) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Let $1\le p<\infty$.

(a) $H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})$ is a Banach space for every $s\in\mathbb{R}$;

(b) if $s_1>s_0$, the inclusion

$$H^{s_1,p}_{L_{\mathbf{E}}}(M,\mathbf{E})\hookrightarrow H^{s_0,p}_{L_{\mathbf{E}}}(M,\mathbf{E})$$

is continuous and has dense image;

(c) for $r>0$ and $s\in\mathbb{R}$, $J^{\mathbf{E}}_{r,p}$ extends to an isometric isomorphism

$$J^{\mathbf{E}}_{r,p}\colon H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})\longrightarrow H^{s+r,p}_{L_{\mathbf{E}}}(M,\mathbf{E});$$

(d) if $s>0$, $J^{\mathbf{E}}_{s,p}(\Gamma_c(\mathbf{E}))$ is dense in $H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})$;

(e) if $1<p<\infty$, p' is the conjugate exponent, and $s\in\mathbb{R}$, integral duality, initially defined on $L^p(M,\mathbf{E})\times L^{p'}(M,\overline{\mathbf{E}})$, extends uniquely to a continuous complex-bilinear pairing

$$\mathfrak{b}_{s,p;\mathbf{E}}\colon H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})\times H^{-s,p'}_{L_{\overline{\mathbf{E}}}}(M,\overline{\mathbf{E}})\longrightarrow\mathbb{C}$$

and induces the complex-linear isometric isomorphism

$$H^{-s,p'}_{L_{\overline{\mathbf{E}}}}(M,\overline{\mathbf{E}}) \longrightarrow \big(H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})\big)', \qquad \mathbf{w} \longmapsto \big[\mathbf{u} \longmapsto \mathfrak{b}_{s,p;\mathbf{E}}(\mathbf{u},\mathbf{w})\big]. \tag{12.7}$$

Equivalently, using (12.6), we obtain

$$\overline{H^{-s,p'}_{L_{\mathbf{E}}}(M,\mathbf{E})} \longrightarrow \big(H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})\big)', \qquad \overline{\mathbf{v}} \longmapsto \left[\mathbf{u} \longmapsto \int_M \mathbf{h}_{\mathbf{E}}(\mathbf{u},\mathbf{v})\, d\lambda_{\mathbf{g}}\right].$$

In the last formula, the integral has its literal meaning when $\mathbf{u} \in L^p(M,\mathbf{E})$ and $\mathbf{v} \in L^{p'}(M,\mathbf{E})$; for elements of general orders, it denotes, by definition, the unique continuous extension $\mathfrak{b}_{s,p;\mathbf{E}}(\mathbf{u}, \mathfrak{C}_{-s,p',\mathbf{E}}(\overline{\mathbf{v}}))$. This convention does not assign pointwise values to a distribution of negative order.

Proof. Parts (a)–(c) are Theorem B.4.19 applied to the semigroup $(P^{\mathbf{E},p}_t)_{t\geq 0}$. For (d), if $\mathbf{u} = J^{\mathbf{E}}_{s,p}\mathbf{f}$, choose $\mathbf{f}_j \in \Gamma_c(\mathbf{E})$ with $\mathbf{f}_j \to \mathbf{f}$ in $L^p(M,\mathbf{E})$. Then

$$\|J^{\mathbf{E}}_{s,p}\mathbf{f}_j - \mathbf{u}\|_{H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})} = \|\mathbf{f}_j - \mathbf{f}\|_{L^p(M,\mathbf{E})} \longrightarrow 0.$$

For duality, self-adjointness on L^2 and consistency of the extensions imply

$$\int_M \mathbf{h}_{\mathbf{E}}(P^{\mathbf{E},p}_t\mathbf{u},\mathbf{v})\, d\lambda_{\mathbf{g}} = \int_M \mathbf{h}_{\mathbf{E}}(\mathbf{u},P^{\mathbf{E},p'}_t\mathbf{v})\, d\lambda_{\mathbf{g}}$$

for $\mathbf{u}$ and $\mathbf{v}$ in dense intersections. The integral defining $J^{\mathbf{E}}_{r,p}$ is dominated by

$$\frac{t^{\frac{r}{2}-1}e^{-t}}{\Gamma(\frac{r}{2})}\|\mathbf{u}\|_{L^p(M,\mathbf{E})}\|\mathbf{v}\|_{L^{p'}(M,\mathbf{E})},$$

which is integrable on $(0,\infty)$. Fubini's theorem for Bochner integrals B.6.26 gives

$$\int_M \mathbf{h}_{\mathbf{E}}(J^{\mathbf{E}}_{r,p}\mathbf{u},\mathbf{v})\, d\lambda_{\mathbf{g}} = \int_M \mathbf{h}_{\mathbf{E}}(\mathbf{u},J^{\mathbf{E}}_{r,p'}\mathbf{v})\, d\lambda_{\mathbf{g}}. \tag{12.8}$$

Proposition B.4.23, applied to the bilinear pairing $L^p(M,\mathbf{E})\times L^{p'}(M,\overline{\mathbf{E}})$ induced by $\mathcal{R}_{\mathbf{E}}$, uses (12.8) and proves that (12.7) is isometric and surjective. It is complex-linear in $\mathbf{w}$ because $\mathcal{R}_{\mathbf{E}}\colon \overline{\mathbf{E}} \to \mathbf{E}^*$ is complex-linear. Composition with the linear isomorphism $\mathfrak{C}_{-s,p',\mathbf{E}}$ gives the equivalent formulation from the conjugate space. In the real case, $\overline{\mathbf{E}} = \mathbf{E}$ and we recover the usual real duality. □

12.4.4 Spectral characterization in L^2

Theorem 12.4.10. (Spectral characterization) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. Let $s > 0$. Then

$$J^{\mathbf{E}}_{s,2} = (I + L_{\mathbf{E}})^{-\frac{s}{2}}$$

and

$$H^{s,2}_{L_{\mathbf{E}}}(M,\mathbf{E}) = \mathcal{D}\big((I + L_{\mathbf{E}})^{\frac{s}{2}}\big).$$

For $\mathbf{u}$ in this space,

$$\|\mathbf{u}\|_{H^{s,2}_{L_{\mathbf{E}}}(M,\mathbf{E})} = \|(I+L_{\mathbf{E}})^{\frac{s}{2}}\mathbf{u}\|_{L^2(M,\mathbf{E})}.$$

In particular,

$$H^{1,2}_{L_{\mathbf{E}}}(M,\mathbf{E}) = W^{1,2}(M,\mathbf{E})$$

and

$$\|\mathbf{u}\|^2_{H^{1,2}_{L_{\mathbf{E}}}(M,\mathbf{E})} = \|\mathbf{u}\|^2_{L^2(M,\mathbf{E})} + \|\nabla^{\mathbf{E}}\mathbf{u}\|^2_{L^2(M,T^*M\otimes\mathbf{E})}.$$

Proof. For $\lambda \geq 0$,

$$(1+\lambda)^{-\frac{s}{2}} = \frac{1}{\Gamma(\frac{s}{2})}\int_0^\infty t^{\frac{s}{2}-1}e^{-t}e^{-t\lambda}\,dt.$$

To justify the passage to spectral calculus precisely, fix $\mathbf{u} \in L^2(M,\mathbf{E})$ and, for $0 < \varepsilon < R < \infty$, set

$$m_{\varepsilon,R}(\lambda) := \frac{1}{\Gamma(\frac{s}{2})}\int_\varepsilon^R t^{\frac{s}{2}-1}e^{-t}e^{-t\lambda}\,dt.$$

On the compact interval $[\varepsilon, R]$, the map $t \mapsto e^{-tL_{\mathbf{E}}}$ is continuous in operator norm: indeed, the spectral calculus in Theorem B.4.6 and the scalar fundamental theorem of calculus give

$$\|e^{-tL_{\mathbf{E}}} - e^{-\tau L_{\mathbf{E}}}\|_{\mathcal{L}(L^2(M,\mathbf{E}))} \leq |t-\tau| \sup_{\lambda\in[0,\infty)} \lambda e^{-\varepsilon\lambda} \leq \frac{|t-\tau|}{e\varepsilon}.$$

Approximating the integral by Riemann sums and using the rules of the same functional calculus yields

$$\frac{1}{\Gamma(\frac{s}{2})}\int_\varepsilon^R t^{\frac{s}{2}-1}e^{-t}e^{-tL_{\mathbf{E}}}\mathbf{u}\,dt = m_{\varepsilon,R}(L_{\mathbf{E}})\mathbf{u}.$$

As $\varepsilon \to 0^+$ and $R \to \infty$, the left-hand side converges to $J^{\mathbf{E}}_{s,2}\mathbf{u}$ by the Bochner dominated convergence theorem B.6.25. On the other hand, $m_{\varepsilon,R}(\lambda) \to (1+\lambda)^{-\frac{s}{2}}$ and $0 \leq m_{\varepsilon,R}(\lambda) \leq 1$. The norm formula in Theorem B.4.6, followed by Lebesgue's dominated convergence theorem B.6.14, implies

$$m_{\varepsilon,R}(L_{\mathbf{E}})\mathbf{u} \longrightarrow (I+L_{\mathbf{E}})^{-\frac{s}{2}}\mathbf{u} \quad \text{in } L^2(M,\mathbf{E}).$$

Consequently, $J^{\mathbf{E}}_{s,2}\mathbf{u} = (I+L_{\mathbf{E}})^{-\frac{s}{2}}\mathbf{u}$. Corollary B.4.8 identifies the range of $(I+L_{\mathbf{E}})^{-\frac{s}{2}}$ with the domain of $(I+L_{\mathbf{E}})^{\frac{s}{2}}$ and shows that these operators are inverses on the respective spaces.
For $s = 1$, Corollary B.4.7 gives

$$\mathcal{D}\big((I+L_{\mathbf{E}})^{\frac{1}{2}}\big) = W^{1,2}(M,\mathbf{E})$$

and

$$\|(I+L_{\mathbf{E}})^{\frac{1}{2}}\mathbf{u}\|^2_{L^2(M,\mathbf{E})} = \|\mathbf{u}\|^2_{L^2(M,\mathbf{E})} + \mathfrak{q}_{\mathbf{E}}(\mathbf{u},\mathbf{u}).$$

The definition of $\mathfrak{q}_{\mathbf{E}}$ completes the proof. □

Proposition 12.4.11. (Spectral, dual, and interpolation compatibility in L^2) Let $(M,\mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric $\mathbf{h}_{\mathbf{E}}$, Hermitian in the complex case, and a compatible connection. First suppose that

$\mathbf{E}$ is complex, and set $B_{\mathbf{E}} := I + L_{\mathbf{E}}$. Let $s_0 < s_1$, $0 < \theta < 1$, and $s_\theta := (1-\theta)s_0 + \theta s_1$. Then

$$[H^{s_0,2}_{L_{\mathbf{E}}}(M,\mathbf{E}), H^{s_1,2}_{L_{\mathbf{E}}}(M,\mathbf{E})]_\theta = H^{s_\theta,2}_{L_{\mathbf{E}}}(M,\mathbf{E}) \tag{12.9}$$

as topological spaces, with the norms determined by spectral calculus. This identification is the identity on the intersection of the two endpoints and commutes with Bessel potentials and the conjugation (12.6). Moreover, if $s > 0$, $\mathbf{w} \in H^{-s,2}_{L_{\overline{\mathbf{E}}}}(M,\overline{\mathbf{E}})$,

$$z := J^{\overline{\mathbf{E}}}_{s,2}\mathbf{w} \in L^2(M,\overline{\mathbf{E}})$$

, and $\mathbf{u} \in H^{s,2}_{L_{\mathbf{E}}}(M,\mathbf{E})$, denote by $\langle \mathbf{u},\mathbf{w}\rangle_{s,2;\mathbf{E}}$ the pairing in Theorem 12.4.9. It is given by the spectral formula

$$\langle \mathbf{u},\mathbf{w}\rangle_{s,2;\mathbf{E}} = \int_M \mathcal{R}_{\mathbf{E}}(z)\big(B^{\frac{s}{2}}_{\mathbf{E}}\mathbf{u}\big)\, d\lambda_{\mathbf{g}}. \tag{12.10}$$

In particular,

$$H^{-s,2}_{L_{\overline{\mathbf{E}}}}(M,\overline{\mathbf{E}}) \xrightarrow{\cong} \big(\mathcal{D}(B^{\frac{s}{2}}_{\mathbf{E}}), \|B^{\frac{s}{2}}_{\mathbf{E}}\cdot\|_{L^2(M,\mathbf{E})}\big)'$$

is precisely the identification in (12.7); passage to the spectral characterization introduces no second duality convention. When interpolating two orders, the pairing at order s_θ is the unique continuous extension of the same pairings on the common spectral core. Thus duality, conjugation, and interpolation give compatible identifications.

If $\mathbf{E}$ is real, the same assertions are obtained in the complexification and restricted to the invariant real subspace; in the dual formula, $\overline{\mathbf{E}}$ and $\mathcal{R}_{\mathbf{E}}$ are omitted and the real bundle inner product is used.

Proof. First prove (12.9) when $0 \le s_0 < s_1$. Write

$$a_j := \frac{s_j}{2}, \qquad a(z) := (1-z)a_0 + za_1, \qquad a := a(\theta), \qquad \delta := a_1 - a_0.$$

By the preceding theorem, $H^{s_j,2}_{L_{\mathbf{E}}}(M,\mathbf{E}) = \mathcal{D}(B^{a_j}_{\mathbf{E}})$, with norm $\|B^{a_j}_{\mathbf{E}}\cdot\|_{L^2(M,\mathbf{E})}$. Spectral calculus gives

$$\|B^{it}_{\mathbf{E}}\mathbf{v}\|_{L^2(M,\mathbf{E})} = \|\mathbf{v}\|_{L^2(M,\mathbf{E})}, \qquad t \in \mathbb{R}. \tag{12.11}$$

Let $\mathbf{u} \in \mathcal{D}(B^a_{\mathbf{E}})$. For $\varepsilon > 0$, the family

$$F_\varepsilon(z) := e^{\varepsilon(z-\theta)^2} B^{a-a(z)}_{\mathbf{E}}\mathbf{u}$$

is admissible for the complex method. Indeed, this is first verified after spectrally truncating $\mathbf{u}$ to the interval $[1,N]$; the spectral norm formula and dominated convergence then allow us to let $N \to \infty$, uniformly on closed substrips and in the two boundary norms. For $j \in \{0,1\}$ and $t \in \mathbb{R}$,

$$B^{a_j}_{\mathbf{E}} F_\varepsilon(j+it) = e^{\varepsilon(j+it-\theta)^2} B^{a-it\delta}_{\mathbf{E}}\mathbf{u}.$$

Identity (12.11) gives

$$\|F_\varepsilon(j+it)\|_{H^{s_j,2}_{L_{\mathbf{E}}}(M,\mathbf{E})} \le e^{\varepsilon(j-\theta)^2} e^{-\varepsilon t^2} \|B^a_{\mathbf{E}}\mathbf{u}\|_{L^2(M,\mathbf{E})}.$$

Since $F_\varepsilon(\theta) = \mathbf{u}$, we let $\varepsilon \to 0^+$ and obtain the embedding of $H^{s_\theta,2}_{L_{\mathbf{E}}}(M,\mathbf{E})$ into the left-hand side of (12.9).

For the reverse embedding, let F be an admissible family with $\mathbf{u} = F(\theta)$, and let

$$\mathscr{C}_{\mathbf{E}} := \bigcup_{N\in\mathbb{N}} \mathbf{1}_{[1,N]}(B_{\mathbf{E}})L^2(M,\mathbf{E}).$$

This subspace is a core for every nonnegative real power of $B_{\mathbf{E}}$. For $\mathbf{v} \in \mathscr{C}_{\mathbf{E}}$, the function

$$\Phi_v(z) := \int_M \mathbf{h}_{\mathbf{E}}\big(F(z), B_{\mathbf{E}}^{a(\overline{z})}\mathbf{v}\big)\, d\lambda_{\mathbf{g}}$$

is holomorphic: the second entry is antiholomorphic, and $\mathbf{h}_{\mathbf{E}}$ is antilinear in that entry. On the boundary $z = j + it$, self-adjointness and (12.11) imply

$$|\Phi_v(j+it)| \le \|F(j+it)\|_{H^{s_j,2}_{L_{\mathbf{E}}}(M,\mathbf{E})} \|B_{\mathbf{E}}^{-a_j} B_{\mathbf{E}}^{a_j - it\delta}\mathbf{v}\|_{L^2(M,\mathbf{E})} = \|F(j+it)\|_{H^{s_j,2}_{L_{\mathbf{E}}}(M,\mathbf{E})} \|\mathbf{v}\|_{L^2(M,\mathbf{E})}.$$

The three-lines lemma 5.7.3 gives

$$\left| \int_M \mathbf{h}_{\mathbf{E}}(\mathbf{u}, B_{\mathbf{E}}^a \mathbf{v})\, d\lambda_{\mathbf{g}} \right| \le \|F\|_{\mathscr{F}} \|\mathbf{v}\|_{L^2(M,\mathbf{E})}.$$

Since $\mathscr{C}_{\mathbf{E}}$ is a core for $B_{\mathbf{E}}^a$, conjugating the preceding inequality gives a bounded linear functional

$$\mathbf{v} \longmapsto \int_M \mathbf{h}_{\mathbf{E}}(B_{\mathbf{E}}^a \mathbf{v}, \mathbf{u})\, d\lambda_{\mathbf{g}}$$

on $\mathscr{C}_{\mathbf{E}}$ with respect to the norm of $L^2(M,\mathbf{E})$. This extends to all of $L^2(M,\mathbf{E})$, and the Riesz representation theorem B.3.12 provides $\mathbf{g} \in L^2(M,\mathbf{E})$ such that

$$\int_M \mathbf{h}_{\mathbf{E}}(B_{\mathbf{E}}^a \mathbf{v}, \mathbf{u})\, d\lambda_{\mathbf{g}} = \int_M \mathbf{h}_{\mathbf{E}}(\mathbf{v}, \mathbf{g})\, d\lambda_{\mathbf{g}}, \qquad \mathbf{v} \in \mathscr{C}_{\mathbf{E}}.$$

Since $\mathscr{C}_{\mathbf{E}}$ is a core for $B_{\mathbf{E}}^a$, the identity extends to all of $v \in \mathcal{D}(B_{\mathbf{E}}^a)$. By the definition of the adjoint and self-adjointness of $B_{\mathbf{E}}^a$, this proves that $\mathbf{u} \in \mathcal{D}(B_{\mathbf{E}}^a)$, $B_{\mathbf{E}}^a \mathbf{u} = \mathbf{g}$, and $\|B_{\mathbf{E}}^a \mathbf{u}\|_{L^2(M,\mathbf{E})} \le \|F\|_{\mathscr{F}}$. Taking the infimum over F gives the reverse embedding.

For arbitrary orders $s_0 < s_1$, choose $r > \max\{0, -s_0\}$. By Theorem 12.4.9, the same potential $J_{r,2}^{\mathbf{E}}$ is a simultaneous isometric isomorphism

$$H^{s_j,2}_{L_{\mathbf{E}}}(M,\mathbf{E}) \longrightarrow H^{s_j+r,2}_{L_{\mathbf{E}}}(M,\mathbf{E}), \qquad j \in \{0,1\},$$

and also at the intermediate order. The complex interpolation theorem for operators 5.7.5, applied to $J_{r,2}^{\mathbf{E}}$ and its inverse on these compatible pairs, reduces the general case to the one already proved.

Now prove (12.10). Set $\mathbf{f} := B_{\mathbf{E}}^{\frac{s}{2}}\mathbf{u}$, so that $\mathbf{u} = J_{s,2}^{\mathbf{E}}\mathbf{f}$. The bilinear symmetry of the potentials, expressed between $\mathbf{E}$ and $\overline{\mathbf{E}}$, gives

$$\langle J_{s,2}^{\mathbf{E}}\mathbf{f}, \mathbf{w}\rangle_{s,2;\mathbf{E}} = \int_M \mathcal{R}_{\mathbf{E}}(J_{s,2}^{\overline{\mathbf{E}}}\mathbf{w})(\mathbf{f})\, d\lambda_{\mathbf{g}},$$

which is exactly the asserted formula. The operators $J_{r,2}$, spectral powers of real exponent, and conjugation commute because their scalar multipliers are real. Finally, spectral truncations form a dense subspace at every order; on this subspace, all the preceding identifications are the same algebraic formulas. Uniqueness

of continuous extensions proves the final compatibility assertion. □

Remark 12.4.12. (Complex interpolation outside L^2) The Hilbert space proof uses the fact that $(I + L_{\mathbf{E}})^{it}$ is unitary on L^2 for $t \in \mathbb{R}$. For $1 < p < \infty$, the argument requires a bound for these powers on $L^p(M, \mathbf{E})$; heat contractivity alone does not provide this bound for an abstract semigroup. Lemma 13.3.26 will prove it for the covariant Laplacian on a complete manifold, and Theorem 13.3.27 will establish the corresponding interpolation result. Comparison with localized norms additionally requires bounded geometry of the base and bundle; it is established in Theorem 14.5.6.

Corollary 12.4.13. Let $(M, \mathbf{g})$ be a connected, complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle of finite rank with a bundle metric and a compatible connection. If $m \in \mathbb{N}$ and $1 \le p < \infty$, then

$$H^{2m,p}_{L_{\mathbf{E}}}(M, \mathbf{E}) = \mathcal{D}\big((I + L_{\mathbf{E},p})^m\big)$$

and

$$\|\mathbf{u}\|_{H^{2m,p}_{L_{\mathbf{E}}}(M,\mathbf{E})} = \|(I + L_{\mathbf{E},p})^m \mathbf{u}\|_{L^p(M,\mathbf{E})}.$$

Proof. Proposition 12.4.2 gives

$$J^{\mathbf{E}}_{2m,p} = (I + L_{\mathbf{E},p})^{-m}.$$

The range of this iterated resolvent is the domain of $(I+L_{\mathbf{E},p})^m$, and the range norm agrees with the indicated norm. □

Corollary 12.4.14. (Comparison on a closed manifold) If M is closed, then, for every $m \in \mathbb{N}_0$,

$$H^{m,2}_{L_{\mathbf{E}}}(M, \mathbf{E}) = H^m(M, \mathbf{E})$$

and there exist constants $c_m, C_m > 0$, depending only on m and the fixed data $(M, g, \mathbf{E}, \mathbf{h}_{\mathbf{E}}, \nabla^{\mathbf{E}})$, such that

$$c_m \|\mathbf{u}\|_{H^m(M,\mathbf{E})} \le \|\mathbf{u}\|_{H^{m,2}_{L_{\mathbf{E}}}(M,\mathbf{E})} \le C_m \|\mathbf{u}\|_{H^m(M,\mathbf{E})}, \qquad \mathbf{u} \in H^m(M, \mathbf{E}).$$

Proof. For $m = 0$, the two norms agree. Let $m = 2q$ with $q \ge 1$. Corollary 11.5.1 gives

$$\mathcal{D}(L^q_{\mathbf{E}}) = H^{2q}(M, \mathbf{E})$$

and constants $a_q, A_q > 0$ for which

$$a_q \|\mathbf{u}\|_{H^{2q}(M,\mathbf{E})} \le \|\mathbf{u}\|_{L^2(M,\mathbf{E})} + \|L^q_{\mathbf{E}}\mathbf{u}\|_{L^2(M,\mathbf{E})} \le A_q \|\mathbf{u}\|_{H^{2q}(M,\mathbf{E})}.$$

For $\lambda \ge 0$,

$$1 + \lambda^{2q} \le (1 + \lambda)^{2q} \le 2^{2q-1}(1 + \lambda^{2q}).$$

Spectral calculus, together with

$$\big(\|\mathbf{u}\|^2_{L^2(M,\mathbf{E})} + \|L^q_{\mathbf{E}}\mathbf{u}\|^2_{L^2(M,\mathbf{E})}\big)^{\frac{1}{2}} \le \|\mathbf{u}\|_{L^2(M,\mathbf{E})} + \|L^q_{\mathbf{E}}\mathbf{u}\|_{L^2(M,\mathbf{E})} \le \sqrt{2}\,\big(\|\mathbf{u}\|^2_{L^2(M,\mathbf{E})} + \|L^q_{\mathbf{E}}\mathbf{u}\|^2_{L^2(M,\mathbf{E})}\big)^{\frac{1}{2}},$$

proves the asserted inequality with $c_{2q} = \frac{a_q}{\sqrt{2}}$ and $C_{2q} = 2^{q-\frac{1}{2}} A_q$.
For $m = 2q+1$, spectral calculus gives

$$\mathcal{D}\big((I+L_{\mathbf{E}})^{q+\frac{1}{2}}\big) = \Big\{ \mathbf{u} \in \mathcal{D}\big((I+L_{\mathbf{E}})^{q}\big) \,\Big|\, (I+L_{\mathbf{E}})^{q}\mathbf{u} \in \mathcal{D}\big((I+L_{\mathbf{E}})^{\frac{1}{2}}\big) \Big\}.$$

Theorem 12.4.10 identifies the last domain with $W^{1,2}(M,\mathbf{E})$. Set

$$\mathcal{N}_q(\mathbf{u})^2 := \sum_{j=0}^{q} \|L_{\mathbf{E}}^{j}\mathbf{u}\|^2_{L^2(M,\mathbf{E})} + \|\nabla^{\mathbf{E}} L_{\mathbf{E}}^{q}\mathbf{u}\|^2_{L^2(M,T^*M\otimes\mathbf{E})}.$$

The identity $\|\nabla^{\mathbf{E}} L_{\mathbf{E}}^{j}\mathbf{u}\|^2_{L^2(M,T^*M\otimes\mathbf{E})} = \langle L_{\mathbf{E}}^{j+1}\mathbf{u}, L_{\mathbf{E}}^{j}\mathbf{u}\rangle_{L^2(M,\mathbf{E})}$ and Cauchy–Schwarz give

$$\|\nabla^{\mathbf{E}} L_{\mathbf{E}}^{j}\mathbf{u}\|^2_{L^2(M,T^*M\otimes\mathbf{E})} \le \frac{1}{2}\big(\|L_{\mathbf{E}}^{j+1}\mathbf{u}\|^2_{L^2(M,\mathbf{E})} + \|L_{\mathbf{E}}^{j}\mathbf{u}\|^2_{L^2(M,\mathbf{E})}\big), \qquad 0 \le j < q.$$

If $\|\mathbf{u}\|_{\Delta_B,2q+1}$ denotes the norm in Theorem 9.1.42, these inequalities imply

$$\mathcal{N}_q(\mathbf{u})^2 \le \|\mathbf{u}\|^2_{\Delta_B,2q+1} \le (q+1)\mathcal{N}_q(\mathbf{u})^2.$$

The cited theorem provides $\alpha_q, b_q > 0$, depending only on q and the fixed geometric data, such that

$$\alpha_q \|\mathbf{u}\|^2_{H^{2q+1}(M,\mathbf{E})} \le \|\mathbf{u}\|^2_{\Delta_B,2q+1} \le b_q \|\mathbf{u}\|^2_{H^{2q+1}(M,\mathbf{E})}.$$

On the other hand, for $\lambda \ge 0$,

$$\frac{1}{q+2}\left(\sum_{j=0}^{q} \lambda^{2j} + \lambda^{2q+1}\right) \le (1+\lambda)^{2q+1} \le 2^{2q}\left(\sum_{j=0}^{q} \lambda^{2j} + \lambda^{2q+1}\right).$$

Spectral calculus turns this polynomial comparison into

$$\frac{1}{\sqrt{q+2}}\mathcal{N}_q(\mathbf{u}) \le \|(I+L_{\mathbf{E}})^{q+\frac{1}{2}}\mathbf{u}\|_{L^2(M,\mathbf{E})} \le 2^q \mathcal{N}_q(\mathbf{u}).$$

Consequently, we may take

$$c_{2q+1} := \sqrt{\frac{\alpha_q}{(q+1)(q+2)}}, \qquad C_{2q+1} := 2^q\sqrt{b_q}.$$

Moreover, $\Gamma(\mathbf{E})$ is dense in both norms: it is dense in $H^{2q+1}(M,\mathbf{E})$ by definition and, since M is compact, it is also dense in $H^{2q+1,2}_{L_{\mathbf{E}}}(M,\mathbf{E})$. Indeed, spectral calculus gives

$$J^{\mathbf{E}}_{2q+1,2}(\Gamma(\mathbf{E})) \subseteq \bigcap_{k\in\mathbb{N}} \mathcal{D}(L_{\mathbf{E}}^{k}) = \Gamma(\mathbf{E}),$$

while part (d) of Theorem 12.4.9 states that the subset on the left-hand side is dense in $H^{2q+1,2}_{L_{\mathbf{E}}}(M,\mathbf{E})$. Thus the inequalities extend to the completions and simultaneously prove equality of the two spaces. □

Remark 12.4.15. (Comparison beyond the compact case) The equality $H^{1,2}_{L^2_{\mathbf{E}}}(M,\mathbf{E}) = W^{1,2}(M,\mathbf{E})$ holds on every complete manifold. For higher orders and for $p \neq 2$, identifying the Bessel scale with the spaces defined by covariant derivatives requires global elliptic estimates. The chapter on elliptic operators provides these estimates on closed manifolds, while the chapter on bounded geometry explains the uniform hypotheses needed in the noncompact case. Completeness alone guarantees the existence of the Bessel scale, but not global equivalence with a norm formed from finitely many covariant derivatives.

Remark 12.4.16. (Choice of operator) The construction can be carried out with other self-adjoint elliptic operators bounded from below, provided that their semigroups admit consistent extensions to $L^p(M,\mathbf{E})$. In this chapter, we chose the connection Laplacian because it is determined by $(g,\mathbf{h}_{\mathbf{E}},\nabla^{\mathbf{E}})$, its quadratic form is exactly the energy of the connection, and Kato's inequality gives a direct comparison with the scalar semigroup.

13

Sobolev spaces on manifolds of bounded geometry

An estimate obtained in a chart may be correct and yet provide no global information: its constant may grow as the center of the chart tends to infinity. On a compact manifold, choosing a finite cover suffices. On a noncompact manifold, we need another property: the ability to repeat the same local argument with radii and constants independent of the point.

Bounded geometry makes this possible. The injectivity radius provides normal charts of a common size; bounds on the curvature and its derivatives control the metric in these charts. From these data we will construct covers of uniformly bounded multiplicity and partitions of unity whose derivatives remain bounded. These are the conditions that allow us to sum the local estimates without losing control of the norm.

We will then compare spaces defined by localization with those defined using covariant derivatives or powers of the Laplacian. In this comparison, we must distinguish integer regularity from fractional regularity and, within the latter, the different orders of summation defining Besov and Triebel–Lizorkin spaces. We will retain these distinctions in interpolation and duality arguments as well.

The manifolds in this chapter are assumed to have no boundary. The case with boundary is developed in Chapter 14, where normal charts near the boundary are replaced by Fermi charts, and Euclidean norms by restriction norms on the half-space.

Uniformity in noncompact spaces

On a compact manifold, a finite cover allows the distortions of the charts and the metric to be absorbed into a single constant. This advantage disappears in the noncompact case. Bounded geometry replaces finiteness by uniformity: charts of controlled size, bounded multiplicity, and estimates independent of the center. Eichhorn's work and the framework of uniformly regular manifolds developed by Amann provide two closely related ways of turning this geometric uniformity into a stable theory of function spaces [53, 6].

13.1 Riemannian manifolds of bounded geometry

In the analytic study of a Riemannian manifold, it is essential to have local coordinate systems in which the geometry is controlled and comparable to its Euclidean counterpart. One of the most effective tools for this purpose is normal coordinates, constructed using the Riemannian exponential map at a point. These coordinates give a particularly simple representation of the metric near their center and facilitate the transfer of classical techniques from $\mathbb{R}^n$ to manifolds.

However, this procedure has limitations: at some distance, the exponential map may cease to be a diffeomorphism onto its image because conjugate points occur or distinct geodesics issuing from the same point intersect. This leads to the need to quantify the largest radius within which normal coordinates behave appropriately.

This parameter is the *injectivity radius* of the manifold, which plays a central role in geometry and analysis. A positive lower bound for this radius allows us to use normal charts of a common size. To control their metric coefficients and derivatives as well, we will need the curvature bounds introduced below. Both conditions enter into comparisons of Sobolev, Besov, and Triebel–Lizorkin norms.

Definition 13.1.1. (Injectivity radius) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and let $p \in M$. The *injectivity radius at* p, denoted by $\operatorname{inj}(p)$, is the supremum of the numbers $r > 0$ for which the Riemannian exponential map

$$\exp_p : B_{\mathbf{g}_p}(0, r) \subset T_pM \longrightarrow M$$

is a diffeomorphism onto its image.
The *injectivity radius of* M is defined by

$$\operatorname{inj}(M) := \inf_{p \in M} \operatorname{inj}(p).$$

Remark 13.1.2. Let M be a Riemannian manifold without boundary. If $\operatorname{inj}(M) > 0$, then every connected component of M is complete. Indeed, choose $0 < r < \operatorname{inj}(M)$. Every unit-speed geodesic defined on a maximal interval $[0, b)$, with $b < \infty$, can be extended from any time $t_0 < b$ for at least a time r, since $\exp_{\gamma(t_0)}$ is defined on the ball of radius r. Taking $b - r < t_0 < b$ gives an extension beyond b, a contradiction. Thus, each component is geodesically complete; the Hopf–Rinow Theorem 2.9.9 implies its metric completeness.

Since $\operatorname{inj}(M) \geq 0$, there are only two possibilities: $\operatorname{inj}(M) = 0$ or $\operatorname{inj}(M) > 0$. The first behavior can occur, for example, on manifolds containing geodesic loops of arbitrarily small length, as illustrated in the following figure.

Remark 13.1.3. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, and suppose that its injectivity radius satisfies $\operatorname{inj}(M) > 0$. Then, for each $p \in M$ and every $0 < r < \operatorname{inj}(M)$, the exponential map

$$\exp_p : B_{\mathbf{g}_p}(0, r) \subseteq T_pM \longrightarrow B_{\mathbf{g}}(p, r) \subseteq M$$

is a diffeomorphism.
In particular, every point $q \in B_{\mathbf{g}}(p, r)$ can be joined to p by a unique minimizing geodesic of length less than r, given by

$$\gamma(t) = \exp_p(tv), \qquad t \in [0, 1],$$

where $v \in T_pM$ satisfies $\|v\|_{\mathbf{g}_p} < r$ and $\exp_p(v) = q$.

Figure 13.1. Schematic representation of a manifold with geodesic loops of arbitrarily small length, a phenomenon that can give rise to zero injectivity radius.

To quantify how closely the Riemannian metric approximates the Euclidean metric in normal coordinates, we will study the Taylor expansion of its coefficients. The following proposition makes this comparison explicit.

Proposition 13.1.4. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, and let $p \in \mathrm{Int}(M)$. If (U, φ) is a normal coordinate chart centered at p, with $\varphi(U)$ convex and $\varphi(p) = 0$, then, for every $q \in U$, writing $x = (x^1, \dots, x^n) = \varphi(q)$, we have the following Taylor expansion:

$$(g_{ij} \circ \varphi^{-1})(x) = \delta_{ij} - \frac{1}{3} R_{iklj}(p) x^k x^l + R_{2,0,g_{ij}\circ\varphi^{-1}}(x),$$

where, for every $\varepsilon > 0$, there exists $\delta_\varepsilon > 0$ such that

$$|R_{2,0,g_{ij}\circ\varphi^{-1}}(x)| \leq \varepsilon \|x\|^2 \quad \text{if } \|x\| < \delta_\varepsilon.$$

Proof. Since $p \in \mathrm{Int}(M)$, we may consider the manifold without boundary $\mathrm{Int}(M)$ with the restricted metric. By Proposition 2.8.9 applied to this manifold, in normal coordinates centered at p we have

$$g_{ij}(p) = \delta_{ij}, \qquad \Gamma_{ij}^k(p) = 0.$$

By Corollary 2.4.16 (metric compatibility),

$$\partial_k g_{ij} = g_{mj}\Gamma_{ik}^m + g_{im}\Gamma_{jk}^m. \tag{13.1}$$

Evaluating at p and using $g_{mj}(p) = \delta_{mj}$, $g_{im}(p) = \delta_{im}$, and the vanishing of the Christoffel symbols at p, we obtain

$$(\partial_k g_{ij})(p) = 0.$$

Thus, the first-order derivatives vanish at p, and the corresponding linear term does not appear in the Taylor expansion.

Now, for arbitrary $v = v^i \partial_i|_p \in T_pM$, Proposition 2.8.9 gives $\gamma_v(t) = (tv^1, \dots, tv^n)$, so the geodesic equation

$$\frac{d^2x^k}{dt^2}(t) + \frac{dx^i}{dt}(t)\frac{dx^j}{dt}(t)\Gamma_{ij}^k(x(t)) = 0$$

with $x(t) = \gamma_v(t)$ becomes

$$\Gamma_{ij}^k(tv)v^iv^j = 0.$$

Differentiating with respect to t gives:

$$0 = \frac{d}{dt}(\Gamma_{ij}^k(tv)v^iv^j) = \left(\frac{d}{dt}(\Gamma_{ij}^k(tv))\right)v^iv^j = \partial_l(\Gamma_{ij}^k)(tv)\frac{d(tv^l)}{dt}v^iv^j = \partial_l(\Gamma_{ij}^k)(tv)v^iv^jv^l.$$

Evaluating at $t = 0$ gives

$$\partial_l\Gamma_{ij}^k(p)v^iv^jv^l = 0.$$

This is a homogeneous polynomial of degree 3 that vanishes identically (since v was arbitrary). The coefficient of each term $v^iv^jv^l$ is the sum over 6 permutations of these indices (i, j and l). Since $\partial_l\Gamma_{ij}^k = \partial_l\Gamma_{ji}^k$, we obtain

$$\partial_l\Gamma_{ij}^k(p) + \partial_i\Gamma_{jl}^k(p) + \partial_j\Gamma_{li}^k(p) = 0. \tag{13.2}$$

We now differentiate (13.1) once more:

$$\partial_l\partial_k g_{ij} = \partial_l\left(g_{mj}\Gamma_{ik}^m + g_{im}\Gamma_{jk}^m\right) = (\partial_l g_{mj})\Gamma_{ik}^m + g_{mj}(\partial_l\Gamma_{ik}^m) + (\partial_l g_{im})\Gamma_{jk}^m + g_{im}(\partial_l\Gamma_{jk}^m).$$

Evaluating at p and again using the vanishing of the Christoffel symbols and the partial derivatives of order 1 at p, only terms containing derivatives of the Christoffel symbols remain. Consequently,

$$(\partial_l\partial_k g_{ij})(p) = g_{mj}(p)(\partial_l\Gamma_{ik}^m)(p) + g_{im}(p)(\partial_l\Gamma_{jk}^m)(p).$$

Finally, since the metric coefficients evaluated at p are Kronecker deltas, we are left with:

$$(\partial_l\partial_k g_{ij})(p) = (\partial_l\Gamma_{ik}^j)(p) + (\partial_l\Gamma_{jk}^i)(p). \tag{13.3}$$

On the other hand, Proposition 2.10.3 gives

$$R_{ijk}{}^l = \partial_i\Gamma_{jk}^l - \partial_j\Gamma_{ik}^l + \Gamma_{jk}^m\Gamma_{im}^l - \Gamma_{ik}^m\Gamma_{jm}^l,$$

so evaluating at p and using the vanishing of the Christoffel symbols at p, we obtain

$$R_{ikl}{}^j(p) = \partial_i\Gamma_{kl}^j(p) - \partial_k\Gamma_{il}^j(p), \qquad R_{ilk}{}^j(p) = \partial_i\Gamma_{lk}^j(p) - \partial_l\Gamma_{ik}^j(p).$$

Adding these terms gives

$$R_{ikl}{}^j(p) + R_{ilk}{}^j(p) = 2\partial_i\Gamma_{kl}^j(p) - \partial_l\Gamma_{ik}^j(p) - \partial_k\Gamma_{il}^j(p)$$

and using (13.2) with k and j interchanged, we obtain

$$\partial_l\Gamma_{ik}^j(p) + \partial_i\Gamma_{kl}^j(p) + \partial_k\Gamma_{li}^j(p) = 0,$$

so that

$$R_{ikl}{}^j + R_{ilk}{}^j = 3\partial_i\Gamma_{kl}^j(p).$$

Since $g_{ij} = \delta_{ij}$ at p, the preceding identity can be written in terms of the Riemann curvature tensor as follows:

$$R_{iklj}(p) + R_{ilkj}(p) = R_{ikl}{}^{j}(p) + R_{ilk}{}^{j}(p) = 3\partial_i \Gamma^j_{kl}(p).$$

Interchanging i and l gives

$$R_{likj}(p) + R_{lkij}(p) = 3\partial_l \Gamma^j_{ik}(p)$$

and interchanging i and l, and then i and j, gives

$$R_{ljki}(p) + R_{lkji}(p) = 3\partial_l \Gamma^i_{jk}(p).$$

Using identity (13.3), we obtain

$$3\partial_l \partial_k g_{ij}(p) = R_{likj}(p) + R_{lkij}(p) + R_{ljki}(p) + R_{lkji}(p).$$

By Corollary 2.10.7, $R_{lkij}(p) = -R_{lkji}(p)$ and $R_{ljki}(p) = R_{kilj}(p)$, so

$$\partial_l \partial_k g_{ij}(p) = \frac{1}{3}\big(R_{likj}(p) + R_{kilj}(p)\big) = -\frac{1}{3}(R_{iklj}(p) + R_{ilkj}(p)),$$

where the last equality uses $R_{likj}(p) = -R_{ilkj}(p)$ and $R_{kilj}(p) = -R_{iklj}(p)$.
By (Taylor's) Theorem 1.4.9,

$$\begin{aligned}(g_{ij} \circ \varphi^{-1})(x) &= \delta_{ij} + \partial_k g_{ij}(p)x^k + \frac{1}{2}\partial_k \partial_l g_{ij}(p)x^k x^l + R_{2,0,g_{ij}\circ\varphi^{-1}}(x) \\ &= \delta_{ij} - \frac{1}{6}\big(R_{iklj}(p) + R_{ilkj}(p)\big)x^k x^l + R_{2,0,g_{ij}\circ\varphi^{-1}}(x) \\ &= \delta_{ij} - \frac{1}{3}R_{iklj}(p)x^k x^l + R_{2,0,g_{ij}\circ\varphi^{-1}}(x).\end{aligned}$$

In the last equality, the dummy indices k and l are interchanged in the second summand. □

Thus, curvature determines the first deviation of the metric from the Euclidean metric in normal coordinates. Its covariant derivatives enter into higher-order expansions; see [106]. However, an expansion at each center does not by itself provide a uniform radius or bound for its remainders. To obtain this control, we will work directly with the Jacobi equation. The hypotheses that make this possible are as follows.

Definition 13.1.5. (Manifolds of bounded geometry) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary. We say that M has bounded geometry if the following two conditions hold:

(a) $\operatorname{inj}(M) > 0$.

(b) For each $k \in \mathbb{N}_0$, there exists $C_k > 0$ such that

$$\sup_{x \in M} |\nabla^k \mathbf{R}(x)|_{\mathbf{g}} \leq C_k.$$

Here $\mathbf{R} \in \Gamma(T^{(1,3)}(TM))$ is the curvature tensor of Definition 2.10.1, $\nabla^k \mathbf{R}$ is its kth derivative for the tensor connection induced by the Levi–Civita connection, and $|\cdot|_{\mathbf{g}}$ is the pointwise norm induced by $\mathbf{g}$ and its dual metric on all tensor factors.

Remark 13.1.6. (Euclidean open subsets and manifold boundary) An open subset of $\mathbb{R}^n$ equipped with the restricted Euclidean metric need not have bounded geometry. For example, let $M = B_{\mathrm{euc}}(0,1)$, regarded as a manifold without boundary. Its curvature is zero, but, for $x \in M$, the exponential map is $\exp_x(v) = x + v$ only as long as the corresponding segment remains in the ball. Consequently,

$$\mathrm{inj}(x) = 1 - |x|, \qquad \mathrm{inj}(M) = 0.$$

The radial geodesic moving toward the sphere reaches it in finite time and cannot be extended within M. Completeness does not appear as a third hypothesis in the preceding definition: it follows from the positive injectivity radius by Remark 13.1.2, and this is precisely the condition that fails here.
The sphere is the boundary of this open set as a Euclidean subset; it is not a boundary included in the manifold M. In contrast, $\overline{B}_{\mathrm{euc}}(0,1)$, with its smooth structure as a compact manifold with boundary and the same Euclidean metric, belongs to the theory with boundary of Chapter 14. These are two distinct geometric objects. The metric matters as well: replacing it by a complete metric can change the conclusion concerning completeness. Thus, the Sobolev and Rellich theorems for arbitrary Euclidean open subsets, particularly the zero-extension arguments for $W_0^{m,p}$, do not follow simply by applying the global bounded-geometry theorems.

Since throughout this chapter we will work with ***normal coordinates*** (also called ***geodesic coordinates***), as well as with coordinates in general, we introduce some terminology that will allow us to refer to them more clearly.

Definition 13.1.7. (Geodesic atlas) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary.
We will denote by

$$\mathcal{A}^{\mathrm{geo}} = (U_i^{\mathrm{geo}}, \varphi_i^{\mathrm{geo}})_{i \in J}$$

an atlas consisting of normal coordinate charts (see Proposition 2.8.9).
More precisely, for each $i \in J$, there exist a point $p_i \in M$, a radius $r_i > 0$, and a linear isomorphism

$$B_{p_i} : \mathbb{R}^n \longrightarrow T_{p_i}M,$$

taking the standard basis of $\mathbb{R}^n$ to an orthonormal basis of $T_{p_i}M$, such that

$$U_i^{\mathrm{geo}} = B_{\mathbf{g}}(p_i, r_i), \qquad \varphi_i^{\mathrm{geo}} = B_{p_i}^{-1} \circ \exp_{p_i}^{-1}.$$

We say that $\mathcal{A}^{\mathrm{geo}}$ is a *uniform geodesic atlas* if there exists $r > 0$ such that $r < \mathrm{inj}(M)$ and

$$U_i^{\mathrm{geo}} = B_{\mathbf{g}}(p_i, r)$$

for every $i \in J$.

The condition that the covariant derivatives of the curvature are bounded can be expressed in other ways which, together with $\mathrm{inj}(M) > 0$, yield useful equivalent characterizations of manifolds of bounded geometry.

Theorem 13.1.8. (Equivalent characterizations of bounded geometry) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary such that $\operatorname{inj}(M) > 0$. The following conditions are equivalent:

(a) For each $k \in \mathbb{N}_0$, there exists $C_k > 0$ such that

$$|\nabla^k \mathbf{R}|_{\mathbf{g}} \leq C_k.$$

(b) There exists r_0, with $0 < r_0 < \operatorname{inj}(M)$, such that the full family of normal charts of radius r_0 satisfies the following condition: for each $k \in \mathbb{N}_0$, there exists $C_{k,r_0} > 0$ such that, in every chart, the components of $\mathbf{g}$ and of its inverse satisfy

$$|D^\alpha g_{ij}| \leq C_{k,r_0}, \qquad |D^\alpha g^{ij}| \leq C_{k,r_0}, \qquad |\alpha| \leq k.$$

By restriction, the same estimates hold for every radius $0 < r \leq r_0$.

Whenever either condition holds, transitions between normal charts of any fixed radius $0 < r \leq r_0$ have uniformly bounded jets of every order: for each $k \in \mathbb{N}_0$, there exists $A_{k,r} > 0$ such that, if the charts i and j overlap,

$$\left|D^\alpha (\varphi_j^{\mathrm{geo}} \circ (\varphi_i^{\mathrm{geo}})^{-1})(x)\right| \leq A_{k,r}, \qquad |\alpha| \leq k,$$

throughout the domain of the transition. The same assertion holds with i and j interchanged.

Proof. Fix a common radius

$$0 < \rho < \min\{\operatorname{inj}(M), 1\}.$$

When necessary, we will decrease it once; all normal charts of radius ρ will still cover M. For each $p \in M$, choose a linear isometry $B_p \colon \mathbb{R}^n \longrightarrow T_pM$ and write

$$\Psi_p(v) := \exp_p(B_p v).$$

We denote by $g_{ij}^{(p)}$ and $g_{(p)}^{ij}$ the components of $\Psi_p^* \mathbf{g}$ and of its inverse metric, respectively, in the standard basis of $\mathbb{R}^n$.

First assume (1). For $v \in B(0, \rho)$ and $i \in \{1, \dots, n\}$, the variation

$$\alpha_i(s, t) := \exp_p\big(tB_p(v + se_i)\big)$$

produces the Jacobi field $\mathbf{J}_i(t) = \partial_s \alpha_i(0, t)$ along $\gamma_v(t) = \Psi_p(tv)$. Its initial data and equation are

$$\mathbf{J}_i(0) = 0, \qquad \frac{D\mathbf{J}_i}{dt}(0) = B_p e_i, \qquad \frac{D^2\mathbf{J}_i}{dt^2} + \mathbf{R}(\mathbf{J}_i, \dot\gamma_v)\dot\gamma_v = 0.$$

Moreover, $\mathbf{J}_i(1) = d\Psi_p(v)e_i$. Parallel transport the basis $(B_p e_a)_{a=1}^n$ along γ_v. In this frame, the equation is a linear system

$$y_i''(t) + \mathcal{R}_{p,v}(t) y_i(t) = 0, \qquad y_i(0) = 0, \qquad y_i'(0) = e_i,$$

and $\|\mathcal{R}_{p,v}(t)\| \leq C_0 \|v\|^2$. Writing it as a first-order system and applying Lemma 1.8.19 gives a bound for

$\|y_i\| + \|y_i'\|$ independent of p and v. The integral form of the equation also gives

$$\|y_i(t) - te_i\| \le C_0\|v\|^2 \int_0^t (t-\tau)\|y_i(\tau)\|\,d\tau.$$

Decrease ρ, depending only on C_0 and n, so that the right-hand side at $t=1$ is less than $\frac{1}{2\sqrt{n}}$ for every i. If $\mathbf{Y}(v)$ is the matrix whose columns are $y_i(1)$, then

$$\|\mathbf{Y}(v) - I\|_{\mathrm{op}} \le \|\mathbf{Y}(v) - I\|_{\mathrm{HS}} < \frac{1}{2}.$$

By the Neumann series, $\mathbf{Y}(v)$ is invertible and $\|\mathbf{Y}(v)^{-1}\|_{\mathrm{op}} \le 2$, uniformly in p and v. Since the parallel frame is orthonormal,

$$g_{ij}^{(p)}(v) = \langle \mathbf{J}_i(1), \mathbf{J}_j(1)\rangle_{\mathbf{g}},$$

which proves the uniform ellipticity of the coefficient matrix $(g_{ij}^{(p)})$.
We now justify the derivatives of arbitrary order. Fix $m \in \mathbb{N}_0$ and vectors $w_0, \dots, w_m \in \{e_1, \dots, e_n\}$ and, for sufficiently small $\boldsymbol{s} = (s_0, \dots, s_m)$, consider the multiparameter variation

$$\alpha(\boldsymbol{s}, t) := \exp_p\left(tB_p\left(v + \sum_{a=0}^{m} s_a w_a \right)\right), \qquad 0 \le t \le 1.$$

Let $\boldsymbol{\mathcal{E}} := \alpha^* TM$, and denote by $\mathbb{D}$ the connection on $\boldsymbol{\mathcal{E}}$ induced by the Levi–Civita connection. Set

$$D_t := \mathbb{D}_{\partial_t}, \qquad D_a := \mathbb{D}_{\partial_{s_a}}, \qquad \mathbf{T} := d\alpha(\partial_t), \qquad \mathbf{A}_a := d\alpha(\partial_{s_a}).$$

For each $\boldsymbol{s}$, the curve $t \mapsto \alpha(\boldsymbol{s}, t)$ is geodesic; moreover, since the Levi–Civita connection is torsion-free,

$$D_t \mathbf{T} = 0, \qquad D_a \mathbf{T} = D_t \mathbf{A}_a.$$

With the convention $\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z} = \nabla_{\mathbf{X}}\nabla_{\mathbf{Y}}\mathbf{Z} - \nabla_{\mathbf{Y}}\nabla_{\mathbf{X}}\mathbf{Z} - \nabla_{[\mathbf{X},\mathbf{Y}]}\mathbf{Z}$, the commutators on the pullback bundle are precisely

$$(D_a D_t - D_t D_a)\mathbf{Z} = \mathbf{R}(\mathbf{A}_a, \mathbf{T})\mathbf{Z}, \qquad (D_a D_b - D_b D_a)\mathbf{Z} = \mathbf{R}(\mathbf{A}_a, \mathbf{A}_b)\mathbf{Z}.$$

In particular, differentiating $D_t \mathbf{T} = 0$ in direction s_a gives, with this sign,

$$D_t^2 \mathbf{A}_a + \mathbf{R}(\mathbf{A}_a, \mathbf{T})\mathbf{T} = 0.$$

We will carry out the induction without permuting covariant derivatives. For an ordered word $I = (a_1, \dots, a_k)$, write

$$|I| = k, \qquad D_I := D_{a_k} \cdots D_{a_1}, \qquad I^- := (a_1, \dots, a_{k-1}),$$

and set $D_\varnothing = \mathrm{id}$. Introduce the operator

$$\mathcal{L}\mathbf{Z} := D_t^2 \mathbf{Z} + \mathbf{R}(\mathbf{Z}, \mathbf{T})\mathbf{T}, \qquad \mathcal{L} \colon \Gamma(\boldsymbol{\mathcal{E}}) \longrightarrow \Gamma(\boldsymbol{\mathcal{E}}).$$

A direct calculation using the preceding commutators gives, for every $\mathbf{Z} \in \Gamma(\boldsymbol{\mathcal{E}})$,

$$\mathcal{L}(D_a\mathbf{Z}) = D_a(\mathcal{L}\mathbf{Z}) + \mathcal{C}(\mathbf{A}_a, \mathbf{Z}),$$

where $\mathcal{C}(\mathbf{A}, \mathbf{Z}) \in \Gamma(\boldsymbol{\mathcal{E}})$ is

$$\begin{aligned}\mathcal{C}(\mathbf{A}, \mathbf{Z}) = & -(\nabla_{\mathbf{T}}\mathbf{R})(\mathbf{A}, \mathbf{T})\mathbf{Z} - \mathbf{R}(D_t\mathbf{A}, \mathbf{T})\mathbf{Z} - 2\mathbf{R}(\mathbf{A}, \mathbf{T})D_t\mathbf{Z} \\ & -(\nabla_{\mathbf{A}}\mathbf{R})(\mathbf{Z}, \mathbf{T})\mathbf{T} - \mathbf{R}(\mathbf{Z}, D_t\mathbf{A})\mathbf{T} - \mathbf{R}(\mathbf{Z}, \mathbf{T})D_t\mathbf{A}.\end{aligned}$$

Indeed,

$$D_t^2 D_a\mathbf{Z} = D_a D_t^2\mathbf{Z} - (\nabla_{\mathbf{T}}\mathbf{R})(\mathbf{A}_a, \mathbf{T})\mathbf{Z} - \mathbf{R}(D_t\mathbf{A}_a, \mathbf{T})\mathbf{Z} - 2\mathbf{R}(\mathbf{A}_a, \mathbf{T})D_t\mathbf{Z},$$

and the derivative of $\mathbf{R}(\mathbf{Z}, \mathbf{T})\mathbf{T}$, using $D_a\mathbf{T} = D_t\mathbf{A}_a$, contributes precisely the remaining three terms. This verifies both the signs and the tensor spaces: each summand of $\mathcal{C}(\mathbf{A}, \mathbf{Z})$ is a section of $\boldsymbol{\mathcal{E}}$.
For a distinguished letter $b \in \{0, \dots, m\}$, define

$$\mathbf{Z}_{I;b} := D_I\mathbf{A}_b \in \Gamma(\boldsymbol{\mathcal{E}}), \qquad \widetilde{\mathbf{Q}}_{\varnothing;b} := 0,$$

and, if $I = (I^-, a)$, define recursively

$$\widetilde{\mathbf{Q}}_{I;b} := D_a\widetilde{\mathbf{Q}}_{I^-;b} + \mathcal{C}(\mathbf{A}_a, \mathbf{Z}_{I^-;b}) \in \Gamma(\boldsymbol{\mathcal{E}}).$$

We prove the recurrence by induction on $|I|$. For $I = \varnothing$, the Jacobi equation gives

$$\mathcal{L}\mathbf{Z}_{\varnothing;b} = \mathcal{L}\mathbf{A}_b = 0 = \widetilde{\mathbf{Q}}_{\varnothing;b}.$$

Now suppose that $\mathcal{L}\mathbf{Z}_{I^-;b} = \widetilde{\mathbf{Q}}_{I^-;b}$ and write $I = (I^-, a)$. Since $\mathbf{Z}_{I;b} = D_a\mathbf{Z}_{I^-;b}$, the preceding commutation identity gives, term by term,

$$\begin{aligned}\mathcal{L}\mathbf{Z}_{I;b} &= \mathcal{L}(D_a\mathbf{Z}_{I^-;b}) \\ &= D_a(\mathcal{L}\mathbf{Z}_{I^-;b}) + \mathcal{C}(\mathbf{A}_a, \mathbf{Z}_{I^-;b}) \\ &= D_a\widetilde{\mathbf{Q}}_{I^-;b} + \mathcal{C}(\mathbf{A}_a, \mathbf{Z}_{I^-;b}) \\ &= \widetilde{\mathbf{Q}}_{I;b}.\end{aligned}$$

Thus, induction on $|I|$ proves the identity

$$\mathcal{L}\mathbf{Z}_{I;b} = \widetilde{\mathbf{Q}}_{I;b}.$$

This recurrence enumerates all summands. To make this explicit, consider formal expressions obtained by contracting, using $\mathbf{g}$, factors $\nabla^r\mathbf{R}$, $\mathbf{T}$, $\mathbf{Z}_{J;c}$, and $D_t\mathbf{Z}_{J;c}$, leaving a single free vector index. Define a formal derivation $\mathfrak{d}_a$ by the Leibniz rule on products and contractions and by the rules

$$\begin{aligned}\mathfrak{d}_a\mathbf{T} &= D_t\mathbf{A}_a, & \mathfrak{d}_a\mathbf{Z}_{J;c} &= \mathbf{Z}_{(J,a);c}, \\ \mathfrak{d}_a(D_t\mathbf{Z}_{J;c}) &= D_t\mathbf{Z}_{(J,a);c} + \mathbf{R}(\mathbf{A}_a, \mathbf{T})\mathbf{Z}_{J;c}, & \mathfrak{d}_a(\nabla^r\mathbf{R}) &= \nabla_{\mathbf{A}_a}(\nabla^r\mathbf{R}) = (\nabla^{r+1}\mathbf{R})(\mathbf{A}_a, \cdot).\end{aligned}$$

In the last rule, $\cdot$ represents, in their original order, the r differentiation arguments already present; the

intrinsic indices of $\mathbf{R}$ remain within the tensor value. The new argument is placed first. The remaining tensor arguments are also differentiated, one at a time, by the Leibniz rule. Differentiating the contractions produces no terms because $\nabla\mathbf{g} = 0$. Let $\mathfrak{C}_{a,J;b}$ be the six summands, with their coefficients, of

$$\begin{aligned}&-(\nabla_{\mathbf{T}}\mathbf{R})(\mathbf{A}_a,\mathbf{T})\mathbf{Z}_{J;b} - \mathbf{R}(D_t\mathbf{A}_a,\mathbf{T})\mathbf{Z}_{J;b} - 2\mathbf{R}(\mathbf{A}_a,\mathbf{T})D_t\mathbf{Z}_{J;b}\\ &\quad-(\nabla_{\mathbf{A}_a}\mathbf{R})(\mathbf{Z}_{J;b},\mathbf{T})\mathbf{T} - \mathbf{R}(\mathbf{Z}_{J;b},D_t\mathbf{A}_a)\mathbf{T} - \mathbf{R}(\mathbf{Z}_{J;b},\mathbf{T})D_t\mathbf{A}_a.\end{aligned}$$

We now define finite multisets of expressions by

$$\mathfrak{A}_{\varnothing;b} := \varnothing, \qquad \mathfrak{A}_{(J,a);b} := \mathfrak{d}_a\mathfrak{A}_{J;b} \sqcup \mathfrak{C}_{a,J;b},$$

where $\mathfrak{d}_a\mathfrak{A}_{J;b}$ contains all summands produced by the preceding rules, retaining multiplicities and coefficients. Let us verify the resulting equality. For $I = \varnothing$, both sides are zero because $\widetilde{\mathbf{Q}}_{\varnothing;b} = 0$ and $\mathfrak{A}_{\varnothing;b} = \varnothing$. Suppose that $\widetilde{\mathbf{Q}}_{J;b} = \sum_{\mathfrak{a}\in\mathfrak{A}_{J;b}} \mathfrak{a}$ and let $I = (J,a)$. Covariant differentiation D_a acts on each product and contraction exactly according to the rules defining $\mathfrak{d}_a$. Hence,

$$\widetilde{\mathbf{Q}}_{I;b} = D_a\widetilde{\mathbf{Q}}_{J;b} + \mathcal{C}(\mathbf{A}_a,\mathbf{Z}_{J;b}) = \sum_{\mathfrak{a}\in\mathfrak{A}_{J;b}} \mathfrak{d}_a\mathfrak{a} + \sum_{\mathfrak{c}\in\mathfrak{C}_{a,J;b}} \mathfrak{c} = \sum_{\mathfrak{a}\in\mathfrak{A}_{(J,a);b}} \mathfrak{a}.$$

This proves by induction on the length of I that

$$\widetilde{\mathbf{Q}}_{I;b} = \sum_{\mathfrak{a}\in\mathfrak{A}_{I;b}} \mathfrak{a}. \tag{13.4}$$

Thus, $\mathfrak{A}_{(J,a);b}$ is determined by $\mathfrak{A}_{J;b}$ through the preceding union, which preserves the order of the letters and indexes every summand.

The indexing also has an exact grading. Assign weight zero to $\mathbf{T}$ and weight $|J|+1$ to every occurrence of $\mathbf{Z}_{J;c}$ or $D_t\mathbf{Z}_{J;c}$; in particular, $\mathbf{A}_c = \mathbf{Z}_{\varnothing;c}$ has weight one. If $|I| = k \geq 1$, every summand of (13.4) satisfies

$$\sum_{\text{occurrences of } \mathbf{Z}_{J;c} \text{ or } D_t\mathbf{Z}_{J;c}} (|J|+1) = k+1. \tag{13.5}$$

It contains one or more factors $\nabla^r\mathbf{R}$, with $0 \leq r \leq k$, and each field factor contains at most one derivative D_t. Moreover, every field appearing in the source has weight at most k, strictly less than the weight $k+1$ of the unknown $\mathbf{Z}_{I;b}$. We verify the four assertions simultaneously. If $|I| = 1$, write $I = (a)$. The six terms of $\mathfrak{C}_{a,\varnothing;b}$ contain the fields $\mathbf{A}_a$ and $\mathbf{A}_b$, or one of their derivatives D_t; their total weight is $1+1 = 2 = |I|+1$. They contain a factor $\mathbf{R}$ or $\nabla\mathbf{R}$, contain no second time derivatives, and the fields appearing in them have weight one.

Now assume the assertions hold for a word J of length $k-1$, and let $I = (J,a)$. In the terms arising from $\mathfrak{d}_a\mathfrak{A}_{J;b}$, the Leibniz rule makes $\mathfrak{d}_a$ act on one factor at a time. If it acts on $\mathbf{Z}_{L;c}$ or $D_t\mathbf{Z}_{L;c}$, it replaces that factor by one whose weight is exactly one greater; the additional curvature term in the rule for $D_t\mathbf{Z}_{L;c}$ also introduces $\mathbf{A}_a$, again of weight one. If it acts on $\mathbf{T}$, it introduces $D_t\mathbf{A}_a$, of weight one; and if it acts on $\nabla^r\mathbf{R}$, it raises the order of the curvature derivative from r to $r+1$ and introduces the argument $\mathbf{A}_a$. In every case, the total weight increases by exactly one, from k to $k+1$, no $D_t^2\mathbf{Z}$ appears, and the curvature order remains at most k. Finally, the six new terms of $\mathfrak{C}_{a,J;b}$ have weight $1+(|J|+1) = k+1$, curvature order at most one,

and only first time derivatives. Since the field of greatest weight among them is $\mathbf{Z}_{J;b}$, of weight k, the entire source contains only fields of weight less than $k+1$. This completes the induction.

Restricting to $\boldsymbol{s}=0$, set

$$\mathbf{Y}_{I;b} := \mathbf{Z}_{I;b}|_{\boldsymbol{s}=0}, \qquad \mathbf{Q}_{I;b} := \widetilde{\mathbf{Q}}_{I;b}|_{\boldsymbol{s}=0} \in \Gamma(\gamma_v^* TM).$$

Therefore,

$$\frac{D^2\mathbf{Y}_{I;b}}{dt^2} + \mathbf{R}(\mathbf{Y}_{I;b}, \dot\gamma_v)\dot\gamma_v = \mathbf{Q}_{I;b}.$$

All initial data are explicit. Since $\alpha(\boldsymbol{s},0)=p$,

$$\mathbf{A}_b(\boldsymbol{s},0)=0, \qquad D_t\mathbf{A}_b(\boldsymbol{s},0)=B_p w_b;$$

and this, together with the same commutators, implies

$$\begin{aligned} &\mathbf{Y}_{\varnothing;b}(0)=0, \quad \frac{D\mathbf{Y}_{\varnothing;b}}{dt}(0)=B_p w_b,\\ &\mathbf{Y}_{I;b}(0)=0, \quad \frac{D\mathbf{Y}_{I;b}}{dt}(0)=0, \qquad |I|\ge 1. \end{aligned}$$

Indeed, at $t=0$, all purely parametric derivatives of $\mathbf{A}_b(\boldsymbol{s},0)=0$ vanish, and every term arising when D_t is commuted with a nonempty word contains one of these fields; moreover, $B_p w_b$ does not depend on $\boldsymbol{s}$.

Restricting (13.4) preserves the grading (13.5): it replaces $\mathbf{T}$ by $\dot\gamma_v$, $\mathbf{Z}_{J;c}$ by $\mathbf{Y}_{J;c}$, and $D_t\mathbf{Z}_{J;c}$ by $\frac{D\mathbf{Y}_{J;c}}{dt}$. Since $|\dot\gamma_v|_{\mathbf{g}} = |B_p v|_{\mathbf{g}_p} = \|v\|_{\mathbb{R}^n} \le \rho$, the hypothesis on $\nabla^r\mathbf{R}$ allows the bound to be expressed using L^∞ norms over the interval. For $k\in\mathbb{N}$, let $\mathcal{W}_{m,k} := \bigcup_{\nu=0}^{k-1}\{0,\dots,m\}^\nu$ be the set of words of length less than k, including the empty word. Define

$$\mathcal{M}_k := \sum_{J\in\mathcal{W}_{m,k}}\sum_{c=0}^{m}\left(\|\mathbf{Y}_{J;c}\|_{L^\infty([0,1])} + \left\|\frac{D\mathbf{Y}_{J;c}}{dt}\right\|_{L^\infty([0,1])}\right),$$

with the pointwise norms induced by $\mathbf{g}$. The index set of the sum is finite. By the grading already proved, each field factor in $\mathbf{Q}_{I;b}$ has weight at most k when $|I|=k$. Therefore, there exist $C_k>0$ and $N_k\in\mathbb{N}$, independent of p, v, and the chosen coordinate directions, such that

$$\|\mathbf{Q}_{I;b}\|_{L^\infty([0,1])} \le C_k(1+\mathcal{M}_k)^{N_k}, \qquad |I|=k.$$

Here C_k and N_k depend only on n, k, ρ, the bounds $\|\nabla^r \mathrm{Rm}_{\mathbf{g}}\|_\infty$ for $0\le r\le k$, and the finite number of contractions produced by the recurrence $\widetilde{\mathbf{Q}}_{(I^-,a);b} = D_a\widetilde{\mathbf{Q}}_{I^-;b} + \mathcal{C}(\mathbf{A}_a, \mathbf{Z}_{I^-;b})$; in particular, they do not depend on the center p.

To establish the bounds, fix v and use along γ_v the orthonormal frame obtained by parallel transport of $(B_p e_r)_{r=1}^n$. In this frame, the last equation has the form

$$y''_{I;b}(t) + \mathcal{R}_{p,v}(t)y_{I;b}(t) = q_{I;b}(t), \qquad \|\mathcal{R}_{p,v}(t)\|_{\mathrm{op},\mathbb{R}^n} \le C_0\rho^2.$$

It is equivalent to the first-order system

$$\frac{d}{dt}\begin{pmatrix} y_{I;b} \\ y'_{I;b}\end{pmatrix} = \begin{pmatrix} 0 & I \\ -\mathcal{R}_{p,v}(t) & 0\end{pmatrix}\begin{pmatrix} y_{I;b} \\ y'_{I;b}\end{pmatrix} + \begin{pmatrix} 0 \\ q_{I;b}\end{pmatrix}.$$

We proceed by induction on the weight. For weight one, $I = \varnothing$ and the equation is the homogeneous Jacobi equation with initial data $y_{\varnothing;b}(0) = 0$ and $y'_{\varnothing;b}(0) = w_b$; the estimate obtained at the beginning of the proof provides a constant B_1 such that $\mathcal{M}_1 \le B_1$.

Suppose that, for some $k \ge 1$, all fields of weight at most k satisfy the corresponding bounds, and hence $\mathcal{M}_k \le B_k$. If $|I| = k$, the preceding estimate gives

$$\|q_{I;b}\|_{L^\infty([0,1])} \le C_k(1 + B_k)^{N_k} =: Q_k.$$

Let $z_{I;b} = (y_{I;b}, y'_{I;b})$. The matrix of the first-order system has norm at most $L := 1 + C_0\rho^2$. Since $z_{I;b}(0) = 0$ for $k \ge 1$, the integral inequality associated with the system is

$$|z_{I;b}(t)| \le L \int_0^t |z_{I;b}(\tau)|\, d\tau + tQ_k.$$

Grönwall's Lemma 1.8.19 implies

$$\|y_{I;b}\|_{L^\infty([0,1])} + \|y'_{I;b}\|_{L^\infty([0,1])} \le 2Q_k e^L.$$

There are only finitely many words I and letters b, their number depending on k and m. Adding these bounds to those forming $\mathcal{M}_k$ gives a constant B_{k+1} with $\mathcal{M}_{k+1} \le B_{k+1}$. This constant depends only on the geometric bounds listed above and on $B_1, \dots, B_k$, never on p, v, or the chosen letters. This completes the induction on the weight.

It remains to pass from these covariant derivatives to ordinary derivatives of the matrices. To this end, over the full variation, let $(\mathbf{E}_r(s,t))_{r=1}^n$ be the frame determined by

$$D_t\mathbf{E}_r = 0, \qquad \mathbf{E}_r(s,0) = B_p e_r.$$

It is smooth in s and orthonormal for every s. If $\mathbf{W}_{I;r} := D_I\mathbf{E}_r$, then

$$D_t\mathbf{W}_{\varnothing;r} = 0, \qquad \mathbf{W}_{\varnothing;r}(0) = B_p e_r,$$

and, defining $\mathbf{S}_{\varnothing;r} := 0$ and, for $I = (I^-, a)$,

$$\mathbf{S}_{I;r} := D_a\mathbf{S}_{I^-;r} - \mathbf{R}(\mathbf{A}_a, \mathbf{T})\mathbf{W}_{I^-;r},$$

the commutator fixed above gives precisely

$$D_t\mathbf{W}_{I;r} = \mathbf{S}_{I;r}, \qquad \mathbf{W}_{I;r}(0) = 0 \quad (|I| \ge 1).$$

After expanding $D_a\mathbf{S}_{I^-;r}$, its right-hand side contains only curvature, the variational fields already bounded, and $\mathbf{W}_{J;r}$ with $|J| < |I|$. For $I = \varnothing$, $\mathbf{W}_{\varnothing;r} = \mathbf{E}_r$ is parallel and unit length, so $|\mathbf{W}_{\varnothing;r}|_{\mathbf{g}} = 1$. If $I = (a)$, then

$$\mathbf{S}_{(a);r} = -\mathbf{R}(\mathbf{A}_a, \mathbf{T})\mathbf{E}_r, \qquad \mathbf{W}_{(a);r}(t) = \int_0^t \mathbf{S}_{(a);r}(\tau)\, d\tau,$$

where the integral is taken after identifying the fibers by parallel transport; the bounds on $\mathbf{R}$, $\mathbf{A}_a$, and $\mathbf{T}$ bound both sides uniformly. Now suppose all $\mathbf{W}_{J;r}$ with $|J| < k$ are bounded, and let $|I| = k$. The full Leibniz

expansion of $\mathbf{S}_{I;r}$ contains only these lower-order fields, curvature derivatives of order at most $k-1$, and the variational fields already bounded. Therefore, there exists C_k such that $\|\mathbf{S}_{I;r}\|_{L^\infty([0,1])} \le C_k$. Since $\mathbf{W}_{I;r}(0) = 0$,

$$\mathbf{W}_{I;r}(t) = \int_0^t \mathbf{S}_{I;r}(\tau)\, d\tau, \qquad \|\mathbf{W}_{I;r}\|_{L^\infty([0,1])} \le C_k.$$

This completes the induction.

Now take $w_0 = e_j$. If

$$y_j^r(v,t) := \langle \mathbf{J}_j(t), \mathbf{E}_r(v,t)\rangle_{\mathbf{g}},$$

the variations with $w_1,\dots,w_k$ compute its ordinary derivatives in v. More precisely, for an ordered word $I = (a_1,\dots,a_k)$ and a subset $S \subseteq \{1,\dots,k\}$, denote by I_S the subword retaining the original order. Metric compatibility of the connection and the Leibniz rule give the exact triangular identity

$$\partial_I y_j^r(v,t) = \sum_{S\subseteq\{1,\dots,k\}} \left\langle \mathbf{Y}_{I_S;0}(t), \mathbf{W}_{I_{S^c};r}(t)\right\rangle_{\mathbf{g}},$$

where $\partial_I = \partial_{s_{a_k}} \cdots \partial_{s_{a_1}}|_{s=0}$. The term corresponding to $S = \{1,\dots,k\}$ is $\langle \mathbf{Y}_{I;0}, \mathbf{E}_r\rangle_{\mathbf{g}}$, and all the other terms contain fewer derivatives on $\mathbf{A}_0$. The bounds obtained for $\mathbf{Y}_{I;0}$ and $\mathbf{W}_{I;r}$ therefore imply uniform bounds for all ordinary derivatives of $y_j^r(v,t)$.

At $t = 1$, the matrix $\mathbf{Y}(v) = (y_j^r(v,1))_{rj}$ represents $d\Psi_p(v)$ in the parallel frame, and

$$g_{ij}^{(p)}(v) = \langle \mathbf{J}_i(1), \mathbf{J}_j(1)\rangle_{\mathbf{g}} = \sum_{r=1}^n y_i^r(v,1) y_j^r(v,1).$$

The scalar Leibniz rule thus gives, for every multi-index α,

$$\sup_{p\in M} \sup_{v\in B(0,\rho)} |D^\alpha g_{ij}^{(p)}(v)| < \infty.$$

The uniform ellipticity already established gives a uniform bound for $g_{(p)}^{ij}$. For $|\alpha| \ge 1$, differentiate the identity $\sum_{\ell=1}^n g_{(p)}^{i\ell} g_{\ell j}^{(p)} = \delta_j^i$, isolate the term containing $\beta = \alpha$, and multiply by the inverse metric. Componentwise, this gives

$$D^\alpha g_{(p)}^{ik} = - \sum_{\substack{\beta\in\mathbb{N}_0^n \\ \beta\le\alpha,\ \beta\ne\alpha}} \binom{\alpha}{\beta} \sum_{\ell,j=1}^n (D^\beta g_{(p)}^{i\ell})(D^{\alpha-\beta} g_{\ell j}^{(p)}) g_{(p)}^{jk}.$$

Induction on $|\alpha|$ is now direct. For $|\alpha| = 0$, we already have the uniform bound for $g_{(p)}^{ij}$. Suppose all derivatives $D^\beta g_{(p)}^{ij}$ with $|\beta| < k$ are bounded, and let $|\alpha| = k$. In every summand of the preceding formula, $|\beta| < k$ and $1 \le |\alpha - \beta| \le k$; by the induction hypothesis, the bounds already proved for $D^{\alpha-\beta} g_{\ell j}^{(p)}$, and the bound for $g_{(p)}^{jk}$, every product is uniformly bounded. The sum contains finitely many terms, their number depending only on α. Thus, $D^\alpha g_{(p)}^{ik}$ is also uniformly bounded, and induction proves the assertion for all derivatives of the components $g_{(p)}^{ij}$.

We have proved (2) with $r_0 := \rho$. For $0 < r \le r_0$, the bounds in charts of radius r follow by restricting the charts of radius r_0.

We now prove the additional assertion about coordinate transitions. Fix $0 < r \le r_0$. On an overlap, set $\Phi = \varphi_j^{\mathrm{geo}} \circ (\varphi_i^{\mathrm{geo}})^{-1}$. The tensor identity

$$g_{ab}^{(i)} = \sum_{\ell,m=1}^{n} (g_{\ell m}^{(j)} \circ \Phi)(\partial_a \Phi^\ell)(\partial_b \Phi^m)$$

and uniform ellipticity bound $D\Phi$: indeed, evaluating the equality on a vector ξ, the lower bound for $g^{(j)}$ and the upper bound for $g^{(i)}$ give $c|D\Phi\,\xi|^2 \le C|\xi|^2$. Interchanging i and j bounds the differential of the inverse transition. The Christoffel symbols and all their derivatives are uniformly bounded because their components are universal expressions in $g^{ab}_{(i)}$ and the derivatives of $g^{(i)}_{ab}$. The transformation law for the connection reads

$$\partial_a \partial_b \Phi^k = \Gamma^c_{i,ab}\, \partial_c \Phi^k - \Gamma^k_{j,\ell m}(\Phi) \partial_a \Phi^\ell \partial_b \Phi^m.$$

This equality bounds $D^2\Phi$. For the inductive step, suppose that, for some $m \ge 2$, all derivatives of Φ of order at most m are uniformly bounded, and let $\alpha \in \mathbb{N}_0^n$ with $|\alpha| = m-1$. Apply D^α to the preceding identity. The Leibniz rule expresses the derivative of the first summand in terms of derivatives of Γ_i of order at most $m-1$ and derivatives of Φ of order at most m.

For the second summand, first apply the Leibniz rule to its three factors. In the composite factor, set $A := \Gamma^k_{j,\ell m}$. The Faà di Bruno formula of Theorem 1.1.19, written in the same partial-derivative notation used here, states that, for $1 \le |\mu| \le m-1$,

$$D^\mu (A \circ \Phi)(x) = \sum_{\substack{\beta \in \mathbb{N}_0^n,\ 1 \le |\beta| \le |\mu| \\ \gamma = (\gamma_1, \dots, \gamma_{|\beta|}),\quad |\gamma_\nu| > 0 \\ \gamma_1 + \cdots + \gamma_{|\beta|} = \mu \\ l = (l_1, \dots, l_{|\beta|}),\quad l_\nu \in \{1, \dots, n\} \\ \#\{\nu \mid l_\nu = a\} = \beta_a,\quad 1 \le a \le n}} c_{\mu,\beta,\gamma,l}\, (D^\beta A)(\Phi(x)) \prod_{\nu=1}^{|\beta|} D^{\gamma_\nu} \Phi^{l_\nu}(x). \tag{13.6}$$

In each term, $|\beta| \le |\mu| \le m-1$, $\#\{\nu \mid l_\nu = a\} = \beta_a$ for $1 \le a \le n$, and $1 \le |\gamma_\nu| \le |\mu| \le m-1$. Thus, the derivatives of A are bounded by the metric bounds, and the derivatives of Φ appearing in (13.6) are bounded by the induction hypothesis. The other two factors are first derivatives of Φ; after applying the Leibniz rule, they involve derivatives of order at most m. Every term on the right-hand side is therefore bounded by a constant independent of the charts. The left-hand side is $D^\alpha \partial_a \partial_b \Phi^k$, of order $m+1$, which completes the induction: every multi-index of length $m+1 \ge 2$ can be written as $\alpha + e_a + e_b$, allowing $a = b$. Interchanging i and j gives the same estimate for the inverse transition.

It remains to prove that (2) implies (1). Fix $x \in M$ and use the normal chart of radius r_0 centered at x. The formula

$$\Gamma^\ell_{ij} = \frac{1}{2} \sum_{a=1}^{n} g^{\ell a} \left(\partial_i g_{ja} + \partial_j g_{ia} - \partial_a g_{ij} \right)$$

gives, for each multi-index α, the exact identity

$$\partial^\alpha \Gamma^\ell_{ij} = \frac{1}{2} \sum_{a=1}^{n} \sum_{\substack{\beta \in \mathbb{N}_0^n \\ \beta \le \alpha}} \binom{\alpha}{\beta} (\partial^\beta g^{\ell a}) \left(\partial^{\alpha-\beta+e_i} g_{ja} + \partial^{\alpha-\beta+e_j} g_{ia} - \partial^{\alpha-\beta+e_a} g_{ij} \right).$$

The sum over a and β is finite, and condition (2) bounds each of its factors uniformly.

The curvature components satisfy

$$R^{\ell}{}_{ijk} = \partial_i \Gamma^{\ell}_{jk} - \partial_j \Gamma^{\ell}_{ik} + \sum_{m=1}^{n} \left(\Gamma^{m}_{jk}\Gamma^{\ell}_{im} - \Gamma^{m}_{ik}\Gamma^{\ell}_{jm} \right).$$

This formula and the Leibniz rule give uniform bounds for all partial derivatives of R. Finally, the coordinate formula for the covariant derivative of a tensor consists of its partial derivative plus a finite sum of contractions with Christoffel symbols. We proceed by induction on q. For $q = 0$, the components of R and all their partial derivatives are uniformly bounded by the preceding calculation. Suppose that each component of $\nabla^q R$ is a finite universal sum of products of partial derivatives of R and partial derivatives of the Christoffel symbols, all of order at most q. Write the curvature tensor as a tensor of type $(0,4)$, lowering its contravariant index using $\mathbf{g}$. Lemma 9.1.28 gives, for $I = (i_1, \dots, i_{q+4}) \in \{1, \dots, n\}^{q+4}$ and $a \in \{1, \dots, n\}$,

$$(\nabla_a \nabla^q R)_{i_1 \cdots i_{q+4}} = \partial_a (\nabla^q R)_{i_1 \cdots i_{q+4}} - \sum_{\nu=1}^{q+4} \sum_{c=1}^{n} \Gamma^{c}_{a i_\nu} (\nabla^q R)_{i_1 \cdots i_{\nu-1} c i_{\nu+1} \cdots i_{q+4}}.$$

When differentiating the products in the induction hypothesis, the Leibniz rule increases by one the order of exactly one factor; the connection terms add a factor Γ without increasing the other orders. Thus, each component of $\nabla^{q+1} R$ has the same form with orders at most $q+1$. All these components are uniformly bounded, completing the induction. At the center of the normal chart, $g_{ij}(x) = \delta_{ij}$; consequently, the tensor norm of $\nabla^q \mathbf{R}(x)$ is bounded by a constant independent of x. Since x was arbitrary, this gives (1) and concludes the equivalence. □

To justify the calculation of the injectivity radius for the nonpositive-curvature models appearing below, we record the required global result.

Theorem 13.1.9. (Cartan–Hadamard) Let $(M, \mathbf{g})$ be a complete, connected Riemannian manifold without boundary whose sectional curvature is nonpositive. For every $p \in M$, the exponential map

$$\exp_p \colon T_pM \longrightarrow M$$

is a covering map. If, in addition, M is simply connected, then $\exp_p$ is a global diffeomorphism and $\operatorname{inj}(p) = +\infty$.

Proof. Let γ be a geodesic starting at p, and let $\mathbf{J}$ be a Jacobi field perpendicular to $\dot\gamma$, with $\mathbf{J}(0) = 0$. The Jacobi equation and the curvature hypothesis give

$$\frac{1}{2}\frac{d^2}{dt^2}\|\mathbf{J}(t)\|_{\mathbf{g}}^2 = \left\| \frac{D\mathbf{J}}{dt}(t) \right\|_{\mathbf{g}}^2 - \left\langle \mathbf{R}(\mathbf{J}, \dot\gamma)\dot\gamma, \mathbf{J} \right\rangle_{\mathbf{g}} \geq 0.$$

If $\mathbf{J}$ vanished again, the nonnegative convex function $\|\mathbf{J}\|_{\mathbf{g}}^2$ would vanish between the two endpoints; uniqueness for the Jacobi equation would imply $\mathbf{J} \equiv 0$. Thus, there are no conjugate points and $d\exp_p(v)$ is invertible for every $v \in T_pM$; hence, $\exp_p$ is a local diffeomorphism.

To make the differential estimate precise, decompose the initial datum of a Jacobi field with $\mathbf{J}(0) = 0$ into its components parallel and perpendicular to $\dot\gamma(0)$. If P_t denotes parallel transport along γ, the parallel component is exactly $\mathbf{J}_{\parallel}(t) = tP_t(D_t\mathbf{J}(0)_{\parallel})$. For the perpendicular component, at points where $f(t) := \|\mathbf{J}(t)\|_{\mathbf{g}}$

does not vanish, the Jacobi equation gives

$$f''(t) = \frac{\|D_t\mathbf{J}\|_{\mathbf{g}}^2 f(t)^2 - \langle D_t\mathbf{J},\mathbf{J}\rangle_{\mathbf{g}}^2 - \langle \mathbf{R}(\mathbf{J},\dot\gamma)\dot\gamma,\mathbf{J}\rangle_{\mathbf{g}} f(t)^2}{f(t)^3} \geq 0.$$

Here we used Cauchy–Schwarz and the nonpositive sectional curvature. Since $f(0) = 0$ and $f'(0^+) = \|D_t\mathbf{J}(0)\|_{\mathbf{g}}$, convexity implies $f(t) \geq t\|D_t\mathbf{J}(0)\|_{\mathbf{g}}$. The parallel and perpendicular components remain orthogonal. Evaluating at $t = 1$ gives

$$\|d\exp_p(v)w\|_{\mathbf{g}} \geq \|w\|_{\mathbf{g}_p}, \qquad v, w \in T_pM.$$

Consequently, the metric $\exp_p^*\mathbf{g}$ dominates the Euclidean metric of T_pM and is complete: a Cauchy sequence for $\exp_p^*\mathbf{g}$ is Cauchy in T_pM. If v is its limit, continuity and positivity of $\exp_p^*\mathbf{g}$ provide a neighborhood V of v and constants $c_v, C_v > 0$ such that

$$c_v\|w\|_{\mathbf{g}_p}^2 \leq (\exp_p^*\mathbf{g})_z(w,w) \leq C_v\|w\|_{\mathbf{g}_p}^2, \qquad z \in V, \quad w \in T_pM.$$

The sequence then converges for the distance of $\exp_p^*\mathbf{g}$ as well.

The exponential map is surjective by Hopf–Rinow (Theorem 2.9.9). We record the passage from local isometry to covering map. Let $y \in M$, and choose $\varepsilon > 0$ so that $\exp_y$ is a diffeomorphism on the ball of radius ε. For each $x \in \exp_p^{-1}(y)$, completeness of $(T_pM, \exp_p^*\mathbf{g})$ allows us to define

$$s_x(\exp_y v) := \exp_x^{\exp_p^*\mathbf{g}}\big((d\exp_p)_x^{-1}v\big), \qquad |v|_{\mathbf{g}_y} < \varepsilon.$$

A local isometry maps geodesics to geodesics and preserves their initial data; geodesic uniqueness proves $\exp_p \circ s_x = \mathrm{id}_{B_{\mathbf{g}}(y,\varepsilon)}$. The images of s_x are disjoint: if two contained the same point, the lifts of the reversed radial geodesic, with the same initial datum determined by $d\exp_p$, would coincide and have the same endpoint over y. Finally, if $q \in \exp_p^{-1}(B_{\mathbf{g}}(y,\varepsilon))$, lift from q the radial geodesic ending at y; completeness extends the lift to its endpoint $x \in \exp_p^{-1}(y)$, and the reversed geodesic shows that $q = s_x(\exp_p(q))$. Therefore,

$$\exp_p^{-1}(B_{\mathbf{g}}(y,\varepsilon)) = \coprod_{x \in \exp_p^{-1}(y)} s_x(B_{\mathbf{g}}(y,\varepsilon)),$$

and each summand projects diffeomorphically onto the ball. This proves that $\exp_p$ is a covering map. Since the finite-dimensional vector space T_pM is simply connected, it is the universal covering space; if M is also simply connected, the covering has only one sheet. The last assertion follows from Definition 13.1.1. □

Example 13.1.10. We present some fundamental examples of smooth Riemannian manifolds without boundary and with bounded geometry, explicitly verifying the conditions of Definition 13.1.5.

(a) Euclidean space $(\mathbb{R}^n, \overline{\mathbf{g}})$ has bounded geometry.

Work in the standard coordinates of $\mathbb{R}^n$. In these coordinates, $\overline{g}_{ij} = \delta_{ij}$, so $\partial_k\overline{g}_{ij} = 0$ for all $i, j, k \in \{1, \dots, n\}$.

By Corollary 2.4.11, the Christoffel symbols of the Levi–Civita connection satisfy $\Gamma_{ij}^k = 0$ for all $i, j, k \in \{1, \dots, n\}$.

Substituting into Proposition 2.10.3 gives $R_{ijk}{}^{l} = 0$ for all $i,j,k,l \in \{1,\dots,n\}$, and consequently $\mathbf{R} = 0$. Therefore, $\nabla^m \mathbf{R} = 0$, $\forall m \in \mathbb{N}_0$.

We now study the exponential map. Let $p \in \mathbb{R}^n$ and $v \in T_p\mathbb{R}^n \cong \mathbb{R}^n$. In standard coordinates, the geodesic equation is $\dfrac{d^2x^k}{dt^2}(t) = 0$, $k \in \{1,\dots,n\}$, since $\Gamma^k_{ij} = 0$.

Integrating twice shows that every solution has the form $x(t) = a + tb$, with $a,b \in \mathbb{R}^n$. Imposing the initial conditions $x(0) = p$, $\dfrac{dx}{dt}(0) = v$, gives $a = p$ and $b = v$, so the geodesic with initial data (p,v) is given by $\gamma_v(t) = p + tv$.

By definition of the exponential map, $\exp_p(v) = \gamma_v(1)$, and therefore $\exp_p(v) = p + v$.

In particular, the exponential map $\exp_p \colon \mathbb{R}^n \longrightarrow \mathbb{R}^n$ is a global diffeomorphism, with inverse given by $q \mapsto q - p$. Consequently, $\operatorname{inj}(p) = +\infty$ for every $p \in \mathbb{R}^n$, and therefore $\operatorname{inj}(\mathbb{R}^n) = +\infty$.

We conclude that $(\mathbb{R}^n, \overline{\mathbf{g}})$ has bounded geometry.

(b) Consider the upper half-plane

$$\mathbb{H}^2 := \{(x,y) \in \mathbb{R}^2 \mid y > 0\}$$

equipped with the Riemannian metric

$$\mathbf{g} = \frac{(\mathbf{d}x)^2 + (\mathbf{d}y)^2}{y^2}.$$

Work in the global coordinates induced by the inclusion $\mathbb{H}^2 \subseteq \mathbb{R}^2$, namely $(x^1,x^2) = (x,y)$. Denote the coordinate fields by $\partial_i := \partial/\partial x^i$.

The coefficients of the metric and its inverse are given by $g_{ij} = \dfrac{1}{y^2}\delta_{ij}$ and $g^{ij} = y^2\delta_{ij}$. In particular, $g_{11} = g_{22} = \dfrac{1}{y^2}$ and $g_{12} = g_{21} = 0$.

Since g_{ij} depends only on the variable $y = x^2$, $\partial_1 g_{ij} = 0$ for all $i,j \in \{1,2\}$, whereas $\partial_2 g_{11} = \partial_2 g_{22} = -\dfrac{2}{y^3}$ and $\partial_2 g_{12} = \partial_2 g_{21} = 0$.

Using Corollary 2.4.11, we obtain

$$\Gamma^k_{ij} = \frac{1}{2}g^{k\ell}\left(\partial_i g_{j\ell} + \partial_j g_{i\ell} - \partial_\ell g_{ij}\right).$$

First compute the symbols with upper index 1. Since $g^{11} = y^2$ and $g^{12} = 0$, we have

$$\Gamma^1_{11} = \frac{1}{2}g^{1\ell}\left(\partial_1 g_{1\ell} + \partial_1 g_{1\ell} - \partial_\ell g_{11}\right) = 0.$$

Moreover,

$$\Gamma^1_{12} = \frac{1}{2}g^{1\ell}\left(\partial_1 g_{2\ell} + \partial_2 g_{1\ell} - \partial_\ell g_{12}\right) = \frac{1}{2}g^{11}\partial_2 g_{11} = \frac{1}{2}y^2\left(-\frac{2}{y^3}\right) = -\frac{1}{y}.$$

By symmetry of the Levi–Civita connection, $\Gamma^1_{21} = \Gamma^1_{12} = -\dfrac{1}{y}$. Finally,

$$\Gamma^1_{22} = \frac{1}{2}g^{1\ell}\left(\partial_2 g_{2\ell} + \partial_2 g_{2\ell} - \partial_\ell g_{22}\right) = 0.$$

Now compute the symbols with upper index 2. Since $g^{22} = y^2$ and $g^{21} = 0$, we obtain

$$\Gamma^2_{11} = \frac{1}{2}g^{2\ell}\left(\partial_1 g_{1\ell} + \partial_1 g_{1\ell} - \partial_\ell g_{11}\right) = -\frac{1}{2}g^{22}\partial_2 g_{11} = -\frac{1}{2}y^2\left(-\frac{2}{y^3}\right) = \frac{1}{y}.$$

Similarly,

$$\Gamma^2_{12} = \frac{1}{2}g^{2\ell}\left(\partial_1 g_{2\ell} + \partial_2 g_{1\ell} - \partial_\ell g_{12}\right) = 0,$$

and, by symmetry, $\Gamma^2_{21} = 0$. Lastly,

$$\Gamma^2_{22} = \frac{1}{2}g^{2\ell}\left(\partial_2 g_{2\ell} + \partial_2 g_{2\ell} - \partial_\ell g_{22}\right) = \frac{1}{2}g^{22}\partial_2 g_{22} = \frac{1}{2}y^2\left(-\frac{2}{y^3}\right) = -\frac{1}{y}.$$

Thus,

$$\Gamma^1_{11} = 0, \qquad \Gamma^1_{12} = \Gamma^1_{21} = -\frac{1}{y}, \qquad \Gamma^1_{22} = 0,$$

$$\Gamma^2_{11} = \frac{1}{y}, \qquad \Gamma^2_{12} = \Gamma^2_{21} = 0, \qquad \Gamma^2_{22} = -\frac{1}{y}.$$

We now compute the curvature tensor using Proposition 2.10.3:

$$R_{ijk}{}^{\ell} = \partial_i \Gamma^\ell_{jk} - \partial_j \Gamma^\ell_{ik} + \Gamma^m_{jk}\Gamma^\ell_{im} - \Gamma^m_{ik}\Gamma^\ell_{jm}.$$

Consider the component $R_{122}{}^1$. We have

$$\partial_1 \Gamma^1_{22} = 0, \qquad \partial_2 \Gamma^1_{12} = \partial_2\left(-\frac{1}{y}\right) = \frac{1}{y^2}.$$

Moreover,

$$\Gamma^m_{22}\Gamma^1_{1m} = \Gamma^1_{22}\Gamma^1_{11} + \Gamma^2_{22}\Gamma^1_{12} = 0 + \left(-\frac{1}{y}\right)\left(-\frac{1}{y}\right) = \frac{1}{y^2},$$

and

$$\Gamma^m_{12}\Gamma^1_{2m} = \Gamma^1_{12}\Gamma^1_{21} + \Gamma^2_{12}\Gamma^1_{22} = \left(-\frac{1}{y}\right)\left(-\frac{1}{y}\right) + 0 = \frac{1}{y^2}.$$

Therefore,

$$R_{122}{}^1 = 0 - \frac{1}{y^2} + \frac{1}{y^2} - \frac{1}{y^2} = -\frac{1}{y^2}.$$

Lowering indices gives

$$R_{1221} = g_{1\ell}R_{122}{}^\ell = g_{11}R_{122}{}^1 = \frac{1}{y^2}\left(-\frac{1}{y^2}\right) = -\frac{1}{y^4}.$$

We now compute the sectional curvature of the plane spanned by ∂_1 and ∂_2. By definition,

$$K(\partial_1, \partial_2) = \frac{\langle \mathbf{R}(\partial_1, \partial_2)\partial_2, \partial_1\rangle}{\langle \partial_1, \partial_1\rangle\langle \partial_2, \partial_2\rangle - \langle \partial_1, \partial_2\rangle^2}.$$

The denominator is

$$\langle \partial_1, \partial_1\rangle\langle \partial_2, \partial_2\rangle - \langle \partial_1, \partial_2\rangle^2 = g_{11}g_{22} - (g_{12})^2 = \frac{1}{y^4},$$

whereas the numerator is

$$\langle \mathbf{R}(\partial_1,\partial_2)\partial_2,\partial_1\rangle = R_{1221} = -\frac{1}{y^4}.$$

Consequently,

$$K(\partial_1,\partial_2) = \frac{-\frac{1}{y^4}}{\frac{1}{y^4}} = -1.$$

We have proved that the sectional curvature is constant and equal to -1. By Theorem 2.10.12, it follows that

$$\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z} = -\big(\mathbf{g}(\mathbf{Y},\mathbf{Z})\mathbf{X} - \mathbf{g}(\mathbf{X},\mathbf{Z})\mathbf{Y}\big).$$

We now verify that $\nabla\mathbf{R} = 0$. By definition of the covariant derivative of a tensor of type $(1,3)$,

$$(\nabla_{\mathbf{W}}\mathbf{R})(\mathbf{X},\mathbf{Y})\mathbf{Z} = \nabla_{\mathbf{W}}\big(\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z}\big) - \mathbf{R}(\nabla_{\mathbf{W}}\mathbf{X},\mathbf{Y})\mathbf{Z} - \mathbf{R}(\mathbf{X},\nabla_{\mathbf{W}}\mathbf{Y})\mathbf{Z} - \mathbf{R}(\mathbf{X},\mathbf{Y})\nabla_{\mathbf{W}}\mathbf{Z}.$$

Substituting the preceding expression for $\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z}$ gives

$$\nabla_{\mathbf{W}}\big(\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z}\big) = -\nabla_{\mathbf{W}}\big(\mathbf{g}(\mathbf{Y},\mathbf{Z})\mathbf{X} - \mathbf{g}(\mathbf{X},\mathbf{Z})\mathbf{Y}\big).$$

Applying the Leibniz rule for the connection gives

$$\nabla_{\mathbf{W}}\big(\mathbf{g}(\mathbf{Y},\mathbf{Z})\mathbf{X}\big) = \mathbf{W}\big(\mathbf{g}(\mathbf{Y},\mathbf{Z})\big)\mathbf{X} + \mathbf{g}(\mathbf{Y},\mathbf{Z})\nabla_{\mathbf{W}}\mathbf{X},$$

$$\nabla_{\mathbf{W}}\big(\mathbf{g}(\mathbf{X},\mathbf{Z})\mathbf{Y}\big) = \mathbf{W}\big(\mathbf{g}(\mathbf{X},\mathbf{Z})\big)\mathbf{Y} + \mathbf{g}(\mathbf{X},\mathbf{Z})\nabla_{\mathbf{W}}\mathbf{Y}.$$

Therefore,

$$\nabla_{\mathbf{W}}\big(\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z}\big) = -\Big(\mathbf{W}(\mathbf{g}(\mathbf{Y},\mathbf{Z}))\mathbf{X} + \mathbf{g}(\mathbf{Y},\mathbf{Z})\nabla_{\mathbf{W}}\mathbf{X} - \mathbf{W}(\mathbf{g}(\mathbf{X},\mathbf{Z}))\mathbf{Y} - \mathbf{g}(\mathbf{X},\mathbf{Z})\nabla_{\mathbf{W}}\mathbf{Y}\Big).$$

Now using compatibility of the Levi–Civita connection with the metric,

$$\mathbf{W}(\mathbf{g}(\mathbf{Y},\mathbf{Z})) = \mathbf{g}(\nabla_{\mathbf{W}}\mathbf{Y},\mathbf{Z}) + \mathbf{g}(\mathbf{Y},\nabla_{\mathbf{W}}\mathbf{Z}), \qquad \mathbf{W}(\mathbf{g}(\mathbf{X},\mathbf{Z})) = \mathbf{g}(\nabla_{\mathbf{W}}\mathbf{X},\mathbf{Z}) + \mathbf{g}(\mathbf{X},\nabla_{\mathbf{W}}\mathbf{Z}),$$

we obtain

$$\begin{aligned}\nabla_{\mathbf{W}}\big(\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z}\big) = -\Big(&\mathbf{g}(\nabla_{\mathbf{W}}\mathbf{Y},\mathbf{Z})\mathbf{X} + \mathbf{g}(\mathbf{Y},\nabla_{\mathbf{W}}\mathbf{Z})\mathbf{X} + \mathbf{g}(\mathbf{Y},\mathbf{Z})\nabla_{\mathbf{W}}\mathbf{X}\\ &-\mathbf{g}(\nabla_{\mathbf{W}}\mathbf{X},\mathbf{Z})\mathbf{Y} - \mathbf{g}(\mathbf{X},\nabla_{\mathbf{W}}\mathbf{Z})\mathbf{Y} - \mathbf{g}(\mathbf{X},\mathbf{Z})\nabla_{\mathbf{W}}\mathbf{Y}\Big).\end{aligned}$$

On the other hand,

$$\mathbf{R}(\nabla_{\mathbf{W}}\mathbf{X},\mathbf{Y})\mathbf{Z} = -\big(\mathbf{g}(\mathbf{Y},\mathbf{Z})\nabla_{\mathbf{W}}\mathbf{X} - \mathbf{g}(\nabla_{\mathbf{W}}\mathbf{X},\mathbf{Z})\mathbf{Y}\big),$$

$$\mathbf{R}(\mathbf{X},\nabla_{\mathbf{W}}\mathbf{Y})\mathbf{Z} = -\big(\mathbf{g}(\nabla_{\mathbf{W}}\mathbf{Y},\mathbf{Z})\mathbf{X} - \mathbf{g}(\mathbf{X},\mathbf{Z})\nabla_{\mathbf{W}}\mathbf{Y}\big),$$

$$\mathbf{R}(\mathbf{X},\mathbf{Y})\nabla_{\mathbf{W}}\mathbf{Z} = -\big(\mathbf{g}(\mathbf{Y},\nabla_{\mathbf{W}}\mathbf{Z})\mathbf{X} - \mathbf{g}(\mathbf{X},\nabla_{\mathbf{W}}\mathbf{Z})\mathbf{Y}\big).$$

Substituting these expressions into the definition of $(\nabla_{\mathbf{W}}\mathbf{R})(\mathbf{X},\mathbf{Y})\mathbf{Z}$ shows that each colored term in $\nabla_{\mathbf{W}}\big(\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z}\big)$ cancels exactly with the term of the same color arising from one of the other three

summands. Therefore,

$$(\nabla_{\mathbf{W}}\mathbf{R})(\mathbf{X},\mathbf{Y})\mathbf{Z} = 0$$

for all vector fields $\mathbf{W},\mathbf{X},\mathbf{Y},\mathbf{Z}$. Consequently,

$$\nabla^k\mathbf{R} = 0$$

for every $k \geq 1$.

We also prove the global hypotheses we will use. If $c(t) = (x(t), y(t))$ is a piecewise C^1 curve in $\mathbb{H}^2$, then

$$L_{\mathbf{g}}(c) = \int \frac{\sqrt{|x'(t)|^2 + |y'(t)|^2}}{y(t)}\,dt \geq \int \frac{|y'(t)|}{y(t)}\,dt \geq \bigl|\log y(b) - \log y(a)\bigr|.$$

Let $q_j = (x_j, y_j)$ be a Cauchy sequence for the Riemannian distance. The preceding inequality shows that $(\log y_j)$ is Cauchy; in particular, for large j, $a \leq y_j \leq b$ for some constants $0 < a < b < \infty$. Given two large indices, choose a curve between q_j and q_k whose length is less than $2d_{\mathbf{g}}(q_j, q_k)$. If this length is less than 1, the inequality already proved, applied to each subarc, shows that the coordinate y along the entire curve is at most eb. Consequently,

$$\|x_j - x_k\| \leq eb\, L_{\mathbf{g}}(c) \leq 2eb\, d_{\mathbf{g}}(q_j, q_k).$$

Thus, (x_j) is also Cauchy and q_j converges in the upper half-plane. Let $q = (x, y)$ be its Euclidean limit. For large j, the straight segment from q_j to q lies in a region where the second coordinate is at least $\frac{a}{2}$. In this region, for every vector v, $|v|_{\mathbf{g}} \leq 2a^{-1}|v|$; consequently, $d_{\mathbf{g}}(q_j, q) \leq 2a^{-1}|q_j - q| \to 0$. This proves completeness. The upper half-plane is convex and hence simply connected.

The Cartan–Hadamard Theorem 13.1.9 now applies: for every $p \in \mathbb{H}^2$, the exponential map

$$\exp_p \colon T_p\mathbb{H}^2 \longrightarrow \mathbb{H}^2$$

is a global diffeomorphism. In particular,

$$\operatorname{inj}(p) = +\infty$$

for every $p \in \mathbb{H}^2$, and therefore

$$\operatorname{inj}(\mathbb{H}^2) = +\infty.$$

We conclude that $(\mathbb{H}^2, \mathbf{g})$ has bounded geometry.

(c) The unit sphere $(S^n, \mathbf{g}_{\mathrm{can}})$ has bounded geometry. Its sectional curvature is constant and equal to 1, so Theorem 2.10.12 gives

$$\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z} = \mathbf{g}(\mathbf{Y},\mathbf{Z})\mathbf{X} - \mathbf{g}(\mathbf{X},\mathbf{Z})\mathbf{Y}.$$

Compatibility $\nabla\mathbf{g} = 0$ implies, by the same Leibniz rule used in the hyperbolic example, that $\nabla\mathbf{R} = 0$ and hence $\nabla^k\mathbf{R} = 0$ for every $k \geq 1$.

It remains to compute the injectivity radius, since Cartan–Hadamard does not apply here. For $p \in S^n$

and $v \in T_pS^n \setminus \{0\}$, the geodesic with initial data (p, v) is

$$\gamma_v(t) = \cos\big(t|v|_{\mathbf{g}_{\mathrm{can}},p}\big)p + \sin\big(t|v|_{\mathbf{g}_{\mathrm{can}},p}\big)\frac{v}{|v|_{\mathbf{g}_{\mathrm{can}},p}};$$

this formula is verified by differentiating twice and observing that $\gamma_v''(t) = -|v|^2_{\mathbf{g}_{\mathrm{can}},p}\gamma_v(t)$, whose acceleration is normal to the sphere. Consequently,

$$\exp_p(v) = \cos\big(|v|_{\mathbf{g}_{\mathrm{can}},p}\big)p + \sin\big(|v|_{\mathbf{g}_{\mathrm{can}},p}\big)\frac{v}{|v|_{\mathbf{g}_{\mathrm{can}},p}}.$$

If $|v|_{\mathbf{g}_{\mathrm{can}},p} < \pi$, the Euclidean inner product with p determines $|v|_{\mathbf{g}_{\mathrm{can}},p} = \arccos\langle p, \exp_p(v)\rangle_{\mathbb{R}^{n+1}}$, and the orthogonal component then determines $\frac{v}{|v|_{\mathbf{g}_{\mathrm{can}},p}}$. Thus, $\exp_p$ is injective on $B_{\mathbf{g}_{\mathrm{can}},p}(0,\pi)$. We also verify that it is a local diffeomorphism on this ball. If $v = re$, with $0 < r < \pi$ and $|e| = 1$, write $w = be + w_\perp$, with $w_\perp \perp e$. Differentiating the explicit formula gives

$$d\exp_p(v)w = b(-\sin r\, p + \cos r\, e) + \frac{\sin r}{r}w_\perp, \qquad |d\exp_p(v)w|^2 = b^2 + \left(\frac{\sin r}{r}\right)^2 |w_\perp|^2.$$

The two vector summands are orthogonal, and $\sin r/r > 0$. The differential is therefore invertible; at $v = 0$ it is the identity. Injectivity and the inverse function theorem show that $\exp_p$ is a diffeomorphism onto its image on the indicated ball. In contrast, all vectors of $\mathbf{g}_{\mathrm{can},p}$ norm equal to π are mapped to the antipodal point $-p$. We conclude that

$$\mathrm{inj}(p) = \pi, \qquad \mathrm{inj}(S^n) = \pi.$$

In particular, the sphere also satisfies both conditions of Definition 13.1.5.

In general, a Riemannian manifold of constant sectional curvature has a curvature tensor expressed algebraically in terms of the metric, and hence $\nabla\mathbf{R} = 0$. The models $\mathbb{R}^n$, S^n, and $\mathbb{H}^n$ thus have bounded curvature derivatives of all orders. Their injectivity radii are $+\infty$, π, and $+\infty$, respectively, for the normalizations used here.

Compact Riemannian manifolds have bounded geometry, providing many examples of such manifolds.

Theorem 13.1.11. Let $(M, \mathbf{g})$ be a compact Riemannian manifold without boundary. Then $(M, \mathbf{g})$ has bounded geometry.

Proof. The connected components of a manifold are open and form a cover of M. Compactness gives a finite subcover, so there are only finitely many components. Write

$$M = \bigsqcup_{j=1}^{N} M_j,$$

where each M_j is a connected component of M. Since connected components are closed in every topological space, each M_j is closed in M and hence compact.
Consequently, each Riemannian manifold $(M_j, \mathbf{g}\restriction_{M_j})$ is compact and therefore complete. For each $j \in$

$\{1,\dots,N\}$, Proposition 2.13.15 implies that the function

$$\mathrm{inj}\colon M_j \longrightarrow (0,\infty]$$

is continuous. (Note that $\mathrm{inj}_M(p) = \mathrm{inj}_{M_j}(p)\ \forall p \in M_j$, since M_j is a connected component of M and the geodesics of a manifold lie in a single connected component; this is why we simply denote it by $\mathrm{inj}(p)$.) Moreover, since $\mathrm{inj}(p) > 0$ for every $p \in M_j$, there exists $p_j \in M_j$ such that

$$\mathrm{inj}(p_j) = \min_{p\in M_j} \mathrm{inj}(p) > 0.$$

Define

$$c := \min_{j\in\{1,\dots,N\}} \mathrm{inj}(p_j) > 0.$$

Then $\mathrm{inj}(p) \geq c$ for every $p \in M$, and consequently $\mathrm{inj}(M) > 0$. On the other hand, for each $k \in \mathbb{N}_0$, the tensor $\nabla^k R$ is smooth on M, so the function

$$p \longmapsto |\nabla^k R(p)|_{\mathbf{g}}$$

is continuous. Since M is compact, for each $k \in \mathbb{N}_0$ there exists $C_k > 0$ such that $|\nabla^k R|_{\mathbf{g}} \leq C_k$. Therefore, $(M,\mathbf{g})$ has bounded geometry. □

A localized norm depends on three choices: the charts, their domains, and the cutoff functions. It is useful to collect them into a single object so that we can compare two constructions without losing track of any of these choices.

Definition 13.1.12. (Trivialization) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary. We say that $\mathcal{T} = (U_i,\varphi_i,h_i)_{i\in J}$ is a *trivialization* of M if $(U_i,\varphi_i)_{i\in J}$ is an atlas of M and $(h_i)_{i\in J}$ is a partition of unity subordinate to the open cover $(U_i)_{i\in J}$.

For an infinite cover, local finiteness alone does not allow estimates to be summed with a common constant. We need a uniform bound for the number of charts that may be involved in each overlap.

Definition 13.1.13. If X is a topological space and $(U_i)_{i\in J}$ is an open cover of X, we say that the cover is uniformly locally finite if there exists $L > 0$ such that, for each $i \in J$,

$$\#\{j \in J \mid U_j \cap U_i \neq \varnothing\} \leq L.$$

We say that a trivialization is *uniformly locally finite* if its underlying cover has this property.

Definition 13.1.14. Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry. If $\mathcal{T} = (U_i,\varphi_i,h_i)_{i\in I}$ is a uniformly locally finite trivialization of M, we say that $\mathcal{T}$ is *admissible* if the following conditions hold:

(B1) Let $r_0 > 0$ be a radius for which condition (2) of Theorem 13.1.8 holds. There exists a uniform geodesic atlas

$$\mathcal{A} = (U_j^{\mathrm{geo}},\varphi_j^{\mathrm{geo}})_{j\in J}$$

of common radius $0 < r \leq \frac{r_0}{10}$, with centers p_j, for which the balls $B_{\mathbf{g}}(p_j,\frac{r}{4})$ are pairwise disjoint and

Figure 13.2. A uniformly locally finite cover. For any open set U_i in the cover, shown in blue, the number of open sets in the cover meeting it, shown in orange, is bounded by a constant L independent of i.

the balls $B_{\mathbf{g}}(p_j, \frac{r}{2})$ cover M. Moreover, there exists $N \in \mathbb{N}$ such that

$$\sup_{i \in I} \#\{j \in J \mid U_i \cap U_j^{\mathrm{geo}} \neq \varnothing\} \leq N$$

and

$$\sup_{j \in J} \#\{i \in I \mid U_i \cap U_j^{\mathrm{geo}} \neq \varnothing\} \leq N.$$

Finally, for each $k \in \mathbb{N}_0$, there exists $C_k > 0$ with the following property: if $U_i \cap U_j^{\mathrm{geo}} \neq \varnothing$ and $|\alpha| \leq k$, then

$$\sup_{x \in \varphi_j^{\mathrm{geo}}(U_i \cap U_j^{\mathrm{geo}})} \left| D^\alpha \left(\varphi_i \circ (\varphi_j^{\mathrm{geo}})^{-1} \right)(x) \right| \leq C_k,$$

and

$$\sup_{y \in \varphi_i(U_i \cap U_j^{\mathrm{geo}})} \left| D^\alpha \left(\varphi_j^{\mathrm{geo}} \circ \varphi_i^{-1} \right)(y) \right| \leq C_k.$$

(B2) For each $k \in \mathbb{N}_0$, there exists $c_k > 0$ such that, for every $i \in I$ and every multi-index $|\alpha| \leq k$,

$$\sup_{x \in \varphi_i(U_i)} \left| D^\alpha (h_i \circ \varphi_i^{-1})(x) \right| \leq c_k.$$

(B3) For each $i \in I$, there exists a function $\chi_i \in C_c^\infty(U_i)$ such that

$$0 \leq \chi_i \leq 1, \qquad \chi_i = 1 \quad \text{on a neighborhood of } \operatorname{supp}(h_i),$$

and, for each $k \in \mathbb{N}_0$, there exists $d_k > 0$, independent of i, for which

$$\sup_{x \in \varphi_i(U_i)} \left| D^\alpha (\chi_i \circ \varphi_i^{-1})(x) \right| \leq d_k, \qquad |\alpha| \leq k.$$

The functions χ_i in item (B3) will be called *auxiliary cutoff functions* of the trivialization. Their presence allows a localized expression to be extended by zero, denoted by a tilde, before a coordinate change is applied. The condition is not redundant: bounds on the derivatives of h_i do not by themselves provide a uniform separation

between $\operatorname{supp}(h_i)$ and the boundary of U_i.

Lemma 13.1.15. (Uniform margin for cutoff functions) The auxiliary functions in (B3) can be chosen so that there exists $\delta > 0$, independent of $i \in I$, with

$$\operatorname{dist}_{\mathbb{R}^n}\big(\varphi_i(\operatorname{supp}\chi_i), \mathbb{R}^n \setminus \varphi_i(U_i)\big) \geq \delta.$$

The new functions still equal one on a neighborhood of $\operatorname{supp} h_i$ and retain uniform bounds on all their derivatives.

Proof. Temporarily denote the functions in (B3) by χ_i^0. Their coordinate representations, extended by zero, are smooth on $\mathbb{R}^n$. The bound on their first derivatives gives a constant $D > 0$ such that

$$\big\|\widetilde{D\chi_i^0 \circ \varphi_i^{-1}}\big\|_\infty \leq D, \qquad i \in I.$$

Choose $\vartheta \in C^\infty(\mathbb{R})$ with $0 \leq \vartheta \leq 1$, $\vartheta = 0$ on $(-\infty, 1/4]$, and $\vartheta = 1$ on $[1/2, \infty)$, and set $\chi_i = \vartheta \circ \chi_i^0$. If $x \in \varphi_i(\operatorname{supp}\chi_i)$, then $(\chi_i^0 \circ \varphi_i^{-1})(x) \geq 1/4$. For $y \in \mathbb{R}^n \setminus \varphi_i(U_i)$, the extension is zero. The mean value theorem on the Euclidean segment from x to y implies $1/4 \leq D|x - y|$. Taking the infimum over these y gives the margin $\delta = (4D)^{-1}$. The Faà di Bruno formula of Theorem 1.1.19, applied to the fixed function ϑ, provides the higher-order bounds. Since $\chi_i^0 = 1$ near $\operatorname{supp} h_i$, the new function also equals one there. □

From now on, we choose the auxiliary functions with this margin. Thus, the constants in a zero extension or a localized coordinate change incorporate a common positive distance from the artificial boundary of the charts.

Definition 13.1.16. (Quadratic localization system) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry. A *quadratic localization system* is a family

$$\mathcal{Q} = (U_i, \varphi_i, h_i)_{i \in I}$$

such that $(U_i, \varphi_i)_{i \in I}$ is a uniformly locally finite atlas, $h_i \in C_c^\infty(U_i)$, $0 \leq h_i \leq 1$, and

$$\sum_{i \in I} h_i^2 = 1 \qquad \text{on } M.$$

We say that $\mathcal{Q}$ is *admissible* if the atlas satisfies condition (B1), the functions h_i satisfy the estimates in (B2), with h_i in place of the partition functions, and there is a family of auxiliary cutoff functions as in (B3), equal to one on a neighborhood of $\operatorname{supp}(h_i)$.

Remark 13.1.17. If $\mathcal{Q} = (U_i, \varphi_i, h_i)_{i \in I}$ is an admissible quadratic localization system and $\rho_i := h_i^2$, then $\sum_{i \in I} \rho_i = 1$ and

$$\mathcal{T}_{\mathcal{Q}} := (U_i, \varphi_i, \rho_i)_{i \in I}$$

is an admissible trivialization. Indeed, the Leibniz rule converts the uniform derivative bounds for h_i into the corresponding bounds for h_i^2, and the same auxiliary cutoff functions serve both families. This observation distinguishes the quadratic system used in the analysis and synthesis formulas from the genuine partition of unity.

Remark 13.1.18. (Meaning and use of quadratic localization) A quadratic partition is not a second definition of the function spaces. Its usefulness lies in the fact that the same factor h_i enters both the analysis and the synthesis operators. Analysis sends u to the family

$$\left(\widetilde{(h_i u)\circ\varphi_i^{-1}}\right)_{i\in I}.$$

For synthesis, each component is first multiplied by a cutoff function whose support is compact in the chart image, reconstructed on U_i, extended by zero to M, and multiplied by h_i. The precise distributional definition will be given in Proposition 13.3.11. The identity $\sum_{i\in I} h_i^2 = 1$ makes the composition of the two operators exactly the identity before any comparison of norms. This is Amann's convention: the cutoff system appears in [6, Lemma 3.6], the two operators in formulas (4.5)–(4.6), and the retraction–coretraction property in Theorem 4.2 of that reference.

The local definitions of the spaces given below use, instead, an ordinary partition (ρ_i), as in [72, 130]. Lemma 13.3.10 proves that, when $\rho_i = h_i^2$, both localizations satisfy the explicit inequalities with the positive constants c_H, C_H, c_F, C_F of that lemma, independent of the section. It is therefore useful to distinguish the two families in the notation, even though they describe the same space.

Lemma 13.1.19. (Uniform quadratic normalization) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, and let $\mathcal{T} = (U_i,\varphi_i,\psi_i)_{i\in I}$ be an admissible trivialization such that $0\le\psi_i\le 1$ and $\operatorname{supp}\psi_i \Subset U_i$ for every i. Define

$$S(x) := \left(\sum_{j\in I}\psi_j(x)^2\right)^{\frac12}, \qquad h_i(x) := \frac{\psi_i(x)}{S(x)}.$$

Then $\mathcal{Q} = (U_i,\varphi_i,h_i)_{i\in I}$ is an admissible quadratic localization system.

Proof. The sum defining S is locally finite. If L is a uniform bound for the number of members of the cover that can contain a given point, the equality $\sum_{j\in I}\psi_j = 1$ and the Cauchy–Schwarz inequality give

$$1 = \left(\sum_{j\in I}\psi_j(x)\right)^2 \le L\sum_{j\in I}\psi_j(x)^2.$$

Since the functions are nonnegative, we also have $\sum_{j\in I}\psi_j(x)^2 \le (\sum_{j\in I}\psi_j(x))^2 = 1$. Therefore,

$$L^{-\frac12} \le S(x) \le 1 \qquad \text{for every } x\in M.$$

In particular, S is smooth, $0\le h_i\le 1$, $\operatorname{supp} h_i \subseteq \operatorname{supp}\psi_i \Subset U_i$, and

$$\sum_{i\in I} h_i^2 = S^{-2}\sum_{i\in I}\psi_i^2 = 1.$$

It remains to verify uniformity of the derivatives. Fix a chart (U_i,φ_i). Only indices j for which $U_i\cap U_j\neq$

$\varnothing$ contribute, and there are at most L of them. In chart i, the representation of ψ_j is understood to be extended by zero outside $\varphi_i(U_i \cap U_j)$. This extension is smooth: points where ψ_j may be nonzero lie inside $\operatorname{supp}(\psi_j) \Subset U_j$, whereas outside that support the function vanishes on a neighborhood. On the overlap,

$$\psi_j \circ \varphi_i^{-1} = (\psi_j \circ \varphi_j^{-1}) \circ (\varphi_j \circ \varphi_i^{-1}).$$

Bounds for the coordinate transitions follow directly from (B1): near each point of the overlap, insert a geodesic chart from the atlas appearing in that condition and write

$$\varphi_j \circ \varphi_i^{-1} = \big(\varphi_j \circ (\varphi_\nu^{\mathrm{geo}})^{-1}\big) \circ \big(\varphi_\nu^{\mathrm{geo}} \circ \varphi_i^{-1}\big).$$

Condition (B2), these bounds, and the Faà di Bruno formula of Theorem 1.1.19 bound all derivatives of these functions uniformly. The Leibniz rule and the bound L then bound all derivatives of $\sum_{j \in I_i} (\psi_j \circ \varphi_i^{-1})^2$. This last function takes values in the compact interval $[L^{-1}, 1]$. Applying Faà di Bruno once more to $t \mapsto t^{-\frac{1}{2}}$, whose derivatives are bounded on that interval, gives uniform bounds for the derivatives of $S^{-1} \circ \varphi_i^{-1}$. Finally, applying the Leibniz rule to

$$h_i \circ \varphi_i^{-1} = (\psi_i \circ \varphi_i^{-1})(S^{-1} \circ \varphi_i^{-1})$$

gives the estimates in (B2) for h_i. This proves admissibility: the auxiliary cutoff functions of the original trivialization still equal one on a neighborhood of $\operatorname{supp}(h_i) \subseteq \operatorname{supp}(\psi_i)$ and retain the estimates in (B3). □

Remark 13.1.20. The coordinate-transition estimates in (B1) do not depend on the particular normal atlas. Indeed, if $0 < r' \le r_0$, extend the charts of radii r and r' to radius $\max\{r, r'\} \le r_0$ when necessary, apply the additional assertion of Theorem 13.1.8, and restrict again.

The combinatorial condition is also independent of the atlas when the second atlas, of radius $0 < r' \le \frac{r_0}{10}$, has disjoint balls $B_{\mathbf{g}}(p'_j, \frac{r'}{4})$ and the balls $B_{\mathbf{g}}(p'_j, \frac{r'}{2})$ cover M. To verify this, if a chart of radius r meets a chart of radius r', the disjoint ball of radius $\frac{r'}{4}$ associated with the second lies in a ball whose radius does not exceed $r + r' + \frac{r'}{4} < r_0$. The uniform bounds on the metric and its inverse in normal charts, given by Theorem 13.1.8, place the eigenvalues of its matrix between two positive constants independent of the center. Integrating the square root of its determinant gives, for each fixed radius less than r_0, uniform upper and lower bounds for the volume of the balls. Comparing the large ball with the disjoint balls of radius $\frac{r'}{4}$ bounds their number uniformly. Interchanging r and r' gives the other overlap bound. Combining this fact with the two overlap bounds in (B1) also transfers the cross-overlap bounds between $\mathcal{T}$ and the second atlas.

Moreover, (B1) controls transitions between two admissible trivializations. Let $\mathcal{T} = (U_i, \varphi_i)_{i \in I}$ and $\mathcal{T}^\sharp = (U_j^\sharp, \varphi_j^\sharp)_{j \in J}$. By the preceding two paragraphs, we may fix a common uniform geodesic atlas $(U_\nu^{\mathrm{geo}}, \varphi_\nu^{\mathrm{geo}})_{\nu \in K}$ relative to which both satisfy the bounds in (B1). If $p \in U_i \cap U_j^\sharp$, choose ν with $p \in U_\nu^{\mathrm{geo}}$. On a neighborhood of p contained in the triple overlap, we have exactly

$$\varphi_j^\sharp \circ \varphi_i^{-1} = \big(\varphi_j^\sharp \circ (\varphi_\nu^{\mathrm{geo}})^{-1}\big) \circ \big(\varphi_\nu^{\mathrm{geo}} \circ \varphi_i^{-1}\big).$$

The Faà di Bruno formula of Theorem 1.1.19 expresses every derivative of order k of the left-hand side at p as a finite sum of products of derivatives of the two factors of orders at most k. The bounds in (B1) are

independent of i, j, ν; since p is arbitrary, for each $k \in \mathbb{N}_0$ there exists C_k, independent of i, j, such that

$$\left\| D^\alpha \left(\varphi_j^\sharp \circ \varphi_i^{-1} \right) \right\|_{L^\infty(\varphi_i(U_i \cap U_j^\sharp))} \leq C_k, \qquad |\alpha| \leq k.$$

Interchanging the two trivializations gives the same estimate for the inverse transition. The case $\mathcal{T}^\sharp = \mathcal{T}$ provides, in particular, uniform control of the internal transitions of an admissible trivialization.

Normal geodesic coordinates can be used to define a trivialization of any manifold of bounded geometry that is also *uniformly locally finite*; we will call it a ***geodesic trivialization***.

Lemma 13.1.21. (Uniform control of geodesic ball volumes) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry. If $r_0 > 0$ is a radius for which condition (2) of Theorem 13.1.8 holds, then, for each $0 < r \leq r_0$, there exist constants $v_-(r), v_+(r) > 0$ such that

$$v_-(r) \leq \lambda_{\mathbf{g}}(B_{\mathbf{g}}(p, r)) \leq v_+(r), \qquad \forall p \in M.$$

Proof. Fix $0 < r \leq r_0$ and let $p \in M$. The Riemannian exponential map at p induces a normal chart on $B_{\mathbf{g}}(p, r)$. Fix a linear isomorphism

$$B_p : \mathbb{R}^n \longrightarrow T_p M$$

taking the standard basis of $\mathbb{R}^n$ to an orthonormal basis of $T_p M$, and consider the chart

$$\varphi_p := B_p^{-1} \circ \exp_p^{-1} : B_{\mathbf{g}}(p, r) \longrightarrow B_{\mathrm{euc}}(0, r).$$

Denote by $g_{ij}^{(p)}$ and $g_{(p)}^{ij}$ the components of the metric and its inverse in these coordinates. Since $(M, \mathbf{g})$ has bounded geometry, Theorem 13.1.8 implies that there exists a constant $C > 0$, independent of p, such that

$$|g_{ij}^{(p)}(q)| \leq C \qquad \text{and} \qquad |g_{(p)}^{ij}(q)| \leq C, \qquad \forall q \in B_{\mathbf{g}}(p, r),$$

for all $i, j \in \{1, \ldots, n\}$.
Fix $q \in B_{\mathbf{g}}(p, r)$ and let $\lambda_1(q), \ldots, \lambda_n(q)$ be the eigenvalues of the coefficient matrix $(g_{ij}^{(p)}(q))_{i,j=1}^n$. This matrix is symmetric and positive definite. The bound on its entries implies that its Frobenius norm is at most nC; therefore,

$$\lambda_\ell(q) \leq nC, \qquad \ell = 1, \ldots, n.$$

The inverse matrix has coefficients $(g_{(p)}^{ij}(q))$ and its Frobenius norm is also at most nC. Its eigenvalues are $\lambda_\ell(q)^{-1}$, whence

$$\lambda_\ell(q)^{-1} \leq nC \quad \Longrightarrow \quad \lambda_\ell(q) \geq (nC)^{-1}.$$

Multiplying the n inequalities gives directly

$$(nC)^{-n} \leq \det\left(\mathbf{g}^{(p)}(q)\right) \leq (nC)^n, \qquad q \in B_{\mathbf{g}}(p, r),$$

uniformly in p. Consequently,

$$(nC)^{-\frac{n}{2}} \leq \sqrt{\det\left(\mathbf{g}^{(p)}(q)\right)} \leq (nC)^{\frac{n}{2}}.$$

Using the local expression for the Riemannian measure, we obtain

$$\lambda_{\mathbf{g}}(B_{\mathbf{g}}(p,r)) = \int_{B_{\mathrm{euc}}(0,r)} \sqrt{\det\big(\mathbf{g}^{(p)}(\varphi_p^{-1}(x))\big)}\, dx.$$

By the preceding bounds,

$$(nC)^{-\frac{n}{2}}\, \lambda_n(B_{\mathrm{euc}}(0,r)) \le \lambda_{\mathbf{g}}(B_{\mathbf{g}}(p,r)) \le (nC)^{\frac{n}{2}}\, \lambda_n(B_{\mathrm{euc}}(0,r)).$$

It therefore suffices to define

$$v_-(r) := (nC)^{-\frac{n}{2}}\, \lambda_n(B_{\mathrm{euc}}(0,r)) \qquad \text{and} \qquad v_+(r) := (nC)^{\frac{n}{2}}\, \lambda_n(B_{\mathrm{euc}}(0,r)).$$

This concludes the proof. □

Theorem 13.1.22. (Geodesic trivialization) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry. Then there exist $r > 0$ and an admissible trivialization

$$\mathcal{T}^{\mathrm{geo}} = \big(B_{\mathbf{g}}(p_i, 2r), \varphi_i, h_i^{\mathrm{geo}}\big)_{i\in J}$$

of M such that:

(a) For each $i \in J$,

$$\varphi_i = B_{p_i}^{-1} \circ \exp_{p_i}^{-1} : B_{\mathbf{g}}(p_i, 2r) \longrightarrow B_{\mathrm{euc}}(0, 2r) \subseteq \mathbb{R}^n$$

is a normal coordinate chart, where $B_{p_i} : \mathbb{R}^n \longrightarrow T_{p_i}M$ is an isomorphism.

(b) The balls $B_{\mathbf{g}}(p_i, \frac{r}{2})$ are pairwise disjoint.

(c) $M = \bigcup_{i\in J} B_{\mathbf{g}}(p_i, r)$, and the cover $(B_{\mathbf{g}}(p_i, 2r))_{i\in J}$ is uniformly locally finite.

(d) $(h_i^{\mathrm{geo}})_{i\in J}$ is a partition of unity subordinate to $(B_{\mathbf{g}}(p_i, 2r))_{i\in J}$.

(e) For every $k \in \mathbb{N}_0$, there exists $C_k > 0$ such that

$$\left| D^\alpha (h_j^{\mathrm{geo}} \circ \varphi_i^{-1}) \right| \le C_k, \qquad |\alpha| \le k,$$

whenever $B_{\mathbf{g}}(p_i, 2r) \cap B_{\mathbf{g}}(p_j, 2r) \neq \varnothing$.

(f) There exist functions $\chi_i^{\mathrm{geo}} \in C_c^\infty(B_{\mathbf{g}}(p_i, 2r))$, equal to one on a neighborhood of $\mathrm{supp}(h_i^{\mathrm{geo}})$, whose representations in the normal charts have derivatives of every order uniformly bounded in i.

Proof. Since $(M,\mathbf{g})$ has bounded geometry, $\mathrm{inj}(M) > 0$. Let $r_0 > 0$ be a radius for which condition (2) of Theorem 13.1.8 holds. Choose

$$0 < r < \min\left\{ \frac{\mathrm{inj}(M)}{5}, \frac{r_0}{20} \right\}.$$

Consider

$$\mathcal{F} = \{A \subseteq M \mid d(p,q) \ge r \text{ for all } p,q \in A, \text{ with } p \neq q\}.$$

We can order $\mathcal{F}$ by set inclusion $\subseteq$, obtaining a partial order. If $\mathcal{C} \subseteq \mathcal{F}$ is a chain, then $A_{\mathcal{C}} = \bigcup_{A \in \mathcal{C}} A$ belongs to $\mathcal{F}$, since, given $p, q \in A_{\mathcal{C}}$, total ordering of $(\mathcal{C}, \subseteq)$ ensures that both belong to the same member of the chain. Thus, $A_{\mathcal{C}}$ is an upper bound for $\mathcal{C}$, so Zorn's Lemma, Theorem A.0.1, guarantees the existence of a maximal set $A = \{p_i\}_{i \in J}$. Maximality preserves the separation $d(p_i, p_j) \geq r$ whenever $i \neq j$, which implies that the balls $B_{\mathbf{g}}(p_i, \frac{r}{2})$ are disjoint.

We claim that $M = \bigcup_{i \in J} B_{\mathbf{g}}(p_i, r)$. Otherwise, there would exist $x \in M$ with $d(x, p_i) \geq r$ for every $i \in J$. In particular, this gives $x \notin A$, so

$$A \subsetneq A \cup \{x\} \in \mathcal{F},$$

contradicting maximality of A.

For each $i \in J$, since $2r < \operatorname{inj}(M)$, the Riemannian exponential map at p_i induces a normal chart on $B_{\mathbf{g}}(p_i, 2r)$. Define

$$\varphi_i := B_{p_i}^{-1} \circ \exp_{p_i}^{-1} \colon B_{\mathbf{g}}(p_i, 2r) \longrightarrow B_{\mathrm{euc}}(0, 2r),$$

where $B_{p_i} \colon \mathbb{R}^n \longrightarrow T_{p_i} M$ is an isomorphism taking the standard basis to an orthonormal basis. This proves (a).

We now prove that the cover $(B_{\mathbf{g}}(p_i, 2r))_{i \in J}$ is uniformly locally finite. For fixed $i \in J$, define

$$J_i := \{j \in J \mid B_{\mathbf{g}}(p_i, 2r) \cap B_{\mathbf{g}}(p_j, 2r) \neq \varnothing\}.$$

If $j \in J_i$, then $B_{\mathbf{g}}(p_i, 2r) \cap B_{\mathbf{g}}(p_j, 2r) \neq \varnothing$, whence

$$d(p_i, p_j) < 4r, \qquad \text{and therefore} \qquad p_j \in B_{\mathbf{g}}(p_i, 4r).$$

The balls $B_{\mathbf{g}}(p_j, \frac{r}{2})$ are pairwise disjoint, and moreover,

$$B_{\mathbf{g}}(p_j, \tfrac{r}{2}) \subseteq B_{\mathbf{g}}(p_i, \tfrac{9r}{2}), \qquad \forall j \in J_i.$$

By Lemma 13.1.21, there exist constants $v_-, v_+ > 0$ such that

$$\lambda_{\mathbf{g}}\big(B_{\mathbf{g}}(p, \tfrac{r}{2})\big) \geq v_-, \qquad \lambda_{\mathbf{g}}\big(B_{\mathbf{g}}(p, \tfrac{9r}{2})\big) \leq v_+, \qquad \forall p \in M.$$

Summing volumes over $j \in J_i$ gives

$$\sum_{j \in J_i} \lambda_{\mathbf{g}}\big(B_{\mathbf{g}}(p_j, \tfrac{r}{2})\big) \leq \lambda_{\mathbf{g}}\big(B_{\mathbf{g}}(p_i, \tfrac{9r}{2})\big),$$

and therefore

$$\#J_i \, v_- \leq v_+, \qquad \text{whence} \qquad \#J_i \leq \frac{v_+}{v_-}.$$

This implies that the cover $(B_{\mathbf{g}}(p_i, 2r))_{i \in J}$ is uniformly locally finite, proving (c).

We now construct a partition of unity. Use the flat function from the proof of Theorem 1.3.5, which we

write again here:

$$\vartheta(t) := \begin{cases} e^{-1/t}, & t > 0, \\ 0, & t \le 0. \end{cases}$$

All its derivatives at the origin vanish. Define explicitly

$$\psi(x) := \frac{\vartheta\left((\frac{4r}{3})^2 - \|x\|^2\right)}{\vartheta\left((\frac{4r}{3})^2 - \|x\|^2\right) + \vartheta(\|x\|^2 - r^2)}.$$

The denominator does not vanish, and flatness of ϑ at the origin shows that $\psi \in C_c^\infty(\mathbb{R}^n)$. Moreover,

$$0 \le \psi \le 1, \qquad \psi \equiv 1 \text{ on } B_{\text{euc}}(0, r), \qquad \operatorname{supp}(\psi) \subseteq B_{\text{euc}}(0, \frac{3r}{2}).$$

For each $i \in J$, define

$$\psi_i(x) := \begin{cases} \psi(\varphi_i(x)), & x \in B_{\mathbf{g}}(p_i, 2r), \\ 0, & \text{otherwise.} \end{cases}$$

Then ψ_i is smooth and

$$\operatorname{supp}(\psi_i) \subseteq B_{\mathbf{g}}(p_i, \frac{3r}{2}) \subset B_{\mathbf{g}}(p_i, 2r),$$

so its extension by zero is smooth.
Define

$$\Psi(x) := \sum_{i \in J} \psi_i(x).$$

Since the cover $(B_{\mathbf{g}}(p_i, 2r))_{i \in J}$ is uniformly locally finite, for every $x \in M$ there exists a neighborhood U of x such that the set

$$\{i \in J \mid U \cap B_{\mathbf{g}}(p_i, 2r) \neq \varnothing\}$$

is finite. In particular, for every $y \in U$, the sum defining $\Psi(y)$ has finitely many nonzero summands, with a bound independent of $y \in U$. It follows that Ψ is a smooth function on M.
Moreover, since

$$M = \bigcup_{i \in J} B_{\mathbf{g}}(p_i, r)$$

and $\psi_i \equiv 1$ on $B_{\mathbf{g}}(p_i, r)$, for every $x \in M$ there exists $i \in J$ such that $\psi_i(x) = 1$. Consequently,

$$\Psi(x) \ge 1, \qquad \forall x \in M.$$

In particular, Ψ does not vanish on M, so the functions

$$h_i^{\text{geo}}(x) := \frac{\psi_i(x)}{\Psi(x)}$$

are well defined and smooth. Moreover, since $0 \le \psi_i \le 1$ and $\Psi \ge 1$,

$$0 \le h_i^{\text{geo}} \le 1, \qquad \forall i \in J.$$

Thus, $(h_i^{\text{geo}})_{i \in J}$ is a partition of unity subordinate to $(B_{\mathbf{g}}(p_i, 2r))_{i \in J}$, proving (d).

We prove the uniform derivative bounds. For fixed $i, j \in J$ such that $B_{\mathbf{g}}(p_i, 2r) \cap B_{\mathbf{g}}(p_j, 2r) \neq \varnothing$, in normal coordinates we have

$$h_j^{\mathrm{geo}} \circ \varphi_i^{-1} = \frac{\psi_j \circ \varphi_i^{-1}}{\sum_{k \in J_i} \psi_k \circ \varphi_i^{-1}},$$

where J_i is finite and has uniformly bounded cardinality.
First, we show that the functions $\psi_k \circ \varphi_i^{-1}$ have uniformly bounded derivatives of every order. Fix $m \in \mathbb{N}_0$. Since ψ is a fixed cutoff function on $\mathbb{R}^n$ with compact support contained in $B_{\mathrm{euc}}(0, \frac{3r}{2})$, there exists a constant $A_m > 0$ such that

$$|D^\alpha \psi(x)| \leq A_m, \qquad \forall x \in \mathbb{R}^n, \quad |\alpha| \leq m.$$

On the other hand, for each $k \in J_i$,

$$\psi_k \circ \varphi_i^{-1} = \psi \circ \varphi_k \circ \varphi_i^{-1}.$$

The equality is used on $\varphi_i(B_{\mathbf{g}}(p_i, 2r) \cap B_{\mathbf{g}}(p_k, 2r))$. Outside this overlap, $\psi_k \circ \varphi_i^{-1} = 0$. Indeed, $\operatorname{supp} \psi \subset B_{\mathrm{euc}}(0, \frac{3r}{2})$, so ψ_k vanishes on a neighborhood of the boundary of $B_{\mathbf{g}}(p_k, 2r)$. Thus, the coordinate expression is smooth throughout $\varphi_i(B_{\mathbf{g}}(p_i, 2r))$, and its derivatives vanish outside the overlap. Since the geodesic coordinate transitions $\varphi_k \circ \varphi_i^{-1}$ have uniformly bounded derivatives through order m by Theorem 13.1.8, the Faà di Bruno formula of Theorem 1.1.19 implies that there exists a constant $C'_m > 0$, independent of i and k, such that

$$|D^\alpha(\psi_k \circ \varphi_i^{-1})| \leq C'_m, \qquad |\alpha| \leq m.$$

Moreover, since the sum in the denominator involves a uniformly bounded number of terms, for each $m \in \mathbb{N}_0$ there exists a constant $C''_m > 0$ such that

$$\left| D^\alpha \left(\sum_{k \in J_i} \psi_k \circ \varphi_i^{-1} \right) \right| \leq C''_m, \qquad |\alpha| \leq m.$$

On the other hand, for every $x \in B_{\mathrm{euc}}(0, 2r)$,

$$\sum_{k \in J_i} \psi_k \circ \varphi_i^{-1}(x) = \Psi\left(\varphi_i^{-1}(x)\right) \geq 1.$$

Thus, the denominator is uniformly bounded below by 1. Set

$$F_i := \sum_{k \in J_i} \psi_k \circ \varphi_i^{-1}.$$

The lower bound gives $\|F_i^{-1}\|_{L^\infty(B_{\mathrm{euc}}(0,2r))} \leq 1$. For $|\alpha| \geq 1$, applying the Leibniz rule to $F_i^{-1} F_i = 1$ and isolating the term $D^\alpha(F_i^{-1})F_i$ gives the recurrence

$$D^\alpha(F_i^{-1}) = -F_i^{-1} \sum_{\substack{\beta \in \mathbb{N}_0^n \\ \beta \leq \alpha,\ \beta \neq \alpha}} \binom{\alpha}{\beta} D^\beta(F_i^{-1}) D^{\alpha-\beta} F_i.$$

For $|\alpha| = 1$, the right-hand side contains only F_i^{-1} and first derivatives of F_i, which are already bounded. If the derivatives of F_i^{-1} of order less than $|\alpha|$ are uniformly bounded, every term in the sum is bounded by

the induction hypothesis and the bounds on F_i. Thus, order by order, we obtain uniform bounds for all derivatives of F_i^{-1}. Writing

$$h_j^{\mathrm{geo}} \circ \varphi_i^{-1} = (\psi_j \circ \varphi_i^{-1}) \cdot F_i^{-1},$$

the multi-index Leibniz rule and the bounds just proved imply that, for each $m \in \mathbb{N}_0$, there exists a constant $C_m > 0$ such that

$$|D^\alpha (h_j^{\mathrm{geo}} \circ \varphi_i^{-1})| \le C_m, \qquad |\alpha| \le m.$$

This proves (e). The underlying atlas has common radius $2r$; the balls of radius $\frac{2r}{4} = \frac{r}{2}$ are disjoint, and those of radius $\frac{2r}{2} = r$ cover M. Moreover, $2r < \frac{r_0}{10}$ by the choice of radius. The overlap bounds already proved and the additional assertion of Theorem 13.1.8 verify (B1), while (e) verifies (B2).
To construct the auxiliary cutoff functions, use the same flat function and set

$$\chi(x) := \frac{\vartheta\big((\frac{15r}{8})^2 - \|x\|^2\big)}{\vartheta\big((\frac{15r}{8})^2 - \|x\|^2\big) + \vartheta\big(\|x\|^2 - (\frac{7r}{4})^2\big)}.$$

Then $\chi \in C_c^\infty(B_{\mathrm{euc}}(0,2r))$, $0 \le \chi \le 1$, and $\chi = 1$ on $B_{\mathrm{euc}}(0, \frac{7r}{4})$. Define

$$\chi_i^{\mathrm{geo}} := \begin{cases} \chi \circ \varphi_i, & \text{on } B_{\mathbf{g}}(p_i, 2r), \\ 0, & \text{outside } B_{\mathbf{g}}(p_i, 2r). \end{cases}$$

The construction of h_i^{geo} shows that its support is contained in $B_{\mathbf{g}}(p_i, \frac{3r}{2})$; therefore, $\chi_i^{\mathrm{geo}} = 1$ on a neighborhood of that support. In its own chart, its representation is the fixed function χ, so the required bounds are independent of i. This verifies (B3) and the last item of the statement. Therefore, $\mathcal{T}^{\mathrm{geo}}$ is admissible. □

We next present a useful lemma:

Lemma 13.1.23. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathcal{T} = (U_i, \varphi_i, h_i)_{i \in I}$ be a trivialization of M. Suppose that there exists a constant $C > 0$ such that, for every $i \in I$, the components of the metric and its inverse in the chart (U_i, φ_i) satisfy

$$|g_{ab}^{(i)}(p)| \le C \qquad \text{and} \qquad |g_{(i)}^{ab}(p)| \le C$$

for every $p \in U_i$ and all $a, b \in \{1, \dots, n\}$.
Then there exist positive constants c_0, C_0, independent of i and p, such that

$$c_0 \|d(\varphi_i)_p(v)\|^2 \le |v|_{\mathbf{g}}^2 \le C_0 \|d(\varphi_i)_p(v)\|^2, \qquad \forall p \in U_i,\ \forall v \in T_pM.$$

Proof. Fix $i \in I$ and $p \in U_i$. Let $v \in T_pM$ and define

$$w := d(\varphi_i)_p(v) \in \mathbb{R}^n.$$

Since (U_i, φ_i) is a chart, the vector v can be written uniquely as

$$v = w^a \partial_a \Big|_p,$$

so, by definition of the metric coefficients,

$$|v|_{\mathbf{g}}^2 = \mathbf{g}_p(v,v) = \sum_{a,b=1}^{n} g_{ab}^{(i)}(p) w^a w^b. \tag{13.7}$$

Let $\lambda_1(p),\dots,\lambda_n(p)$ be the eigenvalues of the symmetric positive definite matrix $(g_{ab}^{(i)}(p))_{a,b=1}^n$. The bound on its entries gives

$$\left(\sum_{a,b=1}^{n} |g_{ab}^{(i)}(p)|^2 \right)^{1/2} \leq nC,$$

and Theorem C.1.10 implies $\lambda_\ell(p) \leq nC$. The inverse matrix has entries $g_{(i)}^{ab}(p)$, so the same argument applied to it gives

$$\lambda_\ell(p)^{-1} \leq nC \quad \Longrightarrow \quad \lambda_\ell(p) \geq \frac{1}{nC}.$$

The spectral theorem provides an orthonormal basis $(\varepsilon_\ell)_{\ell=1}^n$ in which, if $w = \sum_{\ell=1}^{n} w_\ell \varepsilon_\ell$, the last member of (13.7) is $\sum_{\ell=1}^{n} \lambda_\ell(p) w_\ell^2$. Therefore,

$$\frac{1}{nC} \|d(\varphi_i)_p(v)\|^2 \leq |v|_{\mathbf{g}}^2 \leq nC \, \|d(\varphi_i)_p(v)\|^2.$$

The constants $c_0 = (nC)^{-1}$ and $C_0 = nC$ are independent of i and p, as required. □

Remark 13.1.24. (Meaning of uniform comparison in coordinates) If $\overline{\mathbf{g}}$ is the Euclidean metric and $\boldsymbol{\delta}_i := \varphi_i^* \overline{\mathbf{g}}$, then

$$(\boldsymbol{\delta}_i)_p(v,v) = \|d(\varphi_i)_p(v)\|^2.$$

Thus, the conclusion of the preceding lemma can be abbreviated as $c_0 \boldsymbol{\delta}_i \leq \mathbf{g} \leq C_0 \boldsymbol{\delta}_i$ on the domain of each chart, in the sense of Definition 2.1.5. The lemma's comparison between intrinsic and coordinate quantities consists precisely of evaluating these two metrics on the same vector $v \in T_pM$. Proposition 7.1.9 then provides uniform bounds for covectors, tensors of any fixed type, and volume elements.

Here c_0 and C_0 are independent of the index i because the hypothesis controls the coefficients in all charts and their inverses by a single constant. Applying the comparison separately on each compact set would generally give constants c_i, C_i; an infinite family of charts does not allow them to be replaced by common constants without also proving $\inf_{i\in I} c_i > 0$ and $\sup_{i\in I} C_i < \infty$.

13.2 Uniform regularity as a coordinate formulation of bounded geometry

Bounded geometry is the intrinsic notion adopted in this book. Amann's uniform regularity expresses the same control through an atlas with normalized domains; its usefulness lies in making visible the constants associated with the coefficients, cutoff functions, and localization operators. It does not introduce a uniformity on a set of

configurations; the notion based on neighborhoods of the diagonal is developed in Section 27.2. The spaces BC^j and BUC^j, including the convention on a half-box, were defined in Definition 6.4.1.

Set

$$Q^m := (-1,1)^m, \qquad Q^m_+ := [0,1)\times(-1,1)^{m-1}.$$

If $0<\rho<1$, write $\rho Q^m = (-\rho,\rho)^m$ and $\rho Q^m_+ = [0,\rho)\times(-\rho,\rho)^{m-1}$.

Definition 13.2.1. (Uniformly regular atlas) Let M be a separable smooth manifold of dimension m, with or without boundary. An atlas $\mathfrak{K} = (U_\kappa,\kappa)_{\kappa\in K}$ is *normalized* if

$$\kappa\colon U_\kappa \longrightarrow Q_\kappa, \qquad Q_\kappa \in \{Q^m, Q^m_+\},$$

, with Q^m_+ used precisely for charts meeting the boundary. It is *shrinkable* if there exists a number $\rho\in(0,1)$, common to all charts, such that $\{\kappa^{-1}(\rho Q_\kappa)\mid \kappa\in K\}$ covers M. Its multiplicity is

$$\operatorname{mult}(\mathfrak{K}) := \sup_{p\in M} \#\{\kappa\in K\mid p\in U_\kappa\}.$$

The atlas is *uniformly regular* if it is normalized, shrinkable, has finite multiplicity, and, for each $j\in\mathbb{N}_0$, there exists $C_{\mathrm{tr}}(j)>0$, independent of the charts, such that

$$\|\widetilde{\kappa}\circ\kappa^{-1}\|_{BUC^j(\kappa(U_\kappa\cap U_{\widetilde{\kappa}}),\mathbb{R}^m)} \le C_{\mathrm{tr}}(j)$$

if $U_\kappa\cap U_{\widetilde{\kappa}}\neq\varnothing$. Equivalently, every transition belongs to $BUC^\infty(\kappa(U_\kappa\cap U_{\widetilde{\kappa}}),\mathbb{R}^m)$ and hence to BC^∞ on that domain, with bounds uniform over the charts for each finite-order seminorm.

Definition 13.2.2. (Uniformly regular structure) Let M be a smooth manifold with or without boundary. Two uniformly regular atlases of M are equivalent if there exists $N\in\mathbb{N}$ bounding, in both directions, the number of charts of one atlas meeting any chart of the other, and if, for each $j\in\mathbb{N}_0$, the mixed transitions and their inverses have BUC^j norm bounded by a constant independent of the charts. An equivalence class is a *uniformly regular structure*.

Definition 13.2.3. (Uniformly regular Riemannian manifold) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathfrak{K}$ be a uniformly regular atlas. For each chart, define, without ambiguity concerning pushforwards,

$$\mathbf{g}_\kappa := (\kappa^{-1})^*\mathbf{g}.$$

The metric is *uniformly regular relative to* $\mathfrak{K}$ if there exist $c_{\mathbf{g}}, C_{\mathbf{g}}>0$, independent of κ, such that

$$c_{\mathbf{g}}|\xi|^2 \le \mathbf{g}_\kappa(x)(\xi,\xi) \le C_{\mathbf{g}}|\xi|^2 \tag{13.8}$$

for every $x\in Q_\kappa$ and $\xi\in\mathbb{R}^m$, and if, for each $j\in\mathbb{N}_0$, there exists $G_j>0$, independent of κ, such that

$$\|(g_\kappa)_{ab}\|_{BUC^j(Q_\kappa)} \le G_j, \qquad 1\le a,b\le m. \tag{13.9}$$

A manifold equipped with the corresponding class is called a *uniformly regular Riemannian manifold*.

Bounds on the inverse metric are not an additional hypothesis. Indeed, (13.8) implies $\|\mathbf{g}_\kappa^{-1}(x)\|_{\mathrm{op}} \le c_{\mathbf{g}}^{-1}$. Differentiating $\mathbf{g}_\kappa^{-1}\mathbf{g}_\kappa = I$ gives

$$D(\mathbf{g}_\kappa^{-1})[v] = -\mathbf{g}_\kappa^{-1} D\mathbf{g}_\kappa[v]\mathbf{g}_\kappa^{-1}.$$

For a multi-index $\alpha \neq 0$, applying the Leibniz rule to $\mathbf{g}_\kappa^{-1}\mathbf{g}_\kappa = I$ gives

$$0 = \sum_{\substack{\beta \in \mathbb{N}_0^m \\ \beta \le \alpha}} \binom{\alpha}{\beta} (D^\beta \mathbf{g}_\kappa^{-1})(D^{\alpha-\beta}\mathbf{g}_\kappa).$$

Separating the term $\beta = \alpha$ and multiplying on the right by $\mathbf{g}_\kappa^{-1}$ gives the exact recurrence

$$D^\alpha \mathbf{g}_\kappa^{-1} = - \sum_{\substack{\beta \in \mathbb{N}_0^m \\ \beta \le \alpha,\ \beta \neq \alpha}} \binom{\alpha}{\beta} (D^\beta \mathbf{g}_\kappa^{-1})(D^{\alpha-\beta}\mathbf{g}_\kappa)\mathbf{g}_\kappa^{-1}. \tag{13.10}$$

Order zero is bounded by $c_{\mathbf{g}}^{-1}$. Suppose all derivatives of the inverse of order less than j are bounded, and let $|\alpha| = j$. In each summand of (13.10), we have $|\beta| < j$ and $1 \le |\alpha - \beta| \le j$; the induction hypothesis, the bound G_j for the metric, and the order-zero bound for its inverse control the product. The sum is finite, and its coefficients depend only on α. This proves the bound of order j and completes the induction. Thus, for each j, there exists a constant

$$G_j' = P_j(c_{\mathbf{g}}^{-1}, G_1, \dots, G_j) > 0,$$

where P_j is a universal polynomial with nonnegative coefficients, such that

$$\|(\mathbf{g}_\kappa^{-1})^{ab}\|_{BUC^j(Q_\kappa)} \le G_j' \tag{13.11}$$

for all charts and indices. The same transformation rule, the Faà di Bruno formula of Theorem 1.1.19, and the bounds on mixed transitions show that the definition is independent of the representative atlas.

Theorem 13.2.4. (From bounded geometry to uniform regularity) Every Riemannian manifold without boundary and with bounded geometry admits a uniformly regular structure. The atlas constants can be chosen to depend on m, a common normal radius, and the curvature bounds in Definition 13.1.5, never on the chart.

Proof. Let $i_0 := \mathrm{inj}(M) > 0$, and let $r_0 > 0$ be the radius in Theorem 13.1.8. Choose $a > 0$ so that

$$4a\sqrt{m} < \min\{i_0, r_0\}, \qquad \delta := \frac{a}{4}, \qquad \rho := \frac{1}{2}.$$

By the maximality argument of Theorem 13.1.22, there exists a family $(p_i)_{i\in I}$ that is δ-separated and whose balls of radius δ cover M. Choose isometries $B_i : \mathbb{R}^m \longrightarrow T_{p_i}M$ and define

$$\kappa_i^{-1}(x) := \exp_{p_i}(B_i(ax)), \qquad x \in Q^m.$$

The charts are well defined because $aQ^m \subset B(0, a\sqrt{m})$. If $p \in B_{\mathbf{g}}(p_i, \delta)$, then $p = \exp_{p_i}(B_i v)$ with $|v| < \frac{a}{4}$ and $\frac{v}{a} \in \rho Q^m$. Thus, the shrunken charts cover M.
If $U_i \cap U_j \neq \varnothing$, then $d_{\mathbf{g}}(p_i, p_j) < 2a\sqrt{m}$. The balls $B_{\mathbf{g}}(p_j, \frac{\delta}{2})$ are pairwise disjoint and, for every index meeting

U_i, lie in $B_{\mathbf{g}}(p_i, 2a\sqrt{m}+\frac{\delta}{2})$. With the constants from Lemma 13.1.21, we obtain

$$\operatorname{mult}(\mathfrak{K}) \le N_0 := \left\lceil \frac{v_+(2a\sqrt{m}+\frac{\delta}{2})}{v_-(\frac{\delta}{2})} \right\rceil. \tag{13.12}$$

Let $\varphi_i = B_i^{-1} \circ \exp_{p_i}^{-1}$ be the unscaled normal chart. If $U_i \cap U_j \neq \varnothing$, then $d_{\mathbf{g}}(p_i, p_j) < 2a\sqrt{m}$ and, for every $x \in Q^m$,

$$d_{\mathbf{g}}\big(p_j, \exp_{p_i}(B_i(ax))\big) < 3a\sqrt{m}.$$

The choice $4a\sqrt{m} < \min\{i_0, r_0\}$ therefore allows the coordinate transition to be extended to all of Q^m by

$$T_{ji}^{\mathrm{ext}}(x) := a^{-1} B_j^{-1} \exp_{p_j}^{-1}\big(\exp_{p_i}(B_i(ax))\big).$$

Theorem 13.1.8 provides constants $A_\ell > 0$, independent of i, j, for these exponential comparisons at the preceding radii. Since, on the actual domain of the transition,

$$\kappa_j \circ \kappa_i^{-1}(x) = a^{-1}(\varphi_j \circ \varphi_i^{-1})(ax),$$

we have, for $\ell \ge 1$,

$$\sup_{x \in \kappa_i(U_i \cap U_j)} \|D^\ell(\kappa_j \circ \kappa_i^{-1})(x)\|_{\mathrm{op}} \le a^{\ell-1} A_\ell, \tag{13.13}$$

and the order-zero bound for the actual transition is $\sqrt{m}$ because its image lies in Q^m. Since Q^m is convex, the estimate of order $\ell+1$ for T_{ji}^{ext} and the mean value theorem give

$$\|D^\ell T_{ji}^{\mathrm{ext}}(x) - D^\ell T_{ji}^{\mathrm{ext}}(y)\|_{\mathrm{op}} \le a^\ell A_{\ell+1} |x-y|, \qquad x, y \in Q^m.$$

Restricting to each overlap domain gives the required uniform continuity; the constants depend only on $a, m, A_1, \dots, A_{\ell+1}$.

Denote by C_ℓ the bounds for the metric coefficients and their inverses in normal charts of radius $2a\sqrt{m}$. The transformation rule under the rescaling $x \mapsto ax$ is, componentwise,

$$(g_{\kappa_i})_{bc}(x) = a^2 (g_{\varphi_i})_{bc}(ax).$$

The bounds on the entries of $(g_{\varphi_i})_{bc}$ and $(g_{\varphi_i})^{bc}$ imply, by the spectral argument of Lemma 13.1.23, that the eigenvalues of $(g_{\varphi_i})_{bc}$ lie in $[(mC_0)^{-1}, mC_0]$. Consequently,

$$c_{\mathbf{g}} := \frac{a^2}{mC_0}, \qquad C_{\mathbf{g}} := a^2 m C_0$$

satisfy (13.8). Moreover,

$$\|D^\ell (\mathbf{g}_{\kappa_i})_{ab}\|_{L^\infty(Q^m)} \le a^{\ell+2} C_\ell, \qquad 0 \le \ell \le j.$$

Summing these bounds provides $G_j := \sum_{\ell=0}^{j} a^{\ell+2} C_\ell$ in (13.9); the bound of order $j+1$ gives uniform continuity of the derivative of order j. This verifies all axioms for the uniformly regular atlas and metric. □

Theorem 13.2.5. (Full comparison in the absence of boundary) A Riemannian manifold without boundary is uniformly regular if and only if it has bounded geometry in the sense of Definition 13.1.5.

Proof. The implication from bounded geometry is the preceding theorem. For the converse, let $\mathfrak{K}$ be a uniformly regular atlas with shrinking factor $\rho \in (0,1)$ and the metric bounds in (13.8). Work in the normalized charts $Q^m = (-1,1)^m$; there are no boundary charts here. The formula

$$\Gamma^a_{bc} = \frac{1}{2}\sum_{d=1}^{m} g^{ad}(\partial_b g_{cd} + \partial_c g_{bd} - \partial_d g_{bc})$$

and (13.10) provide constants $A_0, A_1 \geq 0$ such that

$$\|\Gamma(x)\|_{\mathrm{op}} \leq A_0, \qquad \|D\Gamma(x)\|_{\mathrm{op}} \leq A_1, \qquad x \in Q^m,$$

uniformly over the charts. Regard $\Gamma(x)$ as a bilinear form with values in $\mathbb{R}^m$ and use Euclidean norms. Set $\delta = 1 - \rho > 0$. Choose $a > 0$ independent of the chart and small enough that

$$2a < \frac{\delta}{2}, \qquad 4A_0 a \leq \frac{1}{2}, \qquad b := 4A_1 a^2 + 4A_0 a \leq \frac{1}{4}.$$

Let $p \in M$. The shrinking property allows us to choose a chart κ with $x = \kappa(p) \in \rho Q^m$. For $v \in \mathbb{R}^m$, $|v| < a$, solve the coordinate geodesic equation

$$z''(t) = -\Gamma(z(t))(z'(t), z'(t)), \qquad z(0) = x, \quad z'(0) = v.$$

As long as $0 \leq t \leq 1$ and $|z'(t)| \leq 2a$, its integral form gives

$$|z'(t)| \leq a + 4A_0 a^2 \leq \frac{3}{2}a, \qquad |z(t) - x| \leq 2a < \frac{\delta}{2}.$$

By continuity, the speed cannot reach $2a$ before $t = 1$. The position remains at distance at least $\delta/2$ from the boundary of the cube, and the velocity remains bounded. Thus, the solution stays in a compact subset of the domain of the first-order equation for (z, z'), so Theorem B.13.4 extends it to all of $[0,1]$. In particular, the exponential map is defined on these initial vectors.

Fix $w \in \mathbb{R}^m$ and denote by $Y(t) = D_v z(t)[w]$ the variation with respect to the initial velocity. Smooth dependence of ODE solutions on their data, Theorem B.13.5, and differentiation of the equation give

$$\begin{aligned} Y''(t) = &-D\Gamma(z(t))[Y(t)](z'(t), z'(t)) - 2\Gamma(z(t))(Y'(t), z'(t)), \\ Y(0) = 0, &\qquad Y'(0) = w. \end{aligned}$$

Let $S = \max_{0 \leq t \leq 1} |Y'(t)|$. Since $|Y(t)| \leq S$, the integrated equation gives

$$|Y'(t) - w| \leq (4A_1 a^2 + 4A_0 a)S = bS.$$

Thus, $S \leq |w| + bS$, whence

$$S \leq \frac{|w|}{1-b}, \qquad |Y(1) - w| \leq \frac{b}{1-b}|w| \leq \frac{1}{3}|w|.$$

If $F_x(v) = z(1)$, we have obtained $\|DF_x(v) - I\|_{\mathrm{op}} \le 1/3$ on $B(0,a)$. This domain is convex; integrating the derivative along the segment between v and w gives

$$|F_x(v) - F_x(w) - (v-w)| \le \frac{1}{3}|v-w|, \qquad |F_x(v) - F_x(w)| \ge \frac{2}{3}|v-w|.$$

Thus, F_x is injective and its derivative is invertible. The inverse function theorem makes it a diffeomorphism onto its image. Since F_x is the coordinate expression of $\exp_p$ and

$$|d\kappa_p(\mathbf{v})| \le c_{\mathbf{g}}^{-1/2}|\mathbf{v}|_{\mathbf{g}_p}, \qquad \mathbf{v} \in T_pM,$$

the exponential map is a diffeomorphism onto its image on the tangent ball of radius $a\sqrt{c_{\mathbf{g}}}$. This bound is independent of p and proves

$$\mathrm{inj}(M) \ge a\sqrt{c_{\mathbf{g}}} > 0.$$

Completeness of the components now follows from Remark 13.1.2.
The curvature bounds remain. In each chart,

$$R_{ijb}{}^{a} = \partial_i \Gamma^a_{jb} - \partial_j \Gamma^a_{ib} + \sum_{d=1}^{m} (\Gamma^d_{jb}\Gamma^a_{id} - \Gamma^d_{ib}\Gamma^a_{jd}).$$

Every coordinate derivative of order k of these components is a finite sum of products of derivatives of Γ of orders at most $k+1$. These are uniformly bounded by the metric bounds through order $k+2$ and the recurrence for its inverse. To pass to covariant derivatives, use the tensor formula: add to the coordinate derivative a term ΓT for each contravariant index and subtract one for each covariant index. At order zero, we have just bounded R. If the components of $\nabla^j R$ have been expressed as sums of products of coordinate derivatives of R and Γ, applying this formula and the Leibniz rule produces an expression of the same type for $\nabla^{j+1}R$, with orders increased by at most one. Induction provides uniform bounds for all these components. Finally, (13.8) and the inverse-metric bounds convert component bounds into the tensor bounds $\sup_{p\in M} |\nabla^k \mathbf{R}(p)|_{\mathbf{g}} < \infty$ for every $k \in \mathbb{N}_0$. Both bounded-geometry conditions hold. □

The definitions and this equivalence correspond to [6, Definitions 3.1–3.3 and Theorem 3.5].

Proposition 13.2.6. (Amann's localization system) Let M be a smooth manifold with or without boundary, and let $\mathfrak{K}$ be a uniformly regular atlas of M with shrinking factor ρ. There exist functions $\pi_\kappa \in C_c^\infty(U_\kappa, [0,1])$ and a function $\chi \in C_c^\infty(Q^m, [0,1])$ such that

$$\sum_{\kappa \in K} \pi_\kappa^2 = 1, \qquad \chi = 1 \quad \text{en } \mathrm{supp}(\pi_\kappa \circ \kappa^{-1}),$$

and, for each $j \in \mathbb{N}_0$, there exists $D_j > 0$, independent of κ, with

$$\|\pi_\kappa \circ \kappa^{-1}\|_{BUC^j(Q_\kappa)} \le D_j.$$

If $\mathfrak{K}$ is the atlas constructed in Theorem 13.2.4, or a uniformly regular atlas equivalent to it, this is also an admissible quadratic localization system in the sense of Definition 13.1.16.

Proof. Choose $\rho < \theta < \theta' < 1$. For $0 < a < b < 1$, let

$$\eta_{a,b}(t) := \frac{\vartheta(b^2 - t^2)}{\vartheta(b^2 - t^2) + \vartheta(t^2 - a^2)}, \qquad t \in \mathbb{R},$$

where ϑ is the flat function used in the proof of Theorem 1.3.5. If $b_0 = (\rho + \theta)/2$, define

$$\psi(x_1, \dots, x_m) := \prod_{a=1}^{m} \eta_{\rho,b_0}(x_a).$$

Then $\psi \in C_c^\infty(Q^m, [0,1])$, it equals one on ρQ^m, and its support lies in $[-b_0, b_0]^m \subset \theta Q^m$. On a half-box, use its restriction. Let $\psi_\kappa = \psi \circ \kappa$ on U_κ, extended by zero, and set

$$S(p) := \left(\sum_{\kappa \in K} \psi_\kappa(p)^2 \right)^{\frac{1}{2}}, \qquad \pi_\kappa := \frac{\psi_\kappa}{S}.$$

The family of supports entering this sum is not merely locally finite: the number of these supports meeting any given chart has a uniform bound. We prove both assertions at once. Set

$$N := \operatorname{mult}(\mathfrak{K}), \qquad \varepsilon := \frac{1 - \theta}{2 \max\{1, C_{\mathrm{tr}}(1)\}} > 0.$$

Fix a chart κ_0 and consider the indices κ for which $\operatorname{supp} \psi_\kappa \cap U_{\kappa_0} \neq \varnothing$. For each one, choose $q_\kappa \in \operatorname{supp} \psi_\kappa \cap U_{\kappa_0}$. Then $\kappa(q_\kappa) \in \operatorname{supp} \psi \subset \theta Q_\kappa$, whose distance from the nongeometric faces of Q_κ is at least $1 - \theta$. The bound BUC^1 for $\kappa \circ \kappa_0^{-1}$ and the first-exit-time argument, applied to each segment starting at $\kappa_0(q_\kappa)$, show that

$$B\big(\kappa_0(q_\kappa), \varepsilon\big) \cap Q_{\kappa_0} \subseteq \kappa_0(U_\kappa \cap U_{\kappa_0}). \tag{13.14}$$

On a half-box, a path contained in Q_{κ_0} cannot leave through the geometric face: chart transitions preserve the boundary. Thus, only distance from the nongeometric faces enters the argument.
All sets on the left-hand side of (13.14) lie in the bounded set

$$W := \{x \in \mathbb{R}^m \mid \operatorname{dist}(x, Q_{\kappa_0}) < \varepsilon\}.$$

Since Q_{κ_0} is a box or a half-box, there exists $c_m > 0$, depending only on the dimension, such that

$$\lambda_m\big(B(z, \varepsilon) \cap Q_{\kappa_0}\big) \geq c_m \varepsilon^m, \qquad z \in Q_{\kappa_0}.$$

On the other hand, each point of U_{κ_0} belongs to at most N charts. Summing the indicator functions of the preceding balls and integrating over W gives

$$\#\{\kappa \mid \operatorname{supp} \psi_\kappa \cap U_{\kappa_0} \neq \varnothing\} c_m \varepsilon^m \leq N \lambda_m(W).$$

The measure of W has a bound depending only on m and ε, not on κ_0. Thus, there exists an integer N_1, independent of the chart, bounding the cardinality of the preceding index set. This proves, in particular, local finiteness of the family of supports.
Since the shrunken charts cover, $1 \leq S \leq \sqrt{N}$. In chart κ, at most N_1 functions of the form $\psi \circ \widetilde{\kappa} \circ \kappa^{-1}$

contribute. The Faà di Bruno formula of Theorem 1.1.19, the transition bounds, and the Leibniz rule bound all their BUC^j norms by constants independent of the indices. If $F_\kappa := \sum_{\widetilde{\kappa}\in K} \psi_{\widetilde{\kappa}}^2$ is expressed in chart κ, then $1 \le F_\kappa \le N$ and $S^{-1} = F_\kappa^{-1/2}$. For $|\alpha| \ge 1$, the same formula is a finite sum of terms of the form

$$c_{\alpha,q,\beta} F_\kappa^{-\frac{1}{2}-q} \prod_{\nu=1}^{q} D^{\beta_\nu} F_\kappa, \qquad \beta_\nu \neq 0, \quad \beta_1 + \cdots + \beta_q = \alpha,$$

with $1 \le q \le |\alpha|$. The lower bound for F_κ and its derivative bounds explicitly control every product, uniformly over the charts. Applying the Leibniz rule to $\pi_\kappa = \psi_\kappa S^{-1}$ gives the required bounds. Moreover, $\sum_{\kappa\in K} \pi_\kappa^2 = S^{-2} \sum_{\kappa\in K} \psi_\kappa^2 = 1$.
If $b_1 = (\theta + \theta')/2$, take

$$\chi(x_1,\dots,x_m) := \prod_{a=1}^{m} \eta_{\theta,b_1}(x_a).$$

Then $\chi \in C_c^\infty(Q^m,[0,1])$, it equals one on θQ^m, and its support lies in $\theta' Q^m$. Therefore, $\chi = 1$ on all coordinate supports. When $\mathfrak{K}$ is the rescaled normal atlas of the preceding theorem, the transition bounds already established verify (B1); the bounds just obtained for the cutoffs verify the remaining conditions of Definition 13.1.16. For an equivalent atlas, the bounds on mixed transitions transfer these conditions through the same Faà di Bruno formula and Leibniz rule. □

The preceding system gives the following localization operators. Taking $h_i = \pi_{\kappa_i}$ and $\chi_i := \chi \circ \kappa_i$, the elementary operators on smooth functions are

$$\mathcal{S}_0 u = \left(\widetilde{(h_i u) \circ \varphi_i^{-1}} \right)_{i\in I}, \qquad (\mathcal{R}_0 v)(p) = \sum_{\{i\in I \mid p\in U_i\}} h_i(p)\chi_i(p) v_i(\varphi_i(p)).$$

The second sum is locally finite. Moreover, $\chi_i = 1$ on $\operatorname{supp} h_i$ and $\sum_{i\in I} h_i^2 = 1$; hence, $\mathcal{R}_0\mathcal{S}_0 u = u$. These formulas are used here only on smooth functions. Distributional reconstruction and the Sobolev norm bounds are established after these spaces are defined, using the admissibility conditions verified for this system.

The differential part of (B1) admits the following metric criterion. The overlap hypothesis is kept separate because it does not follow from estimates on the metric coefficients.

Lemma 13.2.7. (Metric criterion for admissibility) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary with $\operatorname{inj}(M) > 0$, and let $\mathcal{T} = (U_i,\varphi_i,h_i)_{i\in I}$ be a uniformly locally finite trivialization. Assume also that the chart images are uniformly normalized: there exists $R > 0$ such that $\varphi_i(U_i) \subseteq B_{\mathrm{euc}}(0,R)$ for every $i \in I$. Suppose that its cover satisfies the two cross-overlap bounds in (B1) relative to a uniform geodesic atlas with the separation and covering properties specified there, chosen with sufficiently small radius. Let $g_{ab}^{(i)}$ and $g_{(i)}^{ab}$ be the coefficients of $\mathbf{g}$ and its inverse in coordinates φ_i. Then $(M,\mathbf{g})$ has bounded geometry and $\mathcal{T}$ satisfies (B1) if and only if, for each $k \in \mathbb{N}_0$, there exists $C_k > 0$ such that, for $|\alpha| \le k$,

$$|D^\alpha g_{ab}^{(i)}| \le C_k \qquad \text{and} \qquad |D^\alpha g_{(i)}^{ab}| \le C_k$$

in every chart (U_i,φ_i).

Proof. ($\Leftarrow$) Suppose that, for every $k \in \mathbb{N}_0$, there exists $C_k > 0$ such that, for every chart (U_i, φ_i) of the trivialization $\mathcal{T}$,

$$|D^\alpha g^{(i)}_{ab}| \le C_k \qquad \text{and} \qquad |D^\alpha g^{ab}_{(i)}| \le C_k, \qquad \forall |\alpha| \le k.$$

First, we prove that $(M, \mathbf{g})$ has bounded geometry. Since $\operatorname{inj}(M) > 0$ by hypothesis, it suffices to show that, for each $m \in \mathbb{N}_0$, there exists a constant $C'_m > 0$ such that

$$|\nabla^m R|_{\mathbf{g}} \le C'_m$$

throughout M.
Fix a chart (U_i, φ_i) of $\mathcal{T}$ and write $\varphi_i = (x^1, \dots, x^n)$.
To simplify notation, denote simply by

$$g_{ab}, \qquad g^{ab}, \qquad \Gamma^c_{ab}, \qquad R_{abc}{}^d$$

the components of the metric, inverse metric, Christoffel symbols, and curvature tensor in these coordinates, which of course depend on i.
By Proposition 2.4.11, the local expression for the Christoffel symbols of the Levi–Civita connection is:

$$\Gamma^c_{ab} = \frac{1}{2} g^{c\ell} \left(\partial_a g_{b\ell} + \partial_b g_{a\ell} - \partial_\ell g_{ab} \right).$$

Applying the Leibniz rule and the hypothesis on the partial derivatives of g_{ab} and g^{ab}, we conclude that, for each $k \in \mathbb{N}_0$, there exists a constant $C^{(1)}_k > 0$, independent of the chart, such that

$$|D^\alpha \Gamma^c_{ab}| \le C^{(1)}_k, \qquad |\alpha| \le k.$$

Now using the local expression for the curvature tensor (Proposition 2.10.3),

$$R_{abc}{}^\ell = \partial_a \Gamma^\ell_{bc} - \partial_b \Gamma^\ell_{ac} + \Gamma^m_{bc} \Gamma^\ell_{am} - \Gamma^m_{ac} \Gamma^\ell_{bm},$$

the Leibniz rule again gives, for each $k \in \mathbb{N}_0$, a constant $C^{(2)}_k > 0$, independent of the chart, such that

$$|D^\alpha R_{abc}{}^\ell| \le C^{(2)}_k, \qquad |\alpha| \le k.$$

Finally, by Lemma 9.1.28, the coordinate components of $\nabla^m R$ are finite linear combinations of partial derivatives of the components of R of order at most m, with coefficients polynomial in the Christoffel symbols and their partial derivatives of order at most $m-1$. Since all these quantities are uniformly bounded, for each $m \in \mathbb{N}_0$ there exists a constant $C''_m > 0$ such that the components of $\nabla^m R$ are uniformly bounded in every chart of $\mathcal{T}$.
Moreover, the uniform bounds on the components of the metric and its inverse imply that, for the fixed tensor type of $\nabla^m R$, there exists $C_{m,\mathbf{g}} > 0$, independent of the chart, such that the pointwise norm induced by $\mathbf{g}$ does not exceed $C_{m,\mathbf{g}}$ times the Euclidean norm of its components. Consequently, for each $m \in \mathbb{N}_0$, there exists a constant $C'_m > 0$ such that

$$|\nabla^m R|_{\mathbf{g}} \le C'_m$$

throughout M. This proves that $(M,\mathbf{g})$ has bounded geometry.

We now prove that $\mathcal{T}$ satisfies (B1). Let $r_0>0$ be a radius for which condition (2) of Theorem 13.1.8 holds, and let

$$\mathcal{A}^{\mathrm{geo}}=(U_j^{\mathrm{geo}},\varphi_j^{\mathrm{geo}})_{j\in J}$$

be the geodesic atlas in the hypothesis. Here "sufficiently small radius" means that its common radius satisfies $0<r\le\frac{r_0}{10}$. Fix $i\in I$ and $j\in J$ such that

$$U_i\cap U_j^{\mathrm{geo}}\neq\varnothing.$$

Write

$$\varphi_i=(x^1,\dots,x^n),\qquad \varphi_j^{\mathrm{geo}}=(y^1,\dots,y^n).$$

Denote by

$$\widetilde{g}_{ab},\qquad \widetilde{g}^{ab},\qquad \widetilde{\Gamma}^c_{ab}$$

the components of the metric and its inverse and the Christoffel symbols in geodesic coordinates y.

Since we have already proved that $(M,\mathbf{g})$ has bounded geometry, Theorem 13.1.8 implies that, in the uniform geodesic atlas, the components $\widetilde{g}_{ab}$, $\widetilde{g}^{ab}$, and all their partial derivatives are uniformly bounded. In particular, for each $k\in\mathbb{N}_0$, there exists $A_k>0$ such that

$$|D^\alpha\widetilde{g}_{ab}|\le A_k\qquad\text{and}\qquad |D^\alpha\widetilde{g}^{ab}|\le A_k,\qquad\forall|\alpha|\le k.$$

Order zero is controlled by normalization: the image of $\varphi_i\circ(\varphi_j^{\mathrm{geo}})^{-1}$ lies in $B_{\mathrm{euc}}(0,R)$ and that of its inverse in $B_{\mathrm{euc}}(0,r)$. Metric bounds do not replace this hypothesis, since translating the origin of a chart leaves its metric coefficients unchanged. We now begin with first derivatives of the coordinate transition

$$\varphi_i\circ(\varphi_j^{\mathrm{geo}})^{-1}\qquad\text{and}\qquad \varphi_j^{\mathrm{geo}}\circ\varphi_i^{-1}.$$

By hypothesis, the components of the metric and its inverse in chart (U_i,φ_i) are uniformly bounded. Since $(M,\mathbf{g})$ also has bounded geometry, the same holds in the geodesic chart $(U_j^{\mathrm{geo}},\varphi_j^{\mathrm{geo}})$. By Lemma 13.1.23, there exist positive constants c_0,C_0, independent of i, j, and the point considered, such that

$$c_0\|d\varphi_i(v)\|^2\le|v|_{\mathbf{g}}^2\le C_0\|d\varphi_i(v)\|^2$$

for every $v\in TM\restriction_{U_i}$, and

$$c_0\|d\varphi_j^{\mathrm{geo}}(v)\|^2\le|v|_{\mathbf{g}}^2\le C_0\|d\varphi_j^{\mathrm{geo}}(v)\|^2$$

for every $v\in TM\restriction_{U_j^{\mathrm{geo}}}$.

Now let

$$F_{ij}:=\varphi_i\circ(\varphi_j^{\mathrm{geo}})^{-1}.$$

Fix $p\in U_i\cap U_j^{\mathrm{geo}}$ and let $\xi\in\mathbb{R}^n$. Define

$$v:=(d\varphi_j^{\mathrm{geo}}|_p)^{-1}(\xi)\in T_pM.$$

Then

$$d\varphi_i|_p(v) = d(\varphi_i \circ (\varphi_j^{\mathrm{geo}})^{-1})|_{\varphi_j^{\mathrm{geo}}(p)}(\xi) = DF_{ij}\big(\varphi_j^{\mathrm{geo}}(p)\big)\,\xi.$$

Applying the preceding inequalities to this vector v gives

$$c_0\big\|DF_{ij}\big(\varphi_j^{\mathrm{geo}}(p)\big)\,\xi\big\|^2 \le |v|_{\mathbf{g}}^2 \le C_0\|\xi\|^2.$$

Therefore,

$$\big\|DF_{ij}\big(\varphi_j^{\mathrm{geo}}(p)\big)\,\xi\big\| \le \sqrt{\frac{C_0}{c_0}}\|\xi\|,$$

and hence

$$\big\|DF_{ij}\big(\varphi_j^{\mathrm{geo}}(p)\big)\big\|_{\mathrm{op}} \le \sqrt{\frac{C_0}{c_0}}.$$

Since the operator norm of DF_{ij} is uniformly bounded, the partial derivatives of order 1 are uniformly bounded.

For the inverse transition, define

$$G_{ij} := \varphi_j^{\mathrm{geo}} \circ \varphi_i^{-1},$$

Now taking $v = (d\varphi_i|_p)^{-1}(\xi)$ and applying the preceding two metric inequalities with the charts interchanged gives, for every $p \in U_i \cap U_j^{\mathrm{geo}}$,

$$\big\|DG_{ij}\big(\varphi_i(p)\big)\big\|_{\mathrm{op}} \le \sqrt{\frac{C_0}{c_0}}.$$

We turn to second derivatives. Applying item (c) of Lemma 2.4.12 to the charts (U_i, φ_i) and $(U_j^{\mathrm{geo}}, \varphi_j^{\mathrm{geo}})$ gives, for every $p \in U_i \cap U_j^{\mathrm{geo}}$,

$$\Gamma_{rs}^k(p) = \frac{\partial x^k}{\partial y^c}(p)\frac{\partial y^a}{\partial x^r}(p)\frac{\partial y^b}{\partial x^s}(p)\widetilde{\Gamma}_{ab}^c(p) + \frac{\partial x^k}{\partial y^c}(p)\frac{\partial^2 y^c}{\partial x^r \partial x^s}(p).$$

Multiplying by $\dfrac{\partial y^m}{\partial x^k}(p)$ and using the chain rule, we conclude that

$$\frac{\partial^2 y^m}{\partial x^r \partial x^s}(p) = \frac{\partial y^m}{\partial x^k}(p)\Gamma_{rs}^k(p) - \frac{\partial y^a}{\partial x^r}(p)\frac{\partial y^b}{\partial x^s}(p)\widetilde{\Gamma}_{ab}^m(p).$$

Since

$$y^m = \pi_m \circ \varphi_j^{\mathrm{geo}} = \pi_m \circ G_{ij} \circ \varphi_i$$

on $U_i \cap U_j^{\mathrm{geo}}$, we obtain

$$\frac{\partial^2 G_{ij}^m}{\partial x^r \partial x^s}\big(\varphi_i(p)\big) = \frac{\partial G_{ij}^m}{\partial x^k}\big(\varphi_i(p)\big)\,\Gamma_{rs}^k(p) - \frac{\partial G_{ij}^a}{\partial x^r}\big(\varphi_i(p)\big)\frac{\partial G_{ij}^b}{\partial x^s}\big(\varphi_i(p)\big)\,\widetilde{\Gamma}_{ab}^m(p).$$

The first derivatives of G_{ij} are already known to be uniformly bounded, as are the components of Γ and $\widetilde{\Gamma}$. Thus, the second derivatives of G_{ij} are uniformly bounded as well.

Interchanging the roles of the two charts in item (c) of Lemma 2.4.12 gives, for every $p \in U_i \cap U_j^{\mathrm{geo}}$,

$$\widetilde{\Gamma}_{ab}^{c}(p) = \frac{\partial y^c}{\partial x^k}(p)\frac{\partial x^r}{\partial y^a}(p)\frac{\partial x^s}{\partial y^b}(p)\,\Gamma_{rs}^{k}(p) + \frac{\partial y^c}{\partial x^k}(p)\frac{\partial^2 x^k}{\partial y^a \partial y^b}(p).$$

Multiplying by $\dfrac{\partial x^m}{\partial y^c}(p)$ gives

$$\frac{\partial^2 x^m}{\partial y^a \partial y^b}(p) = \frac{\partial x^m}{\partial y^c}(p)\,\widetilde{\Gamma}_{ab}^{c}(p) - \frac{\partial x^r}{\partial y^a}(p)\frac{\partial x^s}{\partial y^b}(p)\,\Gamma_{rs}^{m}(p).$$

Since

$$x^m = \pi_m \circ \varphi_i = \pi_m \circ F_{ij} \circ \varphi_j^{\mathrm{geo}}$$

on $U_i \cap U_j^{\mathrm{geo}}$, we obtain

$$\frac{\partial^2 F_{ij}^m}{\partial y^a \partial y^b}\big(\varphi_j^{\mathrm{geo}}(p)\big) = \frac{\partial F_{ij}^m}{\partial y^c}\big(\varphi_j^{\mathrm{geo}}(p)\big)\,\widetilde{\Gamma}_{ab}^{c}(p) - \frac{\partial F_{ij}^r}{\partial y^a}\big(\varphi_j^{\mathrm{geo}}(p)\big)\frac{\partial F_{ij}^s}{\partial y^b}\big(\varphi_j^{\mathrm{geo}}(p)\big)\,\Gamma_{rs}^{m}(p).$$

Thus, the second derivatives of F_{ij} are also uniformly bounded.

We now proceed by induction on the order of differentiation. Suppose that, for some $k \geq 2$, all partial derivatives of F_{ij} and G_{ij} of order at most k are already known to be uniformly bounded. We will show that those of order $k+1$ are uniformly bounded as well.

Consider the identity

$$\frac{\partial^2 F_{ij}^m}{\partial y^a \partial y^b}\big(\varphi_j^{\mathrm{geo}}(p)\big) = \frac{\partial F_{ij}^m}{\partial y^c}\big(\varphi_j^{\mathrm{geo}}(p)\big)\,\widetilde{\Gamma}_{ab}^{c}(p) - \frac{\partial F_{ij}^r}{\partial y^a}\big(\varphi_j^{\mathrm{geo}}(p)\big)\frac{\partial F_{ij}^s}{\partial y^b}\big(\varphi_j^{\mathrm{geo}}(p)\big)\,\Gamma_{rs}^{m}(p).$$

Composing with $(\varphi_j^{\mathrm{geo}})^{-1}$ gives, on the corresponding Euclidean open subset,

$$\frac{\partial^2 F_{ij}^m}{\partial y^a \partial y^b} = \frac{\partial F_{ij}^m}{\partial y^c}\,(\widetilde{\Gamma}_{ab}^{c} \circ (\varphi_j^{\mathrm{geo}})^{-1}) - \frac{\partial F_{ij}^r}{\partial y^a}\frac{\partial F_{ij}^s}{\partial y^b}\,(\Gamma_{rs}^{m} \circ \varphi_i^{-1} \circ F_{ij}).$$

Now let α be a multi-index with $|\alpha| \leq k-1$. Apply D^α to this identity. By the Leibniz rule, the first term on the right-hand side is a finite sum of products of derivatives of F_{ij} of order at most k and derivatives of $\widetilde{\Gamma}_{ab}^{c} \circ (\varphi_j^{\mathrm{geo}})^{-1}$ of order at most $k-1$, all uniformly bounded.

For the second term, use the Leibniz rule again and, when differentiating the composition

$$(\Gamma_{rs}^{m} \circ \varphi_i^{-1}) \circ F_{ij},$$

apply the Faà di Bruno formula of Theorem 1.1.19 in the form stated there. If

$$H := \Gamma_{rs}^{m} \circ \varphi_i^{-1}, \qquad F_{ij} = (F_{ij}^1, \ldots, F_{ij}^n),$$

then, for $1 \le |\beta| \le k-1$,

$$D^\beta (H \circ F_{ij})(y) = \sum_{\substack{\delta \in \mathbb{N}_0^n \\ 1 \le |\delta| \le |\beta|}} \sum_{\substack{\gamma_1, \dots, \gamma_{|\delta|} \in \mathbb{N}_0^n \\ \gamma_1 + \cdots + \gamma_{|\delta|} = \beta \\ |\gamma_\nu| > 0}} \sum_{\substack{\ell_1, \dots, \ell_{|\delta|} \in \{1, \dots, n\} \\ \#\{\nu \mid \ell_\nu = a\} = \delta_a}} c_{\beta, \delta, \gamma, \ell} \big(D^\delta H\big)(F_{ij}(y)) \prod_{\nu=1}^{|\delta|} D^{\gamma_\nu} F_{ij}^{\ell_\nu}(y). \tag{13.15}$$

The sum is finite, and its coefficients depend only on the multi-indices. Each summand satisfies $|\delta| \le |\beta| \le k-1$ and $1 \le |\gamma_\nu| \le |\beta| \le k-1$. Derivatives of H are bounded by the bounds already obtained for the Christoffel symbols in chart i, and derivatives of F_{ij} are bounded by the induction hypothesis. Consequently, every derivative

$$D^\beta \big((\Gamma_{rs}^m \circ \varphi_i^{-1}) \circ F_{ij} \big), \qquad |\beta| \le k-1,$$

is bounded by a constant independent of i, j. After applying the Leibniz rule to the three factors of the second term, no derivative of F_{ij} on the right-hand side has order greater than k. The left-hand side is $D^\alpha \partial_{y^a} \partial_{y^b} F_{ij}^m$; varying a, b and the multi-indices α with $|\alpha| = k-1$ gives every derivative of order $k+1$. We conclude that they are uniformly bounded.

For the inverse transition, begin with the identity

$$\frac{\partial^2 G_{ij}^m}{\partial x^r \partial x^s}\big(\varphi_i(p)\big) = \frac{\partial G_{ij}^m}{\partial x^k}\big(\varphi_i(p)\big)\, \Gamma_{rs}^k(p) - \frac{\partial G_{ij}^a}{\partial x^r}\big(\varphi_i(p)\big) \frac{\partial G_{ij}^b}{\partial x^s}\big(\varphi_i(p)\big)\, \widetilde{\Gamma}_{ab}^m(p),$$

which, after composition with φ_i^{-1}, takes the form

$$\frac{\partial^2 G_{ij}^m}{\partial x^r \partial x^s} = \frac{\partial G_{ij}^m}{\partial x^k} (\Gamma_{rs}^k \circ \varphi_i^{-1}) - \frac{\partial G_{ij}^a}{\partial x^r} \frac{\partial G_{ij}^b}{\partial x^s} (\widetilde{\Gamma}_{ab}^m \circ (\varphi_j^{\mathrm{geo}})^{-1} \circ G_{ij}),$$

and shows that all derivatives of order $k+1$ of G_{ij} are uniformly bounded as well. Here we use exactly (13.15) with $H = \widetilde{\Gamma}_{ab}^m \circ (\varphi_j^{\mathrm{geo}})^{-1}$ and with F_{ij} replaced by G_{ij}; the same bounds on $|\delta|$ and $|\gamma_\nu|$ ensure that only derivatives covered by the induction hypothesis occur.

By induction, for each $k \in \mathbb{N}_0$ there exists a constant $C_k > 0$, independent of i and j, such that

$$|D^\alpha F_{ij}| \le C_k \qquad \text{and} \qquad |D^\alpha G_{ij}| \le C_k$$

for every $|\alpha| \le k$. Together with the two cross-overlap bounds assumed in the statement, this proves (B1).

($\Rightarrow$) Now suppose that $(M, \mathbf{g})$ has bounded geometry and condition (B1) holds.

Let

$$\mathcal{A}^{\mathrm{geo}} = (U_j^{\mathrm{geo}}, \varphi_j^{\mathrm{geo}})_{j \in J}$$

be one of the uniform geodesic atlases for which (B1) holds. Fix $i \in I$ and $j \in J$ such that

$$U_i \cap U_j^{\mathrm{geo}} \neq \varnothing.$$

Write

$$\varphi_i = (x^1, \dots, x^n), \qquad \varphi_j^{\mathrm{geo}} = (y^1, \dots, y^n),$$

and let

$$F_{ij} := \varphi_i \circ (\varphi_j^{\mathrm{geo}})^{-1}, \qquad G_{ij} := \varphi_j^{\mathrm{geo}} \circ \varphi_i^{-1}.$$

By (B1), for each $k \in \mathbb{N}_0$ there exists a constant $C_k > 0$ such that all partial derivatives of F_{ij} and G_{ij} of order at most k are uniformly bounded.

Since $(M, \mathbf{g})$ has bounded geometry, Theorem 13.1.8 implies that, in the uniform geodesic atlas, the components of the metric and its inverse have uniformly bounded derivatives of every order. Denote by

$$\widetilde{g}_{ab}, \qquad \widetilde{g}^{ab}$$

the components of the metric and inverse metric in coordinates y. Then, for each $k \in \mathbb{N}_0$, there exists $A_k > 0$ such that

$$|D^\alpha \widetilde{g}_{ab}| \le A_k \qquad \text{and} \qquad |D^\alpha \widetilde{g}^{ab}| \le A_k$$

for every $|\alpha| \le k$.

Applying item (a) of Lemma 2.4.12 to the charts (U_i, φ_i) and $(U_j^{\mathrm{geo}}, \varphi_j^{\mathrm{geo}})$ gives, for every $p \in U_i \cap U_j^{\mathrm{geo}}$,

$$g_{rs}(p) = \frac{\partial y^a}{\partial x^r}(p) \frac{\partial y^b}{\partial x^s}(p)\, \widetilde{g}_{ab}(p).$$

Since

$$y^a = \pi_a \circ G_{ij} \circ \varphi_i$$

on $U_i \cap U_j^{\mathrm{geo}}$, composing with φ_i^{-1} gives

$$g_{rs} \circ \varphi_i^{-1} = \frac{\partial G_{ij}^a}{\partial x^r} \frac{\partial G_{ij}^b}{\partial x^s} \left(\widetilde{g}_{ab} \circ (\varphi_j^{\mathrm{geo}})^{-1} \circ G_{ij} \right).$$

Set

$$K_{ab} := \widetilde{g}_{ab} \circ (\varphi_j^{\mathrm{geo}})^{-1}.$$

The Leibniz rule for three factors gives, for every multi-index α,

$$D^\alpha (g_{rs} \circ \varphi_i^{-1}) = \sum_{\substack{\alpha_1, \alpha_2, \alpha_3 \in \mathbb{N}_0^n \\ \alpha_1 + \alpha_2 + \alpha_3 = \alpha}} \frac{\alpha!}{\alpha_1! \alpha_2! \alpha_3!} D^{\alpha_1}(\partial_r G_{ij}^a) D^{\alpha_2}(\partial_s G_{ij}^b) \cdot D^{\alpha_3}(K_{ab} \circ G_{ij}). \tag{13.16}$$

For the last factor, apply (13.15) with $H = K_{ab}$ and with F_{ij} replaced by G_{ij}. Its summands therefore contain derivatives $D^\delta K_{ab}$ of order $|\delta| \le |\alpha_3|$ and products of derivatives of G_{ij} of positive orders summing to $|\alpha_3|$. The first two factors of (13.16) contain derivatives of G_{ij} of orders at most $|\alpha_1| + 1$ and $|\alpha_2| + 1$. All these quantities have uniform bounds by (B1) and the geodesic estimates. Thus, the derivative

$$D^\alpha (g_{rs} \circ \varphi_i^{-1})$$

is uniformly bounded. Therefore, for each $k \in \mathbb{N}_0$, there exists a constant $C_k' > 0$ such that

$$|D^\alpha (g_{rs} \circ \varphi_i^{-1})| \le C_k', \qquad \forall |\alpha| \le k.$$

Now using the identity

$$D^\alpha g_{rs} = \big(D^\alpha (g_{rs} \circ \varphi_i^{-1})\big) \circ \varphi_i,$$

we conclude that the partial derivatives of the components g_{rs} are uniformly bounded in every chart of $\mathcal{T}$. To bound the inverse-metric coefficients, apply item (b) of Lemma 2.4.12. For every $p \in U_i \cap U_j^{\mathrm{geo}}$,

$$g^{rs}(p) = \frac{\partial x^r}{\partial y^a}(p) \frac{\partial x^s}{\partial y^b}(p)\, \widetilde{g}^{ab}(p).$$

Since

$$x^r = \pi_r \circ F_{ij} \circ \varphi_j^{\mathrm{geo}}$$

on $U_i \cap U_j^{\mathrm{geo}}$, composing with $(\varphi_j^{\mathrm{geo}})^{-1}$ gives

$$(g^{rs} \circ \varphi_i^{-1} \circ F_{ij}) = \frac{\partial F_{ij}^r}{\partial y^a} \frac{\partial F_{ij}^s}{\partial y^b}\, (\widetilde{g}^{ab} \circ (\varphi_j^{\mathrm{geo}})^{-1}).$$

Now composing with G_{ij} yields

$$g^{rs} \circ \varphi_i^{-1} = \left(\frac{\partial F_{ij}^r}{\partial y^a} \circ G_{ij}\right) \left(\frac{\partial F_{ij}^s}{\partial y^b} \circ G_{ij}\right) (\widetilde{g}^{ab} \circ (\varphi_j^{\mathrm{geo}})^{-1} \circ G_{ij}).$$

For this identity, the Leibniz rule again distributes α among three factors. If, for example, $Q_a^r := \partial_{y^a} F_{ij}^r$ the formula (13.15), applied to $Q_a^r \circ G_{ij}$, contains derivatives of Q_a^r of order at most $|\alpha|$, that is, derivatives of F_{ij} of order at most $|\alpha|+1$, and derivatives of G_{ij} of order at most $|\alpha|$. The third factor is treated with $H = \widetilde{g}^{ab} \circ (\varphi_j^{\mathrm{geo}})^{-1}$. The bounds in (B1) and the geodesic bounds control all factors uniformly. We conclude that, for each multi-index α, there exists $C_\alpha'' > 0$, independent of i, j, such that

$$|D^\alpha (g^{rs} \circ \varphi_i^{-1})| \le C_\alpha''.$$

Consequently, the partial derivatives of the components g^{rs} are uniformly bounded as well.
This concludes the proof. □

13.3 Fractional Sobolev, Besov, and Triebel–Lizorkin spaces on Riemannian manifolds of bounded geometry

Geodesic trivializations allow us to define fractional Sobolev spaces on Riemannian manifolds of bounded geometry.

Definition 13.3.1. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, and let

$$\mathcal{T}^{\mathrm{geo}} = (U_i^{\mathrm{geo}}, \varphi_i^{\mathrm{geo}}, h_i^{\mathrm{geo}})_{i \in J}$$

be a geodesic trivialization as in Theorem 13.1.22. Let $s \in \mathbb{R}$ and $1 < p < \infty$. For $u \in \mathcal{D}'(M)$ and $i \in J$, the

distribution $(h_i^{\mathrm{geo}}u)\circ(\varphi_i^{\mathrm{geo}})^{-1}$ has compact support in $\varphi_i^{\mathrm{geo}}(U_i^{\mathrm{geo}})$. Denote its extension by zero by

$$\widetilde{(h_i^{\mathrm{geo}}u)\circ(\varphi_i^{\mathrm{geo}})^{-1}}\in\mathcal{D}'(\mathbb{R}^n)$$

. Define

$$H^{s,p}(M):=\left\{u\in\mathcal{D}'(M)\,\middle|\,\left(\sum_{i\in J}\left\|\widetilde{(h_i^{\mathrm{geo}}u)\circ(\varphi_i^{\mathrm{geo}})^{-1}}\right\|^p_{H^{s,p}(\mathbb{R}^n)}\right)^{\frac{1}{p}}<\infty\right\}.$$

$$\|u\|_{H^{s,p}(M)}:=\left(\sum_{i\in J}\left\|\widetilde{(h_i^{\mathrm{geo}}u)\circ(\varphi_i^{\mathrm{geo}})^{-1}}\right\|^p_{H^{s,p}(\mathbb{R}^n)}\right)^{\frac{1}{p}}.$$

Remark 13.3.2. The coordinate component of $h_i^{\mathrm{geo}}u$ is understood in the sense of Proposition 10.2.34. A tilde always indicates extension by zero from the coordinate open subset $\varphi_i^{\mathrm{geo}}(U_i^{\mathrm{geo}})$ to $\mathbb{R}^n$. This extension is well defined because the support of $h_i^{\mathrm{geo}}u$ lies in $\operatorname{supp}(h_i^{\mathrm{geo}})\Subset U_i^{\mathrm{geo}}$. Second countability of M and local finiteness of the cover imply that J is countable, so the sum in the definition is a well-defined series.

Later we will show that this definition is independent of the chosen geodesic trivialization. To formulate this independence, it is useful to introduce the same construction for a uniformly locally finite trivialization.

Definition 13.3.3. Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, and let $\mathcal{T}=(U_i,\varphi_i,h_i)_{i\in I}$ be an admissible trivialization. Let $s\in\mathbb{R}$ and $1<p<\infty$. For $u\in\mathcal{D}'(M)$, define

$$H^{s,p}_{\mathcal{T}}(M):=\left\{u\in\mathcal{D}'(M)\,\middle|\,\left(\sum_{i\in I}\left\|\widetilde{(h_iu)\circ\varphi_i^{-1}}\right\|^p_{H^{s,p}(\mathbb{R}^n)}\right)^{\frac{1}{p}}<\infty\right\},$$

with norm

$$\|u\|_{H^{s,p}_{\mathcal{T}}(M)}:=\left(\sum_{i\in I}\left\|\widetilde{(h_iu)\circ\varphi_i^{-1}}\right\|^p_{H^{s,p}(\mathbb{R}^n)}\right)^{\frac{1}{p}}.$$

The tilde indicates extension by zero from $\varphi_i(U_i)$ to $\mathbb{R}^n$; it is well defined because of the auxiliary cutoff function in (B3).

In general, the spaces $H^{s,p}_{\mathcal{T}}(M)$ depend on the chosen trivialization, and if M does not have bounded geometry, they may lack desirable functional properties. For Riemannian manifolds of bounded geometry and admissible trivializations, all these Sobolev spaces coincide and have good properties, as we will see below.

Lemma 13.3.4. (Uniform transfer between two localizations) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry. Let

$$\mathcal{T}=(U_i,\varphi_i,h_i)_{i\in I},\qquad \mathcal{T}^\sharp=(U_j^\sharp,\varphi_j^\sharp,h_j^\sharp)_{j\in J}$$

be two admissible trivializations of M. Let $(\chi_i)_{i\in I}$ and $(\chi_j^\sharp)_{j\in J}$ be families of auxiliary cutoff functions, so that

$$\operatorname{supp}(\chi_i)\Subset U_i,\qquad \operatorname{supp}(\chi_j^\sharp)\Subset U_j^\sharp,$$

and each function equals one on a neighborhood of the support of the corresponding partition-of-unity element. For $U_i \cap U_j^\sharp \neq \varnothing$, set

$$\Omega_{ij} := \varphi_i(U_i \cap U_j^\sharp), \qquad \Omega_{ji}^\sharp := \varphi_j^\sharp(U_i \cap U_j^\sharp)$$

and

$$\Phi_{ji} := \varphi_j^\sharp \circ \varphi_i^{-1} : \Omega_{ij} \longrightarrow \Omega_{ji}^\sharp.$$

The function

$$\eta_{ij} := (h_i \chi_j^\sharp) \circ \varphi_i^{-1}$$

has compact support in Ω_{ij}. Denote its extension by zero by $\widetilde{\eta}_{ij} \in C_c^\infty(\mathbb{R}^n)$.
For a distribution $v \in \mathcal{D}'(\mathbb{R}^n)$, the expression $v \circ \Phi_{ji}$ means the pullback of $v \restriction_{\Omega_{ji}^\sharp}$ by Φ_{ji}, defined by

$$\langle v \circ \Phi_{ji}, \varphi \rangle_{\Omega_{ij}} := \left\langle v, \widetilde{(\varphi \circ \Phi_{ji}^{-1}) \left| \det D\Phi_{ji}^{-1} \right|} \right\rangle_{\mathbb{R}^n}, \qquad \varphi \in C_c^\infty(\Omega_{ij}). \tag{13.17}$$

The tilde on the right-hand side denotes extension by zero from $\Omega_{ji}^\sharp$ to $\mathbb{R}^n$. This is smooth because the function being extended has compact support in $\Omega_{ji}^\sharp$. Define

$$P_{ij} v := \widetilde{\eta_{ij}(v \circ \Phi_{ji})}, \tag{13.18}$$

where the tilde on the right-hand side indicates extension by zero from Ω_{ij} to $\mathbb{R}^n$.
If $A^s(\mathbb{R}^n)$ is one of the spaces

$$H^{s,p}(\mathbb{R}^n), \qquad F_{p,q}^s(\mathbb{R}^n), \qquad B_{p,q}^s(\mathbb{R}^n)$$

in the Banach ranges of Lemma 6.4.3, there exists a constant $C > 0$, independent of i and j, such that

$$\|P_{ij} v\|_{A^s(\mathbb{R}^n)} \leq C \|v\|_{A^s(\mathbb{R}^n)}. \tag{13.19}$$

Moreover, for every $u \in \mathcal{D}'(M)$,

$$P_{ij} \left(\widetilde{(h_j^\sharp u) \circ (\varphi_j^\sharp)^{-1}} \right) = \widetilde{(h_i h_j^\sharp u) \circ \varphi_i^{-1}}. \tag{13.20}$$

Proof. The support of $h_i \chi_j^\sharp$ is contained in

$$\operatorname{supp}(h_i) \cap \operatorname{supp}(\chi_j^\sharp) \Subset U_i \cap U_j^\sharp.$$

Thus, η_{ij} vanishes on a relative neighborhood of $\partial\Omega_{ij}$, and its extension by zero is smooth. On Ω_{ij},

$$\eta_{ij} = (h_i \circ \varphi_i^{-1}) \left[(\chi_j^\sharp \circ (\varphi_j^\sharp)^{-1}) \circ \Phi_{ji} \right].$$

The Leibniz rule, the bounds in (B2) and (B3), and the Faà di Bruno formula of Theorem 1.1.19 show that,

for each $k \in \mathbb{N}_0$, there exists $C_k > 0$, independent of i and j, such that

$$\|\widetilde{\eta}_{ij}\|_{BC^k(\mathbb{R}^n)} \leq C_k.$$

The derivatives of Φ_{ji} and Φ_{ji}^{-1} are uniformly controlled by (B1) and Remark 13.1.20.
Let K be a common bound for the entries of $D\Phi_{ji}$ and $D\Phi_{ji}^{-1}$ on all overlaps. The Leibniz formula for the determinant gives

$$|\det D\Phi_{ji}| \leq n! K^n.$$

Moreover,

$$\frac{1}{|\det D\Phi_{ji}(x)|} = |\det D\Phi_{ji}^{-1}(\Phi_{ji}(x))| \leq n! K^n.$$

Thus, the Jacobians are bounded above and uniformly bounded away from zero. To apply the localized version of the coordinate-change lemma, we also verify the margins. Choose the cutoffs according to Lemma 13.1.15. The support of h_i lies in the region where $\chi_i = 1$, and the support of $\chi_j^\sharp$ is separated from the boundary of its chart by a fixed distance. The first-derivative bounds for the charts and their inverses convert these two margins into a ball of common radius $\rho > 0$ around each point of the support of η_{ij}, contained in Ω_{ij}, and an analogous margin in chart j. To verify the first assertion, follow a coordinate segment from that point: as long as its image remains in both charts, its speed in the second is uniformly bounded; a segment shorter than the margin divided by that bound cannot reach the boundary of the second chart. The margin in the first chart ensures that the segment is defined throughout this path.
Condition (B1) at order zero places all coordinate domains in a fixed Euclidean ball. We can cover the support of η_{ij} by a uniformly bounded number of balls of radius $\rho/4$, with subordinate cutoffs whose derivatives have uniform bounds. On each larger ball, of radius ρ, the hypotheses of the localized version of Lemma 6.4.3 hold. For order s, fix an integer $k > |s| + n + 1$; derivatives of the multipliers through order k and of the transitions through order $k+1$ are controlled by (B1)–(B3). The local estimate, summed over this uniformly finite cover, proves (13.19) with a common constant.
Finally, $\chi_j^\sharp h_j^\sharp = h_j^\sharp$. On Ω_{ij}, the definition of the pullback of distributions and compatibility of coordinate representations give

$$\eta_{ij}\left[\widetilde{\left((h_j^\sharp u)\circ(\varphi_j^\sharp)^{-1}\right)}\circ\Phi_{ji}\right] = (h_i\chi_j^\sharp h_j^\sharp u)\circ\varphi_i^{-1}.$$

Both sides have compact support in Ω_{ij}. Extending them by zero to $\mathbb{R}^n$ proves (13.20). □

Theorem 13.3.5. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, and let $\mathcal{T} = (U_i, \varphi_i, h_i)_{i\in I}$ be an admissible trivialization of M. Let $s \in \mathbb{R}$ and $1 < p < \infty$. Then

$$H_{\mathcal{T}}^{s,p}(M) = H^{s,p}(M),$$

where $H^{s,p}(M)$ is defined as in Definition 13.3.1. More precisely, there exist constants $c, C > 0$, independent of u, such that

$$c\|u\|_{H^{s,p}(M)} \leq \|u\|_{H_{\mathcal{T}}^{s,p}(M)} \leq C\|u\|_{H^{s,p}(M)}.$$

Proof. Let

$$\mathcal{T}^{\mathrm{geo}} = (U_j^{\mathrm{geo}}, \varphi_j^{\mathrm{geo}}, h_j^{\mathrm{geo}})_{j\in J}$$

be the trivialization in Theorem 13.1.22. For $i \in I$ and $j \in J$, set

$$J_i := \{j \in J \mid U_i \cap U_j^{\mathrm{geo}} \neq \varnothing\}, \qquad I_j := \{i \in I \mid U_i \cap U_j^{\mathrm{geo}} \neq \varnothing\}.$$

The two cross-overlap bounds in (B1), transferred to the geodesic atlas by Remark 13.1.20, provide integers N_1, N_2 such that

$$\#J_i \le N_1, \qquad \#I_j \le N_2$$

for all indices.

The locally finite identity $\sum_{j\in J} h_j^{\mathrm{geo}} = 1$ can be multiplied by the distribution $h_i u$. After passing to chart i and extending each component by zero, we obtain in $\mathcal{D}'(\mathbb{R}^n)$

$$\widetilde{(h_i u)\circ\varphi_i^{-1}} = \sum_{j\in J_i} \widetilde{(h_i h_j^{\mathrm{geo}} u)\circ\varphi_i^{-1}}.$$

Lemma 13.3.4, applied with $\mathcal{T}^\sharp = \mathcal{T}^{\mathrm{geo}}$, gives a constant $C_0 > 0$, independent of i and j, such that

$$\left\|\widetilde{(h_i h_j^{\mathrm{geo}} u)\circ\varphi_i^{-1}}\right\|_{H^{s,p}(\mathbb{R}^n)} \le C_0 \left\|\widetilde{(h_j^{\mathrm{geo}} u)\circ(\varphi_j^{\mathrm{geo}})^{-1}}\right\|_{H^{s,p}(\mathbb{R}^n)}.$$

Set

$$a_j := \left\|\widetilde{(h_j^{\mathrm{geo}} u)\circ(\varphi_j^{\mathrm{geo}})^{-1}}\right\|_{H^{s,p}(\mathbb{R}^n)}.$$

Since each sum has at most N_1 terms,

$$\left\|\widetilde{(h_i u)\circ\varphi_i^{-1}}\right\|_{H^{s,p}(\mathbb{R}^n)}^p \le C_0^p N_1^{p-1} \sum_{j\in J_i} a_j^p.$$

Summing over i and rearranging the nonnegative series by Tonelli's Theorem B.6.17 yields

$$\begin{aligned}
\|u\|_{H_{\mathcal{T}}^{s,p}(M)}^p &\le C_0^p N_1^{p-1} \sum_{i\in I}\sum_{j\in J_i} a_j^p \\
&= C_0^p N_1^{p-1} \sum_{j\in J}\sum_{i\in I_j} a_j^p \\
&\le C_0^p N_1^{p-1} N_2 \|u\|_{H^{s,p}(M)}^p.
\end{aligned}$$

The factor N_1 controls the number of terms in each localization, and N_2 controls how many times a geodesic localization appears in the global sum.

For the reverse inequality, use $\sum_{i\in I} h_i = 1$. In the geodesic chart j,

$$\widetilde{(h_j^{\mathrm{geo}} u)\circ(\varphi_j^{\mathrm{geo}})^{-1}} = \sum_{i\in I_j} \widetilde{(h_j^{\mathrm{geo}} h_i u)\circ(\varphi_j^{\mathrm{geo}})^{-1}}.$$

Apply the same lemma with the two trivializations interchanged and repeat the preceding count. Thus,

$$\|u\|_{H^{s,p}(M)} \le C' \|u\|_{H^{s,p}_{\mathcal{T}}(M)}.$$

The two estimates prove equality of the spaces as subspaces of $\mathcal{D}'(M)$ and, for every u in that space,

$$(C')^{-1}\|u\|_{H^{s,p}(M)} \le \|u\|_{H^{s,p}_{\mathcal{T}}(M)} \le C_0 N_1^{1-\frac{1}{p}} N_2^{\frac{1}{p}} \|u\|_{H^{s,p}(M)}.$$

□

Having defined fractional Sobolev spaces on Riemannian manifolds, we turn to Besov and Triebel–Lizorkin spaces. On $\mathbb{R}^n$, priority is often given to Besov spaces, which at first sight seem simpler than Triebel–Lizorkin spaces. On a noncompact manifold, the situation changes: Besov spaces do not satisfy the strong localization principle with outer ℓ^p summation when the fine index differs from p, as proved in Theorem 6.4.4; see also [146, Theorem 2.4.7(i)]. We will therefore define Triebel–Lizorkin spaces first by localization and then construct Besov spaces by real interpolation.

Definition 13.3.6. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, let $\mathcal{T} = (U_i, \varphi_i, h_i)_{i\in I}$ be an admissible trivialization, and let $s \in \mathbb{R}$.

(a) If $1 \le p < \infty$ and $1 \le q \le \infty$, define

$$F^s_{p,q,\mathcal{T}}(M) := \left\{ u \in \mathcal{D}'(M) \,\middle|\, \|u\|_{F^s_{p,q,\mathcal{T}}(M)} < \infty \right\},$$

where

$$\|u\|_{F^s_{p,q,\mathcal{T}}(M)} := \left(\sum_{i\in I} \left\| \widetilde{(h_i u)\circ \varphi_i^{-1}} \right\|^p_{F^s_{p,q}(\mathbb{R}^n)} \right)^{\frac{1}{p}}.$$

(b) If $1 \le p < \infty$, $1 \le q \le \infty$, and $-\infty < s_0 < s < s_1 < \infty$, write $s = (1-\Theta)s_0 + \Theta s_1$, with $0 < \Theta < 1$, and define

$$B^s_{p,q,\mathcal{T}}(M) := \left(F^{s_0}_{p,p,\mathcal{T}}(M), F^{s_1}_{p,p,\mathcal{T}}(M)\right)_{\Theta,q}.$$

In the first item, the tilde indicates extension by zero of the coordinate component from $\varphi_i(U_i)$ to $\mathbb{R}^n$. In the indicated ranges, these expressions are norms.

Remark 13.3.7. (a) If $\mathcal{T}$ is the geodesic trivialization in Theorem 13.1.22, we omit the reference to $\mathcal{T}$ and simply write

$$F^s_{p,q}(M) \qquad \text{and} \qquad B^s_{p,q}(M).$$

(b) In the range adopted here, the preceding expressions define norms. Triebel's theory also allows $0 < p < 1$ or $0 < q < 1$, but requires atomic methods for quasi-Banach spaces that will not be needed in this book.

(c) The definition of $F^s_{p,q,\mathcal{T}}(M)$ uses coordinate localization. For Besov spaces, however, we adopt the definition by real interpolation, since the same localization principle as for Triebel–Lizorkin spaces is not generally available.

(d) For every $s \in \mathbb{R}$ and every $1 \le p < \infty$,

$$B^s_{p,p,\mathcal{T}}(M) = F^s_{p,p,\mathcal{T}}(M)$$

and there exist constants $c_{s,p,\mathcal{T}}, C_{s,p,\mathcal{T}} > 0$ such that

$$c_{s,p,\mathcal{T}} \|u\|_{F^s_{p,p,\mathcal{T}}(M)} \le \|u\|_{B^s_{p,p,\mathcal{T}}(M)} \le C_{s,p,\mathcal{T}} \|u\|_{F^s_{p,p,\mathcal{T}}(M)}$$

for every u in the common space.

(e) The definition of $B^s_{p,q,\mathcal{T}}(M)$ is independent of the choice of s_0 and s_1, provided that

$$-\infty < s_0 < s < s_1 < \infty \qquad \text{and} \qquad s = (1-\Theta)s_0 + \Theta s_1.$$

(f) Alternatively, we could have defined

$$B^s_{p,p}(M) := (H^{s_0,p}(M), H^{s_1,p}(M))_{\Theta,p},$$

where $s_0, s_1 \in \mathbb{R}$, $1 < p < \infty$, $0 < \Theta < 1$, and $s = (1-\Theta)s_0 + \Theta s_1$.

Justification of items (d)–(f). To apply interpolation, we construct order-independent analysis and synthesis operators defining a retraction for all the spaces under consideration. Fix the auxiliary cutoff functions χ_i from (B3), set $\Omega_i := \varphi_i(U_i)$, and, for $r \in \mathbb{R}$, write

$$\mathbb{X}_r := \ell^p\big(I; F^r_{p,p}(\mathbb{R}^n)\big).$$

The analysis operator is

$$\mathcal{S}u := \Big(\widetilde{(h_i u)\circ\varphi_i^{-1}}\Big)_{i\in I}.$$

By definition, $\mathcal{S}\colon F^r_{p,p,\mathcal{T}}(M) \to \mathbb{X}_r$ is an isometry.
We define synthesis precisely. In chart i, let

$$a_i(x) := \sqrt{\det\big(\mathbf{g}^{(i)}(\varphi_i^{-1}(x))\big)}.$$

If $z \in \mathcal{D}'(\mathbb{R}^n)$ has compact support contained in Ω_i, the distribution $\mathcal{E}_i z \in \mathcal{D}'(M)$ is determined by

$$\langle \mathcal{E}_i z, \psi\rangle := \Big\langle z, a_i\big((\psi \restriction_{U_i})\circ\varphi_i^{-1}\big)\Big\rangle, \qquad \psi \in C^\infty_c(M).$$

This expression is well defined because it uses the test function only on a neighborhood of the compact support of z; this is the extension of the action established in Proposition 10.2.32. For $v = (v_i)_{i\in I}$, set

$$\mathcal{R}v := \sum_{i\in I} \mathcal{E}_i\big(\widetilde{\chi}_i v_i\big), \qquad \widetilde{\chi}_i := \widetilde{\chi_i\circ\varphi_i^{-1}}.$$

The sum defines a distribution: only finitely many terms contribute on the support of a test function. Since

$\chi_i = 1$ near $\operatorname{supp}(h_i)$ and $\sum_{i\in I} h_i = 1$, we obtain, first on each test function and therefore in $\mathcal{D}'(M)$,

$$\mathcal{R}\mathcal{S}u = \sum_{i\in I} h_i u = u.$$

We show that synthesis is continuous at every order. Localizing $\mathcal{R}v$ with h_j involves only the indices

$$I_j := \{i \in I \mid U_i \cap U_j \neq \varnothing\}.$$

The family I_j has uniformly bounded cardinality. Each summand, written in chart j, is obtained from $\widetilde{\chi}_i v_i$ by a coordinate change and multiplication by a smooth function with uniformly bounded derivatives. Lemma 13.3.4 gives, with a constant C_r independent of i and j,

$$\left\| \widetilde{\left(h_j \mathcal{E}_{\rangle}(\widetilde{\ }_{\rangle}\sqsubseteq_{\rangle})\right)} \circ \varphi_{|}^{-} \widetilde{\chi} \right\|_{F^r_{p,p}(\mathbb{R}^n)} \leq C_r \|v_i\|_{F^r_{p,p}(\mathbb{R}^n)}.$$

Hölder's inequality for the finite sum, followed by Tonelli, then shows that there exists $C_r' > 0$ such that

$$\|\mathcal{R}v\|_{F^r_{p,p,\mathcal{T}}(M)} \leq C_r' \|v\|_{\mathbb{X}_r}.$$

Thus, $F^r_{p,p,\mathcal{T}}(M)$ is a retract of $\mathbb{X}_r$, and the operators $\mathcal{S}$ and $\mathcal{R}$ do not depend on r. Moreover, $\mathcal{S}\mathcal{R}$ is a continuous projection whose closed image is $\mathcal{S}(F^r_{p,p,\mathcal{T}}(M))$. Since $\mathbb{X}_r$ is Banach and $\mathcal{S}$ is isometric, $F^r_{p,p,\mathcal{T}}(M)$ is Banach as well. This verifies that the pairs interpolated below are Banach pairs.

Now let $r_0 < r_1$, $0 < \eta < 1$, and $r = (1-\eta)r_0 + \eta r_1$. The Euclidean identity

$$(F^{r_0}_{p,p}(\mathbb{R}^n), F^{r_1}_{p,p}(\mathbb{R}^n))_{\eta,p} = F^r_{p,p}(\mathbb{R}^n)$$

follows from the dyadic decomposition, $B^t_{p,p}(\mathbb{R}^n) = F^t_{p,p}(\mathbb{R}^n)$, and Proposition 5.7.18; it also holds for $p = 1$. The same proposition gives

$$(\mathbb{X}_{r_0}, \mathbb{X}_{r_1})_{\eta,p} = \mathbb{X}_r.$$

Theorem 5.3.1, applied to $\mathcal{S}$ and $\mathcal{R}$, preserves the identity $\mathcal{R}\mathcal{S} = I$ on the interpolated spaces. Consequently,

$$(F^{r_0}_{p,p,\mathcal{T}}(M), F^{r_1}_{p,p,\mathcal{T}}(M))_{\eta,p} = F^r_{p,p,\mathcal{T}}(M) \tag{13.21}$$

with equivalence of norms. Taking $r_0 = s_0$, $r_1 = s_1$, and $\eta = \Theta$ proves item (d).

For item (e), consider two admissible pairs of endpoints. Choose $a < s < b$ so that all four endpoints lie in (a, b). By (13.21), each endpoint space is a space $(F^a_{p,p,\mathcal{T}}, F^b_{p,p,\mathcal{T}})_{\rho,p}$, with parameter ρ determined affinely by its order. The real reiteration Theorem 5.5.2 reduces both definitions of $B^s_{p,q,\mathcal{T}}(M)$ to the same space

$$(F^a_{p,p,\mathcal{T}}(M), F^b_{p,p,\mathcal{T}}(M))_{\rho_s,q}, \qquad \rho_s = \frac{s-a}{b-a}.$$

This proves independence of the endpoints, including equivalence of the resulting norms.

Finally, if $1 < p < \infty$, the same analysis and synthesis are continuous when $F^r_{p,p}(\mathbb{R}^n)$ is replaced by $H^{r,p}(\mathbb{R}^n)$; the proof uses exactly the preceding multiplication, coordinate-change, and overlap estimates. Item (a) of Theorem 6.3.11 identifies real interpolation of the Euclidean Bessel spaces with $B^s_{p,p}(\mathbb{R}^n) = F^s_{p,p}(\mathbb{R}^n)$.

Interpolating the retraction gives

$$(H^{s_0,p}(M), H^{s_1,p}(M))_{\Theta,p} = F^s_{p,p}(M) = B^s_{p,p}(M),$$

which is item (f). □

These spaces are independent of the chosen trivialization (since the Riemannian manifold has bounded geometry), as we now show:

Theorem 13.3.8. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, and let $\mathcal{T} = (U_i, \varphi_i, h_i)_{i\in I}$ be an admissible trivialization. Let $s \in \mathbb{R}$, $1 \le p < \infty$, and $1 \le q \le \infty$. Then

$$F^s_{p,q,\mathcal{T}}(M) = F^s_{p,q}(M) \qquad \text{and} \qquad B^s_{p,q,\mathcal{T}}(M) = B^s_{p,q}(M)$$

and there exist positive constants c_F, C_F, c_B, C_B, depending on s, p, q and the uniform data of the two trivializations but not on u, such that

$$c_F\|u\|_{F^s_{p,q}(M)} \le \|u\|_{F^s_{p,q,\mathcal{T}}(M)} \le C_F\|u\|_{F^s_{p,q}(M)}$$

and

$$c_B\|u\|_{B^s_{p,q}(M)} \le \|u\|_{B^s_{p,q,\mathcal{T}}(M)} \le C_B\|u\|_{B^s_{p,q}(M)}.$$

Proof. For the scale F, repeat the count in the proof of Theorem 13.3.5. If $\mathcal{T}^{\mathrm{geo}}$ is the geodesic trivialization, in $\mathcal{D}'(\mathbb{R}^n)$ we have

$$\widetilde{(h_i u)\circ\varphi_i^{-1}} = \sum_{j\in J_i} \widetilde{(h_i h_j^{\mathrm{geo}} u)\circ\varphi_i^{-1}}.$$

Lemma 13.3.4, with $A^s = F^s_{p,q}$, gives

$$\left\|\widetilde{(h_i h_j^{\mathrm{geo}} u)\circ\varphi_i^{-1}}\right\|_{F^s_{p,q}(\mathbb{R}^n)} \le C_0 \left\|\widetilde{(h_j^{\mathrm{geo}} u)\circ(\varphi_j^{\mathrm{geo}})^{-1}}\right\|_{F^s_{p,q}(\mathbb{R}^n)}.$$

The constant C_0 depends on s, p, q and the uniform bounds for the cutoff functions, coordinate transitions, and their Jacobians, but not on i or j. If N_1, N_2 are the two cross multiplicities, outer ℓ^p summation gives

$$\|u\|^p_{F^s_{p,q,\mathcal{T}}(M)} \le C_0^p N_1^{p-1} N_2 \|u\|^p_{F^s_{p,q}(M)}.$$

Interchanging the trivializations gives the reverse estimate. The argument remains valid when $q = \infty$, since it applies to the local norms, which are nonnegative numbers, while the outer sum retains exponent $p < \infty$. For the scale B, fix $s_0 < s < s_1$ and $s = (1-\theta)s_0 + \theta s_1$. The identities on the common space $\mathcal{D}'(M)$ define compatible isomorphisms

$$F^{s_\nu}_{p,p,\mathcal{T}}(M) \longrightarrow F^{s_\nu}_{p,p}(M), \qquad \nu \in \{0,1\}.$$

The operator interpolation theorem for the K method 5.3.1, applied also to the inverse identity, gives

$$\left(F^{s_0}_{p,p,\mathcal{T}}, F^{s_1}_{p,p,\mathcal{T}}\right)_{\theta,q} = \left(F^{s_0}_{p,p}, F^{s_1}_{p,p}\right)_{\theta,q}$$

with norms controlled in both directions by the norms of the identities at the two endpoints and their inverses. These are precisely the constants c_B, C_B in the statement. This establishes the asserted equality of Besov spaces. The reiteration Theorem 5.5.2 also shows that the construction is independent of the auxiliary endpoints. □

13.3.1 Comparison with intrinsic definitions

Remark 13.3.9. (Heat on several components) In this chapter, M is not assumed connected. Its components $(M_\nu)_{\nu\in A}$ form an at most countable family, since they are open and M has a countable base. Each is complete by Remark 13.1.2. To apply the constructions of the heat chapter, use

$$L^p(M,\mathbf{E}) = \ell^p\big(A; L^p(M_\nu, \mathbf{E}|_{M_\nu})\big), \qquad 1 \le p < \infty,$$

and define the semigroup componentwise. It is contractive because every component semigroup is contractive. If $\mathbf{u} = (\mathbf{u}_\nu)_{\nu\in A}$, then

$$\|P_t^{\mathbf{E}}\mathbf{u} - \mathbf{u}\|^p_{L^p(M,\mathbf{E})} = \sum_{\nu\in A} \|P_t^{\mathbf{E}|_{M_\nu}}\mathbf{u}_\nu - \mathbf{u}_\nu\|^p_{L^p(M_\nu,\mathbf{E}\restriction_{M_\nu})} \longrightarrow 0 :$$

each summand tends to zero and is bounded by $2^p\|\mathbf{u}_\nu\|^p_{L^p(M_\nu,\mathbf{E}\restriction_{M_\nu})}$, a convergent series. Thus, strong continuity is preserved, including for $p = 1$. The projections onto the components are continuous and commute with the Bochner integrals defining the potentials. The intrinsic scales are therefore constructed with the same semigroup componentwise. The following estimates use constants independent of ν, since the geometric bounds are uniform on all of M. In the scalar case, use the trivial bundle.

The comparison will rely on three distinct mechanisms. The first is uniform transfer between charts, already established in Lemma 13.3.4. The second compares partial and covariant derivatives at integer orders. The third interpolates these integer-order identifications and compares them with the scale generated by the Laplacian. We begin by specifying the role of quadratic partitions.

Lemma 13.3.10. (Equivalence of quadratic localization) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, let $\mathcal{Q} = (U_i, \varphi_i, h_i)_{i\in I}$ be an admissible quadratic localization system, let $\rho_i := h_i^2$, and let $\mathcal{T}_\mathcal{Q} = (U_i, \varphi_i, \rho_i)_{i\in I}$ be the associated trivialization. For $s \in \mathbb{R}$, $1 < p < \infty$, and $1 \le q \le \infty$, there exist constants $c_H, C_H, c_F, C_F > 0$, independent of u, such that

$$c_H\|u\|_{H^{s,p}_{\mathcal{T}_\mathcal{Q}}(M)} \le \left(\sum_{i\in I} \left\|\widetilde{(h_i u)\circ\varphi_i^{-1}}\right\|^p_{H^{s,p}(\mathbb{R}^n)}\right)^{\frac{1}{p}} \le C_H\|u\|_{H^{s,p}_{\mathcal{T}_\mathcal{Q}}(M)}$$

and

$$c_F\|u\|_{F^{s}_{p,q,\mathcal{T}_\mathcal{Q}}(M)} \le \left(\sum_{i\in I} \left\|\widetilde{(h_i u)\circ\varphi_i^{-1}}\right\|^p_{F^{s}_{p,q}(\mathbb{R}^n)}\right)^{\frac{1}{p}} \le C_F\|u\|_{F^{s}_{p,q,\mathcal{T}_\mathcal{Q}}(M)}.$$

When $q = p$, the second comparison also provides localization of $B^s_{p,p}(M)$.

Proof. Fix one of the two choices

$$A^s(\mathbb{R}^n) = H^{s,p}(\mathbb{R}^n) \qquad \text{or} \qquad A^s(\mathbb{R}^n) = F^s_{p,q}(\mathbb{R}^n)$$

and set

$$N_h(u) := \left(\sum_{i\in I} \left\| \widetilde{(h_i u)\circ \varphi_i^{-1}} \right\|^p_{A^s(\mathbb{R}^n)} \right)^{\frac{1}{p}},$$

$$N_\rho(u) := \left(\sum_{i\in I} \left\| \widetilde{(\rho_i u)\circ \varphi_i^{-1}} \right\|^p_{A^s(\mathbb{R}^n)} \right)^{\frac{1}{p}}.$$

By definition, N_ρ is the norm associated with $\mathcal{T}_Q$. Since $\operatorname{supp}(h_i) \Subset U_i$, the function $h_i \circ \varphi_i^{-1}$ has an extension by zero $\widetilde{h_i \circ \varphi_i^{-1}} \in C^\infty_c(\mathbb{R}^n)$, and

$$\widetilde{(\rho_i u)\circ \varphi_i^{-1}} = \widetilde{h_i \circ \varphi_i^{-1}}\, \widetilde{(h_i u)\circ \varphi_i^{-1}}.$$

The multiplier theorem in Lemma 6.4.3 and the uniform bounds on (B2) give a constant $K_0 > 0$, independent of $i \in I$, such that

$$\left\| \widetilde{(\rho_i u)\circ \varphi_i^{-1}} \right\|_{A^s(\mathbb{R}^n)} \le K_0 \left\| \widetilde{(h_i u)\circ \varphi_i^{-1}} \right\|_{A^s(\mathbb{R}^n)}.$$

Raising to the power p and summing over $i \in I$ gives

$$N_\rho(u) \le K_0 N_h(u). \tag{13.22}$$

For the reverse estimate, use the locally finite identity

$$\sum_{j\in I} \rho_j = 1.$$

For each $i \in I$, define

$$I_i := \{ j \in I \mid U_i \cap U_j \neq \varnothing \}.$$

Uniform finiteness of the cover provides $L \in \mathbb{N}$ such that $\#I_i \le L$ for every $i \in I$. Therefore,

$$\widetilde{(h_i u)\circ \varphi_i^{-1}} = \sum_{j\in I_i} \widetilde{(h_i \rho_j u)\circ \varphi_i^{-1}} \quad \text{on } \mathcal{D}'(\mathbb{R}^n). \tag{13.23}$$

Fix $j \in I_i$ and let χ_j be the auxiliary cutoff function associated with ρ_j. On the overlap, set

$$\Omega_{ij} := \varphi_i(U_i \cap U_j), \qquad \Phi_{ji} := \varphi_j \circ \varphi_i^{-1}.$$

In accordance with (13.17), define

$$P^{h,\rho}_{ij} z := \big(\widetilde{(h_i \chi_j)\circ \varphi_i^{-1}} \big)(z \circ \Phi_{ji}).$$

The support of $(h_i \chi_j)\circ \varphi_i^{-1}$ is compact in Ω_{ij}. The proof of Lemma 13.3.4, which does not use the partition-

of-unity identity for this estimate, provides a constant $K_1 > 0$, independent of i and j, such that

$$\|P_{ij}^{h,\rho} z\|_{A^s(\mathbb{R}^n)} \le K_1 \|z\|_{A^s(\mathbb{R}^n)}. \tag{13.24}$$

Since $\chi_j \rho_j = \rho_j$,

$$P_{ij}^{h,\rho}\left(\widetilde{(\rho_j u)\circ\varphi_j^{-1}}\right) = \widetilde{(h_i \rho_j u)\circ\varphi_i^{-1}}.$$

The preceding identities imply

$$\left\|\widetilde{(h_i u)\circ\varphi_i^{-1}}\right\|_{A^s(\mathbb{R}^n)} \le K_1 \sum_{j\in I_i} \left\|\widetilde{(\rho_j u)\circ\varphi_j^{-1}}\right\|_{A^s(\mathbb{R}^n)}.$$

Hölder's inequality for a sum of at most L terms gives

$$\left(\sum_{j\in I_i} a_j\right)^p \le L^{p-1} \sum_{j\in I_i} a_j^p$$

for every family of nonnegative numbers $(a_j)_{j\in I_i}$. Applying this inequality and summing over $i \in I$ gives

$$\begin{aligned} N_h(u)^p &\le K_1^p L^{p-1} \sum_{i\in I}\sum_{j\in I_i} \left\|\widetilde{(\rho_j u)\circ\varphi_j^{-1}}\right\|_{A^s(\mathbb{R}^n)}^p \\ &= K_1^p L^{p-1} \sum_{j\in I} \#I_j \left\|\widetilde{(\rho_j u)\circ\varphi_j^{-1}}\right\|_{A^s(\mathbb{R}^n)}^p \\ &\le K_1^p L^p N_\rho(u)^p. \end{aligned}$$

The intermediate equality uses symmetry of the relation $U_i \cap U_j \neq \varnothing$. Consequently,

$$N_h(u) \le K_1 L N_\rho(u). \tag{13.25}$$

Estimates (13.22) and (13.25) prove the two comparisons. For $A^s = F^s_{p,p}$, also use the Euclidean identification

$$F^s_{p,p}(\mathbb{R}^n) = B^s_{p,p}(\mathbb{R}^n)$$

of Theorem 6.3.14. □

Proposition 13.3.11. (Retraction, interpolation, and distributional duality) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, $s_0, s_1 \in \mathbb{R}$, $s_0 < s_1$, $1 < p < \infty$, and $0 < \theta < 1$. If $s = (1-\theta)s_0 + \theta s_1$, then

$$[H^{s_0,p}(M), H^{s_1,p}(M)]_\theta = H^{s,p}(M) \tag{13.26}$$

and there exist constants $c_I, C_I > 0$, depending on s_0, s_1, θ, p and the uniform localization data, such that

$$c_I \|u\|_{H^{s,p}(M)} \le \|u\|_{[H^{s_0,p}(M), H^{s_1,p}(M)]_\theta} \le C_I \|u\|_{H^{s,p}(M)}.$$

Moreover, the identification of locally integrable functions with regular distributions, constructed using

$d\lambda_{\mathbf{g}}$, induces on $C_c^\infty(M)$ the bilinear pairing

$$\langle v, u\rangle_{\mathbf{g}} := T_v(u) = \int_M uv\, d\lambda_{\mathbf{g}}, \qquad u, v \in C_c^\infty(M). \tag{13.27}$$

For every $r \in \mathbb{R}$, this pairing has a unique continuous bilinear extension

$$\langle \cdot, \cdot \rangle_{r,p;\mathbf{g}} \colon H^{-r,p'}(M) \times H^{r,p}(M) \longrightarrow \mathbb{K},$$

and the operator

$$\mathcal{J}_{r,p;\mathbf{g}} \colon H^{-r,p'}(M) \longrightarrow \big(H^{r,p}(M)\big)', \qquad \mathcal{J}_{r,p;\mathbf{g}}(v)(u) := \langle v, u\rangle_{r,p;\mathbf{g}},$$

is a topological isomorphism. In particular,

$$\big(H^{r,p}(M)\big)' \cong H^{-r,p'}(M) \tag{13.28}$$

and there exist constants $c_D, C_D > 0$, depending on r, p and the uniform localization data, such that

$$c_D \|v\|_{H^{-r,p'}(M)} \le \|\mathcal{J}_{r,p;\mathbf{g}} v\|_{(H^{r,p}(M))'} \le C_D \|v\|_{H^{-r,p'}(M)}.$$

When $\mathbb{K} = \mathbb{C}$, the pairing (13.27) involves no conjugation: it is the distributional duality induced by the Riemann–Lebesgue measure, not the Hermitian inner product of $L^2(M)$.

Proof. Start with a geodesic trivialization and apply Lemma 13.1.19. This gives an admissible quadratic system

$$\mathcal{Q} = (U_i, \varphi_i, h_i)_{i\in I}, \qquad \sum_{i\in I} h_i^2 = 1,$$

and auxiliary cutoff functions $(\chi_i)_{i\in I}$ such that

$$\chi_i = 1 \quad \text{on a neighborhood of } \operatorname{supp}(h_i), \qquad \operatorname{supp}(\chi_i) \Subset U_i.$$

Write

$$\Omega_i := \varphi_i(U_i), \qquad a_i(x) := \sqrt{\det\big(\mathbf{g}^{(i)}(\varphi_i^{-1}(x))\big)}, \qquad x \in \Omega_i.$$

The function $\chi_i \circ \varphi_i^{-1}$ has compact support in Ω_i. Denote by

$$\widetilde{\chi_i} := \widetilde{\chi_i \circ \varphi_i^{-1}} \in C_c^\infty(\mathbb{R}^n)$$

its extension by zero from Ω_i to $\mathbb{R}^n$.

Before defining synthesis, we specify how to reconstruct a distribution from a chart. If $z \in \mathcal{D}'(\mathbb{R}^n)$ and $\operatorname{supp}(z) \Subset \Omega_i$, define $\mathcal{E}_i z \in \mathcal{D}'(M)$ by

$$\langle \mathcal{E}_i z, \psi\rangle := \Big\langle z, a_i\big((\psi \restriction_{U_i}) \circ \varphi_i^{-1}\big)\Big\rangle_{\mathbb{R}^n}, \qquad \psi \in C_c^\infty(M). \tag{13.29}$$

Although the function in the second argument need not have compact support in Ω_i, only its restriction to a neighborhood of $\operatorname{supp}(z)$ is used. The expression is well defined by the extension of the action of a compactly supported distribution established in Proposition 10.2.32. The definition of coordinate components

of a distribution in Proposition 10.2.34 implies

$$\big((\mathcal{E}_i z)\restriction_{U_i}\big)\circ\varphi_i^{-1} = z\restriction_{\Omega_i} \quad \text{on } \mathcal{D}'(\Omega_i). \tag{13.30}$$

Indeed, for $\varphi\in C_c^\infty(\Omega_i)$,

$$\Big\langle\big((\mathcal{E}_i z)\restriction_{U_i}\big)\circ\varphi_i^{-1},\varphi\Big\rangle = \Big\langle \mathcal{E}_i z, \Big(\frac{\varphi}{a_i}\circ\varphi_i\Big)\Big\rangle = \langle z,\varphi\rangle.$$

If z is a locally integrable function with compact support in Ω_i, then $\mathcal{E}_i z$ is the regular distribution associated with the function $z\circ\varphi_i$ on U_i, extended by zero outside U_i. This construction avoids introducing notation for transporting distributions before specifying its meaning.

Define the analysis operator by

$$\mathcal{S}u := \Big(\widetilde{(h_i u)\circ\varphi_i^{-1}}\Big)_{i\in I}$$

and, for $v=(v_i)_{i\in I}$, the synthesis operator by

$$\mathcal{R}v := \sum_{i\in I} h_i\,\mathcal{E}_i(\widetilde{\chi}_i v_i). \tag{13.31}$$

The product $\widetilde{\chi}_i v_i$ has support contained in $\operatorname{supp}(\widetilde{\chi}_i)\Subset\Omega_i$, so $\mathcal{E}_i(\widetilde{\chi}_i v_i)$ is defined by (13.29). The sum in (13.31) is locally finite, since its ith summand has support contained in $\operatorname{supp}(h_i)$ and the family $(U_i)_{i\in I}$ is locally finite.

Definition 5.5.3 specifies the sequence spaces we will use. Lemma 13.3.10, together with independence of the trivialization, shows that, for each $r\in\mathbb{R}$,

$$\mathcal{S}\colon H^{r,p}(M)\longrightarrow \ell^p\big(I;H^{r,p}(\mathbb{R}^n)\big)$$

is continuous.

We prove continuity of $\mathcal{R}$. For $j\in I$, set

$$I_j := \{i\in I \mid U_i\cap U_j\neq\varnothing\}.$$

There exists $L\geq 1$ such that $\#I_j\leq L$ for every $j\in I$. If $i\in I_j$, write

$$\Omega_{ji} := \varphi_j(U_j\cap U_i), \qquad \Phi_{ij} := \varphi_i\circ\varphi_j^{-1}\colon \Omega_{ji}\longrightarrow \varphi_i(U_i\cap U_j),$$

and define

$$\eta_{ji} := (h_j h_i\chi_i)\circ\varphi_j^{-1}\in C_c^\infty(\Omega_{ji}).$$

Its support is compact in Ω_{ji} because

$$\operatorname{supp}(h_j h_i\chi_i)\subseteq\operatorname{supp}(h_j)\cap\operatorname{supp}(h_i)\Subset U_j\cap U_i.$$

Let $z\in\mathcal{D}'(\mathbb{R}^n)$. On the overlap, use the restriction of z to $\varphi_i(U_i\cap U_j)$ and define its distributional composition with Φ_{ij} by

$$\big\langle z\circ\Phi_{ij},\varphi\big\rangle_{\Omega_{ji}} := \Big\langle z, \widetilde{(\varphi\circ\Phi_{ij}^{-1})\,\big|\det D\Phi_{ij}^{-1}\big|}\Big\rangle_{\mathbb{R}^n}, \qquad \varphi\in C_c^\infty(\Omega_{ji}). \tag{13.32}$$

Here the tilde indicates extension by zero from $\varphi_i(U_i \cap U_j)$ to $\mathbb{R}^n$; the extension is smooth because the function's support is compactly contained in that open set. For a locally integrable function, this definition agrees with ordinary composition $x \mapsto z(\Phi_{ij}(x))$. Set

$$P_{ji} z := \widetilde{\eta_{ji}(z \circ \Phi_{ij})},$$

where the tilde indicates extension by zero from Ω_{ji} to $\mathbb{R}^n$. Compactness of the support of η_{ji} inside Ω_{ji} guarantees that this extension is a well-defined distribution. The transformation of the volume densities on the overlap is

$$a_j(x) = a_i(\Phi_{ij}(x)) \left| \det D\Phi_{ij}(x) \right|, \qquad x \in \Omega_{ji}. \tag{13.33}$$

Evaluating both sides against a test function on $C_c^\infty(\Omega_{ji})$, definition (13.29) and (13.33) give

$$\widetilde{\left(h_j h_i \, \mathcal{E}_{\rangle}(\widetilde{\ }_{\rangle} \sqsubseteq_{\rangle})\right)} \circ \varphi_{|}^{-} \overset{\wp}{\chi} = P_{ji} v_i. \tag{13.34}$$

The bounds in (B1)–(B3), the multiplier and coordinate-change theorem in Lemma 6.4.3, and the uniform Jacobian bounds obtained in Lemma 13.3.4 provide a constant $C_r > 0$, independent of i and j, such that

$$\|P_{ji} z\|_{H^{r,p}(\mathbb{R}^n)} \le C_r \|z\|_{H^{r,p}(\mathbb{R}^n)}. \tag{13.35}$$

By (13.34),

$$\left\| \widetilde{(h_j \mathcal{R} v) \circ \varphi_j^{-1}} \right\|_{H^{r,p}(\mathbb{R}^n)} \le C_r \sum_{i \in I_j} \|v_i\|_{H^{r,p}(\mathbb{R}^n)}.$$

Raise to the power p and use the fact that each sum contains at most L terms. Summing over $j \in I$ and counting overlaps again gives

$$\begin{aligned} &\sum_{j \in I} \left\| \widetilde{(h_j \mathcal{R} v) \circ \varphi_j^{-1}} \right\|_{H^{r,p}(\mathbb{R}^n)}^p \\ &\quad \le C_r^p L^{p-1} \sum_{j \in I} \sum_{i \in I_j} \|v_i\|_{H^{r,p}(\mathbb{R}^n)}^p \\ &\quad = C_r^p L^{p-1} \sum_{i \in I} \#I_i \, \|v_i\|_{H^{r,p}(\mathbb{R}^n)}^p \\ &\quad \le C_r^p L^p \sum_{i \in I} \|v_i\|_{H^{r,p}(\mathbb{R}^n)}^p. \end{aligned}$$

The two inequalities of Lemma 13.3.10 compare the left-hand side with the norm of $H^{r,p}(M)$ through c_H and C_H. Consequently,

$$\|\mathcal{R} v\|_{H^{r,p}(M)} \le C_r' \|v\|_{\ell^p(I; H^{r,p}(\mathbb{R}^n))}. \tag{13.36}$$

Since $\chi_i = 1$ on a neighborhood of $\operatorname{supp}(h_i)$,

$$\widetilde{\chi}_i \widetilde{(h_i u) \circ \varphi_i^{-1}} = \widetilde{(h_i u) \circ \varphi_i^{-1}}.$$

The identity (13.30), applied to the distribution $h_i u$, and the equality $\sum_{i\in I} h_i^2 = 1$ give

$$\mathcal{R}\mathcal{S}u = \sum_{i\in I} h_i^2 u = u.$$

Thus, $\mathcal{S}$ is a coretraction and $\mathcal{R}$ a retraction, and the same pair works at every real order. These identities also establish completeness before interpolation: the operator $\mathcal{S}\mathcal{R}$ is a continuous projection on the Banach space $\ell^p(I;H^{r,p}(\mathbb{R}^n))$, and its image is exactly $\mathcal{S}(H^{r,p}(M))$. This image is closed, being the kernel of $I-\mathcal{S}\mathcal{R}$. The norm comparisons for $\mathcal{S}$ and its inverse $\mathcal{R}$ identify $H^{r,p}(M)$ with that image; therefore, $H^{r,p}(M)$ is a Banach space.

This pair also proves density of $C_c^\infty(M)$ in $H^{r,p}(M)$. Finitely supported sequences with components in $C_c^\infty(\mathbb{R}^n)$ are dense in $\ell^p(I;H^{r,p}(\mathbb{R}^n))$. If a sequence of this kind approximates $\mathcal{S}u$, its image under $\mathcal{R}$ belongs to $C_c^\infty(M)$ and converges to u in $H^{r,p}(M)$ by (13.36).

Apply complex interpolation. Proposition 5.7.12 and the Euclidean identity of Theorem 6.3.11 give

$$\begin{aligned}[\ell^p(I;H^{s_0,p}(\mathbb{R}^n)),\ell^p(I;H^{s_1,p}(\mathbb{R}^n))]_\theta \\ = \ell^p(I;H^{s,p}(\mathbb{R}^n)).\end{aligned}$$

Interpolate $\mathcal{S}$ and $\mathcal{R}$ at the endpoints and use $\mathcal{R}\mathcal{S}=I$. The endpoint norms of these operators, their interpolated norms, and the localization bounds produce the constants $c_I, C_I > 0$ in the statement; in particular, for every u in the common space of (13.26),

$$c_I\|u\|_{H^{s,p}(M)} \le \|u\|_{[H^{s_0,p}(M),H^{s_1,p}(M)]_\theta} \le C_I\|u\|_{H^{s,p}(M)}.$$

We turn to duality. According to Definition 10.2.10, each $v\in L^1_{\mathrm{loc}}(M)$ determines the regular distribution

$$T_v(u) = \int_M uv\,d\lambda_{\mathbf{g}}, \qquad u\in C_c^\infty(M).$$

Thus, (13.27) is the restriction to smooth functions of the duality between $\mathcal{D}'(M)$ and $\mathcal{D}(M)$ induced by the Riemann–Lebesgue measure.

The metric criterion of Lemma 13.2.7 and the Faà di Bruno formula of Theorem 1.1.19 show that a_i, a_i^{-1}, and all their derivatives are bounded by constants independent of i. If $v\in\mathcal{D}'(M)$ and $u\in C_c^\infty(M)$, then

$$\begin{aligned}v(u) &= v\left(\sum_{i\in I} h_i^2 u\right) \\ &= \sum_{i\in I}\left\langle \widetilde{(h_i v)\circ\varphi_i^{-1}}, a_i\widetilde{((h_i u)\circ\varphi_i^{-1})}\right\rangle_{\mathbb{R}^n}.\end{aligned} \tag{13.37}$$

The sum is finite because u has compact support. The second equality is precisely the definition of the coordinate component of a distribution in Proposition 10.2.34. When v is smooth, apply the change-of-variables formula in each chart:

$$\int_{U_i}\eta\,d\lambda_{\mathbf{g}} = \int_{\Omega_i}(\eta\circ\varphi_i^{-1})(x)a_i(x)\,d\lambda_n(x).$$

The preceding identity then becomes

$$\int_M uv\,d\lambda_{\mathbf{g}} = \sum_{i\in I}\int_{\Omega_i} \big((h_i u)\circ\varphi_i^{-1}\big)\big((h_i v)\circ\varphi_i^{-1}\big)a_i\,dx. \tag{13.38}$$

Let $v \in H^{-r,p'}(M)$ and $u \in C_c^\infty(M)$. Euclidean duality from Proposition 6.1.3, uniform continuity of multiplication by a_i, and Hölder's inequality for sequences, applied to (13.37), give

$$\begin{aligned}|v(u)| &\le C\left(\sum_{i\in I}\left\|\widetilde{(h_i u)\circ\varphi_i^{-1}}\right\|^p_{H^{r,p}(\mathbb{R}^n)}\right)^{\frac{1}{p}}\\ &\quad\cdot\left(\sum_{i\in I}\left\|\widetilde{(h_i v)\circ\varphi_i^{-1}}\right\|^{p'}_{H^{-r,p'}(\mathbb{R}^n)}\right)^{\frac{1}{p'}}\\ &\le C'\|u\|_{H^{r,p}(M)}\|v\|_{H^{-r,p'}(M)}.\end{aligned}$$

By the density already proved, $u \mapsto v(u)$ has a unique continuous extension to $H^{r,p}(M)$. Define $\langle v,u\rangle_{r,p;\mathbf{g}}$ as the value of this extension. Then

$$\langle v,u\rangle_{r,p;\mathbf{g}} = v(u), \qquad v\in H^{-r,p'}(M),\quad u\in C_c^\infty(M), \tag{13.39}$$

and, for two smooth functions, the right-hand side is $\displaystyle\int_M uv\,d\lambda_{\mathbf{g}}$. This explicitly shows how the measure induces the pairing and proves continuity of $\mathcal{J}_{r,p;\mathbf{g}}$.

It remains to prove surjectivity. Let $\Lambda \in (H^{r,p}(M))'$. By (13.36), $\Lambda\circ\mathcal{R}$ is continuous on $\ell^p(I;H^{r,p}(\mathbb{R}^n))$. Euclidean duality and Lemma 5.5.4 provide

$$w=(w_i)_{i\in I}\in \ell^{p'}(I;H^{-r,p'}(\mathbb{R}^n))$$

such that

$$(\Lambda\circ\mathcal{R})(z)=\sum_{i\in I}\langle w_i,z_i\rangle_{\mathbb{R}^n} \tag{13.40}$$

for every $z=(z_i)_{i\in I}$, and

$$\|w\|_{\ell^{p'}(I;H^{-r,p'}(\mathbb{R}^n))}\le C\|\Lambda\|.$$

Since $\operatorname{supp}(\chi_i)\Subset U_i$, the function

$$(\chi_i\circ\varphi_i^{-1})a_i^{-1}$$

has a smooth extension by zero to $\mathbb{R}^n$. Denote it by

$$m_i := \widetilde{(\chi_i\circ\varphi_i^{-1})a_i^{-1}} \in C_c^\infty(\mathbb{R}^n).$$

Its derivatives are uniformly bounded. Define

$$v := \sum_{i\in I} h_i\,\mathcal{E}_i(m_i w_i). \tag{13.41}$$

The proof of (13.36), with $-r, p'$ in place of r, p and with the multipliers m_i, shows that $v \in H^{-r,p'}(M)$ and

$$\|v\|_{H^{-r,p'}(M)} \le C\|w\|_{\ell^{p'}(I;H^{-r,p'}(\mathbb{R}^n))} \le C'\|\Lambda\|. \tag{13.42}$$

If $u \in C_c^\infty(M)$, only finitely many terms of (13.41) act on u. The definition of $\mathcal{E}_i$ and the rule for multiplying a distribution by a smooth function give

$$\begin{aligned}
\langle v, u\rangle_{r,p;\mathbf{g}} &= v(u) \\
&= \sum_{i\in I} \left\langle m_i w_i, a_i \widetilde{\left((h_i u)\circ \varphi_i^{-1}\right)} \right\rangle_{\mathbb{R}^n} \\
&= \sum_{i\in I} \left\langle w_i, \widetilde{(\chi_i h_i u)\circ \varphi_i^{-1}} \right\rangle_{\mathbb{R}^n} \\
&= \sum_{i\in I} \left\langle w_i, \widetilde{(h_i u)\circ \varphi_i^{-1}} \right\rangle_{\mathbb{R}^n} \\
&= (\Lambda\circ\mathcal{R})(\mathcal{S}u) = \Lambda(u).
\end{aligned}$$

The third equality uses $\chi_i = 1$ near $\operatorname{supp}(h_i)$, and the penultimate equality uses (13.40) and $\mathcal{R}\mathcal{S} = I$. Density of $C_c^\infty(M)$ extends the equality to all of $H^{r,p}(M)$, so $\mathcal{J}_{r,p;\mathbf{g}}$ is surjective. If $\mathcal{J}_{r,p;\mathbf{g}}(v) = 0$, then v vanishes on $C_c^\infty(M)$ and is the zero distribution. Thus, it is also injective. The direct estimate provides C_D, and (13.42) provides c_D in (13.28). □

Corollary 13.3.12. (Functional connection with Amann's localization) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, let $\mathfrak{K}$ be the atlas constructed in Theorem 13.2.4 or an equivalent uniformly regular atlas, and let $\mathcal{Q}_{\mathfrak{K}} = (U_i, \varphi_i, h_i)_{i\in I}$ be the quadratic system of Proposition 13.2.6. For $s \in \mathbb{R}$ and $1 < p < \infty$, the analysis and synthesis operators defined by

$$\mathcal{S}_{\mathfrak{K}} u := \left(\widetilde{(h_i u)\circ\varphi_i^{-1}}\right)_{i\in I}, \qquad \mathcal{R}_{\mathfrak{K}} v := \sum_{i\in I} h_i\, \mathcal{E}_i(\widetilde{\chi}_i v_i)$$

are continuous, satisfy $\mathcal{R}_{\mathfrak{K}}\mathcal{S}_{\mathfrak{K}} = \mathrm{id}_{H^{s,p}(M)}$, and there exist constants $c_{s,p}, C_{s,p}, D_{s,p} > 0$ such that

$$c_{s,p}\|u\|_{H^{s,p}(M)} \le \|\mathcal{S}_{\mathfrak{K}} u\|_{\ell^p(I;H^{s,p}(\mathbb{R}^m))} \le C_{s,p}\|u\|_{H^{s,p}(M)} \tag{13.43}$$

and

$$\|\mathcal{R}_{\mathfrak{K}} v\|_{H^{s,p}(M)} \le D_{s,p}\|v\|_{\ell^p(I;H^{s,p}(\mathbb{R}^m))}.$$

The constants depend on m, s, p, the multiplicity, and bounds on coordinate transitions and cutoffs through the order required by the local multipliers; they do not depend on i, u, or v.

For $1 \le q \le \infty$, the localized norm with factors h_i and the norm of $F^s_{p,q}(M)$ defined using the ordinary partition $\rho_i = h_i^2$ also satisfy both inequalities of Lemma 13.3.10, with constants $c_F, C_F > 0$ independent of u; when $q = p$, the same assertion holds for $B^s_{p,p}(M)$.

Proof. Proposition 13.2.6 proves that $\mathcal{Q}_{\mathfrak{K}}$ is admissible. Lemma 13.3.10 provides the two inequalities in (13.43) and the Triebel–Lizorkin and Besov comparisons. The distributional construction of $\mathcal{E}_i$, local finiteness of the sum, the synthesis bound, and the identity $\mathcal{R}\mathcal{S} = I$ were proved in Proposition 13.3.11; its proof

uses only admissibility of the quadratic system and therefore applies unchanged to $\mathcal{Q}_{\tilde{\mathfrak{K}}}$. The stated dependencies are those of the multipliers, chart transitions, and the sum of at most L terms appearing in that proof. □

Amann's uniform regularity thus describes the same norms through normalized charts. Comparisons with the quadratic system allow Euclidean estimates to be used with constants independent of the chart. To do the same for sections, we must also control the bundle connection and the transition matrices of its frames.

Definition 13.3.13. (Bounded geometry of a vector bundle) Let $(M,\mathbf{g})$ be a Riemannian manifold of bounded geometry without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle of finite rank equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$, Hermitian when the bundle is complex, and a compatible connection $\nabla^{\mathbf{E}}$. Denote the curvature of $\nabla^{\mathbf{E}}$ by

$$\mathbf{R}^{\mathbf{E}}\in\Gamma\big(\Lambda^2T^*M\otimes\operatorname{End}(\mathbf{E})\big)$$

. We say that $(\mathbf{E},\mathbf{h}_{\mathbf{E}},\nabla^{\mathbf{E}})$ is a *bundle of bounded geometry* if, for each $k\in\mathbb{N}_0$, there exists $C_k^{\mathbf{E}}>0$ such that

$$\sup_{x\in M}\Big|(\nabla^{\Lambda^2T^*M\otimes\operatorname{End}(\mathbf{E})})^k\mathbf{R}^{\mathbf{E}}(x)\Big|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\le C_k^{\mathbf{E}}. \tag{13.44}$$

Here we use the product connection induced by the Levi–Civita connection and $\nabla^{\mathbf{E}}$.

Proposition 13.3.14. (Covariant derivatives and localization at integer orders) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, let $\mathbf{E}\to M$ be a bundle of bounded geometry of rank $r_{\mathbf{E}}$, and let

$$\mathcal{T}^{\mathrm{geo}}=(U_i,\varphi_i,h_i)_{i\in I}$$

be a geodesic trivialization. On U_i, use the synchronous frame $\mathbf{e}_i=(\mathbf{e}_{i,1},\dots,\mathbf{e}_{i,r_{\mathbf{E}}})$ of Proposition 8.2.26 and write

$$\mathbf{u}=\sum_{a=1}^{r_{\mathbf{E}}}u_i^a\mathbf{e}_{i,a}.$$

Set $W^{0,p}(M,\mathbf{E}):=L^p(M,\mathbf{E})$. If $m\in\mathbb{N}_0$ and $1\le p<\infty$, there exist constants $c_{m,p},C_{m,p}>0$ such that, for every $\mathbf{u}\in W^{m,p}(M,\mathbf{E})$,

$$\begin{aligned}c_{m,p}\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}&\le\left(\sum_{i\in I}\sum_{a=1}^{r_{\mathbf{E}}}\Big\|\widetilde{(h_iu_i^a)\circ\varphi_i^{-1}}\Big\|_{W^{m,p}(\mathbb{R}^n)}^p\right)^{\frac1p}\\&\le C_{m,p}\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.\end{aligned} \tag{13.45}$$

If also $1<p<\infty$, then for the trivial rank-one bundle we obtain

$$W^{m,p}(M)=H^{m,p}(M) \tag{13.46}$$

and there exist constants $c_{m,p}^{WH},C_{m,p}^{WH}>0$, depending on the uniform geometric data but not on $\mathbf{u}$, such that

$$c_{m,p}^{WH}\|\mathbf{u}\|_{W^{m,p}(M)}\le\|\mathbf{u}\|_{H^{m,p}(M)}\le C_{m,p}^{WH}\|\mathbf{u}\|_{W^{m,p}(M)}.$$

Proof. In the construction of Theorem 13.1.22, we have $U_i = B_{\mathbf{g}}(p_i, 2r)$. Since $3r < \operatorname{inj}(M)$ and $3r$ remains within the uniform radius of the metric criterion for bounded geometry, the normal chart extends to

$$\widehat{\varphi}_i \colon \widehat{U}_i := B_{\mathbf{g}}(p_i, 3r) \longrightarrow B_{\mathrm{euc}}(0, 3r), \qquad \widehat{\varphi}_i \restriction_{U_i} = \varphi_i.$$

The uniform bounds on the metric, transitions between geodesic charts, and covariant derivatives of $\mathbf{R}^{\mathbf{E}}$ verify precisely the hypotheses of Proposition 8.2.26. In particular, the synchronous frame $\mathbf{e}_i$ is defined on a neighborhood of $\overline{U_i}$, and its connection coefficients have bounds independent of i. Moreover, each (U_i, φ_i) is a regular coordinate ball in the sense of Chapter 9. We may therefore apply Lemma 9.1.44 to every section $\mathbf{v}$ with compact support in U_i.

The constants in that lemma depend, through order m, on the components of the metric and its inverse, the volume density, the bundle metric in the chosen frame, and the connection coefficients. In the present normal charts and synchronous frames, all these quantities and their derivatives are uniformly bounded by the metric criterion for bounded geometry and Proposition 8.2.26. Since the synchronous frame is orthonormal,

$$\left| \sum_{a=1}^{r_{\mathbf{E}}} z^a \mathbf{e}_{i,a}(x) \right|_{\mathbf{h}_{\mathbf{E}}(x)} = |z| \qquad (x \in U_i,\ z \in \mathbb{K}^{r_{\mathbf{E}}}),$$

and this identity allows the sum of the component norms in Lemma 9.1.44 to be replaced by their ℓ^p sum. Thus, there exist $c_m^{\mathrm{loc}}, C_m^{\mathrm{loc}} > 0$, independent of i, such that

$$\begin{aligned} c_m^{\mathrm{loc}} \left(\sum_{a=1}^{r_{\mathbf{E}}} \left\| \widetilde{v_i^a \circ \varphi_i^{-1}} \right\|_{W^{m,p}(\mathbb{R}^n)}^p \right)^{\frac{1}{p}} &\le \left(\sum_{q=0}^{m} \|\nabla^q \mathbf{v}\|_{L^p(U_i, T^{(0,q)}(TM)|_{U_i} \otimes \mathbf{E}|_{U_i})}^p \right)^{\frac{1}{p}} \\ &\le C_m^{\mathrm{loc}} \left(\sum_{a=1}^{r_{\mathbf{E}}} \left\| \widetilde{v_i^a \circ \varphi_i^{-1}} \right\|_{W^{m,p}(\mathbb{R}^n)}^p \right)^{\frac{1}{p}}. \end{aligned} \tag{13.47}$$

Apply this comparison to $\mathbf{v} = h_i \mathbf{u}$. For $q \in \{0, \dots, m\}$, the iterated Leibniz rule for the product connection is a finite sum, with coefficients depending only on q, of terms obtained by contracting

$$\nabla^{q-\ell} h_i \otimes \nabla^{\ell} \mathbf{u}, \qquad \ell \in \{0, \dots, q\}.$$

In particular,

$$|\nabla^q (h_i \mathbf{u})|_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}} \le C_q \sum_{\ell=0}^{q} |\nabla^{q-\ell} h_i|_{\mathbf{g}} \, |\nabla^{\ell} \mathbf{u}|_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}}. \tag{13.48}$$

The derivatives of h_i are uniformly bounded. Since each point belongs to at most L supports, raising (13.48) to the power p, summing over $i \in I$, and integrating gives

$$\sum_{i \in I} \sum_{q=0}^{m} \|\nabla^q (h_i \mathbf{u})\|_{L^p(U_i, T^{(0,q)}(TM)|_{U_i} \otimes \mathbf{E}|_{U_i})}^p \le C \sum_{\ell=0}^{m} \|\nabla^{\ell} \mathbf{u}\|_{L^p(M, T^{(0,\ell)}(TM) \otimes \mathbf{E})}^p. \tag{13.49}$$

The first local inequality in (13.47), applied for each $i \in I$, proves the right-hand inequality of (13.45).

For the opposite comparison, use the locally finite identity

$$\mathbf{u} = \sum_{i \in I} h_i \mathbf{u}.$$

For each $q \in \{0, \dots, m\}$, we have, distributionally and pointwise when $\mathbf{u}$ is smooth,

$$\nabla^q \mathbf{u} = \sum_{i \in I} \nabla^q (h_i \mathbf{u}).$$

At each point there are at most L nonzero summands, so

$$|\nabla^q \mathbf{u}|^p_{\mathbf{g},\mathbf{h}_\mathbf{E}} \le L^{p-1} \sum_{i \in I} |\nabla^q (h_i \mathbf{u})|^p_{\mathbf{g},\mathbf{h}_\mathbf{E}}.$$

Integrate, sum over $q \in \{0, \dots, m\}$, and use the second inequality in (13.47). This gives the left-hand inequality of (13.45).

To extend the comparisons to a section $\mathbf{u} \in W^{m,p}(M, \mathbf{E})$, the Meyers–Serrin Theorem 9.1.48 provides $\mathbf{u}_j \in \Gamma(\mathbf{E}) \cap W^{m,p}(M, \mathbf{E})$ with $\mathbf{u}_j \to \mathbf{u}$ in $W^{m,p}(M, \mathbf{E})$. Denote by $\mathcal{S}\mathbf{v}$ the family of components $\widetilde{(h_i v_i^a) \circ \varphi_i^{-1}}$ appearing in (13.45). The upper bound, applied to $\mathbf{u}_j - \mathbf{u}_k$, gives

$$\|\mathcal{S}\mathbf{u}_j - \mathcal{S}\mathbf{u}_k\|_{\ell^p(I \times \{1,\dots,r_\mathbf{E}\}; W^{m,p}(\mathbb{R}^n))} \le C_{m,p} \|\mathbf{u}_j - \mathbf{u}_k\|_{W^{m,p}(M,\mathbf{E})}.$$

Completeness of this sequence space gives a limit V. For each fixed i, a, multiplication by h_i and local equivalence of norms give convergence to $\widetilde{(h_i u_i^a) \circ \varphi_i^{-1}}$ in $W^{m,p}(\mathbb{R}^n)$. Since projection onto a component is continuous, $V = \mathcal{S}\mathbf{u}$. Consequently, $\mathcal{S}\mathbf{u}_j \to \mathcal{S}\mathbf{u}$ in the norm of the entire family, not merely componentwise. Continuity of the norms allows limits to be taken in both inequalities applied to $\mathbf{u}_j$ and proves (13.45) for $\mathbf{u}$. The argument includes $p = 1$: the factor L^{p-1} is then one, and the sequence space remains complete. For the trivial rank-one bundle and $1 < p < \infty$, Theorem 6.3.10 uniformly identifies the local norms $W^{m,p}(\mathbb{R}^n)$ and $H^{m,p}(\mathbb{R}^n)$ using its Euclidean constants. Combining them with $c_{m,p}$ and $C_{m,p}$ from (13.45) gives precisely $c^{WH}_{m,p}$ and $C^{WH}_{m,p}$ on $C^\infty_c(M)$. To justify compactly supported approximation as well, enumerate the partition and set $\chi_J := \sum_{i=1}^{J} h_i$. Then $0 \le \chi_J \le 1$, each χ_J has compact support, and, on every fixed compact set, $\chi_J = 1$ for sufficiently large J. Uniform local finiteness and the bounds on $\nabla^q h_i$ give $\sup_{J \in \mathbb{N}} \|\nabla^q \chi_J\|_{L^\infty(M, T^{(0,q)}(TM))} < \infty$ for each q. For $0 \le q \le m$, the Leibniz rule gives a constant independent of J with

$$|\nabla^q_w((1 - \chi_J)\mathbf{u})|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \le C_q \sum_{\ell=0}^{q} |\nabla^{q-\ell}(1 - \chi_J)|_\mathbf{g} |\nabla^\ell_w \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}.$$

Every factor of the first type eventually vanishes on each fixed compact set and is uniformly bounded. The pth power of the right-hand side is dominated by $C \sum_{\ell=0}^{m} |\nabla^\ell_w \mathbf{u}|^p_{\mathbf{g},\mathbf{h}_\mathbf{E}} \in L^1(M)$. Theorem B.6.14, applied at each order and to their finite sum, proves $\chi_J \mathbf{u} \to \mathbf{u}$ in $W^{m,p}(M, \mathbf{E})$. To retain compact support in the smooth approximation, fix $\psi_J \in C^\infty_c(M)$ equal to one near $\operatorname{supp} \chi_J$. If $\mathbf{v}_{J,k} \to \chi_J \mathbf{u}$ in $W^{m,p}(M, \mathbf{E})$ is the Meyers–Serrin approximation, then

$$\|\psi_J \mathbf{v}_{J,k} - \chi_J \mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \le C_J \|\mathbf{v}_{J,k} - \chi_J \mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

Choose $k(J)$ so that this last expression is less than 2^{-J}. The sections $\psi_J \mathbf{v}_{J,k(J)} \in \Gamma_c(\mathbf{E})$ converge to $\mathbf{u}$ in $W^{m,p}(M,\mathbf{E})$, proving the asserted density. Density of $C_c^\infty(M)$ in $H^{m,p}(M)$, proved in Proposition 13.3.11, and the preceding approximation show that both spaces are completions of the same subspace with respect to these two explicit comparisons. The identification preserves their realizations in $\mathcal{D}'(M)$ and proves (13.46). □

Corollary 13.3.15. (Uniform control of the Bochner commutator) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, and let $\mathbf{E} \to M$ be a bundle of bounded geometry. For $\ell \in \mathbb{N}_0$, let

$$\mathbf{E}_\ell := T^{(0,\ell)}(TM) \otimes \mathbf{E}$$

carry the induced metric and product connection. Write

$$\nabla_\ell := \nabla^{\mathbf{E}_\ell} : \Gamma(\mathbf{E}_\ell) \longrightarrow \Gamma(\mathbf{E}_{\ell+1}), \qquad \nabla^m := \nabla_{\ell+m-1} \circ \cdots \circ \nabla_\ell,$$

with the new index in the first covariant factor, and set $\Delta_{B,\ell} = (\nabla_\ell)_h^* \nabla_\ell = -\operatorname{tr}_{\mathbf{g}}(\nabla_\ell^2)$, where the trace contracts the first two differentiation factors, for the positive-sign Bochner Laplacian. If $m \in \mathbb{N}$, then, for every $\mathbf{u} \in \Gamma_c(\mathbf{E}_\ell)$,

$$\Delta_{B,\ell+m}(\nabla^m \mathbf{u}) - \nabla^m(\Delta_{B,\ell}\mathbf{u}) = \sum_{j=0}^{m} \nabla^j \operatorname{Rm} * \nabla^{m-j}\mathbf{u}. \tag{13.50}$$

Here Rm represents $\mathbf{R}^M$ or $\mathbf{R}^{\mathbf{E}}$ according to the term, and $*$ absorbs the tensor contractions and their universal coefficients. Moreover, there exists $C_{\ell,m} > 0$ such that

$$\left|\Delta_{B,\ell+m}(\nabla^m \mathbf{u}) - \nabla^m(\Delta_{B,\ell}\mathbf{u})\right|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}} \le C_{\ell,m} \sum_{q=0}^{m} |\nabla^q \mathbf{u}|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}. \tag{13.51}$$

Proof. Apply Lemma 9.1.41 to the section $\mathbf{u}$ of the bundle $\mathbf{E}_\ell$. That result is formulated for the positive Bochner Laplacians of the induced tensor bundles and gives (13.50) directly.
The curvature of $\mathbf{E}_\ell$ is the sum of the action of $\mathbf{R}^{\mathbf{E}}$ on the bundle factor and the action of $\mathbf{R}^M$ on each of the ℓ covariant factors. Bounded geometry of M and $\mathbf{E}$ bounds all covariant derivatives of these curvatures. Every term on the right-hand side of (13.50) is therefore bounded by a uniform multiple of $|\nabla^{m-j}\mathbf{u}|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}$. The finite sum gives (13.51). □

Proposition 13.3.16. (Perturbed chain of Bochner Laplacians) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, let $\mathbf{E} \to M$ be a bundle of bounded geometry, and let $N \in \mathbb{N}$. For $\ell \in \{0,\dots,N\}$, write

$$\mathbf{E}_\ell := T^{(0,\ell)}(TM) \otimes \mathbf{E}, \qquad \nabla_\ell := \nabla^{\mathbf{E}_\ell} : \Gamma(\mathbf{E}_\ell) \longrightarrow \Gamma(\mathbf{E}_{\ell+1}), \qquad L_{\ell,0} := (\nabla_\ell)_h^* \nabla_\ell = -\operatorname{tr}_{\mathbf{g}}(\nabla_\ell^2) \quad \text{on } \Gamma_c(\mathbf{E}_\ell),$$

, and let $L_{\ell,p}$ be the positive generator of the covariant semigroup on $L^p(M,\mathbf{E}_\ell)$. There exist self-adjoint sections

$$\mathbf{V}_\ell \in \Gamma\big(\operatorname{End}(\mathbf{E}_\ell)\big), \qquad \mathbf{V}_0 = 0,$$

and sections

$$\mathbf{W}_\ell \in \Gamma\big(\operatorname{Hom}(\mathbf{E}_\ell, \mathbf{E}_{\ell+1})\big), \qquad 0 \le \ell < N,$$

satisfying

$$\nabla_\ell (L_{\ell,0} + \mathbf{V}_\ell)\mathbf{u} - (L_{\ell+1,0} + \mathbf{V}_{\ell+1})\nabla_\ell \mathbf{u} = \mathbf{W}_\ell \mathbf{u}, \qquad \mathbf{u} \in \Gamma_c(\mathbf{E}_\ell). \tag{13.52}$$

For each $a \in \mathbb{N}_0$, there exists a constant $C_{N,a} > 0$ such that

$$\sup_{\ell\in\{0,\dots,N\}} \sup_{x\in M} |\nabla^a \mathbf{V}_\ell(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}} + \max_{\ell\in\{0,\dots,N-1\}} \sup_{x\in M} |\nabla^a \mathbf{W}_\ell(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \le C_{N,a}. \tag{13.53}$$

There exists $\mu_N > 0$ such that, for $1 \le p < \infty$ and $\ell \in \{0,\dots,N\}$, the operator

$$B_{\ell,p} := \mu_N I + L_{\ell,p} + \mathbf{V}_\ell, \qquad \mathcal{D}(B_{\ell,p}) = \mathcal{D}(L_{\ell,p}), \tag{13.54}$$

satisfies

$$\|e^{-tB_{\ell,p}}\|_{\mathcal{L}(L^p(M,\mathbf{E}_\ell))} \le e^{-t}, \qquad t \ge 0.$$

In particular, $-(B_{\ell,p} - I)$ generates a contraction C_0-semigroup.

Proof. The bundle $\mathbf{E}_\ell$ is equipped with the product metric and connection. Its curvature is the sum of the action of $\mathbf{R}^\mathbf{E}$ on the factor $\mathbf{E}$ and the action of $\mathbf{R}^M$ on each of the ℓ covariant factors. Therefore, $\mathbf{E}_\ell$ has bounded geometry.

For a vector bundle $\mathbf{F} \to M$ equipped with a bundle metric $\mathbf{h}_\mathbf{F}$ and a compatible connection $\nabla^\mathbf{F}$, define the homomorphisms $\mathcal{V}_\mathbf{F} \in \Gamma(\operatorname{End}(T^*M \otimes \mathbf{F}))$ and $\mathcal{W}_\mathbf{F} \in \Gamma(\operatorname{Hom}(\mathbf{F}, T^*M \otimes \mathbf{F}))$ by

$$(\mathcal{V}_\mathbf{F}\mathbf{a})(\mathbf{X}) = \mathbf{a}(\operatorname{Ric}^\sharp \mathbf{X}) + 2\sum_{i=1}^n \mathbf{R}^\mathbf{F}(\mathbf{e}_i, \mathbf{X})\mathbf{a}(\mathbf{e}_i), \tag{13.55}$$

$$(\mathcal{W}_\mathbf{F}\mathbf{v})(\mathbf{X}) = \sum_{i=1}^n (\nabla_{\mathbf{e}_i} \mathbf{R}^\mathbf{F})(\mathbf{e}_i, \mathbf{X})\mathbf{v}. \tag{13.56}$$

Here $\mathbf{X} \in T_xM$ is arbitrary, $\mathbf{a} \in T_x^*M \otimes \mathbf{F}_x$, $\mathbf{v} \in \mathbf{F}_x$, and $(\mathbf{e}_i)_{i=1}^n$ is an orthonormal basis of T_xM. The sums are metric contractions and hence independent of the basis. The exact first-order identity proved in Lemma 9.1.41 states that

$$\nabla^\mathbf{F} \Delta_B^\mathbf{F} \mathbf{v} - \Delta_B^{T^*M\otimes\mathbf{F}}(\nabla^\mathbf{F}\mathbf{v}) = \mathcal{V}_\mathbf{F}(\nabla^\mathbf{F}\mathbf{v}) + \mathcal{W}_\mathbf{F}\mathbf{v}. \tag{13.57}$$

The homomorphism $\mathcal{V}_\mathbf{F}$ is self-adjoint. Indeed, $\operatorname{Ric}^\sharp$ is symmetric and, for the second term, the block taking component i to component j is $2\mathbf{R}^\mathbf{F}(\mathbf{e}_i, \mathbf{e}_j)$. Metric compatibility of the connection and antisymmetry of the curvature give

$$\big(\mathbf{R}^\mathbf{F}(\mathbf{e}_i, \mathbf{e}_j)\big)^* = -\mathbf{R}^\mathbf{F}(\mathbf{e}_i, \mathbf{e}_j) = \mathbf{R}^\mathbf{F}(\mathbf{e}_j, \mathbf{e}_i),$$

which is exactly the relation between the adjoints of transposed blocks. If $\mathbf{F}$ has bounded geometry, all covariant derivatives of $\mathcal{V}_\mathbf{F}$ and $\mathcal{W}_\mathbf{F}$ are uniformly bounded, since both are obtained by contractions of the curvature of $\mathbf{F}$, of $\mathbf{R}^M$, and of its first covariant derivative.

Define recursively

$$\mathbf{V}_0 := 0, \qquad \mathbf{V}_{\ell+1} := I_{T^*M} \otimes \mathbf{V}_\ell + \mathcal{V}_{\mathbf{E}_\ell}, \qquad \mathbf{W}_\ell := \nabla \mathbf{V}_\ell + \mathcal{W}_{\mathbf{E}_\ell}. \tag{13.58}$$

Here we use the canonical identification $\mathbf{E}_{\ell+1} = T^*M \otimes \mathbf{E}_\ell$. For $\mathbf{u} \in \Gamma_c(\mathbf{E}_\ell)$, the Leibniz rule gives

$$\nabla_\ell(\mathbf{V}_\ell \mathbf{u}) = (I_{T^*M} \otimes \mathbf{V}_\ell)\nabla_\ell \mathbf{u} + (\nabla \mathbf{V}_\ell)\mathbf{u}.$$

Adding this identity to (13.57), with $\mathbf{F} = \mathbf{E}_\ell$, gives

$$\begin{aligned}\nabla_\ell(L_{\ell,0} + \mathbf{V}_\ell)\mathbf{u} - (L_{\ell+1,0} + \mathbf{V}_{\ell+1})\nabla_\ell \mathbf{u} \\ = (\nabla \mathbf{V}_\ell + \mathcal{W}_{\mathbf{E}_\ell})\mathbf{u} = \mathbf{W}_\ell \mathbf{u}.\end{aligned}$$

This is (13.52). Let us verify self-adjointness. The initial case is $\mathbf{V}_0 = 0$. If $\mathbf{V}_\ell$ is self-adjoint, then $I_{T^*M} \otimes \mathbf{V}_\ell$ is self-adjoint for the product metric of $\mathbf{E}_{\ell+1} = T^*M \otimes \mathbf{E}_\ell$; since $\mathcal{V}_{\mathbf{E}_\ell}$ is also self-adjoint, the recurrence (13.58) shows that $\mathbf{V}_{\ell+1}$ is self-adjoint. This completes the induction. To verify the bounds, fix $a \in \mathbb{N}_0$. Denote by $v_{\ell,a}$ a bound for $\|\nabla^a \mathbf{V}_\ell\|_\infty$, and by $A_{\ell,a}, D_{\ell,a}$ the bounds for $\|\nabla^a \mathcal{V}_{\mathbf{E}_\ell}\|_\infty$ and $\|\nabla^a \mathcal{W}_{\mathbf{E}_\ell}\|_\infty$ already obtained from the curvatures. The connection preserves the identity tensor, so (13.58) implies

$$v_{0,a} = 0, \qquad v_{\ell+1,a} \le C_{n,a}\big(v_{\ell,a} + A_{\ell,a}\big), \qquad \ell \in \{0, \dots, N-1\}.$$

This recurrence starts at zero and has exactly N steps. In particular, each $v_{\ell,a}$ is bounded by a finite sum of the $A_{j,a}$ with $j < \ell$, multiplied by powers of $C_{n,a}$. Moreover,

$$\|\nabla^a \mathbf{W}_\ell\|_\infty \le C_{n,a}\big(v_{\ell,a+1} + D_{\ell,a}\big).$$

Bounds at order $a+1$ follow from the same recurrence, independently of those at order a. Taking the maximum over the finitely many indices in the chain gives (13.53). This specifies which derivatives of the potentials enter each constant.

Theorem 12.3.2, applied to $\mathbf{E}_\ell$, states that $-L_{\ell,p}$ generates a contraction semigroup. Multiplication by $\mathbf{V}_\ell$ is a bounded operator on $L^p(M, \mathbf{E}_\ell)$, and its norm is bounded by the supremum norm of its values as operators on the fibers. If $\mathbf{h}_{\mathbf{E}_\ell}$ denotes the product metric induced by $\mathbf{g}$ and $\mathbf{h}_{\mathbf{E}}$, set

$$\|\mathbf{V}_\ell\|_{\infty,\mathrm{op}} := \operatorname*{ess\,sup}_{x \in M} \sup_{0 \neq v \in (\mathbf{E}_\ell)_x} \frac{|\mathbf{V}_\ell(x)v|_{\mathbf{h}_{\mathbf{E}_\ell}}}{|v|_{\mathbf{h}_{\mathbf{E}_\ell}}}.$$

Thus, the norm of the multiplication operator does not exceed

$$\|\mathbf{V}_\ell\|_{\infty,\mathrm{op}}.$$

Choose

$$\mu_N \ge 1 + \max_{\ell \in \{0,\dots,N\}} \|\mathbf{V}_\ell\|_{\infty,\mathrm{op}}.$$

Proposition B.4.17, applied to the generator $-L_{\ell,p}$ and perturbation $-\mathbf{V}_\ell$, gives

$$\|e^{-tB_{\ell,p}}\|_{\mathcal{L}(L^p(M,\mathbf{E}_\ell))} \le \exp\big(-t\big(\mu_N - \|\mathbf{V}_\ell\|_{\infty,\mathrm{op}}\big)\big) \le e^{-t}.$$

Finally,

$$e^{-t(B_{\ell,p}-I)} = e^t e^{-tB_{\ell,p}},$$

so $\|e^{-t(B_{\ell,p}-I)}\|_{\mathcal{L}(L^p(M,\mathbf{E}_\ell))} \le 1$. This is the contraction semigroup generated by $-(B_{\ell,p}-I)$. □

The preceding differential identity will also be used for sections without compact support. For this, we need to identify the operator's L^2 domain, not only its local expression.

Lemma 13.3.17. (Maximal domain of the perturbed Laplacian) Let $(\mathbf{F},\mathbf{h}_\mathbf{F},\nabla^\mathbf{F}) \to M$ be a bundle of bounded geometry over a manifold without boundary and with bounded geometry. Let $\mathbf{V}$ be a smooth, bounded, self-adjoint endomorphism, and let $B = L_{\mathbf{F},2}+\mathbf{V}+\mu I$ be the realization through the energy form. If $\mathbf{w},\mathbf{f} \in L^2(M,\mathbf{F})$ and $B\mathbf{w} = \mathbf{f}$ distributionally, then $\mathbf{w} \in \mathcal{D}(B)$ and the equality holds in L^2.

Proof. Local elliptic regularity gives $\mathbf{w} \in H^2_{\mathrm{loc}}$. Take the cutoffs χ_J constructed in the proof of Proposition 13.3.14. They have compact support, satisfy $0 \le \chi_J \le 1$, converge locally to one, and $|d\chi_J| \le C$ with a constant independent of J. Test the equation against $\chi_J^2\mathbf{w}$, using a smooth approximation on its support. The real part of integration by parts gives

$$\begin{aligned}\|\chi_J\nabla\mathbf{w}\|^2_{L^2(M,T^*M\otimes\mathbf{F})} &\le \|\mathbf{f}\|_{L^2(M,\mathbf{F})}\|\mathbf{w}\|_{L^2(M,\mathbf{F})}\\ &\quad + (\|\mathbf{V}\|_\infty + |\mu|)\|\mathbf{w}\|^2_{L^2(M,\mathbf{F})}\\ &\quad + 2\|\chi_J\nabla\mathbf{w}\|_{L^2(M,T^*M\otimes\mathbf{F})}\big\||d\chi_J|\mathbf{w}\big\|_{L^2(M,\mathbf{F})}.\end{aligned}$$

Young's inequality allows half of the energy term to be absorbed and gives a bound independent of J. Fatou implies $\nabla\mathbf{w} \in L^2$. Compactly supported density from the cited proposition then shows that $\mathbf{w}$ belongs to the form domain. For every test section $\boldsymbol{\varphi}$,

$$\int_M \langle\nabla\mathbf{w},\nabla\boldsymbol{\varphi}\rangle\, d\lambda_\mathbf{g} + \int_M \langle(\mathbf{V}+\mu I)\mathbf{w},\boldsymbol{\varphi}\rangle\, d\lambda_\mathbf{g} = \int_M \langle\mathbf{f},\boldsymbol{\varphi}\rangle\, d\lambda_\mathbf{g}.$$

All three terms are continuous for the form norm; density extends the equality to the entire form domain. The definition of the operator associated with a closed form gives $\mathbf{w} \in \mathcal{D}(B)$ and $B\mathbf{w} = \mathbf{f}$. □

The identification of fractional domains needed below will be obtained by interpolation. Before using functional calculus, it is useful to record interpolation of the covariant spaces at the two integer orders entering the square root.

Proposition 13.3.18. (Interpolation between orders zero and two for bundles) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, and let $\mathbf{F} \to M$ be a finite-rank bundle of bounded geometry. If $1 < p < \infty$, then

$$[L^p(M,\mathbf{F}), W^{2,p}(M,\mathbf{F})]_{1/2} = W^{1,p}(M,\mathbf{F}) \tag{13.59}$$

with equivalence of norms.

Proof. If $\mathbf{F}$ is real, perform interpolation in the complexified bundle and restrict to the real subspace at the end; the connection, metric, and localization operators complexify without changing their norms on real sections. Use the same geodesic trivialization $\mathcal{T}^{\mathrm{geo}} = (U_i,\varphi_i,h_i)_{i\in I}$ and synchronous frames $\mathbf{e}_i = (\mathbf{e}_{i,1},\dots,\mathbf{e}_{i,r})$ as in Proposition 13.3.14. As in the definition of an admissible trivialization, choose functions $\chi_i \in C^\infty_c(U_i)$

such that

$$\chi_i = 1 \quad \text{on a neighborhood of } \operatorname{supp}(h_i),$$

and whose derivatives in coordinates φ_i are uniformly bounded in i. Denote their extensions by zero by

$$\widetilde{\chi}_i := \widetilde{\chi_i \circ \varphi_i^{-1}} \in C_c^\infty(\mathbb{R}^n)$$

.

For $k \in \{0,1,2\}$, define the analysis operator

$$\mathcal{S}_{\mathbf{F}}\mathbf{u} := \left(\widetilde{(h_i u_i^a) \circ \varphi_i^{-1}}\right)_{(i,a)\in I\times\{1,\dots,r\}}, \qquad \mathbf{u} \restriction_{U_i} = \sum_{a=1}^{r} u_i^a \mathbf{e}_{i,a}.$$

Proposition 13.3.14 shows that $\mathcal{S}_{\mathbf{F}}$ is continuous from $W^{k,p}(M,\mathbf{F})$ to

$$\ell^p\left(I \times \{1,\dots,r\}; W^{k,p}(\mathbb{R}^n)\right),$$

with a norm depending on k,p and the uniform data, but not on the chart.

Construct a synthesis operator that works simultaneously at all three orders. If $v = (v_i^a)_{i,a}$ is a family with finitely many nonzero components and each $v_i^a \in C_c^\infty(\mathbb{R}^n)$, set

$$\mathcal{R}_{\mathbf{F}} v := \sum_{i\in I}\sum_{a=1}^{r} \left[\left((\widetilde{\chi}_i v_i^a) \restriction_{\varphi_i(U_i)}\right) \circ \varphi_i\right] \mathbf{e}_{i,a}, \tag{13.60}$$

where each summand is extended by zero outside U_i. The product with χ_i has compact support in U_i, so this extension is smooth. For a general family, the formula is first interpreted on each compact set: only uniformly finitely many charts contribute, and the sum is locally finite.

We prove continuity of synthesis. In a chart U_j, the components of the ith summand of (13.60) are obtained from $v_i = (v_i^1,\dots,v_i^r)$ through three operations: multiplication by a cutoff with uniformly bounded derivatives, a coordinate change $\varphi_i \circ \varphi_j^{-1}$, and multiplication by the transition matrix between the synchronous frames $\mathbf{e}_i$ and $\mathbf{e}_j$. The bounded-geometry bounds for synchronous frames and geodesic transitions imply that, for $k \in \{0,1,2\}$, these three operations are bounded on $W^{k,p}$ with a constant independent of i,j. If I_j denotes the set of indices whose charts meet U_j, there exists $L \geq 1$ with $\#I_j \leq L$. By the inequality

$$\left(\sum_{i\in I_j} a_i\right)^p \leq L^{p-1} \sum_{i\in I_j} a_i^p, \qquad a_i \geq 0,$$

the local equivalence of Proposition 13.3.14 gives

$$\|\mathcal{R}_{\mathbf{F}} v\|_{W^{k,p}(M,\mathbf{F})} \leq C_{k,p} \|v\|_{\ell^p(I\times\{1,\dots,r\};W^{k,p}(\mathbb{R}^n))}, \qquad k \in \{0,1,2\}. \tag{13.61}$$

By density, $\mathcal{R}_{\mathbf{F}}$ extends continuously to all three sequence spaces.

If $v = \mathcal{S}_{\mathbf{F}}\mathbf{u}$, the equality $\chi_i = 1$ near $\operatorname{supp}(h_i)$ makes the ith reconstructed term exactly $h_i\mathbf{u}$. Since $(h_i)_{i\in I}$ is a

partition of unity,

$$\mathcal{R}_{\mathbf{F}}\mathcal{S}_{\mathbf{F}}\mathbf{u} = \sum_{i\in I} h_i \mathbf{u} = \mathbf{u}. \tag{13.62}$$

Thus, the same analysis–synthesis pair is a coretraction–retraction at orders $0, 1, 2$.
By Theorem 6.3.14 and interpolation of the Euclidean Bessel scale,

$$[L^p(\mathbb{R}^n), W^{2,p}(\mathbb{R}^n)]_{1/2} = W^{1,p}(\mathbb{R}^n)$$

with equivalent norms. Proposition 5.7.12 allows us to take the outer ℓ^p sum and the finitely many bundle components. Now interpolate $\mathcal{S}_{\mathbf{F}}$ and $\mathcal{R}_{\mathbf{F}}$ between orders 0 and 2 and use (13.62). This gives both inclusions in (13.59), and the endpoint operator norms provide the equivalence constants. □

The second tool is a global elliptic L^p estimate with uniform constants. We prove it directly for the operators in the chain, making explicit the constants that will be used for the square root.

Proposition 13.3.19. (L^p domain of the chain operators) Under the hypotheses of Proposition 13.3.16, let $1 < p < \infty$. For each $\ell \in \{0, \dots, N\}$,

$$\mathcal{D}(B_{\ell,p}) = W^{2,p}(M, \mathbf{E}_\ell) \tag{13.63}$$

and there exist constants $c^{(2)}_{\ell,p}, C^{(2)}_{\ell,p} > 0$ such that

$$c^{(2)}_{\ell,p}\|\mathbf{u}\|_{W^{2,p}(M,\mathbf{E}_\ell)} \le \|B_{\ell,p}\mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} \le C^{(2)}_{\ell,p}\|\mathbf{u}\|_{W^{2,p}(M,\mathbf{E}_\ell)}. \tag{13.64}$$

The constants can be chosen uniformly as ℓ ranges over the finite set $\{0, \dots, N\}$.

Proof. Fix ℓ and denote by

$$\mathcal{B}_\ell := \mu_N I + L_{\ell,0} + \mathbf{V}_\ell$$

the smooth differential expression whose realization is $B_{\ell,p}$. In a uniform geodesic chart and the synchronous frame of $\mathbf{E}_\ell$, this operator has the form

$$\mathcal{B}_i = -g_i^{ab}(x)\partial_a\partial_b + A_i^a(x)\partial_a + C_i(x). \tag{13.65}$$

The matrices A_i^a, C_i and all derivatives we will need are uniformly bounded; the same holds for g_i^{ab} and its derivatives. There are constants $0 < \lambda_0 \le \Lambda_0 < \infty$, independent of i, such that

$$\lambda_0|\xi|^2 \le g_i^{ab}(x)\xi_a\xi_b \le \Lambda_0|\xi|^2. \tag{13.66}$$

These bounds follow from the metric criterion for bounded geometry and the bounds of Proposition 13.3.16.
We begin with a constant-coefficient estimate. For a point x_0 in the chart, set

$$q_{x_0}(\xi) := g_i^{ab}(x_0)\xi_a\xi_b, \qquad P_{x_0} := -g_i^{ab}(x_0)\partial_a\partial_b.$$

If $|\alpha| \le 2$, the symbol

$$m_{\alpha,x_0}(\xi) := \frac{(i\xi)^\alpha}{1 + q_{x_0}(\xi)}$$

satisfies the hypotheses of Theorem 6.3.1 with constants independent of x_0 and i. Indeed, differentiating it r times gives a finite sum of quotients whose denominators are powers of $1 + q_{x_0}$ and whose numerators are polynomials in ξ with coefficients bounded by λ_0, Λ_0; using (13.66) gives

$$|D_\xi^\beta m_{\alpha,x_0}(\xi)| \le C_{\alpha,\beta} |\xi|^{-|\beta|}, \qquad \xi \neq 0,$$

for every multi-index required by Mikhlin. Therefore,

$$\|v\|_{W^{2,p}(\mathbb{R}^n)} \le C_p \|(I + P_{x_0})v\|_{L^p(\mathbb{R}^n)}, \qquad v \in C_c^\infty(\mathbb{R}^n), \tag{13.67}$$

with C_p independent of x_0 and i.

We will also use an elementary intermediate-order inequality. For $0 < \varepsilon \le 1$ and $j \in \{1, \dots, n\}$, the symbol

$$\frac{i\varepsilon\xi_j}{1 + \varepsilon^2|\xi|^2}$$

and its Mikhlin derivatives are uniformly bounded in ε. Applying it to $(I - \varepsilon^2\Delta)v$ and summing over j gives

$$\|Dv\|_{L^p(\mathbb{R}^n)} \le C_p \left(\varepsilon \|D^2 v\|_{L^p(\mathbb{R}^n)} + \varepsilon^{-1} \|v\|_{L^p(\mathbb{R}^n)} \right), \qquad v \in W^{2,p}(\mathbb{R}^n). \tag{13.68}$$

The first derivatives of g_i^{ab} have a uniform bound. Choose $r > 0$ independent of the chart and small enough that, on every Euclidean ball of radius $2r$ contained in a larger chart,

$$\|g_i^{ab} - g_i^{ab}(x_0)\|_{L^\infty(B_{\mathrm{euc}}(x_0, 2r))} \le \delta,$$

where $\delta > 0$ is fixed so that the corresponding term can be absorbed in (13.67). If $v \in C_c^\infty(B_{\mathrm{euc}}(x_0, 2r))$, write

$$(I + P_{x_0})v = \mathcal{B}_i v + (g_i^{ab} - g_i^{ab}(x_0))\partial_a\partial_b v - A_i^a \partial_a v + (I - C_i)v.$$

The constant-coefficient estimate, the choice of δ, and (13.68), with ε sufficiently small and then fixed, give

$$\|v\|_{W^{2,p}(\mathbb{R}^n)} \le C \left(\|\mathcal{B}_i v\|_{L^p(\mathbb{R}^n)} + \|v\|_{L^p(\mathbb{R}^n)} \right), \tag{13.69}$$

with a constant independent of the chart.

The compactly supported estimate implies an interior estimate without assuming a global second-order norm a priori. Let $r \le s < t \le 2r$, and choose $\zeta_{s,t} \in C_c^\infty(B_{\mathrm{euc}}(x_0, t))$ such that $\zeta_{s,t} = 1$ on $B_{\mathrm{euc}}(x_0, s)$ and

$$|D\zeta_{s,t}| \le C(t-s)^{-1}, \qquad |D^2\zeta_{s,t}| \le C(t-s)^{-2}.$$

If u is smooth on a neighborhood of $\overline{B_{\mathrm{euc}}(x_0, 2r)}$, apply (13.69) to $\zeta_{s,t}u$. The Leibniz rule gives

$$\|D^2 u\|_{L^p(B_s)} \le C\|\mathcal{B}_i u\|_{L^p(B_t)} + \frac{C}{t-s}\|Du\|_{L^p(B_t)} + C\left(1 + \frac{1}{(t-s)^2}\right)\|u\|_{L^p(B_t)}. \tag{13.70}$$

Here and in the next two formulas, we abbreviate $B_\rho = B_{\mathrm{euc}}(x_0,\rho)$.

We need to eliminate the first-order term on the right-hand side. The balls B_t, $r \le t \le 2r$, are Lipschitz domains obtained from one another by dilations with factors in the compact interval $[1,2]$. Extend $u\restriction_{B_t}$ by Theorem 3.6.2 and apply (13.68) to the extension. The second-order estimate for the extension operator also contains $\|Du\|_{L^p(B_t)}$; multiply by the small parameter in the interpolation inequality and absorb that term into the left-hand side. Since the radii lie in the fixed interval $[r,2r]$, the extension and absorption constants are uniform. We thus obtain

$$\|Du\|_{L^p(B_t)} \le \eta \|D^2 u\|_{L^p(B_t)} + C\eta^{-1}\|u\|_{L^p(B_t)}, \qquad 0<\eta\le\eta_0. \tag{13.71}$$

Take $\eta = \varepsilon(t-s)$, with $\varepsilon>0$ fixed and sufficiently small. If

$$\Phi(\rho) := \|D^2 u\|_{L^p(B_\rho)},$$

the preceding two estimates give numbers $0<\vartheta<1$ and $C>0$, independent of the chart, such that

$$\Phi(s) \le \vartheta\Phi(t) + C\|\mathcal{B}_i u\|_{L^p(B_{2r})} + \frac{C}{(t-s)^2}\|u\|_{L^p(B_{2r})}, \qquad r\le s<t\le 2r. \tag{13.72}$$

To iterate this inequality, choose $\rho\in(\sqrt{\vartheta},1)$ and set

$$r_k := 2r - r\rho^k, \qquad k\in\mathbb{N}_0.$$

Then $r_0 = r$, $r_k \uparrow 2r$, and $r_{k+1}-r_k = r(1-\rho)\rho^k$. Iterating (13.72) m times gives

$$\begin{aligned}\Phi(r) \le \vartheta^m\Phi(r_m) &+ C\sum_{k=0}^{m-1}\vartheta^k\|\mathcal{B}_i u\|_{L^p(B_{2r})}\\ &+ \frac{C}{r^2(1-\rho)^2}\sum_{k=0}^{m-1}\Big(\frac{\vartheta}{\rho^2}\Big)^k\|u\|_{L^p(B_{2r})}.\end{aligned}$$

Since u is smooth on a neighborhood of $\overline{B_{2r}}$, $\Phi(2r)<\infty$, so $\vartheta^m\Phi(r_m)\to 0$. Both geometric series converge, and, since r is the same in all charts, we arrive at

$$\|u\|_{W^{2,p}(B_r)} \le C\left(\|\mathcal{B}_i u\|_{L^p(B_{2r})} + \|u\|_{L^p(B_{2r})}\right). \tag{13.73}$$

The first-order component is recovered from (13.71); the order-zero terms are already on the right-hand side.

To obtain the global estimate, sum the interior estimates over a cover of bounded multiplicity. Use the geodesic trivialization of Theorem 13.1.22: the balls $V_i := B_{\mathbf{g}}(p_i,r)$ cover M, and the larger balls $U_i := B_{\mathbf{g}}(p_i,2r)$ have uniformly bounded multiplicity. In normal coordinates and synchronous frames, uniform comparison of covariant and Euclidean norms, together with (13.73), gives, for every smooth section $\mathbf{u}$ with $\mathbf{u},\mathcal{B}_\ell\mathbf{u}\in L^p$,

$$\|\mathbf{u}\|^p_{W^{2,p}(M,\mathbf{E}_\ell)} \le C\sum_{i\in I}\|\mathbf{u}\|^p_{W^{2,p}(V_i,\mathbf{E}_\ell)}$$

$$\le C \sum_{i\in I} \left(\|\mathcal{B}_\ell \mathbf{u}\|^p_{L^p(U_i,\mathbf{E}_\ell)} + \|\mathbf{u}\|^p_{L^p(U_i,\mathbf{E}_\ell)} \right)$$
$$\le C \left(\|\mathcal{B}_\ell \mathbf{u}\|^p_{L^p(M,\mathbf{E}_\ell)} + \|\mathbf{u}\|^p_{L^p(M,\mathbf{E}_\ell)} \right).$$

Consequently,

$$\|\mathbf{u}\|_{W^{2,p}(M,\mathbf{E}_\ell)} \le C \left(\|\mathcal{B}_\ell \mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} + \|\mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} \right). \tag{13.74}$$

All sums have nonnegative terms; the last inequality uses only the uniform multiplicity bound of (U_i). Thus, the argument is valid even when the global second-order norm is not known to be finite beforehand: the interior estimate makes each summand finite, and Tonelli allows them to be summed directly.
The realization $B_{\ell,p}$ has a bounded inverse given by

$$B^{-1}_{\ell,p}\mathbf{f} = \int_0^\infty e^{-tB_{\ell,p}}\mathbf{f}\, dt,$$

and estimate $\|e^{-tB_{\ell,p}}\| \le e^{-t}$ of Proposition 13.3.16 implies

$$\|B^{-1}_{\ell,p}\|_{\mathcal{L}(L^p(M,\mathbf{E}_\ell))} \le 1. \tag{13.75}$$

Now let $\mathbf{f} \in L^p(M,\mathbf{E}_\ell)$. Choose $\mathbf{f}_j \in \Gamma_c(\mathbf{E}_\ell)$ with $\mathbf{f}_j \to \mathbf{f}$ in L^p and set $\mathbf{u}_j = B^{-1}_{\ell,p}\mathbf{f}_j$. Consistency of the semigroups as p varies shows that, since $\mathbf{f}_j \in L^2 \cap L^p$,

$$\mathbf{u}_j = B^{-1}_{\ell,2}\mathbf{f}_j.$$

Local elliptic regularity applied to $\mathcal{B}_\ell \mathbf{u}_j = \mathbf{f}_j$ shows that $\mathbf{u}_j$ is smooth. Applying (13.74) to $\mathbf{u}_j - \mathbf{u}_k$ and using (13.75) gives

$$\|\mathbf{u}_j - \mathbf{u}_k\|_{W^{2,p}(M,\mathbf{E}_\ell)} \le C\|\mathbf{f}_j - \mathbf{f}_k\|_{L^p(M,\mathbf{E}_\ell)}.$$

By completeness, $\mathbf{u}_j$ converges in $W^{2,p}$ to a section $\mathbf{v}$. At the same time, $\mathbf{u}_j \to B^{-1}_{\ell,p}\mathbf{f}$ in L^p, so $\mathbf{v} = B^{-1}_{\ell,p}\mathbf{f}$. Thus, $\mathcal{D}(B_{\ell,p}) \subseteq W^{2,p}$ and

$$\|\mathbf{u}\|_{W^{2,p}(M,\mathbf{E}_\ell)} \le C\|B_{\ell,p}\mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)}, \qquad \mathbf{u} \in \mathcal{D}(B_{\ell,p}).$$

For the opposite inclusion, let $\mathbf{u} \in W^{2,p}(M,\mathbf{E}_\ell)$. Compactly supported density from Proposition 13.3.14 provides $\mathbf{u}_j \in \Gamma_c(\mathbf{E}_\ell)$ with $\mathbf{u}_j \to \mathbf{u}$ in $W^{2,p}$. The local expression (13.65) shows that $\mathcal{B}_\ell \mathbf{u}_j$ converges in L^p. Since $B_{\ell,p}$ is closed and agrees with $\mathcal{B}_\ell$ on compactly supported sections, it follows that $\mathbf{u} \in \mathcal{D}(B_{\ell,p})$. The evident continuity of the second-order differential expression gives the right-hand inequality in (13.64). This proves (13.63) and equivalence of norms. Since the chain contains only finitely many bundles and all geometric data involved have uniform bounds, the constants may be taken uniformly in ℓ. □

To pass from order two to order one, we need a bound on imaginary powers. We will prove it within the book using a Bellman function and the Poisson semigroup. The algebraic part is separated into the following lemma.

Lemma 13.3.20. (Bellman function for two Hilbert norms) Let $2 \le p < \infty$ and $q = p/(p-1)$. There exist constants $\delta_p, c_p, C_p > 0$ and a function $\mathcal{B}_p \colon H_1 \times H_2 \to [0,\infty)$, defined for any real Hilbert spaces H_1, H_2, with the following properties.

(a) $\mathcal{B}_p$ is of class C^1, is C^2 away from the hypersurface $|\xi|^p = |\eta|^q$ and the axes, and

$$0 \le \mathcal{B}_p(\xi,\eta) \le C_p\left(|\xi|^p + |\eta|^q\right).$$

(b) Its radial derivatives are nonnegative.

(c) At every point of second-order differentiability, there exists $\tau = \tau(\xi,\eta) > 0$ such that, for $a \in H_1$ and $b \in H_2$,

$$d^2\mathcal{B}_p(\xi,\eta)[(a,b),(a,b)] \geq c_p\big(\tau|a|^2 + \tau^{-1}|b|^2\big). \tag{13.76}$$

In particular,

$$d^2\mathcal{B}_p(\xi,\eta)[(a,b),(a,b)] \geq 2c_p|a||b|. \tag{13.77}$$

(d) With the same choice of τ,

$$|d\mathcal{B}_p(\xi,\eta)[(a,b)]|^2 \leq C_p\mathcal{B}_p(\xi,\eta)\big(\tau|a|^2 + \tau^{-1}|b|^2\big). \tag{13.78}$$

The constants depend only on p, not on the dimensions of H_1, H_2.

Proof. For $u, v \geq 0$, set

$$\beta_p(u,v) := u^p + v^q + \delta_p \begin{cases} u^2v^{2-q}, & u^p \leq v^q, \\ \dfrac{2}{p}u^p + \left(\dfrac{2}{q} - 1\right)v^q, & u^p \geq v^q. \end{cases}$$

On the boundary $u^p = v^q$, the two additional expressions agree. Indeed, there $v = u^{p-1}$ and $u^2v^{2-q} = u^p$, while $\frac{2}{p} + \frac{2}{q} - 1 = 1$. The first derivatives also agree:

$$2uv^{2-q} = 2u^{p-1}, \qquad (2-q)u^2v^{1-q} = (2-q)v^{q-1}.$$

Thus, β_p is C^1. Define

$$\mathcal{B}_p(\xi,\eta) := \beta_p(|\xi|,|\eta|).$$

The bound in item (a) follows from $u^2v^{2-q} \leq v^q$ when $u^p \leq v^q$ and from the definition in the other region. The radial derivatives are nonnegative if $0 < \delta_p \leq 1$.
We verify quantitative convexity. First suppose that $u^p \leq v^q$ and set

$$\tau := v^{2-q}.$$

The relation $u \leq v^{q-1}$ implies

$$u^{p-2} \leq v^{2-q}, \qquad u^2v^{-q} \leq v^{q-2}, \qquad uv^{1-q} \leq 1.$$

The second derivatives of the correction u^2v^{2-q} are

$$2v^{2-q}, \qquad 2(2-q)uv^{1-q}, \qquad -(2-q)(q-1)u^2v^{-q}.$$

Consequently,

$$\partial_{uu}\beta_p \geq 2\delta_p\tau,$$

$$\partial_{vv}\beta_p \geq (q-1)\big(q - \delta_p(2-q)\big)\tau^{-1}, \qquad |\partial_{uv}\beta_p| \leq 2\delta_p(2-q).$$

Choose $\delta_p > 0$ small enough that $q - \delta_p(2-q) \geq q/2$ and the mixed term can be absorbed using

$$2|ab| \leq \varepsilon\tau a^2 + \varepsilon^{-1}\tau^{-1}b^2.$$

Thus, for some $c_p > 0$,

$$\partial_{uu}\beta_p\, a^2 + 2\partial_{uv}\beta_p\, ab + \partial_{vv}\beta_p\, b^2 \geq c_p(\tau a^2 + \tau^{-1}b^2). \tag{13.79}$$

Moreover,

$$\frac{\partial_u\beta_p}{u} \geq 2\delta_p\tau, \qquad \frac{\partial_v\beta_p}{v} \geq q\tau^{-1}.$$

If $u^p \geq v^q$, set $\tau := u^{p-2}$. The correction is diagonal, and the relation $v \leq u^{p-1}$, together with $q-2 \leq 0$, gives

$$v^{q-2} \geq u^{2-p} = \tau^{-1}.$$

Hence,

$$\partial_{uu}\beta_p\, a^2 + \partial_{vv}\beta_p\, b^2 \geq c_p(\tau a^2 + \tau^{-1}b^2), \tag{13.80}$$

and the same bounds, with another constant, hold for $(\partial_u\beta_p)/u$ and $(\partial_v\beta_p)/v$.
For a radial function of two Hilbert-space variables, the Hessian decomposes into its radial and orthogonal parts. Suppose $u = |\xi| > 0$ and $v = |\eta| > 0$, and define the signed radial components

$$a_{\mathrm{r}} := \left\langle a, \frac{\xi}{u} \right\rangle_{H_1}, \qquad b_{\mathrm{r}} := \left\langle b, \frac{\eta}{v} \right\rangle_{H_2}.$$

The corresponding orthogonal decompositions are

$$a = a_{\parallel} + a_{\perp}, \qquad a_{\parallel} = a_{\mathrm{r}}\frac{\xi}{u}, \qquad \langle a_{\perp}, \xi\rangle_{H_1} = 0,$$

$$b = b_{\parallel} + b_{\perp}, \qquad b_{\parallel} = b_{\mathrm{r}}\frac{\eta}{v}, \qquad \langle b_{\perp}, \eta\rangle_{H_2} = 0.$$

Differentiating the norm along the line $\xi + ta$ gives

$$\frac{d}{dt}|\xi + ta|\Big|_{t=0} = a_{\mathrm{r}},$$
$$\frac{d^2}{dt^2}|\xi + ta|\Big|_{t=0} = \frac{|a|^2 - a_{\mathrm{r}}^2}{u} = \frac{|a_{\perp}|^2}{u}.$$

The formulas for $\eta + tb$ are analogous. The chain rule then gives, in each region of second-order differentiability,

$$d^2\mathcal{B}_p(\xi,\eta)[(a,b),(a,b)] = (\partial_{uu}\beta_p)a_{\mathrm{r}}^2 + 2(\partial_{uv}\beta_p)a_{\mathrm{r}}b_{\mathrm{r}} + (\partial_{vv}\beta_p)b_{\mathrm{r}}^2 + \frac{\partial_u\beta_p}{u}|a_{\perp}|^2 + \frac{\partial_v\beta_p}{v}|b_{\perp}|^2,$$

where the derivatives of β_p are evaluated at (u,v). Apply (13.79) to the real numbers $a_{\mathrm{r}}, b_{\mathrm{r}}$ in the first region, and (13.80) in the second. Together with the bounds for $(\partial_u\beta_p)/u$ and $(\partial_v\beta_p)/v$, and decreasing c_p if

necessary, this gives

$$d^2\mathcal{B}_p(\xi,\eta)[(a,b),(a,b)] \geq c_p\big(\tau(a_{\mathrm{r}}^2+|a_\perp|^2)+\tau^{-1}(b_{\mathrm{r}}^2+|b_\perp|^2)\big) = c_p\big(\tau|a|^2+\tau^{-1}|b|^2\big).$$

This proves (13.76). The inequality $\tau A^2+\tau^{-1}B^2 \geq 2AB$ gives (13.77).
The gradient bound remains. In the first region, the relations already used give

$$|\partial_u\beta_p| \leq C_p u\tau, \qquad |\partial_v\beta_p| \leq C_p v\tau^{-1},$$

and therefore

$$\frac{|\partial_u\beta_p|^2}{\tau}+|\partial_v\beta_p|^2\tau \leq C_p(u^p+v^q) \leq C_p\beta_p(u,v).$$

In the second region, write $v=u^{p-1}\rho$, with $0\leq\rho\leq 1$. Since $q-1=1/(p-1)$, we have

$$v^{2q-2}u^{p-2} = u^p\rho^{2(q-1)} \leq u^p,$$

and the explicit formulas for $\partial_u\beta_p$ and $\partial_v\beta_p$ give

$$|\partial_u\beta_p|^2\tau^{-1}+|\partial_v\beta_p|^2\tau \leq C_p(u^p+v^q).$$

The Cauchy–Schwarz inequality with weights τ,τ^{-1} proves (13.78). Points on the axes follow by taking limits. When $p=2$, we have $q=2$, and the same function reduces to a piecewise quadratic form whose pieces agree globally; the preceding argument remains valid with $\tau=1$. □

Theorem 13.3.21. (Laplace multipliers and imaginary powers of Bochner–Schrödinger operators) Let $(M,\mathbf{g})$ be a complete Riemannian manifold without boundary, and let $\mathbf{F}\to M$ be a real or Hermitian vector bundle of finite rank equipped with a bundle metric and a compatible connection. Let $\mathbf{W}\in\Gamma(\mathrm{End}(\mathbf{F}))$ be smooth and self-adjoint, and suppose that

$$\langle \mathbf{W}(x)v,v\rangle \geq |v|^2 \quad \text{for every } x\in M, \quad v\in\mathbf{F}_x. \tag{13.81}$$

Let $B_2=L_{\mathbf{F},2}+\mathbf{W}$ be the self-adjoint realization on L^2, and suppose that its semigroup extends consistently to semigroups C_0 on $L^r(M,\mathbf{F})$, $1\leq r<\infty$, satisfying

$$\|e^{-sB_r}\|_{\mathcal{L}(L^r)} \leq e^{-s}, \qquad s\geq 0. \tag{13.82}$$

If $\mathbf{F}$ is real, the complex powers and multipliers below are understood on the complexification, and the estimates are subsequently restricted to real sections whenever the corresponding operator preserves that subspace. Then, for every $1<p<\infty$, the spectral powers B_2^{it} extend consistently to a C_0 group of bounded operators B_p^{it} on $L^p(M,\mathbf{F})$. There exist constants $C_p,\omega_p>0$, independent of the dimension of M and the rank of $\mathbf{F}$, such that

$$\|B_p^{it}\|_{\mathcal{L}(L^p(M,\mathbf{F}))} \leq C_p e^{\omega_p|t|}, \qquad t\in\mathbb{R}. \tag{13.83}$$

More generally, if $C_2:=B_2^{1/2}$ and, for $1<p<\infty$, $-C_p$ denotes the generator of the subordinated Poisson

semigroup on $L^p(M,\mathbf{F})$, and if $\psi \in L^\infty(0,\infty)$, then the spectral multiplier

$$m_\psi(C_2), \qquad m_\psi(\lambda) := \lambda \int_0^\infty \psi(s) e^{-s\lambda}\, ds, \quad \lambda \geq 1, \tag{13.84}$$

extends to L^p and

$$\|m_\psi(C_p)\|_{\mathcal{L}(L^p)} \leq C_p \|\psi\|_{L^\infty(0,\infty)}. \tag{13.85}$$

Proof. The proof is first carried out for compactly supported sections and then extended to L^p by density. If the bundle is complex, regard it as a real bundle with inner product given by the real part of the Hermitian metric; the norms are unchanged.

The Poisson semigroup. For $t > 0$ and $1 \leq r < \infty$, define

$$P_t^{(r)}\mathbf{f} := \frac{t}{2\sqrt{\pi}} \int_0^\infty s^{-3/2} e^{-\frac{t^2}{4s}} e^{-sB_r}\mathbf{f}\, ds. \tag{13.86}$$

The integral is a Bochner integral. The scalar subordination identity

$$e^{-t\sqrt{\lambda}} = \frac{t}{2\sqrt{\pi}} \int_0^\infty s^{-3/2} e^{-\frac{t^2}{4s}} e^{-s\lambda}\, ds, \qquad \lambda > 0,$$

follows by the substitution $u = t/(2\sqrt{s})$ in the Gaussian integral. On L^2, the spectral theorem shows that $P_t^{(2)} = e^{-tC_2}$. Moreover, (13.82) and the same formula with $\lambda = 1$ give

$$\|P_t^{(r)}\|_{\mathcal{L}(L^r)} \leq e^{-t}. \tag{13.87}$$

Consistency of the heat semigroups implies consistency of the $P_t^{(r)}$. For $1 < r < \infty$, denote the generator of $(P_t^{(r)})_{t\geq 0}$ by $-C_r$. On L^2, we have $C_2 = B_2^{1/2}$, and consistency shows that the resolvents and Laplace calculi of the operators C_r agree on intersections of the spaces L^r.

Let $\mathbf{f} \in \Gamma_c(\mathbf{F})$. For $t > 0$, $\mathbf{U}(t) := P_t^{(2)}\mathbf{f}$ belongs to the domain of every power of B_2, since $\lambda^m e^{-t\sqrt{\lambda}}$ is bounded on $[1,\infty)$ for each m. Local elliptic regularity implies that $\mathbf{U}$ is smooth on $(0,\infty)\times M$, and spectral calculus gives

$$\partial_t^2 \mathbf{U} = B_2\mathbf{U} = -\operatorname{tr}_{\mathbf{g}}(\nabla^2\mathbf{U}) + \mathbf{W}\mathbf{U}. \tag{13.88}$$

Bilinear estimate. Let p, q be conjugate exponents. By symmetry, we may assume $p \geq 2$; if $p < 2$, interchange p, q and the two sections. Let $\mathbf{f} \in \Gamma_c(\mathbf{F})$ and $\mathbf{g} \in \Gamma_c(\mathbf{F})$, and set

$$\mathbf{U}(t) = P_t\mathbf{f}, \qquad \mathbf{V}(t) = P_t\mathbf{g}.$$

Apply Lemma 13.3.20 to the real fibers of $\mathbf{F}$ and write

$$b_\varepsilon(t,x) := \mathcal{B}_p\big((\mathbf{U}(t,x),\varepsilon),(\mathbf{V}(t,x),\varepsilon)\big) - \mathcal{B}_p((0,\varepsilon),(0,\varepsilon)), \qquad \varepsilon > 0.$$

Here we adjoin a parallel real direction to each fiber; thus, the two arguments of $\mathcal{B}_p$ never vanish. The function $\mathcal{B}_p$ is C^1 and piecewise C^2. On the set where the arguments have norm at least ε, its gradient is locally Lipschitz. Integrating by parts separately in the two regions $|\mathbf{U}_\varepsilon|^p < |\mathbf{V}_\varepsilon|^q$ and $|\mathbf{U}_\varepsilon|^p > |\mathbf{V}_\varepsilon|^q$, the interface terms cancel because the first derivatives of $\mathcal{B}_p$ agree there. The following chain rule therefore

holds almost everywhere and distributionally. Equivalently, it can be obtained by approximating $\mathcal{B}_p$ by convolution on compact sets away from the axes and passing to the limit.

Let

$$\mathscr{L} := \partial_t^2 + \operatorname{tr}_{\mathbf{g}} \nabla^2$$

be the scalar operator on $(0,\infty)\times M$. The Hessian formula for a radial function on a Hilbert fiber, together with (13.88), shows that the first-order terms in $\mathbf{U},\mathbf{V}$ are given by the Hessian of $\mathcal{B}_p$ applied to the time and covariant derivatives. The order-zero terms are

$$\frac{\partial_u \beta_p}{|\mathbf{U}_\varepsilon|}\langle \mathbf{W}\mathbf{U},\mathbf{U}\rangle + \frac{\partial_v \beta_p}{|\mathbf{V}_\varepsilon|}\langle \mathbf{W}\mathbf{V},\mathbf{V}\rangle,$$

and are nonnegative by (13.81) and radial monotonicity of the Bellman function. Item (c) of the lemma, applied to each time derivative and each spatial orthonormal direction, provides a measurable function $\tau = \tau(t,x) > 0$ such that

$$\mathscr{L} b_\varepsilon \geq c_p \Big[\tau \big(|\partial_t \mathbf{U}|^2 + |\nabla \mathbf{U}|^2 \big) + \tau^{-1} \big(|\partial_t \mathbf{V}|^2 + |\nabla \mathbf{V}|^2 \big) \Big]. \tag{13.89}$$

In particular, by $\tau A^2 + \tau^{-1} B^2 \geq 2AB$,

$$\mathscr{L} b_\varepsilon \geq 2c_p \big(|\partial_t \mathbf{U}|^2 + |\nabla \mathbf{U}|^2 \big)^{1/2} \big(|\partial_t \mathbf{V}|^2 + |\nabla \mathbf{V}|^2 \big)^{1/2} \tag{13.90}$$

almost everywhere.

Take the cutoff functions χ_j from Lemma 12.1.7. Thus, $0 \leq \chi_j \leq 1$, $\chi_j \to 1$ locally, and $\|d\chi_j\|_\infty \to 0$. Integrate $t\chi_j^2 \mathscr{L} b_\varepsilon$ over $M \times (a,R)$, with $0 < a < R < \infty$. For fixed j, a, R, first let $\varepsilon \downarrow 0$. On this finite time cylinder and on the compact support of $d\chi_j$, the sections $\mathbf{U},\mathbf{V}$ and their first derivatives are bounded. Since $\mathcal{B}_p$ is of class C^1, the function and its gradient are bounded on the compact set of arguments obtained by varying $0 < \varepsilon \leq 1$. This gives a dominating function independent of ε for the boundary and cutoff terms. Dominated convergence therefore permits passage to the limit in every term. Only then let $a \downarrow 0$ and $R \to \infty$. To justify these time limits, observe that, for compactly supported data, spectral calculus on L^2 gives

$$\|C_2^k P_t \mathbf{f}\|_{L^2(M,\mathbf{F})} \leq \sup_{\lambda \geq 1} \lambda^k e^{-t\lambda} \, \|\mathbf{f}\|_{L^2(M,\mathbf{F})},$$

and likewise for $\mathbf{g}$. In particular, terms multiplied by t vanish at $t = \infty$; near zero, use the fact that smooth compactly supported sections belong to the domain of every power of B_2. Time integration produces the value at $t = 0$. In the spatial variable, the divergence formula gives

$$\int_M \chi_j^2 \operatorname{tr}_{\mathbf{g}} \nabla^2 b_\varepsilon \, d\lambda_{\mathbf{g}} = -2 \int_M \chi_j \langle d\chi_j, db_\varepsilon \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}}.$$

The gradient bound (13.78), the weighted inequality (13.89), and Young's inequality allow half of the weighted energy term to be absorbed, leaving

$$\begin{aligned} &\int_0^\infty \int_M t\chi_j^2 \big(|\partial_t \mathbf{U}|^2 + |\nabla \mathbf{U}|^2 \big)^{1/2} \big(|\partial_t \mathbf{V}|^2 + |\nabla \mathbf{V}|^2 \big)^{1/2} \, d\lambda_{\mathbf{g}} \, dt \\ &\qquad \leq C_p \int_M \chi_j^2 \big(|\mathbf{f}|^p + |\mathbf{g}|^q \big) \, d\lambda_{\mathbf{g}} \end{aligned}$$

$$+ C_p \|d\chi_j\|_\infty^2 \int_0^\infty t \left(\|\mathbf{U}(t)\|_{L^p(M,\mathbf{F})}^p + \|\mathbf{V}(t)\|_{L^q(M,\mathbf{F})}^q \right) dt. \tag{13.91}$$

After the limit $\varepsilon \downarrow 0$ on the finite cylinder, the bound in item (a) of the lemma leaves only a multiple of $|\mathbf{U}|^p + |\mathbf{V}|^q$ in the cutoff term. Now use (13.87):

$$\|\mathbf{U}(t)\|_{L^p(M,\mathbf{F})}^p \le e^{-pt} \|\mathbf{f}\|_{L^p(M,\mathbf{F})}^p, \qquad \|\mathbf{V}(t)\|_{L^q(M,\mathbf{F})}^q \le e^{-qt} \|\mathbf{g}\|_{L^q(M,\mathbf{F})}^q.$$

The time integral of the last term in (13.91) is finite and independent of j. As $j \to \infty$, that term disappears and Fatou gives

$$\int_0^\infty \int_M t\, |C_2 P_t \mathbf{f}|\, |C_2 P_t \mathbf{g}|\, d\lambda_{\mathbf{g}}\, dt \le C_p \left(\|\mathbf{f}\|_{L^p(M,\mathbf{F})}^p + \|\mathbf{g}\|_{L^q(M,\mathbf{F})}^q \right). \tag{13.92}$$

We used only the time derivatives $\partial_t P_t = -C_2 P_t$ from the stronger estimate obtained above. Replace $\mathbf{f}$ by $a\mathbf{f}$ and $\mathbf{g}$ by $a^{-1}\mathbf{g}$. Choose $a > 0$ so that $a^p \|\mathbf{f}\|_{L^p(M,\mathbf{F})}^p = a^{-q} \|\mathbf{g}\|_{L^q(M,\mathbf{F})}^q$. The left-hand side is unchanged, and we obtain the homogeneous form

$$\int_0^\infty \int_M t\, |C_2 P_t \mathbf{f}|\, |C_2 P_t \mathbf{g}|\, d\lambda_{\mathbf{g}}\, dt \le C_p \|\mathbf{f}\|_{L^p(M,\mathbf{F})} \|\mathbf{g}\|_{L^q(M,\mathbf{F})}. \tag{13.93}$$

Laplace multipliers. Let $\psi \in L^\infty(0,\infty)$. On L^2, define $m_\psi(C_2)$ by spectral calculus. Since $C_2 \ge I$,

$$\mathbf{g} = \int_0^\infty C_2 P_r \mathbf{g}\, dr$$

in L^2. For $\mathbf{f}, \mathbf{g} \in \Gamma_c(\mathbf{F})$, Fubini, self-adjointness, and the semigroup law give

$$\begin{aligned} \langle m_\psi(C_2)\mathbf{f}, \mathbf{g} \rangle &= \int_0^\infty \int_0^\infty \psi(s) \langle C_2 P_s \mathbf{f}, C_2 P_r \mathbf{g} \rangle\, dr\, ds \\ &= 2 \int_0^\infty \left(\int_0^{2t} \psi(s)\, ds \right) \langle C_2 P_t \mathbf{f}, C_2 P_t \mathbf{g} \rangle\, dt. \end{aligned}$$

The second equality uses the change of variable $t = (s+r)/2$, whose Jacobian is two. By (13.93),

$$|\langle m_\psi(C_2)\mathbf{f}, \mathbf{g} \rangle| \le 4 C_p \|\psi\|_\infty \|\mathbf{f}\|_{L^p(M,\mathbf{F})} \|\mathbf{g}\|_{L^q(M,\mathbf{F})}.$$

Duality between L^p and L^q and density prove (13.85).

Imaginary powers. For $\tau \in \mathbb{R}$, set

$$\psi_\tau(s) := \frac{s^{-2i\tau}}{\Gamma(1 - 2i\tau)}.$$

Since

$$\lambda \int_0^\infty s^{-2i\tau} e^{-s\lambda}\, ds = \Gamma(1 - 2i\tau) \lambda^{2i\tau},$$

the multiplier of (13.84) is $m_{\psi_\tau}(C_2) = C_2^{2i\tau} = B_2^{i\tau}$. Recall the elementary gamma-function bound we need. The beta–gamma identity and Euler's reflection formula give, for $y \in \mathbb{R}$,

$$|\Gamma(1 + iy)|^2 = \Gamma(1 + iy)\Gamma(1 - iy) = \frac{\pi |y|}{\sinh(\pi |y|)}, \tag{13.94}$$

with value one at $y = 0$ by continuity. The reflection formula used here follows from

$$\Gamma(z)\Gamma(1-z) = \int_0^\infty \frac{t^{z-1}}{1+t}\,dt = \frac{\pi}{\sin(\pi z)}, \qquad 0 < \operatorname{Re} z < 1,$$

where the first equality is the substitution $t = x/(1-x)$ in the beta–gamma identity, and the second follows by integrating $w^{z-1}/(1+w)$ over a keyhole contour around the positive axis; the two sides of the cut differ by the factor $e^{2\pi i z}$, and the only interior pole is $w = -1$. The identity, obtained initially for $0 < \operatorname{Re} z < 1$, extends meromorphically to values where both sides are defined. Apply it to $z = iy$ and then use $\Gamma(1+iy) = iy\Gamma(iy)$. From (13.94), we deduce

$$\frac{1}{|\Gamma(1-2i\tau)|} \le C(1+|\tau|)^{-1/2} e^{\pi|\tau|} \le C e^{\pi|\tau|}. \tag{13.95}$$

The Laplace multiplier bound then gives (13.83), for example with $\omega_p = \pi$ after modifying C_p.
Strong continuity on τ remains. On L^2, it follows immediately from spectral calculus. If $p \neq 2$, choose $r \in (1,\infty)$ so that p lies strictly between 2 and r. For a compactly supported section, Hölder interpolates the L^p norm between L^2 and L^r; the L^2 factor tends to zero as $\tau \to \tau_0$, and the L^r factor remains bounded on compact intervals of τ by the estimate already proved. Density of $\Gamma_c(\mathbf{F})$ in L^p and local uniform boundedness of $B_p^{i\tau}$ extend continuity to all of L^p. The group law is verified on $L^2 \cap L^p$ by spectral calculus and then on L^p by density. □

The abstract step that converts the second-order information into a square root is recorded in the following lemma.

Lemma 13.3.22. (Square root by interpolation and imaginary powers) Let X be a reflexive complex Banach space, and let $-B$ be the generator of a C_0-semigroup satisfying $\|e^{-tB}\| \le e^{-t}$ for $t \ge 0$. Suppose that the negative powers B^{-s}, $s > 0$, are defined by the Laplace calculus of that semigroup and that the imaginary powers form a C_0 group satisfying

$$\|B^{it}\|_{\mathcal{L}(X)} \le M e^{\omega|t|}.$$

Equip $\mathcal{D}(B)$ with the norm $\|Bx\|_X$ and $\mathcal{D}(B^{1/2})$ with $\|B^{1/2}x\|_X$. Then

$$[X, \mathcal{D}(B)]_{1/2} = \mathcal{D}(B^{1/2}) \tag{13.96}$$

with equivalence of norms. If X is real, the same assertion holds after complexifying X and B and then restricting to the real subspace.

Proof. The identity is the case $a_0 = 0$, $a_1 = 1$ of domain interpolation. To prove it, fix an integer $N \ge 2$. For $x \in \mathcal{D}(B^N)$ and $\varepsilon > 0$, define on the strip $0 \le \operatorname{Re} z \le 1$

$$F_\varepsilon(z) := e^{\varepsilon(z-1/2)^2} B^{1/2-z} x.$$

Writing $B^{1/2-z}x = B^{1/2-z-N}B^N x$, the power with negative real part is expressed by the Laplace integral; this proves holomorphy in the interior. On the two boundary lines,

$$F_\varepsilon(it) = e^{\varepsilon(it-1/2)^2} B^{-it} B^{1/2} x,$$

$$BF_\varepsilon(1+it) = e^{\varepsilon(1/2+it)^2} B^{-it} B^{1/2} x.$$

The bound on imaginary powers and the Gaussian factor show that F_ε belongs to the Calderón space of the pair $(X, \mathcal{D}(B))$ and that

$$\|x\|_{[X,\mathcal{D}(B)]_{1/2}} \le C \|B^{1/2} x\|_X.$$

If $x \in \mathcal{D}(B^{1/2})$, set $x_\eta = (I+\eta B)^{-N} x$. Laplace functional calculus gives $x_\eta \in \mathcal{D}(B^N)$ and $B^{1/2} x_\eta \to B^{1/2} x$. The preceding estimate applied to differences proves that x_η converges to x in the interpolated space. Thus, $\mathcal{D}(B^{1/2}) \subseteq [X, \mathcal{D}(B)]_{1/2}$.

For the reverse inclusion, let $F \in \mathscr{F}(X, \mathcal{D}(B))$ and $x = F(1/2)$. Fix $\eta > 0$ and set $R_\eta = (I+\eta B)^{-N}$. The function

$$G_{\varepsilon,\eta}(z) := e^{\varepsilon(z-1/2)^2} B^z R_\eta F(z)$$

is holomorphic with values in X. On the boundary,

$$G_{\varepsilon,\eta}(it) = e^{\varepsilon(it-1/2)^2} B^{it} R_\eta F(it),$$

and

$$G_{\varepsilon,\eta}(1+it) = e^{\varepsilon(1/2+it)^2} B^{it} R_\eta B F(1+it).$$

The norms of R_η remain uniformly bounded because the resolvent comes from the same Laplace calculus. The three-lines lemma gives, with a constant independent of η,

$$\|B^{1/2} R_\eta x\|_X \le C \|F\|_{\mathscr{F}(X,\mathcal{D}(B))}.$$

As $\eta \downarrow 0$, $R_\eta x \to x$ in X. By reflexivity, extract a subsequence along which $B^{1/2} R_\eta x$ converges weakly. The graph of the closed operator $B^{1/2}$ is a closed subspace of $X \times X$ and, by convexity, is also weakly closed. It follows that $x \in \mathcal{D}(B^{1/2})$ and

$$\|B^{1/2} x\|_X \le C \|F\|_{\mathscr{F}(X,\mathcal{D}(B))}.$$

Taking the infimum over F proves the reverse inclusion and the second norm comparison. □

Corollary 13.3.23. (Internal first-order estimate for the chain) Under the hypotheses of Proposition 13.3.16, let $1 < p < \infty$. For each $\ell \in \{0, \dots, N\}$,

$$\mathcal{D}(B_{\ell,p}^{1/2}) = W^{1,p}(M, \mathbf{E}_\ell) \tag{13.97}$$

with equivalence of norms. In particular, there exist $\widetilde{a}_{\ell,p}, \widetilde{b}_{\ell,p} > 0$ such that

$$\widetilde{a}_{\ell,p} \left(\|\mathbf{z}\|_{L^p(M,\mathbf{E}_\ell)} + \|\nabla_\ell \mathbf{z}\|_{L^p(M,\mathbf{E}_{\ell+1})} \right) \le \|B_{\ell,p}^{1/2} \mathbf{z}\|_{L^p(M,\mathbf{E}_\ell)} \le \widetilde{b}_{\ell,p} \left(\|\mathbf{z}\|_{L^p(M,\mathbf{E}_\ell)} + \|\nabla_\ell \mathbf{z}\|_{L^p(M,\mathbf{E}_{\ell+1})} \right). \tag{13.98}$$

Proof. The choice of μ_N in Proposition 13.3.16 implies, pointwise,

$$\mu_N I + \mathbf{V}_\ell \ge I$$

as a self-adjoint endomorphism of $\mathbf{E}_\ell$. The same proposition gives

$$\|e^{-tB_{\ell,r}}\|_{\mathcal{L}(L^r)} \le e^{-t} \qquad (1 \le r < \infty).$$

Theorem 13.3.21 therefore applies to $B_{\ell,p}$ and provides the imaginary powers required in Lemma 13.3.22. Proposition 13.3.19 and Proposition 13.3.18 give

$$\mathcal{D}(B_{\ell,p}^{1/2}) = [L^p(M,\mathbf{E}_\ell), \mathcal{D}(B_{\ell,p})]_{1/2} = [L^p(M,\mathbf{E}_\ell), W^{2,p}(M,\mathbf{E}_\ell)]_{1/2} = W^{1,p}(M,\mathbf{E}_\ell).$$

The norm comparisons in these three results, together with the definition of the $W^{1,p}$ norm, produce (13.98). □

Proposition 13.3.24. (Power estimates for the Bochner chain) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, let $\mathbf{E} \to M$ be a bundle of bounded geometry, and let $N \in \mathbb{N}$ and $1 < p < \infty$. Use the operators $B_{\ell,p}$ of Proposition 13.3.16. For $k \in \mathbb{N}_0$ and $\ell \in \{0,\dots,N\}$, define

$$\mathscr{D}^p_{\ell,k} := B_{\ell,p}^{-\frac{k}{2}} L^p(M,\mathbf{E}_\ell), \qquad \|\mathbf{u}\|_{\mathscr{D}^p_{\ell,k}} := \|B_{\ell,p}^{\frac{k}{2}}\mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)}. \tag{13.99}$$

If also $k + \ell \le N$, then

$$\mathscr{D}^p_{\ell,k} = W^{k,p}(M,\mathbf{E}_\ell), \tag{13.100}$$

and there exist constants $c_{\ell,k,p}, C_{\ell,k,p} > 0$ such that

$$\begin{aligned} c_{\ell,k,p} \sum_{j=0}^{k} \|\nabla^j \mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+j})} &\le \|B_{\ell,p}^{\frac{k}{2}}\mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} \\ &\le C_{\ell,k,p} \sum_{j=0}^{k} \|\nabla^j \mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+j})}. \end{aligned} \tag{13.101}$$

Proof. The negative power of (13.99) is understood through

$$B_{\ell,p}^{-\frac{s}{2}}\mathbf{f} = \frac{1}{\Gamma(\frac{s}{2})} \int_0^\infty t^{\frac{s}{2}-1} e^{-tB_{\ell,p}}\mathbf{f}\, dt, \qquad s > 0. \tag{13.102}$$

Since $-(B_{\ell,p} - I)$ generates a contraction semigroup, Theorem B.4.19 guarantees that these powers are injective, their ranges are Banach spaces, and

$$\|B_{\ell,p}^{\frac{a}{2}}\mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} \le \|B_{\ell,p}^{\frac{b}{2}}\mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)}, \qquad 0 \le a \le b, \tag{13.103}$$

for $\mathbf{u} \in \mathscr{D}^p_{\ell,b}$.

The first-order estimate follows by combining elliptic regularity with domain interpolation. Proposition 13.3.19 identifies the domain of $B_{\ell,p}$ with $W^{2,p}$, Theorem 13.3.21 provides its imaginary powers, and Proposition 13.3.18 identifies the interpolated space of order one. Corollary 13.3.23 therefore gives

$$\mathscr{D}^p_{\ell,1} = W^{1,p}(M,\mathbf{E}_\ell). \tag{13.104}$$

Moreover, there exist constants $\widetilde{a}_{\ell,p}, \widetilde{b}_{\ell,p} > 0$ such that

$$\widetilde{a}_{\ell,p}\left(\|\mathbf{z}\|_{L^p(M,\mathbf{E}_\ell)} + \|\nabla_\ell \mathbf{z}\|_{L^p(M,\mathbf{E}_{\ell+1})}\right) \le \|B_{\ell,p}^{\frac{1}{2}}\mathbf{z}\|_{L^p(M,\mathbf{E}_\ell)} \le \widetilde{b}_{\ell,p}\left(\|\mathbf{z}\|_{L^p(M,\mathbf{E}_\ell)} + \|\nabla_\ell \mathbf{z}\|_{L^p(M,\mathbf{E}_{\ell+1})}\right). \tag{13.105}$$

Thus, the starting point of the induction is established by the uniform elliptic regularity, Bellman function, and complex interpolation proved above.

We now develop the commutation step needed at higher orders. Write

$$S_\ell(t) := e^{-tB_{\ell,p}}, \qquad t \ge 0.$$

The covariant semigroups are consistent as p varies. The Dyson–Phillips series of Proposition B.4.17 shows that consistency is retained when the bounded potentials $\mathbf{V}_\ell$ and shift $\mu_N I$ are added.

Before commuting unbounded operators, fix a common regularizing core. Let $\varphi \in C_c^\infty((0,\infty))$ and define

$$\mathcal{R}_{\ell,\varphi}\mathbf{z} := \int_0^\infty \varphi(t) S_\ell(t)\mathbf{z}\, dt. \tag{13.106}$$

The integral is a Bochner integral. We need not assume that $S_\ell(t)\mathbf{z}$ is differentiable for arbitrary data in L^p. Extend φ by zero to $\mathbb{R}$. For small $h > 0$,

$$\frac{S_\ell(h) - I}{h}\mathcal{R}_{\ell,\varphi}\mathbf{z} = \int_0^\infty \frac{\varphi(t-h) - \varphi(t)}{h} S_\ell(t)\mathbf{z}\, dt \longrightarrow -\int_0^\infty \varphi'(t) S_\ell(t)\mathbf{z}\, dt.$$

Convergence is in L^p, by dominated convergence on a compact interval. The definition of the generator $-B_{\ell,p}$ proves the formula for $m = 1$; repeating it with $\varphi', \varphi'', \dots$ gives

$$B_{\ell,p}^m \mathcal{R}_{\ell,\varphi}\mathbf{z} = \int_0^\infty \varphi^{(m)}(t) S_\ell(t)\mathbf{z}\, dt, \qquad m \in \mathbb{N}_0. \tag{13.107}$$

Therefore, $\mathcal{R}_{\ell,\varphi}\mathbf{z} \in \bigcap_{m\in\mathbb{N}} \mathcal{D}(B_{\ell,p}^m)$.

Choose a family $(\varphi_\varepsilon)_{\varepsilon>0}$ of nonnegative functions in $C_c^\infty((0,\varepsilon))$ with integral one. Strong continuity of the semigroup implies

$$\mathcal{R}_{\ell,\varphi_\varepsilon}\mathbf{z} \longrightarrow \mathbf{z} \quad \text{on } L^p(M,\mathbf{E}_\ell).$$

This convergence holds in each space $\mathscr{D}_{\ell,\rho}^p$. Indeed, if $\mathbf{z} = B_{\ell,p}^{-\frac{\rho}{2}}\mathbf{f}$, Laplace functional calculus allows $B_{\ell,p}^{-\frac{\rho}{2}}$ to commute with $S_\ell(t)$, and

$$\|\mathcal{R}_{\ell,\varphi_\varepsilon}\mathbf{z} - \mathbf{z}\|_{\mathscr{D}_{\ell,\rho}^p} = \|\mathcal{R}_{\ell,\varphi_\varepsilon}\mathbf{f} - \mathbf{f}\|_{L^p(M,\mathbf{E}_\ell)} \longrightarrow 0.$$

As the common core, take

$$\mathscr{C}_{\ell,p} := \bigcap_{m\in\mathbb{N}} \mathcal{D}(B_{\ell,p}^m).$$

The preceding regularizations belong to this space and prove its density in every $\mathscr{D}_{\ell,\rho}^p$. Moreover, the power law shows that it is invariant under positive and negative powers of $B_{\ell,p}$ and under $S_\ell(t)$. This invariance will allow the same identity to be applied to $\mathbf{z}$ and $B_{\ell,p}^a\mathbf{z}$.

The geometric identities are first verified on regularizations of compactly supported data. Approximate $\mathbf{z} \in L^p(M,\mathbf{E}_\ell)$ by sections $\mathbf{z}_n \in \Gamma_c(\mathbf{E}_\ell)$. The sections $\mathcal{R}_{\ell,\varphi}\mathbf{z}_n$ belong simultaneously to L^2 and L^p and, by

(13.107), to the domains of every power of $B_{\ell,2}$. Since $B_{\ell,2}$ has the same elliptic principal symbol as the Bochner Laplacian, local elliptic regularity shows that these sections are smooth. The differential identity (13.52) holds locally for them. It also justifies the realizations involved: if $\mathbf{v} \in \bigcap_{m\in\mathbb{N}} \mathcal{D}(B_{\ell,2}^m)$, the first-order estimate gives $\nabla_\ell \mathbf{v}, \nabla_\ell B_{\ell,2}\mathbf{v} \in L^2$. By the differential identity,

$$B_{\ell+1,2}\nabla_\ell \mathbf{v} = \nabla_\ell B_{\ell,2}\mathbf{v} - \mathbf{W}_\ell \mathbf{v} \in L^2 \quad \text{en distribuciones.}$$

Lemma 13.3.17 implies $\nabla_\ell \mathbf{v} \in \mathcal{D}(B_{\ell+1,2})$. Applying the same argument to $S_\ell(t)\mathbf{v}$ and $B_{\ell,2}S_\ell(t)\mathbf{v}$ gives continuity in the graph norms needed to differentiate the product of semigroups. Formulas (13.107), the first-order estimate (13.105), and continuity of $\mathbf{W}_\ell$ allow passage to the limit $n \to \infty$. Thus, every identity established below on $\mathcal{R}_{\ell,\varphi}\mathbf{z}_n$ first passes to $\mathcal{R}_{\ell,\varphi}\mathbf{z}$. Finally, let $\varphi = \varphi_\varepsilon$ and $\varepsilon \to 0^+$. Convergence in all graph norms of finite order extends the identities to $\mathscr{C}_{\ell,p}$.

Functional calculus for Bessel powers shows that, for $\rho \geq 0$,

$$\|S_\ell(t)\mathbf{z}\|_{\mathscr{D}^p_{\ell,\rho}} \leq e^{-t}\|\mathbf{z}\|_{\mathscr{D}^p_{\ell,\rho}}. \tag{13.108}$$

Suppose that, for some $\rho \in \mathbb{N}_0$, multiplication by $\mathbf{W}_\ell$ is continuous from $\mathscr{D}^p_{\ell,\rho}$ to $\mathscr{D}^p_{\ell+1,\rho}$. For $t > 0$, define

$$\mathcal{K}_\ell(t)\mathbf{z} := \int_0^t S_{\ell+1}(t-\tau)\mathbf{W}_\ell S_\ell(\tau)\mathbf{z}\, d\tau. \tag{13.109}$$

The integral converges in $\mathscr{D}^p_{\ell+1,\rho}$ and

$$\|\mathcal{K}_\ell(t)\mathbf{z}\|_{\mathscr{D}^p_{\ell+1,\rho}} \leq C_\rho t e^{-t}\|\mathbf{z}\|_{\mathscr{D}^p_{\ell,\rho}}. \tag{13.110}$$

Let $\mathbf{z} \in \mathscr{C}_{\ell,p}$. On the smooth approximations described above, we may differentiate in L^2 the function

$$\tau \longmapsto S_{\ell+1}(t-\tau)\nabla_\ell S_\ell(\tau)\mathbf{z}, \qquad 0 < \tau < t.$$

The identity

$$\nabla_\ell B_{\ell,p} - B_{\ell+1,p}\nabla_\ell = \mathbf{W}_\ell,$$

which is (13.52) with the same shift on both bundles, gives

$$\frac{d}{d\tau}\left[S_{\ell+1}(t-\tau)\nabla_\ell S_\ell(\tau)\mathbf{z}\right] = -S_{\ell+1}(t-\tau)\mathbf{W}_\ell S_\ell(\tau)\mathbf{z}.$$

Integrate between 0 and t and pass to L^p by consistency. This gives

$$S_{\ell+1}(t)\nabla_\ell \mathbf{z} - \nabla_\ell S_\ell(t)\mathbf{z} = \mathcal{K}_\ell(t)\mathbf{z}. \tag{13.111}$$

The first-order estimate and (13.110) allow this identity to extend by density to $\mathscr{D}^p_{\ell,1}$; at higher orders it is interpreted in the $\mathscr{D}^p_{\ell+1,\rho}$ norm whenever both sides are defined. The expression on the right-hand side, however, is defined and continuous on all of $\mathscr{D}^p_{\ell,\rho}$.

Now consider the square root. For $\mathbf{z} \in \mathscr{C}_{\ell,p}$, the integral formula of Lemma B.4.20, applied first with trun-

cated limits, and (13.111) give

$$\begin{aligned}&\frac{1}{2\sqrt{\pi}}\int_\varepsilon^R t^{-\frac{3}{2}}\left(\nabla_\ell \mathbf{z} - S_{\ell+1}(t)\nabla_\ell \mathbf{z}\right) dt\\ &\quad = \nabla_\ell\left[\frac{1}{2\sqrt{\pi}}\int_\varepsilon^R t^{-\frac{3}{2}}\left(\mathbf{z} - S_\ell(t)\mathbf{z}\right) dt\right] - \frac{1}{2\sqrt{\pi}}\int_\varepsilon^R t^{-\frac{3}{2}}\mathcal{K}_\ell(t)\mathbf{z}\, dt.\end{aligned}$$

The first term on the right-hand side converges to $\nabla_\ell B^{\frac{1}{2}}_{\ell,p}\mathbf{z}$: the bracketed integral converges in $\mathscr{D}^p_{\ell,1}$ because $\mathbf{z}$ belongs to every domain, and we use (13.105). The second term converges in $\mathscr{D}^p_{\ell+1,\rho}$, since

$$\int_0^\infty t^{-\frac{3}{2}}(te^{-t})\, dt = \Gamma\left(\frac{1}{2}\right) < \infty.$$

Closedness of $B^{\frac{1}{2}}_{\ell+1,p}$ and the last assertion of Lemma B.4.20 show that $\nabla_\ell \mathbf{z} \in \mathscr{D}^p_{\ell+1,1}$ and that

$$\Theta_{\ell,1}\mathbf{z} := B^{\frac{1}{2}}_{\ell+1,p}\nabla_\ell \mathbf{z} - \nabla_\ell B^{\frac{1}{2}}_{\ell,p}\mathbf{z} = -\frac{1}{2\sqrt{\pi}}\int_0^\infty t^{-\frac{3}{2}}\mathcal{K}_\ell(t)\mathbf{z}\, dt. \tag{13.112}$$

By (13.110),

$$\|\Theta_{\ell,1}\mathbf{z}\|_{\mathscr{D}^p_{\ell+1,\rho}} \le C'_\rho \|\mathbf{z}\|_{\mathscr{D}^p_{\ell,\rho}}. \tag{13.113}$$

Since $\mathscr{C}_{\ell,p}$ is dense in $\mathscr{D}^p_{\ell,\rho}$, the integral on the right defines the unique extension of $\Theta_{\ell,1}$ to that space.
For $j \in \mathbb{N}$, write formally

$$\Theta_{\ell,j}\mathbf{z} := B^{\frac{j}{2}}_{\ell+1,p}\nabla_\ell \mathbf{z} - \nabla_\ell B^{\frac{j}{2}}_{\ell,p}\mathbf{z}. \tag{13.114}$$

Before using this expression, we must verify that its first term is defined. We do this simultaneously with the defect estimate.
Suppose that, for some $R \in \mathbb{N}_0$, multiplication by $\mathbf{W}_\ell$ is continuous from $\mathscr{D}^p_{\ell,\rho}$ to $\mathscr{D}^p_{\ell+1,\rho}$ for every $\rho \in \{0,\dots,R\}$. We claim that, if $j \ge 1$ and $j-1 \le R$, the following properties hold.

(i) For each $\mathbf{z} \in \mathscr{C}_{\ell,p}$, $\nabla_\ell \mathbf{z} \in \mathscr{D}^p_{\ell+1,j}$, and the identity (13.114) is well defined.

(ii) If $\rho \in \mathbb{N}_0$ and $\rho + j - 1 \le R$, then $\Theta_{\ell,j}$ extends uniquely to a continuous operator

$$\Theta_{\ell,j}\colon \mathscr{D}^p_{\ell,\rho+j-1} \longrightarrow \mathscr{D}^p_{\ell+1,\rho}$$

and there exists $C_{\ell,j,\rho,p} > 0$ such that

$$\|\Theta_{\ell,j}\mathbf{z}\|_{\mathscr{D}^p_{\ell+1,\rho}} \le C_{\ell,j,\rho,p}\|\mathbf{z}\|_{\mathscr{D}^p_{\ell,\rho+j-1}}. \tag{13.115}$$

For $j = 1$, both assertions follow from (13.112) and (13.113). Moreover, the square-root identity extends to the mapping

$$\nabla_\ell\colon \mathscr{D}^p_{\ell,2} \longrightarrow \mathscr{D}^p_{\ell+1,1}. \tag{13.116}$$

Indeed, if $\mathbf{z}_\nu \in \mathscr{C}_{\ell,p}$ converges to $\mathbf{z}$ in $\mathscr{D}^p_{\ell,2}$, the first-order estimate shows that $\nabla_\ell \mathbf{z}_\nu \to \nabla_\ell \mathbf{z}$ in L^p. On the other hand,

$$B^{\frac{1}{2}}_{\ell+1,p}\nabla_\ell \mathbf{z}_\nu = \nabla_\ell B^{\frac{1}{2}}_{\ell,p}\mathbf{z}_\nu + \Theta_{\ell,1}\mathbf{z}_\nu$$

is Cauchy in L^p: the first term is controlled by applying (13.105) to $B^{\frac{1}{2}}_{\ell,p}(\mathbf{z}_\nu - \mathbf{z}_\mu)$, and the second by (13.113) with $\rho = 0$. Closedness of $B^{\frac{1}{2}}_{\ell+1,p}$ proves (13.116) and permits passage to the limit in the identity.

Proceed by induction on j. Suppose both assertions have been proved through order $j-1$, with $j \geq 2$, and let $\mathbf{z} \in \mathscr{C}_{\ell,p}$. The induction hypothesis gives

$$B^{\frac{j-1}{2}}_{\ell+1,p} \nabla_\ell \mathbf{z} = \nabla_\ell B^{\frac{j-1}{2}}_{\ell,p} \mathbf{z} + \Theta_{\ell,j-1}\mathbf{z}. \tag{13.117}$$

The first term on the right belongs to $\mathscr{D}^p_{\ell+1,1}$ by (13.116), applied to $B^{\frac{j-1}{2}}_{\ell,p}\mathbf{z}$. The second also belongs to that space by (13.115) with order $j-1$ and $\rho = 1$; here we use $j - 1 \leq R$. Thus, the left-hand side of (13.117) belongs to the domain of $B^{\frac{1}{2}}_{\ell+1,p}$. This proves that $\nabla_\ell \mathbf{z} \in \mathscr{D}^p_{\ell+1,j}$.

Now apply $B^{\frac{1}{2}}_{\ell+1,p}$ to (13.117) and use the square-root identity on $B^{\frac{j-1}{2}}_{\ell,p}\mathbf{z}$. We obtain the recursion

$$\Theta_{\ell,j}\mathbf{z} = \Theta_{\ell,1}\big(B^{\frac{j-1}{2}}_{\ell,p}\mathbf{z}\big) + B^{\frac{1}{2}}_{\ell+1,p}\Theta_{\ell,j-1}\mathbf{z}. \tag{13.118}$$

If $\rho + j - 1 \leq R$, estimate the first sum using (13.113) in the $\mathscr{D}^p_{\ell+1,\rho}$ norm, and the second using the induction hypothesis in the $\mathscr{D}^p_{\ell+1,\rho+1}$ norm. Thus,

$$\begin{aligned}\|\Theta_{\ell,j}\mathbf{z}\|_{\mathscr{D}^p_{\ell+1,\rho}} &\leq C_\rho \|B^{\frac{j-1}{2}}_{\ell,p}\mathbf{z}\|_{\mathscr{D}^p_{\ell,\rho}} + \|\Theta_{\ell,j-1}\mathbf{z}\|_{\mathscr{D}^p_{\ell+1,\rho+1}} \\ &\leq C_{\ell,j,\rho,p}\|\mathbf{z}\|_{\mathscr{D}^p_{\ell,\rho+j-1}}.\end{aligned}$$

Density of $\mathscr{C}_{\ell,p}$ in the source space provides the unique extension and concludes the induction. In particular, taking $\rho = 0$ gives

$$\|\Theta_{\ell,j}\mathbf{z}\|_{L^p(M,\mathbf{E}_{\ell+1})} \leq C_{\ell,j,p}\|B^{\frac{j-1}{2}}_{\ell,p}\mathbf{z}\|_{L^p(M,\mathbf{E}_\ell)}. \tag{13.119}$$

We now deduce the connection's mapping property between domains. Let $\mathbf{z} \in \mathscr{D}^p_{\ell,j+1}$, and choose $\mathbf{z}_\nu \in \mathscr{C}_{\ell,p}$ with $\mathbf{z}_\nu \to \mathbf{z}$ in $\mathscr{D}^p_{\ell,j+1}$. The first-order estimate gives $\nabla_\ell \mathbf{z}_\nu \to \nabla_\ell \mathbf{z}$ in L^p. On the other hand,

$$B^{\frac{j}{2}}_{\ell+1,p}\nabla_\ell \mathbf{z}_\nu = \nabla_\ell B^{\frac{j}{2}}_{\ell,p}\mathbf{z}_\nu + \Theta_{\ell,j}\mathbf{z}_\nu.$$

The right-hand side is Cauchy in L^p: apply the first-order estimate to $B^{\frac{j}{2}}_{\ell,p}(\mathbf{z}_\nu - \mathbf{z}_\mu)$ for the first term and use (13.119) for the second. Closedness of $B^{\frac{j}{2}}_{\ell+1,p}$ implies $\nabla_\ell \mathbf{z} \in \mathscr{D}^p_{\ell+1,j}$ and permits passage to the limit in the identity. Moreover, the first-order estimate and (13.119) give

$$\begin{aligned}\|\nabla_\ell \mathbf{z}\|_{\mathscr{D}^p_{\ell+1,j}} &\leq C\|B^{\frac{j}{2}}_{\ell,p}\mathbf{z}\|_{\mathscr{D}^p_{\ell,1}} + C\|\mathbf{z}\|_{\mathscr{D}^p_{\ell,j-1}} \\ &\leq C'\|\mathbf{z}\|_{\mathscr{D}^p_{\ell,j+1}}.\end{aligned}$$

We have therefore proved the continuous mapping

$$\nabla_\ell \colon \mathscr{D}^p_{\ell,j+1} \longrightarrow \mathscr{D}^p_{\ell+1,j}. \tag{13.120}$$

We now prove (13.101) by induction on k. The case $k = 0$ is immediate, and the case $k = 1$ is contained in (13.104) and (13.105). Fix $k \in \{2, \dots, N\}$, suppose the assertion has been proved at all orders less than k, and fix

$$0 \le \ell \le N - k.$$

For $\rho \in \{0, \dots, k-2\}$ and $a \in \{0, \dots, \rho\}$, the Leibniz rule and (13.53) give

$$\|\nabla^a(\mathbf{W}_\ell \mathbf{z})\|_{L^p(M,\mathbf{E}_{\ell+a+1})} \le C_a \sum_{b=0}^{a} \|\nabla^b \mathbf{z}\|_{L^p(M,\mathbf{E}_{\ell+b})}. \tag{13.121}$$

Summing over a and applying the induction hypothesis at order ρ yields a continuous operator

$$\mathbf{W}_\ell \colon \mathscr{D}^p_{\ell,\rho} \longrightarrow \mathscr{D}^p_{\ell+1,\rho}, \qquad 0 \le \rho \le k-2. \tag{13.122}$$

The indices are admissible because $\ell + 1 \le N - (k-2)$. Consequently, we may use (13.120) and (13.119) with $j = k - 1$.
Let $\mathbf{u} \in \mathscr{D}^p_{\ell,k}$. By (13.120),

$$\nabla_\ell \mathbf{u} \in \mathscr{D}^p_{\ell+1,k-1}.$$

The inductive estimate at order $k-1$, applied to this section, and the identity defining $\Theta_{\ell,k-1}$ give

$$\begin{aligned}
\|\nabla^k \mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+k})} &\le C\|B_{\ell+1,p}^{\frac{k-1}{2}} \nabla_\ell \mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+1})} \\
&\le C\|\nabla_\ell B_{\ell,p}^{\frac{k-1}{2}} \mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+1})} + C\|\Theta_{\ell,k-1}\mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+1})} \\
&\le C\|B_{\ell,p}^{\frac{k}{2}} \mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} + C\|B_{\ell,p}^{\frac{k-2}{2}} \mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} \\
&\le C'\|B_{\ell,p}^{\frac{k}{2}} \mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)}.
\end{aligned}$$

In the third line, we use (13.105) for the section $B_{\ell,p}^{\frac{k-1}{2}} \mathbf{u}$ and (13.119); in the last, we use (13.103). For lower-order derivatives, the induction hypothesis and the same monotonicity give

$$\sum_{j=0}^{k-1} \|\nabla^j \mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+j})} \le C\|B_{\ell,p}^{\frac{k-1}{2}} \mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} \le C\|B_{\ell,p}^{\frac{k}{2}} \mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)}.$$

Therefore,

$$\sum_{j=0}^{k} \|\nabla^j \mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+j})} \le C\|B_{\ell,p}^{\frac{k}{2}} \mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)}. \tag{13.123}$$

In particular, this estimate proves the continuous inclusion $\mathscr{D}^p_{\ell,k} \subseteq W^{k,p}(M, \mathbf{E}_\ell)$
We prove the reverse estimate on smooth compactly supported sections. Proposition 12.3.4 shows that $\Gamma_c(\mathbf{E}_\ell) \subseteq \mathcal{D}(L_{\ell,p})$. Since the differential operator $L_{\ell,0} + \mathbf{V}_\ell$ preserves $\Gamma_c(\mathbf{E}_\ell)$, $B_{\ell,p}$ preserves it as well. For $r = 1$, we already have $\Gamma_c(\mathbf{E}_\ell) \subseteq \mathcal{D}(B_{\ell,p})$. If $\mathbf{u} \in \Gamma_c(\mathbf{E}_\ell)$ belongs to $\mathcal{D}(B^r_{\ell,p})$, then $B^r_{\ell,p}\mathbf{u} \in \Gamma_c(\mathbf{E}_\ell) \subseteq \mathcal{D}(B_{\ell,p})$; by definition of the domain of a composition, $\mathbf{u} \in \mathcal{D}(B^{r+1}_{\ell,p})$. Induction gives

$$\Gamma_c(\mathbf{E}_\ell) \subseteq \bigcap_{r \in \mathbb{N}} \mathcal{D}(B^r_{\ell,p}).$$

Monotonicity of the scale implies that every section in $\Gamma_c(\mathbf{E}_\ell)$ also belongs to the domains of the fractional powers appearing below. For $\mathbf{u} \in \Gamma_c(\mathbf{E}_\ell)$, apply the first-order estimate to $B_{\ell,p}^{\frac{k-1}{2}}\mathbf{u}$ and then add and subtract the defect $\Theta_{\ell,k-1}\mathbf{u}$:

$$\begin{aligned}\|B_{\ell,p}^{\frac{k}{2}}\mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} &\le C\|B_{\ell,p}^{\frac{k-1}{2}}\mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} + C\|\nabla_\ell B_{\ell,p}^{\frac{k-1}{2}}\mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+1})}\\ &\le C\|B_{\ell,p}^{\frac{k-1}{2}}\mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} + C\|B_{\ell+1,p}^{\frac{k-1}{2}}\nabla_\ell\mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+1})}\\ &\quad + C\|\Theta_{\ell,k-1}\mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+1})}\\ &\le C'\sum_{j=0}^{k}\|\nabla^j\mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+j})}.\end{aligned}$$

In the last inequality, apply the induction hypothesis at order $k-1$ to $\mathbf{u}$ and $\nabla_\ell\mathbf{u}$, and at order $k-2$ to the term controlling $\Theta_{\ell,k-1}\mathbf{u}$. Thus,

$$\|B_{\ell,p}^{\frac{k}{2}}\mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} \le C\sum_{j=0}^{k}\|\nabla^j\mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+j})}, \qquad \mathbf{u}\in\Gamma_c(\mathbf{E}_\ell). \tag{13.124}$$

Let us verify the required density. Let $\mathcal{T}^{\mathrm{geo}} = (U_i,\varphi_i,h_i)_{i\in I}$ be a geodesic trivialization, so that $\sum_{i\in I} h_i = 1$. For finite $F \subseteq I$, set

$$\mathbf{u}_F := \sum_{i\in F} h_i\mathbf{u}.$$

Each $\mathbf{u}_F$ has compact support. The same Leibniz calculation and second overlap count used in Proposition 13.3.14 give

$$\|\mathbf{u}-\mathbf{u}_F\|_{W^{k,p}(M,\mathbf{E}_\ell)}^p \le C\sum_{i\in I\setminus F}\|h_i\mathbf{u}\|_{W^{k,p}(U_i,\mathbf{E}_\ell)}^p. \tag{13.125}$$

The series on the right converges by the direct localization inequality, so its tails tend to zero. Finally, the Meyers–Serrin Theorem 9.1.48 approximates each $\mathbf{u}_F$ by smooth sections. If $\chi_F \in C_c^\infty(M)$ equals one on a neighborhood of $\operatorname{supp}(\mathbf{u}_F)$, multiplying those approximations by χ_F produces a sequence in $\Gamma_c(\mathbf{E}_\ell)$ converging to $\mathbf{u}_F$ in $W^{k,p}$. Therefore, $\Gamma_c(\mathbf{E}_\ell)$ is dense in $W^{k,p}(M,\mathbf{E}_\ell)$.

Now let $\mathbf{u}\in W^{k,p}(M,\mathbf{E}_\ell)$, and choose $\mathbf{u}_n\in\Gamma_c(\mathbf{E}_\ell)$ with $\mathbf{u}_n\to\mathbf{u}$ in $W^{k,p}$. Estimate (13.124) shows that $(B_{\ell,p}^{\frac{k}{2}}\mathbf{u}_n)_n$ is Cauchy in $L^p(M,\mathbf{E}_\ell)$. Moreover, $\mathbf{u}_n\to\mathbf{u}$ in $L^p(M,\mathbf{E}_\ell)$. Positive powers in the Bessel scale are closed operators; consequently,

$$\mathbf{u}\in\mathscr{D}_{\ell,k}^p \quad\text{and}\quad B_{\ell,p}^{\frac{k}{2}}\mathbf{u} = \lim_{n\to\infty} B_{\ell,p}^{\frac{k}{2}}\mathbf{u}_n.$$

Passing to the limit gives

$$\|B_{\ell,p}^{\frac{k}{2}}\mathbf{u}\|_{L^p(M,\mathbf{E}_\ell)} \le C\sum_{j=0}^{k}\|\nabla^j\mathbf{u}\|_{L^p(M,\mathbf{E}_{\ell+j})}. \tag{13.126}$$

Together with (13.123), this proves equality of spaces and both estimates at order k. The induction is complete. □

Theorem 13.3.25. (Bessel potentials and covariant derivatives) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, and let $(\mathbf{E},\mathbf{h}_{\mathbf{E}},\nabla^{\mathbf{E}})$ be a bundle of bounded geometry. If $m\in\mathbb{N}_0$ and $1<p<\infty$, then

$$H^{m,p}_{L_{\mathbf{E}}}(M,\mathbf{E})=W^{m,p}(M,\mathbf{E}).$$

There exist constants $c_{m,p},C_{m,p}>0$, independent of $\mathbf{u}$, such that

$$c_{m,p}\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}\le\|\mathbf{u}\|_{H^{m,p}_{L_{\mathbf{E}}}(M,\mathbf{E})}\le C_{m,p}\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}. \tag{13.127}$$

Proof. The case $m=0$ is immediate. Suppose $m\ge 1$ and apply Proposition 13.3.24 with $N=m$, $\ell=0$, and $k=m$. Since $\mathbf{V}_0=0$, there exist $a_{m,p},b_{m,p}>0$ such that

$$a_{m,p}\sum_{j=0}^{m}\|\nabla^j\mathbf{u}\|_{L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})}\le\|(\mu_m I+L_{\mathbf{E},p})^{\frac{m}{2}}\mathbf{u}\|_{L^p(M,\mathbf{E})}\le b_{m,p}\sum_{j=0}^{m}\|\nabla^j\mathbf{u}\|_{L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})}. \tag{13.128}$$

Lemma B.4.22, applied to the covariant semigroup, shows that

$$\operatorname{Ran}\big((\mu_m I+L_{\mathbf{E},p})^{-\frac{m}{2}}\big)=\operatorname{Ran}\big((I+L_{\mathbf{E},p})^{-\frac{m}{2}}\big)=H^{m,p}_{L_{\mathbf{E}}}(M,\mathbf{E}),$$

and, for $\mathbf{u}$ in this common range,

$$\|Q_{\mu_m,1}\|^{-1}_{\mathcal{L}(L^p(M,\mathbf{E}))}\|\mathbf{u}\|_{\operatorname{Ran}((I+L_{\mathbf{E},p})^{-\frac{m}{2}})}\le\|\mathbf{u}\|_{\operatorname{Ran}((\mu_m I+L_{\mathbf{E},p})^{-\frac{m}{2}})}\le\|Q_{1,\mu_m}\|_{\mathcal{L}(L^p(M,\mathbf{E}))}\|\mathbf{u}\|_{\operatorname{Ran}((I+L_{\mathbf{E},p})^{-\frac{m}{2}})},$$

where the operators $Q_{a,b}$ are those constructed in the proof of that lemma. On the other hand, the finite-sum norms ℓ^p and ℓ^1 satisfy

$$\begin{aligned}\left(\sum_{j=0}^{m}\|\nabla^j\mathbf{u}\|^p_{L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})}\right)^{\frac{1}{p}}&\le\sum_{j=0}^{m}\|\nabla^j\mathbf{u}\|_{L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})}\\&\le(m+1)^{1-\frac{1}{p}}\left(\sum_{j=0}^{m}\|\nabla^j\mathbf{u}\|^p_{L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})}\right)^{\frac{1}{p}}.\end{aligned} \tag{13.129}$$

The parenthesized expression is the norm of $W^{m,p}(M,\mathbf{E})$. The preceding comparisons prove equality of spaces and (13.127).

In the Hermitian case, the preceding estimates are interpreted on the underlying real bundle when the Bellman function is applied. The connection, potentials $\mathbf{V}_\ell$, operators $B_{\ell,p}$, and covariant derivatives commute with the complex structure, and the norm of the underlying real bundle agrees with the Hermitian norm. Theorem 13.3.21 also proves that the extensions obtained are complex-linear. Thus, the preceding comparisons retain the same constants in the complex case. □

To interpolate the scale defined through heat, we need to control powers of imaginary order. Self-adjointness resolves this on L^2. For other exponents, we can represent a section by scalar functions on the unit spheres of its fibers. This representation preserves the L^p norm up to a fixed factor and converts the covariant Laplacian into a shifted scalar Laplacian.

Lemma 13.3.26. (Imaginary powers of the covariant Laplacian) Let $(M,\mathbf{g})$ be a complete Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a finite-rank vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$, Hermitian in the complex case, and a compatible connection $\nabla^{\mathbf{E}}$. For $1<p<\infty$, let $L_{\mathbf{E},p}$ be the positive generator of covariant heat and set $B_p := I + L_{\mathbf{E},p}$. The spectral powers B_2^{it}, with $t\in\mathbb{R}$, extend consistently to bounded operators on $L^p(M,\mathbf{E})$. There exist $C_{p,\mathbf{E}},\omega_{p,\mathbf{E}}>0$, depending only on p, the rank, and the scalar field, such that

$$\|B_p^{it}\|_{\mathcal{L}(L^p(M,\mathbf{E}))}\le C_{p,\mathbf{E}}e^{\omega_{p,\mathbf{E}}|t|},\qquad t\in\mathbb{R}.$$

In the real case, these powers are understood on the complexification.

Proof. If the bundle is real, complexify it with the induced Hermitian metric and connection. The original norm is preserved on real sections, and the complex estimates restrict to them. It therefore suffices to treat a complex bundle with a Hermitian bundle metric. Write $r=\operatorname{rank}_{\mathbb{C}}\mathbf{E}$ and $d=2r$. Consider the manifold

$$\widehat{M}=\mathbb{S}(\mathbf{E}):=\{(x,\mathbf{v})\in\mathbf{E}\mid |\mathbf{v}|_{\mathbf{h}}=1\},\qquad \pi(x,\mathbf{v})=x.$$

The connection splits its tangent space into horizontal and vertical parts. Equip the horizontal part with the metric of M, each fiber with the unit-sphere metric, and declare the two parts orthogonal. Denote the resulting metric by $\widehat{\mathbf{g}}$.

This metric is complete. Indeed, π does not increase lengths. A Cauchy sequence in $\widehat{M}$ projects to a Cauchy sequence in M, converging to some x. Apart from finitely many terms, it lies over a compact set contained in a bundle-trivializing neighborhood of x. The inverse image of that compact set is compact because the fiber is a sphere. Thus, the original sequence has a convergent subsequence and, being Cauchy, converges. The same argument applies componentwise if the sphere bundle is disconnected.

Let $d\sigma_x$ be the invariant probability measure on the sphere of $\mathbf{E}_x$. The volume measure of $\widehat{\mathbf{g}}$, divided by the area of $\mathbb{S}^{d-1}$, is $d\lambda_{\mathbf{g}}(x)\,d\sigma_x(\mathbf{v})$; the preceding orthogonal decomposition verifies this in any local orthonormal frame. Use this normalized measure on $L^p(\widehat{M})$. Normalization does not change operator norms, since it multiplies the norms of arguments and images by the same factor. Define

$$(\mathcal{J}\mathbf{u})(x,\mathbf{v}):=\langle\mathbf{u}(x),\mathbf{v}\rangle_{\mathbf{h}}.$$

Use the Hermitian product linear in its first variable. Invariance of σ_x under fiber isometries gives

$$\|\mathcal{J}\mathbf{u}\|_{L^p(\widehat{M})}=c_{r,p}\|\mathbf{u}\|_{L^p(M,\mathbf{E})},\qquad c_{r,p}^p:=\int_{\mathbb{S}^{d-1}}|\langle\mathbf{e}_1,\mathbf{v}\rangle|^p\,d\sigma(\mathbf{v})>0. \tag{13.130}$$

Consequently, $\mathcal{J}$ has closed image. For $p=2$, we have $c_{r,2}=r^{-1/2}$.

We verify the relation between the Laplacians. If $\mathbf{X}$ is a field on M and $\mathbf{X}^H$ is its horizontal lift, the definition of parallel transport and metric compatibility imply

$$\mathbf{X}^H(\mathcal{J}\mathbf{u})=\mathcal{J}(\nabla_{\mathbf{X}}\mathbf{u}).$$

The fibers are totally geodesic for $\widehat{\mathbf{g}}$. To see this, transport two vertical fields $\mathbf{V},\mathbf{W}$ by the horizontal flow of

$\mathbf{X}^H$. This transport is an isometry of the spheres, so

$$\mathbf{X}^H\langle \mathbf{V},\mathbf{W}\rangle = \langle [\mathbf{X}^H,\mathbf{V}],\mathbf{W}\rangle + \langle \mathbf{V},[\mathbf{X}^H,\mathbf{W}]\rangle.$$

Substituting this identity into the Koszul formula gives $\langle \widehat{\nabla}_{\mathbf{V}}\mathbf{W},\mathbf{X}^H\rangle = 0$. For horizontal fields, every Koszul term paired with $\mathbf{Z}^H$ is the lift of the corresponding term on M. Hence,

$$\langle \widehat{\nabla}_{\mathbf{X}^H}\mathbf{Y}^H,\mathbf{Z}^H\rangle = \mathbf{g}(\nabla^M_{\mathbf{X}}\mathbf{Y},\mathbf{Z})\circ\pi.$$

The vertical component of the repeated derivative is computed with the same formula:

$$2\langle \widehat{\nabla}_{\mathbf{X}^H}\mathbf{X}^H,\mathbf{V}\rangle = -\mathbf{V}\big(\mathbf{g}(\mathbf{X},\mathbf{X})\circ\pi\big) - 2\langle [\mathbf{X}^H,\mathbf{V}],\mathbf{X}^H\rangle = 0.$$

The first term is zero because $\mathbf{V}$ is vertical; the second is zero because the bracket of a projectable field with a vertical field is vertical. Thus, taking the horizontal trace of the second derivative of $\mathcal{J}\mathbf{u}$ gives exactly $\mathcal{J}(\mathrm{tr}_{\mathbf{g}}\nabla^2\mathbf{u})$.

For the vertical trace, fix $\mathbf{v}$ in a fiber and a vector $\mathbf{w}$ tangent to its sphere. The spherical geodesic starting at $\mathbf{v}$ with velocity $\mathbf{w}$ satisfies $\boldsymbol{\gamma}''(0) = -|\mathbf{w}|^2\mathbf{v}$. The function $\langle \mathbf{u}(x),\boldsymbol{\gamma}(\tau)\rangle$ therefore has second derivative at zero equal to $-|\mathbf{w}|^2\langle \mathbf{u}(x),\mathbf{v}\rangle$. Take an orthonormal basis of the $d-1$ tangent vectors of the fiber and sum: the positive-sign vertical Laplacian is $(d-1)$ times $\mathcal{J}\mathbf{u}$. Adding the horizontal and vertical traces gives, for $\mathbf{u}\in\Gamma_c(\mathbf{E})$,

$$L_{\widehat{M}}\mathcal{J}\mathbf{u} = \mathcal{J}\big(L_{\mathbf{E},0}\mathbf{u} + (d-1)\mathbf{u}\big). \tag{13.131}$$

The differential identity also determines the closed realizations. Set $A := I + L_{\widehat{M}}$ and $D_2 := dI + L_{\mathbf{E},2}$. Completeness and the essential self-adjointness theorem of Chapter 12 allow each $\mathbf{u}\in\mathcal{D}(D_2)$ to be approximated by sections in $\Gamma_c(\mathbf{E})$ in the graph norm. Their images under $\mathcal{J}$ have compact support because π has compact fibers. Closedness of A and (13.131) give

$$\mathcal{J}\mathcal{D}(D_2)\subseteq\mathcal{D}(A), \qquad A\mathcal{J}\mathbf{u} = \mathcal{J}D_2\mathbf{u}.$$

If $\lambda>0$ and $\mathbf{f}\in L^2(M,\mathbf{E})$, apply this equality to $\mathbf{u} = (\lambda+D_2)^{-1}\mathbf{f}$. Uniqueness of the solution of the resolvent equation implies

$$(\lambda+A)^{-1}\mathcal{J}\mathbf{f} = \mathcal{J}(\lambda+D_2)^{-1}\mathbf{f}.$$

The resolvents are self-adjoint; the closed image of $\mathcal{J}$ and its orthogonal complement are invariant. Spectral calculus on that subspace then gives $A^{it}\mathcal{J} = \mathcal{J}D_2^{it}$ for $t\in\mathbb{R}$.

The scalar case of Theorem 13.3.21, applied to the operator $A = I + L_{\widehat{M},p}$ on the complete manifold $(\widehat{M},\widehat{\mathbf{g}})$, gives

$$\|A^{it}\|_{\mathcal{L}(L^p(\widehat{M}))}\le M_p e^{\omega_p|t|}, \qquad t\in\mathbb{R}.$$

For $\mathbf{u}\in L^2(M,\mathbf{E})\cap L^p(M,\mathbf{E})$, use spectral intertwining and (13.130); the factor $c_{r,p}$ appears on both sides and cancels. This yields

$$\|D_2^{it}\mathbf{u}\|_{L^p(M,\mathbf{E})}\le M_p e^{\omega_p|t|}\|\mathbf{u}\|_{L^p(M,\mathbf{E})}.$$

Density of the intersection defines the extension D_p^{it} and ensures its consistency, where $D_p = dI + L_{\mathbf{E},p}$.

Finally, pass from the shift d to the shift 1. The integral representation of the resolvent and heat contrac-

tivity give $\|D_p^{-1}\| \le d^{-1}$. Set

$$K_p := (d-1)D_p^{-1}, \qquad G_p := -\sum_{j=1}^{\infty} \frac{K_p^j}{j}.$$

This series converges in operator norm, since $\|K_p\| \le (d-1)/d < 1$, and

$$\|G_p\| \le \sum_{j=1}^{\infty} \frac{((d-1)/d)^j}{j} = \log d.$$

On L^2, $G_2 = \log(I - K_2)$ and $B_2 = D_2(I - K_2)$, so $B_2^{it} = D_2^{it} e^{itG_2}$. The series are consistent on the spaces L^p, and hence

$$\|B_p^{it}\| \le M_p e^{\omega_p |t|} e^{|t| \|G_p\|} \le M_p e^{(\omega_p + \log d)|t|}.$$

We also obtain strong continuity in the parameter. If $p \neq 2$, choose $q \in (1,\infty)$ so that p lies strictly between 2 and q, and $\theta \in (0,1)$ with $1/p = \theta/2 + (1-\theta)/q$. For $\mathbf{u} \in \Gamma_c(\mathbf{E})$, Hölder gives

$$\|(B^{it} - B^{it_0})\mathbf{u}\|_{L^p(M,\mathbf{E})} \le \|(B^{it} - B^{it_0})\mathbf{u}\|_{L^2(M,\mathbf{E})}^{\theta} \|(B^{it} - B^{it_0})\mathbf{u}\|_{L^q(M,\mathbf{E})}^{1-\theta}.$$

The first factor tends to zero by spectral calculus; the second is bounded when t remains in a compact interval, by the estimate already proved with exponent q. Density of $\Gamma_c(\mathbf{E})$ in L^p and the local uniform operator bound extend convergence to every section in L^p. For $p = 2$, spectral continuity applies directly. □

Theorem 13.3.27. (Interpolation of Bessel potentials in bundles) Let $(M, \mathbf{g})$ be a complete Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a finite-rank vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$, Hermitian in the complex case, and a compatible connection $\nabla^{\mathbf{E}}$. Let $L_{\mathbf{E},p}$ be the positive generator of covariant heat and let $1 < p < \infty$. For real bundles, use complexification and restrict the interpolated spaces to real sections. If $0 \le s_0 < s_1$, $0 < \theta < 1$, and $s = (1-\theta)s_0 + \theta s_1$, then

$$[H^{s_0,p}_{L_{\mathbf{E}}}(M,\mathbf{E}), H^{s_1,p}_{L_{\mathbf{E}}}(M,\mathbf{E})]_\theta = H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E}) \tag{13.132}$$

and there exist constants $c_{s_0,s_1,\theta,p}, C_{s_0,s_1,\theta,p} > 0$ such that

$$c_{s_0,s_1,\theta,p} \|\mathbf{u}\|_{H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})} \le \|\mathbf{u}\|_{[H^{s_0,p}_{L_{\mathbf{E}}}(M,\mathbf{E}), H^{s_1,p}_{L_{\mathbf{E}}}(M,\mathbf{E})]_\theta} \le C_{s_0,s_1,\theta,p} \|\mathbf{u}\|_{H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})}.$$

The constants may also depend on the rank of the bundle, which is fixed.

Proof. Set

$$B := I + L_{\mathbf{E},p}, \qquad a_j := \frac{s_j}{2} \quad (j \in \{0,1\}), \qquad a := (1-\theta)a_0 + \theta a_1, \qquad \delta := a_1 - a_0.$$

For $r \ge 0$, the potential B^{-r} is injective and its range is the domain of B^r; moreover,

$$\|\mathbf{u}\|_{H^{2r,p}_{L_{\mathbf{E}}}(M,\mathbf{E})} = \|B^r \mathbf{u}\|_{L^p(M,\mathbf{E})}.$$

It therefore suffices to interpolate the domains $\mathcal{D}(B^{a_j})$ equipped with these norms.
Lemma 13.3.26 proves that imaginary powers of B are bounded on $L^p(M,\mathbf{E})$ and that there exist $M_{p,\mathbf{E}}, \omega_{p,\mathbf{E}} >$

0 such that

$$\|B^{it}\|_{\mathcal{L}(L^p(M,\mathbf{E}))} \le M_{p,\mathbf{E}} e^{\omega_{p,\mathbf{E}}|t|}, \qquad t \in \mathbb{R}. \tag{13.133}$$

This is the analytic estimate allowing the interpolation argument of Chapter 5 to be transferred to the manifold. Use its strip $\mathcal{T} = \{z \in \mathbb{C} \mid 0 < \operatorname{Re} z < 1\}$.
Fix an integer $N > a_1$ and first consider $\mathbf{u} \in \mathcal{D}(B^N)$. For $\varepsilon > 0$ and $z \in \overline{\mathcal{T}}$, set $a(z) := (1-z)a_0 + za_1$ and

$$F_\varepsilon(z) := e^{\varepsilon(z-\theta)^2} B^{a-a(z)}\mathbf{u}.$$

Holomorphy is verified by writing $B^{a-a(z)}\mathbf{u} = B^{a-a(z)-N}B^N\mathbf{u}$: the exponent of the first factor has negative real part throughout the closed strip, and its Laplace integral is holomorphic in the interior. For $z = \sigma + it$, with $\sigma \in [0,1]$, it also factors into the negative real power and $B^{-it\delta}$. The former has norm at most one, and the latter satisfies (13.133). The Gaussian factor makes the family bounded on the strip and its boundary values tend to zero. We have $F_\varepsilon(\theta) = \mathbf{u}$. If $j \in \{0,1\}$ and $t \in \mathbb{R}$, then

$$B^{a_j} F_\varepsilon(j+it) = e^{\varepsilon(j+it-\theta)^2} B^{-it\delta} B^a \mathbf{u}. \tag{13.134}$$

By (13.133), the norm of the right-hand side is bounded by

$$M_{p,\mathbf{E}} \exp\bigl(\varepsilon(j-\theta)^2 - \varepsilon t^2 + \omega_{p,\mathbf{E}}\delta|t|\bigr)\|B^a\mathbf{u}\|_{L^p(M,\mathbf{E})}.$$

Continuity in each endpoint norm follows from the same factorization and strong continuity of the imaginary powers. This expression is bounded and tends to zero as $|t| \to \infty$. Thus, F_ε belongs to the Calderón space of the pair $(\mathcal{D}(B^{a_0}), \mathcal{D}(B^{a_1}))$, and

$$\|\mathbf{u}\|_{[\mathcal{D}(B^{a_0}),\mathcal{D}(B^{a_1})]_\theta} \le C\|B^a\mathbf{u}\|_{L^p(M,\mathbf{E})}. \tag{13.135}$$

Now let $\mathbf{u} \in \mathcal{D}(B^a)$ and set $\mathbf{u}_\eta = (I+\eta B)^{-N}\mathbf{u}$. Then $\mathbf{u}_\eta \in \mathcal{D}(B^N)$ and, since the resolvent commutes with B^a, we have $B^a\mathbf{u}_\eta \to B^a\mathbf{u}$ in $L^p(M,\mathbf{E})$. Estimate (13.135), applied to $\mathbf{u}_\eta - \mathbf{u}_{\eta'}$, shows that $(\mathbf{u}_\eta)$ is Cauchy in the interpolated space. Its limit agrees with $\mathbf{u}$ in $L^p(M,\mathbf{E})$ because the inclusions of both endpoint spaces in $L^p(M,\mathbf{E})$ are continuous. This proves the inclusion and estimate for every $\mathbf{u} \in \mathcal{D}(B^a)$.
We prove the reverse inclusion. Let $F \in \mathscr{F}(\mathcal{D}(B^{a_0}), \mathcal{D}(B^{a_1}))$ and write $\mathbf{u} = F(\theta)$. Regularize the values of F using operators that map them into the domains of the powers we will use. Fix an integer $N > a_1$, take $\eta > 0$, and set

$$R_\eta := (I+\eta B)^{-N}.$$

The operator R_η commutes with powers of B and maps $L^p(M,\mathbf{E})$ into the domain of B^N. Thus, the function

$$G_{\varepsilon,\eta}(z) := e^{\varepsilon(z-\theta)^2} B^{a(z)} R_\eta F(z)$$

is holomorphic with values in $L^p(M,\mathbf{E})$. On the boundary,

$$G_{\varepsilon,\eta}(j+it) = e^{\varepsilon(j+it-\theta)^2} B^{it\delta} R_\eta B^{a_j} F(j+it).$$

Uniform contractivity of R_η, the bound (13.133), and the Gaussian factor give a boundary bound indepen-

dent of η. The three-lines lemma, applied to the pair $(L^p(M,\mathbf{E}), L^p(M,\mathbf{E}))$, gives

$$\|B^a R_\eta \mathbf{u}\|_{L^p(M,\mathbf{E})} \le C\|F\|_{\mathscr{F}}. \tag{13.136}$$

As $\eta \to 0^+$, $R_\eta \mathbf{u} \to \mathbf{u}$ in $L^p(M,\mathbf{E})$. Since $1 < p < \infty$, from (13.136) we can extract a subsequence along which $B^a R_\eta \mathbf{u}$ converges weakly in $L^p(M,\mathbf{E})$. The graph of the closed operator B^a is a closed subspace and hence weakly closed. It follows that $\mathbf{u} \in \mathcal{D}(B^a)$ and

$$\|B^a \mathbf{u}\|_{L^p(M,\mathbf{E})} \le C\|F\|_{\mathscr{F}}.$$

Taking the infimum over functions F with $F(\theta) = \mathbf{u}$ proves the reverse inclusion in (13.135). The constant in that estimate and the constant in (13.135) are $c^{-1}_{s_0,s_1,\theta,p}$ and $C_{s_0,s_1,\theta,p}$, respectively.
Lemma B.4.22 allows any positive shift to be replaced by the shift 1 chosen in the definition of B. □

Theorem 13.3.28. (Uniform localization and Bessel potentials) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, let $s \in \mathbb{R}$, and let $1 < p < \infty$. If $L = \Delta_B = -\Delta$ is the positive realization of the scalar Laplacian, then, as spaces of distributions,

$$H^{s,p}(M) = F^s_{p,2}(M) = H^{s,p}_L(M).$$

More precisely, there exist constants $c_{s,p}, C_{s,p} > 0$ such that

$$c_{s,p}\|u\|_{H^{s,p}(M)} \le \|u\|_{H^{s,p}_L(M)} \le C_{s,p}\|u\|_{H^{s,p}(M)}, \tag{13.137}$$

and there exist $d_{s,p}, D_{s,p} > 0$ such that

$$d_{s,p}\|u\|_{F^s_{p,2}(M)} \le \|u\|_{H^{s,p}(M)} \le D_{s,p}\|u\|_{F^s_{p,2}(M)}. \tag{13.138}$$

The constants do not depend on u.

The interpolation scheme for this identification is that of [146, Section 7.4.5].

Proof. Begin with the identification of the two localized scales. Theorem 6.3.10 gives, for every $v \in \mathcal{S}'(\mathbb{R}^n)$,

$$d_{s,p}\|v\|_{F^s_{p,2}(\mathbb{R}^n)} \le \|v\|_{H^{s,p}(\mathbb{R}^n)} \le D_{s,p}\|v\|_{F^s_{p,2}(\mathbb{R}^n)}.$$

The constants depend only on n, s, p and are therefore the same in all charts. Apply the inequalities to $\widetilde{(h_i u)} \circ \varphi_i^{-1}$, raise to the power p, sum over i, and take the pth root. This proves (13.138); independence of the trivialization was proved earlier.
We now prove (13.137). First suppose $s > 0$ and choose an integer $m > s$. At order zero, Proposition 13.3.14 gives

$$H^{0,p}(M) = L^p(M) = H^{0,p}_L(M).$$

At order m, the same proposition and Theorem 13.3.25, applied to the trivial rank-one bundle, give

$$H^{m,p}(M) = W^{m,p}(M) = H^{m,p}_L(M) \tag{13.139}$$

and the comparisons in (13.45), (13.46), and (13.127) provide positive constants in both directions, independent of u. Set $\theta = \frac{s}{m}$. Proposition 13.3.11 gives

$$[H^{0,p}(M), H^{m,p}(M)]_\theta = H^{s,p}(M),$$

while Theorem 13.3.27 gives

$$[H_L^{0,p}(M), H_L^{m,p}(M)]_\theta = H_L^{s,p}(M).$$

The identity on $C_c^\infty(M)$ is continuous between the two pairs at the endpoints by (13.139). Theorem 5.7.5, applied to the identity and its inverse, proves equality and both estimates for $s > 0$. For $s = 0$, the assertion has already been obtained.

Finally, let $s < 0$ and write $t = -s > 0$. Applying the positive case with conjugate exponent p' and taking duals, Proposition 13.3.11 and the duality item of Theorem 12.4.9 give

$$H^{-t,p}(M) = \big(H^{t,p'}(M)\big)' = \big(H_L^{t,p'}(M)\big)' = H_L^{-t,p}(M).$$

In the real scalar case, both identifications use exactly the distributional pairing induced by $d\lambda_{\mathbf{g}}$. In the complex scalar case, the duality of Theorem 12.4.9 was written using the Hermitian product; composing the representing element with conjugation gives the bilinear distributional pairing of Proposition 13.3.11. The scalar semigroup and its potentials commute with conjugation, so this modification changes neither the space nor its norm. Thus, the equality holds in $\mathcal{D}'(M)$, not merely as an abstract Banach-space isomorphism. The norms of the isomorphisms and their duals produce the constants in (13.137).

The local comparisons and the passage to negative orders are justified by the preceding propositions. □

Corollary 13.3.29. (Agreement of the constructions at integer orders) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and with bounded geometry, $m \in \mathbb{N}_0$, and $1 < p < \infty$. Then

$$W^{m,p}(M) = H^{m,p}(M) = F_{p,2}^m(M) = H_L^{m,p}(M)$$

and there exist constants $c_H, C_H, c_F, C_F, c_L, C_L > 0$, independent of u, such that

$$c_H\|u\|_{W^{m,p}(M)} \le \|u\|_{H^{m,p}(M)} \le C_H\|u\|_{W^{m,p}(M)},$$

$$c_F\|u\|_{W^{m,p}(M)} \le \|u\|_{F_{p,2}^m(M)} \le C_F\|u\|_{W^{m,p}(M)}, \qquad c_L\|u\|_{W^{m,p}(M)} \le \|u\|_{H_L^{m,p}(M)} \le C_L\|u\|_{W^{m,p}(M)}.$$

More generally, if $\mathbf{E} \to M$ is a bundle of bounded geometry, let $\mathbf{u}$ be a section of $\mathbf{E}$. Denote by $N_{m,p}(\mathbf{u})$ the localized component norm defined in (13.45), and by $c_{m,p}, C_{m,p}, c_{m,p}^L, C_{m,p}^L > 0$ the constants in (13.45) and (13.127). Then

$$c_{m,p}\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \le N_{m,p}(\mathbf{u}) \le C_{m,p}\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})},$$
$$c_{m,p}^L\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \le \|\mathbf{u}\|_{H_{L_{\mathbf{E}}}^{m,p}(M,\mathbf{E})} \le C_{m,p}^L\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

The constants do not depend on the section.

Proof. In the scalar case, combine Theorem 13.3.28, Proposition 13.3.14, and the Euclidean identification $H^{m,p}(\mathbb{R}^n) = F_{p,2}^m(\mathbb{R}^n)$. The vector-valued assertion follows directly by combining (13.45) and (13.127). □

Remark 13.3.30. (Uniformity and compactness) The preceding norm comparisons allow local estimates to be summed with uniform constants. When the integrability exponent changes, global embeddings also use the inclusion of outer sums $\ell^p \subseteq \ell^q$ for $p \leq q$; comparison of differential indices does not replace this condition on a manifold of infinite volume. The precise ranges are formulated in Theorem 14.6.2.

Nor does a strict gain in index imply global compactness. Already on $\mathbb{R}^n$, translates of a nonzero smooth compactly supported function preserve its Sobolev norms and can have pairwise disjoint supports; their distances in L^q remain equal to $2^{1/q}\|u\|_{L^q(\mathbb{R}^n)} > 0$ for $q < \infty$. Proposition 14.6.8 obtains compactness after multiplication by a compactly supported cutoff and for families supported in a common compact set. A global conclusion on a noncompact manifold also requires control of mass escaping to infinity, as explained in Remark 14.6.10.

14

Trace theorems in bounded geometry

A smooth function can be restricted to a submanifold without difficulty. For a Sobolev function, however, its values on a set of measure zero are not determined by its equivalence class. The trace resolves this problem when there is sufficient transverse regularity: it is defined by continuity, identifies the space receiving the restriction, and allows us to ask whether every datum in that space admits an extension.

The threshold comes from the Euclidean model. To transfer it to a noncompact manifold, we must control adapted coordinates, frames, and cutoff functions, and justify the sums reconstructing the trace and its right inverse. Fermi charts keep the submanifold visible; in the presence of a boundary, the collar also allows tangential derivatives to be separated from normal jets.

We begin with these geometric constructions and their uniform estimates. We then treat traces of functions and sections, comparison with covariant norms, and Sobolev embeddings. The exposition distinguishes restriction spaces on the half-space from extensions by zero and preserves the order of summation defining each function-space scale; see [72, 130, 6].

The boundary as analytic data

Restricting a smooth function to a submanifold seems elementary; for a Sobolev class, however, it is possible only when there is sufficient transverse regularity. The trace theorem precisely identifies what information survives at the boundary and which space receives it. On noncompact manifolds, the problem also requires collars, Fermi charts, and extensions to be constructed with uniform constants. This combination of adapted geometry and fractional regularity is one of the contemporary forms of global analysis [72, 127].

14.1 The Euclidean model and its compatibility properties

Let $n > k \geq 0$ and $c := n - k$. Identify $\mathbb{R}^k$ with $\{0\}^c \times \mathbb{R}^k \subseteq \mathbb{R}^c \times \mathbb{R}^k$, and, for a smooth function u, write

$$\operatorname{tr}_c u(x') := u(0, x'), \qquad x' \in \mathbb{R}^k.$$

When $k = 0$, $\mathbb{R}^0$ is a point with counting measure; its $H^{t,p}$, $F^t_{p,q}$, and $B^t_{p,q}$ spaces are identified with the scalar field, equipped with its absolute-value norm. This convention includes the boundary of a one-dimensional manifold.

The Euclidean result proved in Theorem 6.7.2 will be used in the following form.

Theorem 14.1.1. (Euclidean trace in arbitrary codimension) Let $1 < p < \infty$, $s > \frac{c}{p}$, and $c = n - k$. Restriction of Schwartz functions extends uniquely to a continuous surjective linear operator

$$\operatorname{tr}_c \colon H^{s,p}(\mathbb{R}^c \times \mathbb{R}^k) \longrightarrow B^{s-\frac{c}{p}}_{p,p}(\mathbb{R}^k).$$

There exists a continuous linear operator

$$\operatorname{ex}_c \colon B^{s-\frac{c}{p}}_{p,p}(\mathbb{R}^k) \longrightarrow H^{s,p}(\mathbb{R}^n)$$

such that $\operatorname{tr}_c \operatorname{ex}_c = \mathrm{id}$. The operators can be chosen to be continuous also on the scales

$$\operatorname{tr}_c \colon F^s_{p,q}(\mathbb{R}^n) \longrightarrow B^{s-\frac{c}{p}}_{p,p}(\mathbb{R}^k), \qquad \operatorname{tr}_c \colon B^s_{p,q}(\mathbb{R}^n) \longrightarrow B^{s-\frac{c}{p}}_{p,q}(\mathbb{R}^k),$$

for $1 \le q \le \infty$, with corresponding right extension operators.

Proof. For the last step when $k = 0$, we need evaluation at a point of $\mathbb{R}$. If $A^s_{p,q}$ denotes $F^s_{p,q}$ or $B^s_{p,q}$, Theorem 4.12.4 in dimension one gives

$$\sum_{j\in\mathbb{N}_0} \|\Delta_j u\|_\infty \le C \sum_{j\in\mathbb{N}_0} 2^{j/p} \|\Delta_j u\|_{L^p(\mathbb{R}^n)} \le C \left(\sum_{j\in\mathbb{N}_0} 2^{-j(s-1/p)} \right) \|u\|_{A^s_{p,q}}, \qquad s > 1/p.$$

In both scales, each $2^{js}\|\Delta_j u\|_{L^p(\mathbb{R}^n)}$ is bounded by the space norm. The series converges uniformly and defines a continuous representative whose evaluation at zero is a continuous trace. A fixed function $\varphi \in \mathcal{S}(\mathbb{R})$ with $\varphi(0) = 1$ gives the coretraction $a \mapsto a\varphi$, common to all orders. This also proves the Bessel case through $H^{s,p} = F^s_{p,2}$.

Write a point of $\mathbb{R}^n$ as $(z_1, \dots, z_c, x')$, with $x' \in \mathbb{R}^k$, and denote by τ_r the restriction $z_r = 0$ after eliminating the variables $z_1, \dots, z_{r-1}$. Theorem 6.7.2 and its coretraction give, for $r \in \{1, \dots, c\}$,

$$\tau_r \colon F^{s-\frac{r-1}{p}}_{p,p}(\mathbb{R}^{n-r+1}) \longrightarrow B^{s-\frac{r}{p}}_{p,p}(\mathbb{R}^{n-r}) = F^{s-\frac{r}{p}}_{p,p}(\mathbb{R}^{n-r}).$$

The equality in the last member is $B^\sigma_{p,p}(\mathbb{R}^d) = F^\sigma_{p,p}(\mathbb{R}^d)$. The condition $s > \frac{c}{p}$ implies

$$s - \frac{r-1}{p} > \frac{1}{p}, \qquad r \in \{1, \dots, c\},$$

so every operator is defined. Since $H^{s,p}(\mathbb{R}^n) = F^s_{p,2}(\mathbb{R}^n)$, the first restriction is applied with second index 2, and its image already has second index p; the remaining $c-1$ restrictions are those above. The composition $\tau_c \cdots \tau_1$ is tr_c and satisfies

$$\|\operatorname{tr}_c u\|_{B^{s-\frac{c}{p}}_{p,p}(\mathbb{R}^k)} \le C \|u\|_{H^{s,p}(\mathbb{R}^n)}.$$

Starting from $F^s_{p,q}(\mathbb{R}^n)$, the first restriction has image $B^{s-\frac{1}{p}}_{p,p} = F^{s-\frac{1}{p}}_{p,p}$, so the preceding calculation applies again. Starting from $B^s_{p,q}(\mathbb{R}^n)$, every restriction preserves the index q and lowers the order by $\frac{1}{p}$. This gives the other two estimates.

Let e_r be the codimension-one coretractions, each inserting the variable z_r. In the construction of Theorem 6.7.2, a single family of profiles in the normal variable is fixed; thus, the same operators e_r act simultaneously on all scales in the statement. Choose those operators and define

$$\mathrm{ex}_c := e_1 e_2 \cdots e_c.$$

The composition is linear and continuous on each of the three scales. Moreover, canceling the factors from the outside inward gives

$$\mathrm{tr}_c \, \mathrm{ex}_c = \tau_c \cdots \tau_1 e_1 \cdots e_c = I.$$

Thus, tr_c is surjective and ex_c is a continuous right inverse. □

For restrictions computed in different charts to represent the same datum, the trace must commute with multiplication by cutoffs and with coordinate changes preserving the submanifold.

Lemma 14.1.2. (Compatibility properties of the Euclidean trace) Let $1 < p < \infty$, $1 \le q \le \infty$, and $s > \frac{c}{p}$. Consider any of the three continuous operators

$$\mathrm{tr}_c \colon H^{s,p}(\mathbb{R}^n) \longrightarrow B^{s-\frac{c}{p}}_{p,p}(\mathbb{R}^k),$$
$$\mathrm{tr}_c \colon F^{s}_{p,q}(\mathbb{R}^n) \longrightarrow B^{s-\frac{c}{p}}_{p,p}(\mathbb{R}^k),$$
$$\mathrm{tr}_c \colon B^{s}_{p,q}(\mathbb{R}^n) \longrightarrow B^{s-\frac{c}{p}}_{p,q}(\mathbb{R}^k).$$

The following properties hold in each case.

(a) Let $a \in C^\infty(\mathbb{R}^n)$. Suppose multiplication by a is continuous on the source space and multiplication by $a \restriction_{\mathbb{R}^k}$ is continuous on the target space. In the cases with fine index $q = \infty$, also assume that both multiplications remain continuous when s is replaced by $s - \varepsilon$ and the order of the target space by $s - \varepsilon - \frac{c}{p}$, for every sufficiently small $\varepsilon > 0$ with $s - \varepsilon > \frac{c}{p}$. Then

$$\mathrm{tr}_c(au) = (a \restriction_{\mathbb{R}^k}) \, \mathrm{tr}_c \, u.$$

(b) Let $\Phi \colon \mathbb{R}^n \longrightarrow \mathbb{R}^n$ be a diffeomorphism preserving $\mathbb{R}^k$. Suppose composition with Φ and with $\Phi \restriction_{\mathbb{R}^k}$ is continuous on the source and target spaces, respectively. In the cases with fine index $q = \infty$, also assume the same continuity after replacing s by $s - \varepsilon$ and the target-space order by $s - \varepsilon - \frac{c}{p}$, for every sufficiently small $\varepsilon > 0$ with $s - \varepsilon > \frac{c}{p}$. Then

$$\mathrm{tr}_c(u \circ \Phi) = (\mathrm{tr}_c \, u) \circ (\Phi \restriction_{\mathbb{R}^k}).$$

(c) The same identities hold componentwise for functions taking values in a finite-dimensional vector space.

Proof. For $u \in \mathcal{S}(\mathbb{R}^n)$, the identities in (a) and (b) are pointwise equalities. First consider $H^{s,p}$ or one of the spaces $F^{s}_{p,q}$ and $B^{s}_{p,q}$ with $q < \infty$. In these cases, Corollary 6.3.9 gives density of $\mathcal{S}(\mathbb{R}^n)$ in the source space. Continuity of the trace, multiplication, and composition permits passage to the limit and proves the identities.

For $F^{s}_{p,\infty}$ and $B^{s}_{p,\infty}$, fix $\varepsilon \in (0, s - c/p)$ and write A for the scale under consideration. Corollary 6.3.9 provides $u_j \in \mathcal{S}(\mathbb{R}^n)$ such that

$$u_j \longrightarrow u \quad \text{in } A^{s-\varepsilon}_{p,\infty}(\mathbb{R}^n).$$

For example, first approximate in the space with fine index p and order $s - \varepsilon/2$, and then use its embedding into the displayed space. The loss of order permits this approximation even though Schwartz functions need not be dense in the original norm.

Traces of the same element taken at two admissible orders agree. Indeed, in codimension one they are defined by the same series of block restrictions in Theorem 6.7.2; its distributional limit is independent of the order used to estimate it. Composing these traces preserves compatibility in codimension c. The estimates place the limit in the target space of order $s - c/p$, even though the approximations converge only at the lower order.

Now apply the pointwise identities of the lemma to u_j. The additional continuities in (a) and (b), all at fine index ∞ and order $s - \varepsilon$, permit passage to the limit on both sides. Continuity of the trace at that order identifies their limits as distributions on $\mathbb{R}^k$. By the compatibility just proved, these limits are the traces of order s. Both sides belong to the target space of order $s - c/p$, so the equality holds there as well.

For (c), fix a basis of the value space and apply the scalar identities to each component. Since there are only finitely many components, all preceding operations and convergences are preserved. □

14.2 Pairs of bounded geometry and uniform Fermi estimates

In the Fermi charts of this section, write the c normal variables first, followed by the k tangential variables. Thus, N is represented by $\{0\}^c \times \mathbb{R}^k$, exactly as in the Euclidean model of the preceding section.

Definition 14.2.1. (Pair of bounded geometry) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary of dimension n, and let $N \subseteq M$ be an embedded submanifold without boundary, closed as a subset of M, of dimension k, with $0 \le k < n$, equipped with the induced metric. Set $c := n - k$. We say that (M, N) is a *pair of bounded geometry* if the following conditions hold.

(a) $(M, \mathbf{g})$ has bounded geometry in the sense of Definition 13.1.5.

(b) $\operatorname{inj}(N) > 0$.

(c) There exists $r_\perp > 0$ such that

$$\exp^{\perp}\colon \left\{(x, v) \in T^{\perp}N \,\middle|\, |v|_{\mathbf{g}} < r_\perp\right\} \longrightarrow M$$

is a diffeomorphism onto its image.

(d) For each $\ell \in \mathbb{N}_0$,

$$\sup_{x \in N} \left|(\nabla^{\mathbf{II}})^{\ell}\mathbf{II}(x)\right|_{\mathbf{g}} < \infty,$$

where the covariant derivatives and pointwise norm are those of Definition 2.11.5.

This is the bounded-geometry condition for the pair (M, N) in [72, Definition 18].

Remark 14.2.2. The third condition is global: it prevents normal tubes based at distinct points of N from meeting at arbitrarily small distance. A uniformly finite local version suffices for continuity of the trace; the global right-inverse construction we will use requires a uniform tubular neighborhood. This distinction corresponds to [72, Remark 33].

Lemma 14.2.3. (Gauss formula and induced geometry) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $N \subseteq M$ be an embedded submanifold without boundary, closed as a subset of M. If (M,N) is a pair of bounded geometry, then $(N,\mathbf{g}\restriction_N)$ is a manifold of bounded geometry. More precisely, for each $\ell \in \mathbb{N}_0$, there exists a constant C'_ℓ, determined by the bounds on $(\nabla^M)^j\mathbf{R}^M$ and $(\nabla^{\mathbf{II}})^j\mathbf{II}$ with $j \le \ell$, such that

$$\left|(\nabla^N)^\ell \mathbf{R}^N\right|_{\mathbf{g}\restriction_N} \le C'_\ell.$$

Proof. For fields $\mathbf{X},\mathbf{Y}$ tangent to N, the orthogonal decomposition of the ambient derivative is

$$\nabla^M_{\mathbf{X}}\mathbf{Y} = \nabla^N_{\mathbf{X}}\mathbf{Y} + \mathbf{II}(\mathbf{X},\mathbf{Y}).$$

If $\mathbf{X},\mathbf{Y},\mathbf{Z},\mathbf{W}$ are tangent, substitute this identity into the definition of $\mathbf{R}^M(\mathbf{X},\mathbf{Y})\mathbf{Z}$, take tangential components, and pair with $\mathbf{W}$. Terms with two tangential derivatives form $\mathbf{R}^N$; normal terms are transformed using

$$\mathbf{g}(\nabla^M_{\mathbf{X}}\eta,\mathbf{W}) = -\mathbf{g}(\eta,\mathbf{II}(\mathbf{X},\mathbf{W})), \qquad \eta \in \Gamma(T^\perp N),$$

which follows by differentiating $\mathbf{g}(\eta,\mathbf{W}) = 0$. This gives the Gauss equation

$$\begin{aligned}\mathbf{g}(\mathbf{R}^N(\mathbf{X},\mathbf{Y})\mathbf{Z},\mathbf{W}) &= \mathbf{g}(\mathbf{R}^M(\mathbf{X},\mathbf{Y})\mathbf{Z},\mathbf{W}) \\ &\quad + \mathbf{g}(\mathbf{II}(\mathbf{X},\mathbf{W}),\mathbf{II}(\mathbf{Y},\mathbf{Z})) - \mathbf{g}(\mathbf{II}(\mathbf{X},\mathbf{Z}),\mathbf{II}(\mathbf{Y},\mathbf{W})).\end{aligned} \tag{14.1}$$

Apply $(\nabla^N)^\ell$ to (14.1), using compatibility with contractions from Proposition 2.4.13 and the Leibniz rule for the operator $*$ from Proposition 9.1.40. To specify the terms involved, define

$$\mathcal{I}_\ell := \left\{ (a,r,b_1,\dots,b_r) \;\middle|\; a,r \in \mathbb{N}_0,\ (b_1,\dots,b_r) \in \mathbb{N}_0^r,\ a + \sum_{j=1}^{r}(b_j+1) \le \ell \right\}.$$

The empty sum is zero when $r = 0$. We claim that $(\nabla^N)^\ell(\mathbf{R}^M\restriction_{TN})$ is a finite sum of contractions, with universal coefficients, of terms

$$\left((\nabla^M)^a\mathbf{R}^M\right)\restriction_N * (\nabla^{\mathbf{II}})^{b_1}\mathbf{II} * \cdots * (\nabla^{\mathbf{II}})^{b_r}\mathbf{II}, \qquad (a,r,b_1,\dots,b_r) \in \mathcal{I}_\ell. \tag{14.2}$$

The case $\ell = 0$ has a single factor: $a = r = 0$. Suppose the expression has been obtained at order ℓ. When a summand is differentiated, the Leibniz rule makes the connection act on exactly one factor. If it acts on the ambient curvature, the leading term replaces a by $a+1$. Comparing the ambient connection with the tangential and normal connections, the Gauss and Weingarten formulas also produce a factor $\mathbf{II}$: replace r by $r+1$ and add the exponent $b_{r+1} = 0$. If the derivative acts on factor number $j \in \{1,\dots,r\}$, it replaces b_j by b_j+1. In all three cases, the weight $a + \sum_{j=1}^{r}(b_j+1)$ increases by one. Metric contractions produce no

additional terms, since the connections preserve the metrics. Thus, all new indices belong to $\mathcal{I}_{\ell+1}$ and the number of terms still depends only on $n, \dim N, \ell+1$. This proves the expression for every $\ell \in \mathbb{N}_0$.
The derivatives of the quadratic Gauss term are

$$(\nabla^{\mathbf{II}})^a \mathbf{II} * (\nabla^{\mathbf{II}})^b \mathbf{II}, \qquad a+b=\ell.$$

The symbol $*$ denotes a universal contraction with the metric, and the number of summands depends only on n, k, ℓ. The hypotheses of Definition 14.2.1 bound every factor and give C'_ℓ. Since $\operatorname{inj}(N) > 0$ is already part of the definition, N has bounded geometry by Definition 13.1.5. □

Lemma 14.2.4. (Uniform estimates for families of differential equations) Let $P \subseteq \mathbb{R}^q$ and $V \subseteq \mathbb{R}^d$ be open, let $P_0 \Subset P$, and let Λ be an index set. Consider

$$\dot{y} = F_\lambda(t,a,y), \qquad y(0) = b_\lambda(a), \qquad a \in P_0.$$

Suppose F_λ is continuous in t, smooth in (a,y), and all its derivatives with respect to (a,y) are jointly continuous. Suppose b_λ is smooth and there exists a compact set $K \Subset V$ with the following property. For all multi-indices $\alpha \in \mathbb{N}_0^q$ and $\beta \in \mathbb{N}_0^d$, there exist constants independent of λ such that

$$\sup_{\lambda\in\Lambda} \sup_{(t,a,y)\in[0,1]\times P_0\times K} \left\| \partial_a^\alpha \partial_y^\beta F_\lambda(t,a,y) \right\| \le C_{\alpha,\beta},$$

$$\sup_{\lambda\in\Lambda} \sup_{a\in P_0} \left\| \partial_a^\alpha b_\lambda(a) \right\| \le C'_\alpha.$$

Here derivatives are ordinary partial derivatives in finite-dimensional spaces, taken componentwise. If the solutions $y_\lambda(t,a)$ exist for $0 \le t \le 1$ and remain in K, then, for each $m \in \mathbb{N}_0$, there exists $C''_m > 0$ such that

$$\sup_{\lambda\in\Lambda} \sup_{a\in P_0} \sup_{t\in[0,1]} \max_{\substack{\alpha\in\mathbb{N}_0^q \\ |\alpha|\le m}} \left\| \partial_a^\alpha y_\lambda(t,a) \right\| \le C''_m.$$

Proof. Fix λ and a parameter a in a neighborhood of P_0 where the solution exists. The integral equation is

$$y_\lambda(t,a) = b_\lambda(a) + \int_0^t F_\lambda(\tau, a, y_\lambda(\tau,a))\, d\tau.$$

On a compact neighborhood of the trajectory, $\partial_y F_\lambda$ is bounded. Subtracting the equations for two parameters and applying Grönwall first proves continuity of $a \mapsto y_\lambda(\cdot,a)$ in $C([0,1])$. For a coordinate direction, set $Z_h(t) := (y_\lambda(t, a+he_\nu) - y_\lambda(t,a))/h$. The fundamental theorem of calculus in the variables (a,y) gives

$$Z_h(t) = \frac{b_\lambda(a+he_\nu) - b_\lambda(a)}{h} + \int_0^t \big(A_h(\tau) Z_h(\tau) + f_h(\tau) \big)\, d\tau,$$

where A_h and f_h are averages of $\partial_y F_\lambda$ and $\partial_{a_\nu} F_\lambda$ along the segment joining the two arguments. By joint continuity, they converge uniformly to $\partial_y F_\lambda(\tau,a,y_\lambda)$ and $\partial_{a_\nu} F_\lambda(\tau,a,y_\lambda)$. Applying Grönwall again to the difference between this equation and its limiting equation proves uniform convergence of Z_h. Thus, $Z_\nu =$

$\partial_{a_\nu} y_\lambda$ exists and satisfies the variational equation

$$\dot{Z}_\nu = (\partial_y F_\lambda)(t,a,y_\lambda) Z_\nu + \partial_{a_\nu} F_\lambda(t,a,y_\lambda), \qquad Z_\nu(0,a) = \partial_{a_\nu} b_\lambda(a).$$

The hypotheses and Grönwall's Lemma 1.8.19 bound Z_ν uniformly, simultaneously for $\nu \in \{1,\dots,q\}$.
The same difference-quotient argument, applied to the variational equations already obtained, proves inductively the existence and continuity of all parameter derivatives. For their uniform bounds, suppose derivatives of order less than $m \geq 2$ have already been bounded. Fix a multi-index $\gamma \in \mathbb{N}_0^q$ with $|\gamma| = m$. Apply ∂_a^γ to the identity

$$\partial_t y_\lambda(t,a) = F_\lambda(t,a,y_\lambda(t,a)).$$

The multivariable Faà di Bruno formula of Theorem 1.1.19, applied componentwise to the function of the variables (a,y) and the mapping $a \mapsto (a, y_\lambda(t,a))$, separates exactly the term in which a derivative with respect to y falls on $\partial_a^\gamma y_\lambda$. This gives

$$\partial_t(\partial_a^\gamma y_\lambda) = (\partial_y F_\lambda)(t,a,y_\lambda)\partial_a^\gamma y_\lambda + Q_{\lambda,\gamma}(t,a),$$

$$\partial_a^\gamma y_\lambda(0,a) = \partial_a^\gamma b_\lambda(a).$$

Each summand of $Q_{\lambda,\gamma}$ is a product of a derivative

$$\partial_a^\alpha \partial_y^\beta F_\lambda(t,a,y_\lambda(t,a))$$

and derivatives $\partial_a^{\gamma_j} y_\lambda$ with $|\gamma_j| < m$. The number of summands depends only on m,q,d. The hypotheses and induction therefore provide a constant K_m such that

$$\|Q_{\lambda,\gamma}(t,a)\| \leq K_m$$

for all parameters considered. Another application of Grönwall's Lemma 1.8.19 bounds $\partial_a^\gamma y_\lambda$ uniformly in $[0,1]$. Since there are only finitely many multi-indices of order at most m, induction proves the estimate in the statement. □

Remark 14.2.5. Lemma 1.8.20 treats a single autonomous field and gives a more precise estimate along each trajectory. The preceding lemma allows time dependence, external parameters, and variable initial data. In particular, dependence on initial data is recovered by taking F_λ independent of a and $b_\lambda(a) = a$.

Proposition 14.2.6. (Uniform Fermi atlas and partition) Let (M,N) be a pair of bounded geometry in the sense of Definition 14.2.1; in particular, M and N are smooth manifolds without boundary of dimensions n and k, respectively. There exist $r_{\mathrm{F}} > 0$, a countable family of points $(p_i)_{i\in I_N} \subseteq N$, Fermi charts

$$\kappa_i \colon B^c_{\mathrm{euc}}(0,2r_{\mathrm{F}}) \times B^k_{\mathrm{euc}}(0,2r_{\mathrm{F}}) \longrightarrow U_i \subseteq M, \qquad i \in I_N,$$

geodesic charts $(\kappa_j)_{j\in I_0}$ whose images cover the complement of a smaller tube and satisfy $U_j \cap N = \varnothing$, and functions $h_\alpha \in C_c^\infty(U_\alpha)$, $\alpha \in I := I_N \sqcup I_0$, with the following properties.

(a) The cover $(U_\alpha)_{\alpha\in I}$ is uniformly locally finite in the sense of Definition 13.1.13.

(b) $\sum_{\alpha\in I} h_\alpha^2 = 1$ on M, and, for every multi-index β, there exists C_β such that

$$\sup_{\alpha\in I}\left\|D^\beta(h_\alpha\circ\kappa_\alpha)\right\|_{L^\infty(\operatorname{dom}\kappa_\alpha)} \le C_\beta.$$

(c) If $i \in I_N$, then

$$\kappa_i(z,u) = \exp^\perp\left(\exp_{p_i}^N(\lambda_i u), \sum_{a=1}^{c} z^a \boldsymbol{\nu}_{i,a}(\exp_{p_i}^N(\lambda_i u))\right), \tag{14.3}$$

where $\lambda_i\colon \mathbb{R}^k \longrightarrow T_{p_i}N$ is an isometry and $(\boldsymbol{\nu}_{i,a})_{a=1}^c$ is an orthonormal frame of the normal bundle obtained by parallel transport for the normal connection along radial geodesics of N. Moreover,

$$\kappa_i^{-1}(N\cap U_i) = \{0\}\times B^k_{\mathrm{euc}}(0, 2r_{\mathrm{F}}).$$

(d) In every chart, including Fermi charts, there exist $0 < c_0 \le C_0 < \infty$ such that

$$c_0\|\zeta\|^2 \le \sum_{a,b=1}^{n} g_{\alpha,ab}(x)\zeta^a\zeta^b \le C_0\|\zeta\|^2. \tag{14.4}$$

For each multi-index β, the functions $D^\beta g_{\alpha,ab}$ and $D^\beta \mathbf{g}_\alpha^{ab}$ are bounded by a constant independent of α.

(e) Transitions between these charts and the geodesic atlas of Theorem 13.1.22, and their inverses, have uniformly bounded derivatives of every order on the domains where they are used. Thus,

$$\mathcal{Q}_{\mathrm{F}} := (U_\alpha, \kappa_\alpha^{-1}, h_\alpha)_{\alpha\in I}$$

is an admissible quadratic localization system and $(U_\alpha, \kappa_\alpha^{-1}, h_\alpha^2)_{\alpha\in I}$ is the associated admissible trivialization.

Proof. Begin by obtaining estimates valid for any center in N. By Lemma 14.2.3, N has bounded geometry. Let $r_{0,N}$ and $r_{0,M}$ be radii for which condition (2) of Theorem 13.1.8 holds on N and M, respectively. Lemma 13.1.21 applies up to these radii. Choose

$$0 < r_{\mathrm{F}} < \min\left\{\frac{1}{8}\operatorname{inj}(N), \frac{r_\perp}{8}, \frac{1}{8}\operatorname{inj}(M), \frac{r_{0,N}}{5}, \frac{r_{0,M}}{5}\right\}.$$

For now, the index i denotes an arbitrary center $p_i \in N$, rather than a previously chosen net. The following estimates are independent of this center. Once all radius reductions have been fixed, we will choose the maximal net and verify the cover multiplicity.

To construct the normal frames, fix an orthonormal basis of $T_{p_i}^\perp N$ and parallel transport it, for the normal connection, along the radial geodesics of N starting at p_i. First specify all connections involved. Denote by ∇^M and ∇^N the Levi–Civita connections of M and N, by

$$\nabla^\perp_{\mathbf{X}}\boldsymbol{\eta} = (\nabla^M_{\mathbf{X}}\boldsymbol{\eta})^\perp$$

the normal connection, by $\nabla^{\mathbf{II}}$ the induced product connection on $T^*N \otimes T^*N \otimes T^\perp N$, and by ∇^F the connection induced by ∇^M on the pullback of TM under each variational mapping F below. Our conventions give the Gauss and Weingarten formulas

$$\nabla^M_{\mathbf{X}}\mathbf{Y} = \nabla^N_{\mathbf{X}}\mathbf{Y} + \mathbf{II}(\mathbf{X},\mathbf{Y}), \qquad \nabla^M_{\mathbf{X}}\eta = -\mathbf{A}_\eta\mathbf{X} + \nabla^\perp_{\mathbf{X}}\eta, \qquad \mathbf{g}(\mathbf{A}_\eta\mathbf{X},\mathbf{Y}) = \mathbf{g}(\mathbf{II}(\mathbf{X},\mathbf{Y}),\eta). \tag{14.5}$$

Taking the normal component in the definition of $\mathbf{R}^M(\mathbf{X},\mathbf{Y})\eta$ and using (14.5) gives the Ricci equation

$$\mathbf{g}(\mathbf{R}^\perp(\mathbf{X},\mathbf{Y})\eta,\zeta) = \mathbf{g}(\mathbf{R}^M(\mathbf{X},\mathbf{Y})\eta,\zeta) + \mathbf{g}([\mathbf{A}_\eta,\mathbf{A}_\zeta]\mathbf{X},\mathbf{Y}). \tag{14.6}$$

Indeed, the normal terms of $\nabla^M_{\mathbf{X}}(-\mathbf{A}_\eta\mathbf{Y})$ and $\nabla^M_{\mathbf{Y}}(-\mathbf{A}_\eta\mathbf{X})$ are $-\mathbf{II}(\mathbf{X},\mathbf{A}_\eta\mathbf{Y})$ and $-\mathbf{II}(\mathbf{Y},\mathbf{A}_\eta\mathbf{X})$; pairing them with ζ gives the commutator of (14.6). Derivatives of this identity are controlled by the following recurrence. At order zero, take exactly the two summands on its right-hand side. To pass from order q to $q+1$, apply the product connection to each contraction and use the exact rule

$$\nabla_{\mathbf{X}}\,\mathrm{contr}(\mathbf{T}_1\otimes\cdots\otimes\mathbf{T}_\ell) = \sum_{j=1}^{\ell}\mathrm{contr}(\mathbf{T}_1\otimes\cdots\otimes\nabla_{\mathbf{X}}\mathbf{T}_j\otimes\cdots\otimes\mathbf{T}_\ell).$$

If the derivative reaches the restriction of $(\nabla^M)^a\mathbf{R}^M$, the Gauss and Weingarten formulas produce $(\nabla^M)^{a+1}\mathbf{R}^M$ and contractions of $(\nabla^M)^a\mathbf{R}^M$ with $\mathbf{II}$. If it reaches a shape operator, the identity

$$\mathbf{g}\big((\nabla_{\mathbf{X}}\mathbf{A})_\eta\mathbf{Y},\mathbf{Z}\big) = \mathbf{g}\big((\nabla^{\mathbf{II}}_{\mathbf{X}}\mathbf{II})(\mathbf{Y},\mathbf{Z}),\eta\big)$$

—understood with the product connections on all arguments—replaces it by a derivative of $\mathbf{II}$. This rule determines a finite family at each order and proves by induction that $(\nabla^\perp)^q\mathbf{R}^\perp$ is a universal sum of contractions of $(\nabla^M)^a\mathbf{R}^M$ and $(\nabla^{\mathbf{II}})^b\mathbf{II}$, with $a,b\le q$, together with undifferentiated copies of $\mathbf{II}$ introduced by Gauss–Weingarten.

If $\omega^\perp_\mu$ and $F^\perp_{\nu\mu}$ are the matrices of the normal connection and its curvature, respectively, in a radial geodesic chart of N, radial gauge satisfies $\sum_{\mu=1}^{k} y^\mu\omega^\perp_\mu(y) = 0$ and the exact identity

$$\omega^\perp_\mu(y) = \int_0^1 s\sum_{\nu=1}^{k} y^\nu F^\perp_{\nu\mu}(sy)\,ds. \tag{14.7}$$

This follows by contracting the structure equation with the radial field and differentiating $s\omega^\perp_\mu(sy)$. For a multi-index α, the Leibniz rule and linearity of y^ν give the full formula

$$\begin{aligned}\partial^\alpha\omega^\perp_\mu(y) = {}& \int_0^1 s^{|\alpha|+1}\sum_{\nu=1}^{k} y^\nu(\partial^\alpha F^\perp_{\nu\mu})(sy)\,ds \\ & + \sum_{\substack{j\in\{1,\dots,k\}\\ \alpha_j>0}} \alpha_j\int_0^1 s^{|\alpha|}(\partial^{\alpha-e_j}F^\perp_{j\mu})(sy)\,ds.\end{aligned}$$

Control is established by simultaneous induction. At order zero, the tensor bound on $\mathbf{R}^\perp$ bounds its com-

ponents $F^{\perp}_{\nu\mu}$ in the orthonormal frame, and the radial formula bounds $\omega^{\perp}$. Suppose derivatives of $\omega^{\perp}$ of order less than q have been controlled. The component identity

$$(\nabla^{\perp}_{\lambda}F^{\perp})_{\nu\mu} = \partial_{\lambda}F^{\perp}_{\nu\mu} + [\omega^{\perp}_{\lambda}, F^{\perp}_{\nu\mu}] - \sum_{\kappa=1}^{k}\left(\Gamma^{\kappa}_{\lambda\nu}F^{\perp}_{\kappa\mu} + \Gamma^{\kappa}_{\lambda\mu}F^{\perp}_{\nu\kappa}\right)$$

and the higher-derivative expression in Lemma 9.1.28 express every ordinary derivative of $F^{\perp}$ of order q through $(\nabla^{\perp})^{a}F^{\perp}$, $a \le q$, derivatives of $\omega^{\perp}$ of order less than q, and already controlled derivatives of the Christoffel symbols of N. The preceding integral formula then bounds derivatives of $\omega^{\perp}$ of order q and closes the induction.

Frame bounds are interpreted through the connection, not through components in an arbitrary trivialization. Indeed,

$$\nabla^{\perp}_{\partial_{\mu}}\boldsymbol{\nu}_{i,a} = \sum_{b=1}^{c}(\omega^{\perp}_{\mu})^{b}{}_{a}\,\boldsymbol{\nu}_{i,b}.$$

Since the frame is orthonormal, this formula bounds its first covariant derivatives; differentiating it, the Leibniz rule and the bounds on $\partial^{\alpha}\omega^{\perp}$ bound derivatives of every order. Gauss–Weingarten converts these normal controls into controls for the ambient connection, adding only factors of $\mathbf{II}$ and its derivatives. In uniform ambient charts, the local expression for the connection finally converts these controls into component bounds. These are the initial data used in the Jacobi equation.

Now consider the normal exponential map as the mapping

$$\mathcal{F}\colon \mathcal{V}_{\perp} := \{(x,\xi) \in T^{\perp}N \mid |\xi|_{\mathbf{g}} < r_{\perp}\} \longrightarrow M, \qquad \mathcal{F}(x,\xi) = \exp^{M}_{x}(\xi).$$

By the tubular hypothesis, its restriction to $\mathcal{V}_{\perp}$ is a diffeomorphism onto its image. Set

$$x_i(u) := \exp^{N}_{p_i}(\lambda_i u), \qquad \boldsymbol{\xi}_i(z,u) := \sum_{a=1}^{c} z^{a}\boldsymbol{\nu}_{i,a}(x_i(u)),$$

and, for $0 \le t \le 1$,

$$F_i(z,u,t) := \mathcal{F}(x_i(u), t\boldsymbol{\xi}_i(z,u)). \tag{14.8}$$

Then $\kappa_i(z,u) = F_i(z,u,1)$.

Write

$$D := \nabla^{F_i}_{\partial_t}, \qquad \nabla_{\mathbf{n}_a} := \nabla^{F_i}_{\partial_{z^a}}, \qquad \nabla_{\mathbf{t}_\mu} := \nabla^{F_i}_{\partial_{u^\mu}},$$

and use the ordered alphabet

$$\mathscr{A} = \{\mathbf{n}_1, \dots, \mathbf{n}_c, \mathbf{t}_1, \dots, \mathbf{t}_k\}.$$

Let

$$\mathbf{T} := dF_i(\partial_t), \qquad \mathbf{J}_{\mathfrak{a}} := dF_i(\partial_{\mathfrak{a}}), \qquad \mathfrak{a} \in \mathscr{A}.$$

Since the domain's coordinate fields commute and ∇^{M} is torsion-free,

$$D\mathbf{T} = 0, \qquad \nabla_{\mathfrak{a}}\mathbf{T} = D\mathbf{J}_{\mathfrak{a}}, \qquad \nabla_{\mathfrak{a}}D\mathbf{Z} - D\nabla_{\mathfrak{a}}\mathbf{Z} = \mathbf{R}^{M}(\mathbf{J}_{\mathfrak{a}}, \mathbf{T})\mathbf{Z}. \tag{14.9}$$

Each $\mathbf{J}_{\mathfrak{a}}$ satisfies the Jacobi equation

$$D^2\mathbf{J}_{\mathfrak{a}} + \mathbf{R}^M(\mathbf{J}_{\mathfrak{a}}, \mathbf{T})\mathbf{T} = 0.$$

Fix words with their exact order retained. For a nonempty word $I = (\mathfrak{a}_1, \dots, \mathfrak{a}_m)$, define

$$\mathbf{Y}_I := \nabla_{\mathfrak{a}_1} \cdots \nabla_{\mathfrak{a}_{m-1}} \mathbf{J}_{\mathfrak{a}_m}. \tag{14.10}$$

The letters of I are not permuted. Introduce the operator

$$\mathcal{L}\mathbf{Z} := D^2\mathbf{Z} + \mathbf{R}^M(\mathbf{Z}, \mathbf{T})\mathbf{T}.$$

From (14.9), $D\mathbf{T} = 0$, and the covariant Leibniz rule, we obtain

$$\mathcal{L}(\nabla_{\mathfrak{a}}\mathbf{Z}) = \nabla_{\mathfrak{a}}(\mathcal{L}\mathbf{Z}) + \mathscr{C}_{\mathfrak{a}}(\mathbf{Z}), \tag{14.11}$$

where

$$\begin{aligned}\mathscr{C}_{\mathfrak{a}}(\mathbf{Z}) = &-2\mathbf{R}^M(\mathbf{J}_{\mathfrak{a}}, \mathbf{T})D\mathbf{Z} - (\nabla^M_{\mathbf{T}}\mathbf{R}^M)(\mathbf{J}_{\mathfrak{a}}, \mathbf{T})\mathbf{Z} - \mathbf{R}^M(D\mathbf{J}_{\mathfrak{a}}, \mathbf{T})\mathbf{Z} \\ &- (\nabla^M_{\mathbf{J}_{\mathfrak{a}}}\mathbf{R}^M)(\mathbf{Z}, \mathbf{T})\mathbf{T} - \mathbf{R}^M(\mathbf{Z}, D\mathbf{J}_{\mathfrak{a}})\mathbf{T} - \mathbf{R}^M(\mathbf{Z}, \mathbf{T})D\mathbf{J}_{\mathfrak{a}}.\end{aligned} \tag{14.12}$$

In particular, the sources $\mathbf{Q}_I$ are defined by the finite recurrence, compatible with the tensor spaces,

$$\mathbf{Q}_{(\mathfrak{a})} := 0, \qquad \mathbf{Q}_{(\mathfrak{a},I)} := \nabla_{\mathfrak{a}}\mathbf{Q}_I + \mathscr{C}_{\mathfrak{a}}(\mathbf{Y}_I), \qquad \mathcal{L}\mathbf{Y}_I = \mathbf{Q}_I. \tag{14.13}$$

The recurrence is closed and indexes every term. Consider formal expressions obtained by contracting, using $\mathbf{g}$, factors $(\nabla^M)^q\mathbf{R}^M$, $\mathbf{T}$, $\mathbf{Y}_J$, and $D\mathbf{Y}_J$, with a single free vector index. Define the formal derivation $\mathfrak{d}_{\mathfrak{a}}^{F_i}$ by the Leibniz rule on products and contractions and by

$$\mathfrak{d}_{\mathfrak{a}}^{F_i}\mathbf{T} = D\mathbf{J}_{\mathfrak{a}}, \qquad \mathfrak{d}_{\mathfrak{a}}^{F_i}\mathbf{Y}_J = \mathbf{Y}_{(\mathfrak{a},J)}, \qquad \mathfrak{d}_{\mathfrak{a}}^{F_i}(D\mathbf{Y}_J) = D\mathbf{Y}_{(\mathfrak{a},J)} + \mathbf{R}^M(\mathbf{J}_{\mathfrak{a}}, \mathbf{T})\mathbf{Y}_J,$$

$$\mathfrak{d}_{\mathfrak{a}}^{F_i}\big((\nabla^M)^q\mathbf{R}^M\big) = \nabla^M_{\mathbf{J}_{\mathfrak{a}}}\big((\nabla^M)^q\mathbf{R}^M\big) = (\nabla^M)^{q+1}\mathbf{R}^M(\mathbf{J}_{\mathfrak{a}}, \cdot).$$

In the last formula, $\cdot$ represents the preceding arguments in their original order, and the new argument is placed first; remaining arguments are differentiated separately by the Leibniz rule. Metric compatibility prevents additional summands when contractions are differentiated. Let $\mathfrak{C}^{F_i}_{\mathfrak{a},I}$ be the multiset of the six summands, with their coefficients, of $\mathscr{C}_{\mathfrak{a}}(\mathbf{Y}_I)$ in (14.12). Define finite multisets by

$$\mathfrak{A}^{F_i}_{(\mathfrak{a})} := \varnothing, \qquad \mathfrak{A}^{F_i}_{(\mathfrak{a},I)} := \mathfrak{d}_{\mathfrak{a}}^{F_i}\mathfrak{A}^{F_i}_I \sqcup \mathfrak{C}^{F_i}_{\mathfrak{a},I}.$$

Here differentiation of a multiset includes all summands produced by the Leibniz rule and preserves coefficients and multiplicities. Induction on (14.13) gives the exact identity

$$\mathbf{Q}_I = \sum_{\mathfrak{b} \in \mathfrak{A}^{F_i}_I} \mathfrak{b}. \tag{14.14}$$

Assign weight zero to $\mathbf{T}$ and weight $|J|$ to every occurrence of $\mathbf{Y}_J$ or $D\mathbf{Y}_J$. For $|I| = m \geq 2$, every summand of

(14.14) satisfies

$$\sum_{\text{occurrences of } \mathbf{Y}_J \text{ or } D\mathbf{Y}_J} |J| = m. \tag{14.15}$$

Moreover, it contains one or more factors $(\nabla^M)^q \mathbf{R}^M$, with $0 \le q \le m-1$; each field carries at most one derivative D, and every field in the source has length at most $m-1$. Indeed, the six summands of $\mathscr{C}_{\mathfrak{a}}(\mathbf{Y}_I)$ have weight $1+|I|$, and every rule of $\mathfrak{d}_{\mathfrak{a}}^{F_i}$ increases the weight by one, never produces $D^2\mathbf{Y}_J$, and increases the order of a curvature derivative by at most one. In particular, the equation of length m contains no field of length m outside the unknown term $\mathbf{Y}_I$.

The initial data are also determined by an exact recurrence. Let

$$\mathbf{X}_\mu := dx_i(\partial_{u^\mu}), \qquad \mathbf{H}_I := \mathbf{Y}_I|_{t=0}, \qquad \mathbf{K}_I := D\mathbf{Y}_I|_{t=0}.$$

For words of length one,

$$\mathbf{H}_{(\mathbf{n}_a)} = 0, \qquad \mathbf{K}_{(\mathbf{n}_a)} = \boldsymbol{\nu}_{i,a}(x_i(u)), \tag{14.16}$$

$$\mathbf{H}_{(\mathbf{t}_\mu)} = \mathbf{X}_\mu, \qquad \mathbf{K}_{(\mathbf{t}_\mu)} = \nabla^M_{\mathbf{X}_\mu}\boldsymbol{\xi}_i = -\mathbf{A}_{\boldsymbol{\xi}_i}\mathbf{X}_\mu + \nabla^\perp_{\mathbf{X}_\mu}\boldsymbol{\xi}_i. \tag{14.17}$$

The last equality fixes the sign and displays separately the second fundamental form and the normal connection. In our coordinates,

$$\mathbf{K}_{(\mathbf{t}_\mu)} = -\sum_{a=1}^{c} z^a \mathbf{A}_{\boldsymbol{\nu}_{i,a}}\mathbf{X}_\mu + \sum_{a=1}^{c} z^a \nabla^\perp_{\mathbf{X}_\mu}\boldsymbol{\nu}_{i,a}.$$

The second summand may be nonzero: radial gauge makes it vanish only in the radial direction of the chart of N.

Denote by $\nabla^0_{\mathfrak{a}}$ the induced connection on $t=0$: for $\mathfrak{a}=\mathbf{t}_\mu$, it is the derivative $\nabla^M_{\mathbf{X}_\mu}$, whereas for $\mathfrak{a}=\mathbf{n}_a$, it is ordinary differentiation with respect to z^a in the fixed space $T_{x_i(u)}M$. For every word I,

$$\mathbf{H}_{(\mathfrak{a},I)} = \nabla^0_{\mathfrak{a}}\mathbf{H}_I, \qquad \mathbf{K}_{(\mathfrak{a},I)} = \nabla^0_{\mathfrak{a}}\mathbf{K}_I - \mathbf{R}^M(\mathbf{H}_{(\mathfrak{a})}, \boldsymbol{\xi}_i)\mathbf{H}_I. \tag{14.18}$$

The second identity is precisely $D\nabla_{\mathfrak{a}} = \nabla_{\mathfrak{a}}D - \mathbf{R}^M(\mathbf{J}_{\mathfrak{a}}, \mathbf{T})$ evaluated at $t=0$.

Formulas (14.16)–(14.18), expanded recursively using (14.5), express all $\mathbf{H}_I, \mathbf{K}_I$ as finite universal sums of contractions of

$$(\nabla^M)^q\mathbf{R}^M, \qquad (\nabla^{\mathbf{II}})^q\mathbf{II}, \qquad (\nabla^\perp)^q\boldsymbol{\nu}_{i,a}, \qquad (\nabla^N)^q\mathbf{X}_\mu,$$

together with powers of z. Thus, ambient curvature appears in the sources $\mathbf{Q}_I$, whereas $\mathbf{II}$ and the normal connection appear precisely in the initial data. The bounded-geometry bounds for M and N, the hypotheses on $\mathbf{II}$, and (14.7) bound all these data uniformly.

We now prove the bounds by induction on word length. Since $\mathbf{T}$ is parallel and $|\mathbf{T}|_{\mathbf{g}} = |\boldsymbol{\xi}_i|_{\mathbf{g}} \le 2r_{\mathrm{F}}$, in a parallel frame along $t \mapsto F_i(z,u,t)$, equation $\mathcal{L}\mathbf{Y}_I = \mathbf{Q}_I$ is a first-order linear system for $(\mathbf{Y}_I, D\mathbf{Y}_I)$ with uniformly bounded matrix. For $m=1$, the source is zero and the data (14.16)–(14.17) are uniformly bounded. If words of length less than m are controlled, (14.13) bounds $\mathbf{Q}_I$ for $|I|=m$, and (14.18) bounds $\mathbf{H}_I, \mathbf{K}_I$. Grönwall's Lemma 1.8.19 gives, with a constant independent of i,z,u,

$$\sup_{t\in[0,1]} \left(|\mathbf{Y}_I(t)|_{\mathbf{g}} + |D\mathbf{Y}_I(t)|_{\mathbf{g}}\right) \le C_m \left(|\mathbf{H}_I|_{\mathbf{g}} + |\mathbf{K}_I|_{\mathbf{g}} + \int_0^1 |\mathbf{Q}_I(s)|_{\mathbf{g}}\, ds \right).$$

More precisely, C_m depends only on the dimension, r_{F}, the bounds on $(\nabla^M)^q\mathbf{R}^M$ for $q \le m-1$, the bounds on $(\nabla^{\mathbf{II}})^q\mathbf{II}$ and the normal connection appearing in the data of order m, and the constants already constructed for words of length less than m; it does not depend on the chart index or (z,u). This explicitly completes the induction for every tangential and normal word.

We pass from covariant to ordinary derivatives without identifying the two. Let $\mathbf{P}_1,\dots,\mathbf{P}_n$ be an orthonormal frame on $t=0$, formed from a controlled tangential frame of N and $\boldsymbol{\nu}_{i,1},\dots,\boldsymbol{\nu}_{i,c}$, and extended by $D\mathbf{P}_r = 0$. For an ordered word $I = (\mathfrak{a}_1,\dots,\mathfrak{a}_m)$, set

$$\partial_I := \partial_{\mathfrak{a}_1}\cdots\partial_{\mathfrak{a}_m}, \qquad \nabla_I := \nabla_{\mathfrak{a}_1}\cdots\nabla_{\mathfrak{a}_m}, \qquad \partial_\varnothing = \nabla_\varnothing = \mathrm{id}.$$

The first letter is the outer operator; this word convention does not change the order of the tensor factors of ∇^m. Also set

$$\mathbf{P}_{r,I} := \nabla_{\mathfrak{a}_1}\cdots\nabla_{\mathfrak{a}_m}\mathbf{P}_r.$$

These words satisfy the triangular recurrence

$$D\mathbf{P}_{r,\varnothing} = 0, \qquad D\mathbf{P}_{r,(\mathfrak{a},I)} = \nabla_{\mathfrak{a}}(D\mathbf{P}_{r,I}) - \mathbf{R}^M(\mathbf{J}_{\mathfrak{a}},\mathbf{T})\mathbf{P}_{r,I}.$$

Their data at $t=0$ are controlled by the frames of TN and $T^\perp N$; the preceding induction and Grönwall's Lemma 1.8.19 bound all $\mathbf{P}_{r,I}$. Finally, if I_S denotes the ordered subword of I whose positions belong to S, the iterated Leibniz rule gives the exact identity

$$\partial_I\langle \mathbf{Z},\mathbf{P}_r\rangle = \sum_{S\subseteq\{1,\dots,|I|\}} \left\langle \nabla_{I_S}\mathbf{Z}, \mathbf{P}_{r,I_{S^c}}\right\rangle. \tag{14.19}$$

The term with $S=\{1,\dots,|I|\}$ contains the highest-order covariant derivative; the others contain lower orders. This triangular relation proves bounds for all ordinary derivatives of the variational fields and, using the geodesic coordinates of M already controlled by Theorem 13.1.8, for all ordinary derivatives of F_i and $\kappa_i = F_i(\cdot,1)$.

On $z=0$,

$$d\kappa_i(\partial_{z^a}) = \boldsymbol{\nu}_{i,a}, \qquad d\kappa_i(\partial_{u^\mu}) = \mathbf{X}_\mu.$$

The two subspaces are orthogonal; the normal block is orthonormal, and the tangential block is the differential of a controlled geodesic chart of N. Thus, there exists $\sigma_0>0$, independent of i,u, such that the smallest singular value of $D\kappa_i(0,u)$ is at least σ_0. The uniform bound for $D^2\kappa_i$ gives

$$\|D\kappa_i(z,u) - D\kappa_i(0,u)\| \le C|z|.$$

Decreasing r_{F} once, impose $2Cr_{\mathrm{F}} \le \frac{\sigma_0}{2}$; then

$$\frac{\sigma_0}{2}|v| \le |D\kappa_i(z,u)v| \le C|v|$$

on all domains.

Bounds for the inverses follow by an explicit induction. If ρ is a coordinate representation of κ_i and $\lambda = \rho^{-1}$, order one is already controlled by

$$D\lambda(y) = D\rho(\lambda(y))^{-1}.$$

Suppose derivatives of λ of orders less than m are uniformly bounded, and fix a multi-index α with $|\alpha| = m \geq 2$. Apply the Faà di Bruno formula of Theorem 1.1.19 componentwise to the identity $\rho \circ \lambda = \mathrm{id}$. For each component a, we obtain

$$0 = D^\alpha(\rho^a \circ \lambda)(y) = \sum_{b=1}^{n} (\partial_b \rho^a)(\lambda(y)) D^\alpha \lambda^b(y) + R^a_\alpha(y),$$

where R^a_α is a finite sum of products of the form

$$c\,(D^\beta \rho^a)(\lambda(y)) \prod_{\ell=1}^{|\beta|} D^{\gamma_\ell} \lambda^{j_\ell}(y), \qquad 2 \leq |\beta| \leq m, \quad \sum_{\ell=1}^{|\beta|} \gamma_\ell = \alpha, \quad |\gamma_\ell| > 0.$$

Since $|\beta| \geq 2$, each $|\gamma_\ell| \leq m-1$; by the induction hypothesis, all factors containing derivatives of λ are uniformly bounded. The derivative bounds already obtained for ρ then bound $R_\alpha = (R^a_\alpha)_{a=1}^n$. In matrix form, the preceding equality is

$$D\rho(\lambda(y)) D^\alpha \lambda(y) = -R_\alpha(y),$$

and hence

$$D^\alpha \lambda(y) = -D\rho(\lambda(y))^{-1} R_\alpha(y).$$

The uniform bound for $D\rho^{-1}$ gives the bound of order m and completes the induction.

On the overlap of two Fermi charts, uniqueness of the normal-exponential representation gives a more precise formula than a mere composition. If

$$\tau_{ji} := x_j^{-1} \circ x_i, \qquad \boldsymbol{\nu}_{i,a}(x_i(u)) = \sum_{b=1}^{c} O_{ji}(u)^b{}_a \, \boldsymbol{\nu}_{j,b}(x_j(\tau_{ji}(u))),$$

then $O_{ji}(u) \in O(c)$ and

$$\kappa_j^{-1} \circ \kappa_i(z,u) = \big(O_{ji}(u) z, \tau_{ji}(u)\big). \tag{14.20}$$

In particular, the transition preserves the zero section and normal fibers and is linear in the normal variable. Moreover,

$$O_{ji}(u)^b{}_a = \mathbf{g}\big(\boldsymbol{\nu}_{j,b}, \boldsymbol{\nu}_{i,a}\big)_{x_i(u)},$$

so (14.19) and the bounds for both frames control all derivatives of O_{ji}; its inverse is its transpose. Transitions between Fermi charts and geodesic charts of M, and their inverses, are controlled by the Faà di Bruno formula of Theorem 1.1.19 and the preceding induction.

The Fermi metric coefficients are

$$g_{AB} = \mathbf{g}(\mathbf{J}_A, \mathbf{J}_B)\big|_{t=1}.$$

The Leibniz rule and (14.19) bound all their derivatives. The two-sided bound for $D\kappa_i$ proves (14.4). Differentiating $G^{-1}G = I$ gives, for $\alpha \neq 0$,

$$(\partial^\alpha G^{-1})G = - \sum_{\substack{\beta \in \mathbb{N}_0^n \\ \beta \leq \alpha,\ \beta \neq \alpha}} \binom{\alpha}{\beta} (\partial^\beta G^{-1})(\partial^{\alpha-\beta} G),$$

which closes the inverse-metric bounds by induction. Likewise,

$$0 < c \le |\det D\kappa_i| \le C, \qquad 0 < c \le \sqrt{\det(\mathbf{g})} \le C,$$

and all derivatives of both Jacobians are bounded: the determinant is polynomial in the entries, and the square root is differentiated on a compact interval contained in $(0,\infty)$.

Now fix $r := r_{\mathrm{F}}$ after all preceding reductions; take it also small enough that $20r < r_{0,M}$ and $10r < r_{0,N}$. Choose a maximal family of centers $p_i \in N$ whose intrinsic balls $B_N(p_i, r/2)$ are disjoint. The balls $B_N(p_i, r)$ cover N: otherwise, another disjoint ball could be added. The family is countable because N is second countable. Its multiplicity, even for balls of radius $4r$, is bounded by comparing volumes of the disjoint balls with the volume of a ball of radius $5r$.

Denote by $U_r(N)$ the image of normal vectors of length less than r. Also choose a maximal ρ-separated net in $M \setminus U_r(N)$, where $0 < \rho < r/8$. Its balls of radius ρ cover this complement, and we use balls of radius 2ρ as charts. These do not meet N. Indeed, since N is closed and M complete, every point at distance less than r from N has a minimizing segment to N orthogonal to N and belongs to $U_r(N)$. The Fermi charts cover $U_{2r}(N)$; consequently, the two families cover M and leave an overlap band.

To compare the two families, count overlaps through volumes of tubular sets over N in the ambient manifold. Use the disjoint sets

$$D_i := \exp^{\perp}\left(\{(x,v) \mid x \in B_N(p_i, r/2),\ |v| < r/2\}\right).$$

Injectivity of the tube makes them disjoint. The Fermi Jacobian bounds and volume bounds on N give, with a uniform constant,

$$\lambda_{\mathbf{g}}(D_i) \ge c\, r^c\, \lambda_{\mathbf{g}|_N}(B_N(p_i, r/2)) \ge c' r^n.$$

If a Fermi chart meets an ambient ball $B_M(x, 2\rho)$, its center is at distance less than $4r + 2\rho$ from x and $D_i \subset B_M(x, 6r)$. The volume of this last ball does not exceed Cr^n. By disjointness, the number of such Fermi charts is at most C/c'. In the reverse direction, the disjoint balls of radius $\rho/2$ based at interior centers whose charts meet a Fermi chart lie in an ambient ball of radius $7r$; each has volume at least $c\rho^n$. This bounds their number by $C(r/\rho)^n$, a fixed constant. The same reasoning compares the Fermi family with any uniform geodesic net at the fixed scale. Between Fermi charts, the normal footpoint of an overlap point lies in both balls of N, so their centers are at distance less than $4r$ in N. Between interior charts, use geodesic packing. This proves uniform local finiteness and both cross-overlap bounds.

Finally, choose model functions

$$\eta_\perp \in C_c^\infty(B^c(0, 2r_{\mathrm{F}})), \qquad \eta_N \in C_c^\infty(B^k(0, 2r_{\mathrm{F}})),$$

equal to one on the balls of radius r_{F}, and use $\eta_\perp(z)\eta_N(u)$ in Fermi charts; in charts away from the submanifold, use a fixed geodesic cutoff. Let $\widetilde{\eta}_\alpha$ be their transports to M. The covering property and uniform multiplicity give

$$1 \le S := \sum_{\alpha \in I} \widetilde{\eta}_\alpha^2 \le C.$$

Only uniformly finitely many summands contribute in any chart. The transition bounds and the Faà di Bruno formula of Theorem 1.1.19 control all derivatives of S and $S^{-\frac{1}{2}}$. Thus,

$$h_\alpha := \widetilde{\eta}_\alpha S^{-\frac{1}{2}}$$

satisfies $\sum_{\alpha\in I} h_\alpha^2 = 1$ and all estimates in (b). To construct auxiliary cutoffs without losing uniformity, choose once and for all functions

$$\widehat{\eta}_\perp \in C_c^\infty(B^c(0,2r_{\mathrm{F}})), \qquad \widehat{\eta}_N \in C_c^\infty(B^k(0,2r_{\mathrm{F}})),$$

with values in $[0,1]$, equal to one on neighborhoods of $\operatorname{supp}\eta_\perp$ and $\operatorname{supp}\eta_N$, respectively. In a Fermi chart, transport the product $\widehat{\eta}_\perp(z)\widehat{\eta}_N(u)$; in the other charts, likewise use a single geodesic profile equal to one near the support of the profile used for $\widetilde{\eta}_\alpha$. The resulting functions χ_α belong to $C_c^\infty(U_\alpha)$, satisfy $0 \le \chi_\alpha \le 1$, and equal one on a neighborhood of $\operatorname{supp} h_\alpha$, since $\operatorname{supp} h_\alpha \subseteq \operatorname{supp}\widetilde{\eta}_\alpha$. Because only these fixed profiles were used, their coordinate derivatives have bounds independent of α; these are exactly the estimates in (B3).

We now have adapted charts, frames, and cutoffs with uniform constants. In the next section, we can apply the Euclidean trace and sum its estimates over this cover. □

14.3 Trace on an interior submanifold

Let $(U_\alpha, \kappa_\alpha^{-1}, h_\alpha)_{\alpha\in I}$ be the quadratic localization system of Proposition 14.2.6. For $i \in I_N$, write

$$\kappa_i^N(u) := \kappa_i(0,u), \qquad U_i^N := U_i \cap N, \qquad h_i^N := h_i \restriction_N .$$

The charts κ_i^N are geodesic charts of N, charts indexed by I_0 do not meet N, and

$$\sum_{i\in I_N} (h_i^N)^2 = 1 \qquad \text{on } N. \tag{14.21}$$

By Theorems 13.3.5 and 13.3.8, together with Lemma 13.3.10, for each $s,t \in \mathbb{R}$ and $1 < p < \infty$ there exist constants $c_M, C_M, c_N, C_N > 0$ such that, for every $u \in H^{s,p}(M)$ and every $v \in B^t_{p,p}(N)$,

$$c_M \|u\|_{H^{s,p}(M)} \le \left(\sum_{\alpha\in I} \|(h_\alpha u)\circ\kappa_\alpha\|^p_{H^{s,p}(\mathbb{R}^n)} \right)^{\frac{1}{p}} \le C_M \|u\|_{H^{s,p}(M)}$$

and

$$c_N \|v\|_{B^t_{p,p}(N)} \le \left(\sum_{i\in I_N} \|(h_i^N v)\circ\kappa_i^N\|^p_{B^t_{p,p}(\mathbb{R}^k)} \right)^{\frac{1}{p}} \le C_N \|v\|_{B^t_{p,p}(N)}.$$

The four constants depend on s,t,p and the uniform data of the pair (M,N), but not on u, v, or the chart indices.

Theorem 14.3.1. (Bessel trace on a submanifold) Let (M,N) be a pair of bounded geometry in the sense of Definition 14.2.1; in particular, M and N are smooth manifolds without boundary of dimensions n and k, respectively. Let $c = n-k$, $1 < p < \infty$, and $s > \frac{c}{p}$. There exists a unique continuous linear operator

$$\mathrm{Tr}_N : H^{s,p}(M) \longrightarrow B^{s-\frac{c}{p}}_{p,p}(N)$$

agreeing with pointwise restriction on $C_c^\infty(M)$. It is surjective and admits a continuous linear operator

$$\mathrm{Ex}_{M,N} : B_{p,p}^{s-\frac{c}{p}}(N) \longrightarrow H^{s,p}(M)$$

such that

$$\mathrm{Tr}_N \,\mathrm{Ex}_{M,N} = \mathrm{id}_{B_{p,p}^{s-\frac{c}{p}}(N)}.$$

Proof. Set $t := s - \frac{c}{p}$. For $u \in H^{s,p}(M)$, define the localizations

$$u_i := \big(h_i u\big) \circ \kappa_i, \qquad i \in I_N,$$

regarded as distributions on $\mathbb{R}^n$ by extension by zero outside the coordinate domain. This is legitimate because $\mathrm{supp}(h_i) \Subset U_i$. By admissibility and the localization principle,

$$\sum_{i \in I_N} \|u_i\|_{H^{s,p}(\mathbb{R}^n)}^p \le C \|u\|_{H^{s,p}(M)}^p. \tag{14.22}$$

Define

$$\mathrm{Tr}_N u := \sum_{i \in I_N} h_i^N \left[\big(\mathrm{tr}_c\, u_i\big) \circ (\kappa_i^N)^{-1} \right]. \tag{14.23}$$

The sum is locally finite. Moreover, each $\mathrm{tr}_c\, u_i$ belongs to $B_{p,p}^t(\mathbb{R}^k)$ by Theorem 14.1.1.
We prove the global estimate. For $j \in I_N$, let

$$A(j) := \left\{ i \in I_N \,\middle|\, U_i^N \cap U_j^N \neq \varnothing \right\}.$$

The cardinality of $A(j)$ is bounded by the multiplicity L. Localizing (14.23) with h_j^N and transporting by κ_j^N to $\mathbb{R}^k$ gives

$$\big(h_j^N \,\mathrm{Tr}_N u\big) \circ \kappa_j^N = \sum_{i \in A(j)} a_{ij} \left[\big(\mathrm{tr}_c\, u_i\big) \circ \Phi_{ij} \right], \tag{14.24}$$

where

$$a_{ij} := (h_j^N h_i^N) \circ \kappa_j^N, \qquad \Phi_{ij} := (\kappa_i^N)^{-1} \circ \kappa_j^N$$

on the overlap, after inserting cutoffs equal to one on the supports involved. Proposition 14.2.6 uniformly bounds all derivatives of a_{ij}, Φ_{ij}, and Φ_{ij}^{-1}. The localized version of Lemma 6.4.3, applied on $B_{p,p}^t$, and Theorem 14.1.1 give

$$\left\| \big(h_j^N \,\mathrm{Tr}_N u\big) \circ \kappa_j^N \right\|_{B_{p,p}^t(\mathbb{R}^k)}^p \le C L^{p-1} \sum_{i \in A(j)} \|u_i\|_{H^{s,p}(\mathbb{R}^n)}^p. \tag{14.25}$$

Sum over j. Each i appears in at most L sets $A(j)$; by (14.22),

$$\|\mathrm{Tr}_N u\|_{B_{p,p}^t(N)}^p \le C \sum_{i \in I_N} \|u_i\|_{H^{s,p}(\mathbb{R}^n)}^p \le C' \|u\|_{H^{s,p}(M)}^p. \tag{14.26}$$

Thus, Tr_N is well defined and continuous. If $u \in C_c^\infty(M)$, Lemma 14.1.2 and (14.21) show that

$$\operatorname{Tr}_N u = \sum_{i \in I_N} (h_i^N)^2 u \restriction_N = u \restriction_N .$$

Density of $C_c^\infty(M)$ in $H^{s,p}(M)$, obtained through the trivialization and Proposition 6.1.3, proves uniqueness. We now construct a right inverse. Choose a fixed function

$$\psi \in C_c^\infty\left(B^c_{\mathrm{euc}}(0, 2r_F) \times B^k_{\mathrm{euc}}(0, 2r_F)\right)$$

equal to one on a common neighborhood of all supports $(h_i \circ \kappa_i)$; this is possible because these supports were obtained from the same rescaled cutoff function. For $f \in B^t_{p,p}(N)$, set

$$f_i := (h_i^N f) \circ \kappa_i^N$$

and define

$$\operatorname{Ex}_{M,N} f := \sum_{i \in I_N} h_i \left[\left(\psi \operatorname{ex}_c f_i \right) \circ \kappa_i^{-1} \right], \tag{14.27}$$

extending each summand by zero outside U_i. The support of ψ makes this extension smooth at the test-function level and, by duality, well defined at the distributional level.

The continuity proof repeats (14.24)–(14.26) with the spaces interchanged. Uniform continuity of multipliers and coordinate changes, the multiplicity L, and continuity of ex_c give

$$\begin{aligned} \| \operatorname{Ex}_{M,N} f \|^p_{H^{s,p}(M)} &\le C \sum_{i \in I_N} \| \psi \operatorname{ex}_c f_i \|^p_{H^{s,p}(\mathbb{R}^n)} \\ &\le C' \sum_{i \in I_N} \| f_i \|^p_{B^t_{p,p}(\mathbb{R}^k)} \le C'' \| f \|^p_{B^t_{p,p}(N)}. \end{aligned} \tag{14.28}$$

Finally, $\psi(0,u) = 1$ on the relevant supports, and $\operatorname{tr}_c \operatorname{ex}_c = \mathrm{id}$. Applying (14.23) to (14.27) and using (14.21) again gives

$$\operatorname{Tr}_N \operatorname{Ex}_{M,N} f = \sum_{i \in I_N} (h_i^N)^2 f = f.$$

This proves both surjectivity and existence of the right inverse. □

Theorem 14.3.2. (Traces in the Besov and Triebel–Lizorkin scales) Let (M,N) be a pair of bounded geometry in the sense of Definition 14.2.1; in particular, M and N are smooth manifolds without boundary of dimensions n and k, respectively. Let $c = n - k$, $1 < p < \infty$, $1 \le q \le \infty$, and $s > \frac{c}{p}$. Then there exist retractions

$$\operatorname{Tr}_N \colon F^s_{p,q}(M) \longrightarrow B^{s-\frac{c}{p}}_{p,p}(N), \qquad \operatorname{Tr}_N \colon B^s_{p,q}(M) \longrightarrow B^{s-\frac{c}{p}}_{p,q}(N),$$

both with continuous linear right extension operators.

Proof. Set $t = s - \frac{c}{p}$. Retain the cutoffs and Fermi charts from the proof of Theorem 14.3.1. For $u \in F^s_{p,q}(M)$, define directly, in the distributional sense, the components

$$u_i = (h_i u) \circ \kappa_i, \qquad i \in I_N.$$

Formula (14.23) defines the trace. If $A(j)$ is the set of indices whose charts meet chart j of N, the chart-change identities of Lemma 14.1.2, the uniform multipliers, and the Euclidean estimate give

$$\left\|(h_j^N \operatorname{Tr}_N u)\circ \kappa_j^N\right\|_{B^t_{p,p}(\mathbb{R}^k)} \le C \sum_{i\in A(j)} \|u_i\|_{F^s_{p,q}(\mathbb{R}^n)}.$$

The cardinality of $A(j)$ is at most the uniform multiplicity L. Raising to the power p, summing over j, and observing that each i appears in at most L sets $A(j)$ gives

$$\|\operatorname{Tr}_N u\|^p_{B^t_{p,p}(N)} \le C \sum_{i\in I_N} \|u_i\|^p_{F^s_{p,q}(\mathbb{R}^n)} \le C'\|u\|^p_{F^s_{p,q}(M)}.$$

The strong localization principle, Theorem 6.4.4, justifies the last inequality and convergence of the reconstruction.

For $f \in B^t_{p,p}(N)$, set $f_i = (h_i^N f)\circ \kappa_i^N$ and use (14.27). The synthesis estimate, uniform multiplicity, and Euclidean coretraction give

$$\begin{aligned}\|\operatorname{Ex}_{M,N} f\|^p_{F^s_{p,q}(M)} &\le C \sum_{i\in I_N} \|\psi \operatorname{ex}_c f_i\|^p_{F^s_{p,q}(\mathbb{R}^n)}\\ &\le C' \sum_{i\in I_N} \|f_i\|^p_{B^t_{p,p}(\mathbb{R}^k)} \le C''\|f\|^p_{B^t_{p,p}(N)}.\end{aligned}$$

This yields the retraction and coretraction in the Triebel–Lizorkin scale.

For Besov, choose $s_0 < s < s_1$, still with $s_0 > \frac{c}{p}$, and $s = (1-\theta)s_0+\theta s_1$. The preceding operators, constructed using the same charts, cutoffs, and Euclidean coretractions, are continuous at both endpoints. Theorem 5.3.1 and the identities

$$(F^{s_0}_{p,p}(M), F^{s_1}_{p,p}(M))_{\theta,q} = B^s_{p,q}(M),$$

$$(B^{s_0-\frac{c}{p}}_{p,p}(N), B^{s_1-\frac{c}{p}}_{p,p}(N))_{\theta,q} = B^{s-\frac{c}{p}}_{p,q}(N)$$

give continuity of both Tr_N and $\operatorname{Ex}_{M,N}$ in the Besov scale.

Finally, in all scales, compatibility of the trace with multipliers and $\operatorname{tr}_c \operatorname{ex}_c = I$ allows the direct calculation

$$\operatorname{Tr}_N \operatorname{Ex}_{M,N} f = \sum_{i\in I_N} (h_i^N)^2 f = f.$$

Equality in distributions also justifies the case $q = \infty$, where density in the space norm has not been assumed. □

For noninteger orders $s = m + \sigma$, with $0 < \sigma < 1$, we will use the norm obtained by localizing Euclidean Slobodeckij norms and summing their pth powers. Proposition 14.5.4 proves independence of these localizations and their equivalence with the intrinsic difference norm defined through parallel transport.

Corollary 14.3.3. ($W^{s,p}$ and integer-order scales) Let (M,N) be a pair of bounded geometry consisting of smooth manifolds without boundary, let $c = \dim M - \dim N$, and let $1 < p < \infty$. If $s > \frac{c}{p}$ and $s \notin \mathbb{N}$, then

$$\operatorname{Tr}_N \colon W^{s,p}(M) \longrightarrow B^{s-\frac{c}{p}}_{p,p}(N)$$

is a retraction. If $m \in \mathbb{N}$ and $m > \frac{c}{p}$, then

$$\mathrm{Tr}_N \colon W^{m,p}(M) \longrightarrow B_{p,p}^{m-\frac{c}{p}}(N)$$

is a retraction.

Proof. For $s \notin \mathbb{N}$, use the global comparison $W^{s,p}(M) = B^s_{p,p}(M)$ of Proposition 14.5.4 and apply the Besov retraction in the preceding theorem with $q = p$. For $m \in \mathbb{N}$, Proposition 13.3.14 gives $W^{m,p}(M) = H^{m,p}(M)$; then apply Theorem 14.3.1. □

14.4 Manifolds with boundary and bounded geometry

On a manifold with boundary, geodesic balls centered at boundary points are unavailable. The appropriate local models are half-spaces, obtained through a uniform geodesic collar.

Definition 14.4.1. (Uniform collar and uniform geodesic collar) Let M be a smooth manifold with nonempty boundary. A *uniform collar* of radius $r_\partial > 0$ is a diffeomorphism

$$\mathcal{C} \colon \partial M \times [0, r_\partial) \longrightarrow U_\partial,$$

where U_∂ is an open neighborhood of ∂M in M and $\mathcal{C}(x, 0) = x$. If $(M, \mathbf{g})$ is Riemannian, $\boldsymbol{\nu}$ is the inward unit normal, and

$$\mathcal{C}(x, t) = \exp_x(t\boldsymbol{\nu}_x),$$

we say the collar is *uniform geodesic*.

Definition 14.4.2. (Bounded geometry with boundary) Let $(M, \mathbf{g})$ be a smooth Riemannian manifold of dimension n with nonempty boundary, and let $\boldsymbol{\nu}$ be the inward unit normal. We say that M has *bounded geometry with nonempty boundary* if the following conditions hold.

(a) There exists $r_\partial > 0$ such that

$$\mathcal{C} \colon \partial M \times [0, r_\partial) \longrightarrow M, \qquad \mathcal{C}(x, t) := \exp_x(t\boldsymbol{\nu}_x), \tag{14.29}$$

is a uniform geodesic collar.

(b) $\mathrm{inj}(\partial M) > 0$ for the induced metric.

(c) For each $0 < r < r_\partial$, there exists $i(r) > 0$ such that, for every

$$x \in M \setminus \mathcal{C}(\partial M \times [0, r)),$$

the mapping $\exp_x$ is defined and is a diffeomorphism from $B_{\mathbf{g}_x}(0, i(r)) \subseteq T_xM$ onto its image.

(d) For each $m \in \mathbb{N}_0$,

$$\sup_{x \in M} |(\nabla^M)^m \mathbf{R}^M(x)|_{\mathbf{g}} < \infty.$$

(e) If $\mathbf{II}$ is the second fundamental form of ∂M, then, for each $m \in \mathbb{N}_0$,

$$\sup_{x \in \partial M} \left| (\nabla^{\mathbf{II}})^m \mathbf{II}(x) \right|_{\mathbf{g}} < \infty.$$

This is the intrinsic formulation of [128, Definition 2.2]; the derivatives in the last item are those of Definition 2.11.5.

Proposition 14.4.3. (Induced geometry on the boundary) Let $(M, \mathbf{g})$ be a Riemannian manifold of bounded geometry with nonempty boundary. Then $(\partial M, \mathbf{g}\restriction_{\partial M})$ is a manifold without boundary and with bounded geometry.

Proof. The second item of the definition gives $\operatorname{inj}(\partial M) > 0$. The Gauss equation (14.1), applied to $N = \partial M$, expresses $\mathbf{R}^{\partial M}$ as the tangential restriction of $\mathbf{R}^M$ plus quadratic contractions of $\mathbf{II}$. Differentiating it ℓ times, calculation (14.2) expresses $(\nabla^{\partial M})^\ell \mathbf{R}^{\partial M}$ as a finite sum of contractions of $(\nabla^M)^a \mathbf{R}^M$ and $(\nabla^{\mathbf{II}})^b \mathbf{II}$, with $a, b \le \ell$. The fourth and fifth items bound all these terms uniformly. Definition 13.1.5 concludes the proof. □

Remark 14.4.4. Schick also proves that the preceding formulation is equivalent to uniform bounds on the metric and its inverse in boundary normal coordinates [128, Theorem 2.5]. Amann assumes bounded geometry already induced on ∂M and proves that his formulation is equivalent to Schick's; see [6, Definition 2.1 and Theorem 2.2]. In the following proofs, we will use the five items of the definition and the preceding proposition directly.

Proposition 14.4.5. (Uniform geodesic–Fermi atlas and collar) Let M be a manifold of bounded geometry with nonempty boundary. There exist fixed radii $r_B, r_I > 0$, a uniformly locally finite cover, and charts of two types:

$$\kappa_i^{\partial} \colon B^{n-1}_{\mathrm{euc}}(0, 2r_B) \times [0, 2r_B) \longrightarrow U_i^{\partial}, \qquad i \in I_{\partial}, \tag{14.30}$$

and interior geodesic charts $\kappa_j^0 \colon B^n_{\mathrm{euc}}(0, 2r_I) \longrightarrow U_j^0$, $j \in I_0$, such that

$$\kappa_i^{\partial}(u, t) = \mathcal{C}\big(\exp_{p_i}^{\partial M}(\lambda_i u), t\big).$$

In these charts, the uniform estimates (14.4) hold for the metric, its inverse, and all their derivatives. There is also a family $h_\alpha \in C_c^\infty(U_\alpha)$ such that

$$\sum_{\alpha \in I} h_\alpha^2 = 1,$$

and its local representations have uniformly bounded derivatives. The family $(U_\alpha, \kappa_\alpha^{-1}, h_\alpha)$ is an admissible quadratic localization system, and $(U_\alpha, \kappa_\alpha^{-1}, h_\alpha^2)$ is the associated admissible trivialization. Moreover, for some $0 < r_0 < r_B$,

$$\partial_t^\ell (h_i \circ \kappa_i^{\partial})(u, t) = 0, \qquad i \in I_{\partial}, \quad \ell \ge 1, \quad 0 \le t < r_0. \tag{14.31}$$

Proof. By Proposition 14.4.3, ∂M has bounded geometry. First consider boundary geodesic charts centered at an arbitrary point, with a common radius smaller than the uniform radius in Theorem 13.1.8. The collar formula gives a Fermi chart at every center. We obtain its estimates before choosing the net of centers; thus,

radius reductions will not affect any covering property already fixed.

In geodesic coordinates of ∂M, set

$$x_i(u) := \exp_{p_i}^{\partial M}(\lambda_i u)$$

and consider the scaled family

$$\widehat{F}_i(r,u,s) := \exp_{x_i(u)}^{M}(sr\,\boldsymbol{\nu}_{x_i(u)}), \qquad 0 \le s \le 1.$$

Then $\kappa_i^{\partial}(u,r) = \widehat{F}_i(r,u,1)$. Apply to this family the ordered-word induction (14.10)–(14.18), with one normal letter $\mathbf{n} = \partial_r$ and tangential letters $\mathbf{t}_\mu = \partial_{u^\mu}$. The connections are ∇^M, the Levi–Civita connection of ∂M, the normal connection of $\partial M \subset M$, and the pullback connection under $\widehat{F}_i$.

To verify the sign explicitly, if

$$\mathbf{J}_X(t) := d\mathcal{C}_{(x,t)}(X,0), \qquad \gamma_x(t) = \mathcal{C}(x,t),$$

then

$$\frac{D^2\mathbf{J}_X}{dt^2} + \mathbf{R}^M(\mathbf{J}_X,\dot\gamma_x)\dot\gamma_x = 0, \qquad \mathbf{J}_X(0) = X, \qquad \frac{D\mathbf{J}_X}{dt}(0) = \nabla^M_X\boldsymbol{\nu} = -\mathbf{A}_{\boldsymbol{\nu}}X.$$

Indeed,

$$\nabla^M_X\boldsymbol{\nu} = -\mathbf{A}_{\boldsymbol{\nu}}X + \nabla^\perp_X\boldsymbol{\nu}, \qquad \mathbf{g}(\nabla^M_X\boldsymbol{\nu},\boldsymbol{\nu}) = \frac{1}{2}X\mathbf{g}(\boldsymbol{\nu},\boldsymbol{\nu}) = 0,$$

and the normal bundle has rank one, so $\nabla^\perp_X\boldsymbol{\nu} = 0$.

For the scaled family, if $\mathbf{X}_\mu = dx_i(\partial_{u^\mu})$, the length-one data are exactly

$$\mathbf{H}_{(\mathbf{n})} = 0, \qquad \mathbf{K}_{(\mathbf{n})} = \boldsymbol{\nu},$$

and

$$\mathbf{H}_{(\mathbf{t}_\mu)} = \mathbf{X}_\mu, \qquad \mathbf{K}_{(\mathbf{t}_\mu)} = -r\mathbf{A}_{\boldsymbol{\nu}}\mathbf{X}_\mu.$$

The data for every longer word are

$$\mathbf{H}_{(\mathfrak{a},I)} = \nabla^0_{\mathfrak{a}}\mathbf{H}_I, \qquad \mathbf{K}_{(\mathfrak{a},I)} = \nabla^0_{\mathfrak{a}}\mathbf{K}_I - \mathbf{R}^M(\mathbf{H}_{(\mathfrak{a})}, r\boldsymbol{\nu})\mathbf{H}_I.$$

Thus, derivatives of $\mathbf{A}_{\boldsymbol{\nu}}$, or equivalently covariant derivatives of $\mathbf{II}$, appear in the initial data with the sign fixed above. The interior sources are exactly

$$\mathbf{Q}_{(\mathfrak{a})} = 0, \qquad \mathbf{Q}_{(\mathfrak{a},I)} = \nabla_{\mathfrak{a}}\mathbf{Q}_I + \mathscr{C}_{\mathfrak{a}}(\mathbf{Y}_I),$$

with $\mathscr{C}_{\mathfrak{a}}$ given by (14.12), which collects the commutation terms. Consequently, at order m, the induction uses only $(\nabla^M)^q\mathbf{R}^M$, $q \le m-1$, derivatives of $\mathbf{II}$ present in the data, and word fields of length less than m.

The Grönwall-based induction of Proposition 14.2.6 bounds all covariant words of $\widehat{F}_i$. At this point, retain that covariant formulation: ambient normal coordinates centered at a point of ∂M are unnecessary. Ordinary derivatives of metric coefficients are obtained by applying the Leibniz rule to inner products of variational fields, as we do next.

Throughout the collar,

$$g_{tt} = 1, \qquad g_{\mu t} = 0.$$

The first identity follows because $t \mapsto \mathcal{C}(x,t)$ is a unit-speed geodesic. For the second, if $\mathbf{J}_\mu = d\kappa_i^\partial(\partial_{u^\mu})$, then

$$\frac{d}{dt}\mathbf{g}(\mathbf{J}_\mu, \partial_t) = \mathbf{g}(\nabla_{\partial_t}\mathbf{J}_\mu, \partial_t) = \mathbf{g}(\nabla_{\mathbf{J}_\mu}\partial_t, \partial_t) = \frac{1}{2}\mathbf{J}_\mu \mathbf{g}(\partial_t, \partial_t) = 0,$$

and orthogonality holds at $t = 0$. Moreover, $g_{\mu\nu} = \mathbf{g}(\mathbf{J}_\mu, \mathbf{J}_\nu)$, so the preceding induction controls all derivatives of the metric.

At $t = 0$, the differential is the orthogonal sum of the differential of the geodesic chart of ∂M and the unit normal. To measure it in different fibers, parallel transport each Jacobi field to its initial fiber. The integral equation and bounds already obtained give

$$\left|P_{t\to 0}\mathbf{J}_X(t) - X\right| \le Ct|X|,$$

with C independent of the center. Choose $r_B > 0$ so that $8Cr_B < 1/2$, $8r_B$ lies within the original collar, and all larger tangential charts lie within the uniform radius of ∂M. Consequently, the Fermi metric is uniformly comparable to $\mathbf{g}|_{\partial M} + dt^2$ in the collar of width $8r_B$. Formula $g_{\mu\nu} = \langle \mathbf{J}_\mu, \mathbf{J}_\nu \rangle$ and the Leibniz rule bound all its derivatives. Differentiating $G^{-1}G = I$ gives the corresponding inverse bounds. In particular, there exist uniform constants $c, C > 0$ such that

$$c\, d\lambda_{\mathbf{g}|_{\partial M}}\, dt \le d\lambda_{\mathbf{g}} \le C\, d\lambda_{\mathbf{g}|_{\partial M}}\, dt.$$

The Jacobians and their derivatives are also bounded, since the determinant is polynomial in the entries and the square root is evaluated on a compact interval in $(0, \infty)$.

The normal variable is preserved exactly under boundary chart transitions. If $\tau_{ji} = x_j^{-1} \circ x_i$, uniqueness of collar coordinates gives

$$(\kappa_j^\partial)^{-1} \circ \kappa_i^\partial(u,t) = (\tau_{ji}(u), t). \tag{14.32}$$

Thus, transitions between boundary charts and their inverses have uniform estimates and preserve t exactly. In choosing r_B, also require that all its fixed multiples used below lie within the uniform boundary radius. Then choose a maximal r_B-separated net in ∂M. Its balls of radius $r_B/2$ are disjoint, those of radius r_B cover ∂M, and the Fermi charts cover $\mathcal{C}(\partial M \times [0, 2r_B))$.

For the interior part, set

$$K := M \setminus \mathcal{C}(\partial M \times [0, r_B/2)).$$

The third item of Definition 14.4.2 provides the radius $i(r_B/4)$. Choose

$$0 < r_I < \min\{r_B/16,\ i(r_B/4)/20\},$$

and, if necessary, reduce it to apply the normal-coordinate estimates obtained from curvature in Chapter 13. Take a maximal r_I-separated net in K. The interior charts are exponentials of radius $2r_I$ centered at this net. Although K has an artificial boundary, the exponentials used are those of M and are defined on full tangent balls by the preceding hypothesis. The Gauss lemma and the first-exit-time argument identify their images with metric balls of that radius. Balls of radius r_I cover K, and the larger charts do not meet ∂M.

We also justify separation from the smaller collar. In the controlled collar, $|dt|_{\mathbf{g}} = 1$. A curve crossing from $t \ge r_B/2$ to $t < r_B/4$ has length at least $r_B/4$. A curve coming from outside the collar must first cross this same

interval of values of t. It cannot leave the collar toward infinity in finite length: comparison with $\mathbf{g}|_{\partial M} + dt^2$ and completeness of ∂M prevent this. Since $2r_I < r_B/8$, all interior charts remain outside $\mathcal{C}(\partial M \times [0, r_B/4))$. The union of the two families covers M; the band $r_B/2 \le t < r_B$ lies in regions covered by both.

Multiplicity among boundary charts is estimated on ∂M, since an overlap point has the same normal footpoint. Among interior charts, compare disjoint balls of radius $r_I/2$ with a ball of radius $5r_I$, within the radius $i(r_B/4)$. For mixed overlaps, an interior chart meeting a boundary chart lies in the controlled collar, and its projection onto ∂M lies in a ball of radius Cr_B. The projection is uniformly Lipschitz by the collar metric comparison. Thus, all disjoint interior balls involved lie in a half-tube of volume at most $C' r_B^n$, and each has volume at least $c' r_I^n$. Their number is bounded by $(C'/c')(r_B/r_I)^n$. In the reverse direction, the boundary centers of charts meeting an interior chart lie in a ball of ∂M of radius $C'' r_B$; packing on ∂M bounds their number. Both nets are countable by second countability. This proves uniform local finiteness and the cross-overlap bounds.

On a mixed overlap, the connection transformation identity gives, for the transition Φ between the two charts,

$$\partial_a \partial_b \Phi^k = \Gamma^c_{ab} \partial_c \Phi^k - \widetilde{\Gamma}^k_{ij}(\Phi) \partial_a \Phi^i \partial_b \Phi^j.$$

Metric comparison bounds $D\Phi$ and its inverse. Successive differentiation of this formula bounds all higher derivatives, since the metrics and their inverses have uniform jets in both systems. Order zero is controlled by their fixed-radius domains. This also gives estimates for mixed transitions, without extending a boundary chart to a normal ball centered outside M.

Fix $0 < r_0 < r_B/4$. For the partition, choose cutoffs $\eta_i^\partial(u)$ on ∂M and a function $\chi(t)$ equal to one for $0 \le t < r_0$. In boundary charts use $\eta_i^\partial(u)\chi(t)$; interior cutoffs vanish on the smaller collar. Normalizing by

$$S^{\frac{1}{2}} = \left(\sum_{\alpha \in I} \widetilde{\eta}_\alpha^2 \right)^{\frac{1}{2}},$$

gives $h_\alpha = \widetilde{\eta}_\alpha S^{-\frac{1}{2}}$. On $0 \le t < r_0$, every summand of S contains the same factor $\chi(t)^2 = 1$, and no interior cutoffs contribute; therefore, $h_i \circ \kappa_i^\partial$ is independent of t in that region. This proves (14.31). The remaining bounds follow through the quadratic normalization used in Proposition 14.2.6. For (B3), before transporting the cutoffs choose slightly wider model functions equal to one on neighborhoods of the supports of $\eta_i^\partial(u)\chi(t)$ and the interior cutoffs, respectively. Their transports provide functions $\chi_\alpha \in C_c^\infty(U_\alpha)$ equal to one near $\operatorname{supp}(h_\alpha)$; since they come from a finite family of fixed profiles, all their coordinate derivatives are bounded by constants independent of α. □

Proposition 14.4.6. (The compact case with boundary) Every compact Riemannian manifold with smooth nonempty boundary satisfies Definition 14.4.2.

Proof. The boundary is a compact Riemannian manifold without boundary; Theorem 13.1.11 gives, in particular, $\operatorname{inj}(\partial M) > 0$. Apply Theorem 2.12.3 to ∂M in the smooth double of M, equipped with a smooth extension of $\mathbf{g}$. Compactness of ∂M provides $r_\partial > 0$ such that the normal exponential is injective on normal vectors of length less than r_∂. Its restriction to the inward normal is therefore the required uniform geodesic collar.

Fix $0 < r < r_\partial$ and set $K := M \setminus \mathcal{C}(\partial M \times [0, r))$. This set is compact and contained in the interior of M. Each

$x \in K$ has a normal ball $B_{\mathbf{g}_x}(0, r_x)$; by smooth dependence of the exponential map, the same conclusion, with radius $\frac{r_x}{2}$, holds for centers in a neighborhood of x. A finite subcover of K and the minimum of these radii give a number $i(r) > 0$ independent of the center, as required by the third item of the definition.
For each $j \in \mathbb{N}_0$, the continuous functions $x \mapsto |\nabla^j \mathbf{R}^M(x)|_{\mathbf{g}}$ and $y \mapsto |\nabla^j \mathbf{II}(y)|_{\mathbf{g}}$ attain a maximum on M and ∂M, respectively. All five items are verified. □

Corollary 14.4.7. (Uniform regularity in the presence of boundary) Let $(M, \mathbf{g})$ be a manifold of bounded geometry with nonempty boundary. The Fermi and interior atlas of Proposition 14.4.5, after fixed rescaling of its domains, defines a uniformly regular Riemannian structure in the sense of Definitions 13.2.1 and 13.2.3. Its constants depend only on the dimension, collar width, interior and boundary injectivity radii, and bounds on $\nabla^j \mathbf{R}^M$ and $\nabla^j \mathbf{II}$ through the required order. Proposition 13.2.6, applied to this normalized atlas, produces an admissible quadratic localization system with the uniform bounds established there.

Proof. Use the radii r_B, r_I of the proposition. Choose $b_B, b_I > 0$ such that $b_B\sqrt{n} < r_B$ and $b_I\sqrt{n} < r_I$. On the boundary and in the interior, respectively, define

$$\bar{\kappa}_i^{-1}(x) := \kappa_i^{\partial}\big(b_B(x_2, \dots, x_n), 2r_B x_1\big), \qquad x \in Q_+^n,$$

$$\bar{\kappa}_j^{-1}(x) := \kappa_j^0(b_I x), \qquad x \in Q^n.$$

These are two fixed linear transformations with bounded inverses; thus, they preserve all uniform bounds, although the constants may depend on b_B, b_I, r_B.
Restriction to cubes is accompanied by a new choice of centers. On ∂M, choose a net of spacing δ_B small enough that the images of tangential cubes of half the side length cover ∂M. This follows from the first-exit-time argument: the metric lower bound gives a uniform minimum length for leaving the smaller cube. The boundary half-boxes thus cover $0 \le t < r_B$. On $K = M \setminus \mathcal{C}(\partial M \times [0, r_B/2))$, choose a net of spacing δ_I less than the minimum length required to leave an interior cube of half the side length. Its half-sized boxes cover K. The interior radii remain less than r_I, so the charts do not meet $t = 0$. These two families cover M after shrinking by the same factor 1/2. The volume arguments of the proposition, applied at the new fixed scales, preserve uniform multiplicity.
The proof of the cited proposition gives, for each $j \in \mathbb{N}_0$, a constant $C_{\mathrm{tr}}(j) > 0$, independent of the charts, bounding all coordinate transitions in BUC^j. It also gives constants $c_g, C_g > 0$ such that

$$c_g|\xi|^2 \le g_\kappa(x)(\xi, \xi) \le C_g|\xi|^2$$

for every chart, every point of its normalized domain, and every $\xi \in \mathbb{R}^n$. For each j, it also provides constants $G_j, G_j' > 0$, independent of the chart, satisfying

$$Q_\alpha := \bar{\kappa}_\alpha(U_\alpha) = \begin{cases} Q_+^n, & \alpha \in I_\partial, \\ Q^n, & \alpha \in I_0, \end{cases} \qquad I := I_\partial \sqcup I_0,$$

and

$$\|(g_{\bar{\kappa}_\alpha})_{ab}\|_{BUC^j(Q_\alpha)} \le G_j, \qquad \|(g_{\bar{\kappa}_\alpha}^{-1})^{ab}\|_{BUC^j(Q_\alpha)} \le G_j', \qquad \alpha \in I.$$

Uniform continuity of derivatives of order j follows by applying the mean value theorem to the bounds of

order $j+1$ in the slightly larger charts used in that proof. Now apply Proposition 13.2.6 to the normalized atlas. This gives cutoffs $\pi_\alpha \in C_c^\infty(U_\alpha,[0,1])$ and a fixed coordinate cutoff $\widehat{\chi}$ such that

$$\sum_{\alpha\in I}\pi_\alpha^2 = 1, \qquad \widehat{\chi}=1 \quad \text{en } \operatorname{supp}(\pi_\alpha\circ\bar{\kappa}_\alpha^{-1}).$$

For each $j\in\mathbb{N}_0$, there exists $D_j>0$, independent of α, with

$$\|\pi_\alpha\circ\bar{\kappa}_\alpha^{-1}\|_{BUC^j(Q_\alpha)}\le D_j, \qquad \alpha\in I.$$

The constant D_j depends only on j, the multiplicity N, the shrinking factor $\rho=\frac{1}{2}$, and $C_{\mathrm{tr}}(0),\dots,C_{\mathrm{tr}}(j)$. These cutoffs are constructed after reselecting the centers and restricting to cubes, so they may differ from the cutoffs h_β in the quadratic localization system of Proposition 14.4.5. □

Theorem 14.4.8. (Full comparison with boundary) A Riemannian manifold with smooth nonempty boundary is uniformly regular if and only if it has bounded geometry with boundary in the sense of Definition 14.4.2.

The implication from bounded geometry to uniform regularity is Corollary 14.4.7, whose proof uses the Fermi atlas already constructed. Conversely, the results in [6, Theorems 2.2 and 3.5, §§2–3] state that a uniformly regular Riemannian atlas recovers a uniform geodesic collar, interior and boundary injectivity radii, and curvature bounds, and that this formulation is equivalent to Schick's through the second-fundamental-form bounds. The intrinsic equivalence with the second-fundamental-form formulation is also found in [128, §2, Definition 2.2 and Theorem 2.5].

Definition 14.4.9. (Localized spaces on a manifold with boundary) Let M be a Riemannian manifold of bounded geometry with nonempty boundary in the sense of Definition 14.4.2, let $\mathbb{R}^n_+ := \mathbb{R}^{n-1}\times[0,\infty)$, and fix the quadratic localization system of Proposition 14.4.5.

(a) For $s\in\mathbb{R}$ and $1<p<\infty$, define

$$H^{s,p}(\mathbb{R}^n_+) := \left\{ U\restriction_{\mathbb{R}^n_+} \,\middle|\, U\in H^{s,p}(\mathbb{R}^n)\right\},$$

with quotient norm

$$\|u\|_{H^{s,p}(\mathbb{R}^n_+)} := \inf_{\substack{U\in H^{s,p}(\mathbb{R}^n)\\ U\restriction_{\mathbb{R}^n_+}=u}} \|U\|_{H^{s,p}(\mathbb{R}^n)}. \tag{14.33}$$

Here and below, distributional restriction is taken to the open set $\mathbb{R}^{n-1}\times(0,\infty)$; we retain the notation $\mathbb{R}^n_+=\mathbb{R}^{n-1}\times[0,\infty)$ because trace values on $t=0$ will be considered later. The restriction mapping is a continuous surjection, and this norm is, by definition, the quotient norm modulo its kernel. In particular, it does not depend on a chosen extension, and $H^{s,p}(\mathbb{R}^n_+)$ is a Banach space.

In all restriction scales of this chapter, a distribution on M means a distribution on $\operatorname{Int}M$. No independent distributions supported on ∂M are added: boundary values will be obtained through trace

operators. The space $H^{s,p}(M)$ consists of those distributions u for which the norm

$$\|u\|_{H^{s,p}(M)} := \left(\sum_{i \in I_\partial} \|(h_i u) \circ \kappa_i^\partial\|^p_{H^{s,p}(\mathbb{R}^n_+)} + \sum_{j \in I_0} \|(h_j u) \circ \kappa_j^0\|^p_{H^{s,p}(\mathbb{R}^n)} \right)^{\frac{1}{p}}. \tag{14.34}$$

is finite.

(b) If $s \in \mathbb{R}$, $1 \le p < \infty$, and $1 \le q \le \infty$, define

$$F^s_{p,q}(\mathbb{R}^n_+) := \left\{ U \restriction_{\mathbb{R}^n_+} \middle| U \in F^s_{p,q}(\mathbb{R}^n) \right\}$$

and

$$\|u\|_{F^s_{p,q}(\mathbb{R}^n_+)} := \inf_{\substack{U \in F^s_{p,q}(\mathbb{R}^n) \\ U \restriction_{\mathbb{R}^n_+} = u}} \|U\|_{F^s_{p,q}(\mathbb{R}^n)}. \tag{14.35}$$

Again, this is the quotient norm of the restriction operator and does not depend on a particular extension. The space $F^s_{p,q}(M)$ consists of the distributions for which

$$\left(\sum_{i \in I_\partial} \|(h_i u) \circ \kappa_i^\partial\|^p_{F^s_{p,q}(\mathbb{R}^n_+)} + \sum_{j \in I_0} \|(h_j u) \circ \kappa_j^0\|^p_{F^s_{p,q}(\mathbb{R}^n)} \right)^{\frac{1}{p}}$$

is finite; this expression is its norm.

(c) For $s \in \mathbb{R}$, $1 \le p < \infty$, and $1 \le q \le \infty$, also define the Euclidean restriction space

$$B^s_{p,q}(\mathbb{R}^n_+) := \left\{ U \restriction_{\mathbb{R}^n_+} \middle| U \in B^s_{p,q}(\mathbb{R}^n) \right\}$$

with quotient norm

$$\|u\|_{B^s_{p,q}(\mathbb{R}^n_+)} := \inf_{\substack{U \in B^s_{p,q}(\mathbb{R}^n) \\ U \restriction_{\mathbb{R}^n_+} = u}} \|U\|_{B^s_{p,q}(\mathbb{R}^n)}. \tag{14.36}$$

Provisionally fix $s_0 < s < s_1$ and $\theta = \frac{s - s_0}{s_1 - s_0}$. Define

$$B^s_{p,q}(M; s_0, s_1) := \left(F^{s_0}_{p,p}(M), F^{s_1}_{p,p}(M) \right)_{\theta,q}. \tag{14.37}$$

Independence of s_0, s_1, which is not assumed in this definition, is proved in Corollary 14.4.15 using a common analysis–synthesis pair. After that corollary, the endpoints will be omitted and the space written simply as $B^s_{p,q}(M)$.

Compositions with parametrizations are understood in the sense of Proposition 10.2.34; in boundary charts, use the restriction norm just defined. On ∂M, use the definitions without boundary from the preceding chapter.

Lemma 14.4.10. (Localized operators between boundary models) Let $s \in \mathbb{R}$ and choose $k \in \mathbb{N}$ with $k > |s| + n + 1$. Consider $H^{s,p}$ for $1 < p < \infty$, $F^s_{p,q}$ for $1 \le p < \infty$, $1 \le q \le \infty$, and $B^s_{p,q}$ for $1 \le p < \infty$, $1 \le q \le \infty$.

(a) Rychkov's cone formula defines a single linear operator

$$\mathbf{E}_+ \colon \mathcal{A}(\mathbb{R}^n_+) \longrightarrow \mathcal{A}(\mathbb{R}^n), \qquad \mathcal{A} \in \{H^{s,p}, F^s_{p,q}, B^s_{p,q}\},$$

such that $(\mathbf{E}_+ u)\restriction_{\mathbb{R}^n_+} = u$. There exist constants $C^H_+(s,p)$, $C^F_+(s,p,q)$, and $C^B_+(s,p,q)$, depending additionally only on n and the fixed kernels, bounding the three norms of $\mathbf{E}_+$.

(b) Let $U', V' \subseteq \mathbb{R}^{n-1}$ be open, $\vartheta \colon U' \longrightarrow V'$ a diffeomorphism of class C^{k+1}, $\lambda > 0$, and $\Psi(x',t) := (\vartheta(x'), \lambda t)$. Suppose there exist $\lambda_-, \lambda_+ > 0$ such that

$$\lambda_- \le \lambda \le \lambda_+, \qquad c_J \le |\det D\vartheta(x')| \le C_J \quad (x' \in U'),$$
$$\|D^\ell \vartheta\|_{L^\infty(U')} + \|D^\ell \vartheta^{-1}\|_{L^\infty(V')} \le A, \qquad \ell \in \{1, \dots, k+1\}.$$

and $\eta \in C^{k+1}_c(U' \times [0,\infty))$ satisfies $\|\eta\|_{BC^{k+1}(U'\times[0,\infty))} \le A_\eta$. Let K_η be the tangential projection of $\operatorname{supp}\eta$. Also fix $R, \delta > 0$ such that

$$\operatorname{supp}\eta \subseteq \overline{B}^{n-1}_{\mathrm{euc}}(0,R) \times [0,R],$$
$$\operatorname{dist}(K_\eta, \mathbb{R}^{n-1} \setminus U') \ge \delta,$$
$$\operatorname{dist}(\vartheta(K_\eta), \mathbb{R}^{n-1} \setminus V') \ge \delta.$$

These distances concern the artificial chart boundaries; the support may meet $t = 0$. The initial formula

$$T^{+\leftarrow+}_{\eta,\Psi} u := \begin{cases} \eta\,(u \circ \Psi), & \text{on } U' \times [0,\infty), \\ 0, & \text{elsewhere in } \mathbb{R}^n_+, \end{cases}$$

defines continuous operators

$$T^{+\leftarrow+}_{\eta,\Psi} \colon \mathcal{A}(\mathbb{R}^n_+) \longrightarrow \mathcal{A}(\mathbb{R}^n_+)$$

in all three scales. Their norms are bounded by constants $M_H, M_F(q), M_B(q)$ depending on $n, s, p, k, c_J, C_J, A, A_\eta, \lambda_-, \lambda_+, R, \delta$ and, in the last two scales, also on q.

(c) Let $\mathbb{X}, \mathbb{Y} \in \{\mathbb{R}^n, \mathbb{R}^n_+\}$, let $U \subseteq \mathbb{Y}$ and $V \subseteq \mathbb{X}$ be relatively open, let $\Phi \colon U \longrightarrow V$ be a diffeomorphism, and let $\zeta \in C^{k+1}_c(U)$. If a half-space occurs and the relevant support meets $t = 0$, assume $\mathbb{X} = \mathbb{Y} = \mathbb{R}^n_+$ and that (ζ, Φ) has the form in (b). In the other cases, assume the relevant supports have distance at least $d > 0$ from every boundary present: $\operatorname{dist}(\operatorname{supp}\zeta, \partial\mathbb{R}^n_+) \ge d$ if $\mathbb{Y} = \mathbb{R}^n_+$ and $\operatorname{dist}(\Phi(\operatorname{supp}\zeta), \partial\mathbb{R}^n_+) \ge d$ if $\mathbb{X} = \mathbb{R}^n_+$. Then

$$T^{\mathbb{Y}\leftarrow\mathbb{X}}_{\zeta,\Phi} \colon \mathcal{A}(\mathbb{X}) \longrightarrow \mathcal{A}(\mathbb{Y})$$

is continuous. For uniform bounds, include the diameter of the supports and their positive separation from the relative boundaries of U and V, together with the coordinate-change bounds required in the localized version of Lemma 6.4.3. If $\widetilde{T}$ denotes the localized full-space operator associated with the same data, r_+ the restriction, and $\mathbf{E}_+$ the operator in (a), the four types are

$(\mathbb{X}, \mathbb{Y})$	$T^{\mathbb{Y}\leftarrow\mathbb{X}}_{\zeta,\Phi}$
$(\mathbb{R}^n, \mathbb{R}^n)$	$\widetilde{T}$
$(\mathbb{R}^n_+, \mathbb{R}^n)$	$\widetilde{T}\mathbf{E}_+$
$(\mathbb{R}^n, \mathbb{R}^n_+)$	$r_+\widetilde{T}$
$(\mathbb{R}^n_+, \mathbb{R}^n_+)$	$r_+\widetilde{T}\mathbf{E}_+$.

In each case, on smooth functions the formula means $T^{\mathbb{Y}\leftarrow\mathbb{X}}_{\zeta,\Phi}u = \zeta(u\circ\Phi)$ on U and zero outside U. The preceding constants also depend on d and bounds for Φ, Φ^{-1}, their Jacobians, and their derivatives through order $k+1$, but not on u.

All these assertions include $s<0$. At endpoint fine indices, the distributional formula specifies the operator.

Proof. Specialize the construction of Lemma 6.5.1 to $\omega = 0$. With its cone kernels, set

$$\mathbf{E}_+ u := \sum_{j\in\mathbb{N}_0} \psi_j * \bigl(\mathbf{1}_{\mathbb{R}^n_+}(\varphi_j * u)\bigr).$$

The identity (6.11) proves $r_+\mathbf{E}_+ = I$. Estimates (6.14) and (6.13) give $C^F_+(s,p,q)$; for $q=2$ and $H^{s,p} = F^s_{p,2}$, they give $C^H_+(s,p)$. For Besov, take the ℓ^q norm outside L^p in the same estimates, giving $C^B_+(s,p,q)$. Fix the Rychkov kernels once, with all vanishing moments required at positive levels. To estimate a particular order s, only finitely many $N > |s|+1$ of these moments are used; the kernels do not change as s varies. This gives a single operator at every order, including $s<0$.

We record the density that will be used. Let $Q_{\mathcal{A}}$ be the restriction quotient mapping from $\mathcal{A}(\mathbb{R}^n)$ to $\mathcal{A}(\mathbb{R}^n_+)$. If $\mathcal{S}(\mathbb{R}^n)$ is dense in $\mathcal{A}(\mathbb{R}^n)$ and $u = Q_{\mathcal{A}}U$, choose $U_j\in\mathcal{S}$ with $U_j\longrightarrow U$; since $\|Q_{\mathcal{A}}\|\le 1$, we have $Q_{\mathcal{A}}U_j\longrightarrow u$. Thus, restrictions of Schwartz functions are dense in $H^{s,p}$, in $F^s_{p,q}$ when $q<\infty$, and in $B^s_{p,q}$ when $p,q<\infty$. This conclusion is neither obtained nor needed at the other indices.

For (b), let $a_1,\dots,a_{k+2}$ be the unique coefficients satisfying

$$\sum_{\nu=1}^{k+2} a_\nu(-\nu)^j = 1, \qquad 0\le j\le k+1,$$

and define

$$\widetilde{\eta}(x',t) := \begin{cases} \eta(x',t), & t\ge 0,\\ \displaystyle\sum_{\nu=1}^{k+2} a_\nu \eta(x',-\nu t), & t<0. \end{cases}$$

The Vandermonde identities match derivatives through order $k+1$. Moreover, $\widetilde{\eta}\in C^{k+1}_c(U'\times\mathbb{R})$ and, with

$$C_k := 1 + \sum_{\nu=1}^{k+2} |a_\nu| \max\{1,\nu^{k+1}\},$$

we have $\|\widetilde{\eta}\|_{BC^{k+1}(U'\times\mathbb{R})}\le C_k A_\eta$. The diffeomorphism $\widetilde{\Psi}(x',t) := (\vartheta(x'),\lambda t)$ preserves the half-spaces. Moreover,

$$D\widetilde{\Psi} = \begin{pmatrix} D\vartheta & 0\\ 0 & \lambda\end{pmatrix}, \qquad D\widetilde{\Psi}^{-1} = \begin{pmatrix} D\vartheta^{-1} & 0\\ 0 & \lambda^{-1}\end{pmatrix}, \qquad |\det D\widetilde{\Psi}| = \lambda|\det D\vartheta|.$$

Consequently, derivatives of $\widetilde{\Psi}$ and $\widetilde{\Psi}^{-1}$ through order $k+1$, and upper and lower bounds for their Jacobians, are controlled by constants depending only on $c_J, C_J, A, \lambda_-, \lambda_+$. The support of $\widetilde{\eta}$ remains in a compact set of diameter controlled by R and separated from the boundary of $U'\times\mathbb{R}$ by δ. The corresponding image margin is also uniform. The localized version of Lemma 6.4.3, with these distances and bounds, and item

(a) give

$$\|r_+ T_{\widetilde{\eta},\widetilde{\Psi}} \mathbf{E}_+ u\|_{H^{s,p}(\mathbb{R}^n_+)} \le C^H_{\mathrm{loc}} C^H_+(s,p) \|u\|_{H^{s,p}(\mathbb{R}^n_+)},$$
$$\|r_+ T_{\widetilde{\eta},\widetilde{\Psi}} \mathbf{E}_+ u\|_{F^s_{p,q}(\mathbb{R}^n_+)} \le C^F_{\mathrm{loc}}(q) C^F_+(s,p,q) \|u\|_{F^s_{p,q}(\mathbb{R}^n_+)},$$
$$\|r_+ T_{\widetilde{\eta},\widetilde{\Psi}} \mathbf{E}_+ u\|_{B^s_{p,q}(\mathbb{R}^n_+)} \le C^B_{\mathrm{loc}}(q) C^B_+(s,p,q) \|u\|_{B^s_{p,q}(\mathbb{R}^n_+)}.$$

The restriction r_+ has norm at most one by the quotient definition. Thus, we may take

$$M_H := C^H_{\mathrm{loc}} C^H_+(s,p), \quad M_F(q) := C^F_{\mathrm{loc}}(q) C^F_+(s,p,q), \quad M_B(q) := C^B_{\mathrm{loc}}(q) C^B_+(s,p,q).$$

The third bound follows directly from the almost-diagonal Besov estimate in Lemma 6.4.3; the outer sum ℓ^p and integration in the K method are not interchanged. These formulas display every stated dependence. In ranges where restrictions of Schwartz functions are dense, they also prove uniqueness of the extension; at the endpoints, the composition $r_+ \widetilde{T} \mathbf{E}_+$ is its distributional definition.

For (c), if the supports are separated from $t = 0$, the effective open sets are open in $\mathbb{R}^n$ and the localized operator $\widetilde{T}$ from the full-space lemma applies without crossing a boundary. Precomposing with $\mathbf{E}_+$ when $\mathbb{X} = \mathbb{R}^n_+$ and postcomposing with r_+ when $\mathbb{Y} = \mathbb{R}^n_+$ gives exactly the four factorizations in the table. If the support meets $t = 0$, the construction in (b) provides $\widetilde{T}$. In H and F, the norms are the product of the localized constant with C^H_+ or C^F_+ whenever $\mathbf{E}_+$ occurs. In B, the same procedure gives the localized constant $C^B_{\mathrm{loc}}(q)$, multiplied by $C^B_+(s,p,q)$ precisely in the two types whose domain is $\mathbb{R}^n_+$; the restriction r_+ has norm at most one. The almost-diagonal argument of the full-space lemma includes $s < 0$, proving the assertions for negative orders through the same local estimates. □

Proposition 14.4.11. (Independence of the boundary atlas) Let M be a Riemannian manifold of bounded geometry with nonempty boundary, and let $\mathcal{T}_1$ and $\mathcal{T}_2$ be two atlases satisfying Proposition 14.4.5. For each space in Definition 14.4.9, there exist constants $c^{\mathcal{A}}_{12}, C^{\mathcal{A}}_{12} > 0$, one pair for each function-space scale $\mathcal{A}$, depending on its indices and the uniform data of both atlases but not on u, such that

$$c^{\mathcal{A}}_{12} \|u\|_{\mathcal{A},\mathcal{T}_1} \le \|u\|_{\mathcal{A},\mathcal{T}_2} \le C^{\mathcal{A}}_{12} \|u\|_{\mathcal{A},\mathcal{T}_1}.$$

For $B^s_{p,q}$, provisionally fix the same interpolation endpoints in both atlases; their independence is proved in Corollary 14.4.15.

The retraction–coretraction argument corresponds to [6, Theorems 4.2 and 4.4].

Proof. Let $\mathcal{T}_1$ and $\mathcal{T}_2$ be the two systems. Insert the identity $\sum_{\beta \in I_2} h^2_{2,\beta} = 1$ into each localization $h_{1,\alpha} u$. The two cross-overlap bounds leave at most L summands per index, where L depends only on the uniform data of both atlases.

Between two boundary charts, using the same collar normal parameter makes the Fermi transition

$$(x', t) \longmapsto \big(\vartheta_{\alpha\beta}(x'), t\big).$$

The bounds in Proposition 14.4.5 provide numbers $c_J, C_J, A, A_\eta > 0$, independent of α, β, verifying the hy-

potheses of Lemma 14.4.10(b). Thus, each boundary–boundary summand has norm at most M_H, $M_F(q)$, or $M_B(q)$ times the source localization norm, according to the scale; these assertions include $s<0$. For two interior charts, use Lemma 6.4.3 on $\mathbb{R}^n$. On a mixed overlap, the interior cutoff supports are separated from $t=0$ by a uniform distance; item (c) of the preceding lemma again reduces the estimate to the full-space case. Denote by $M_{\mathcal{A}}$ the largest constant for scale $\mathcal{A}$. It depends on n,s,p, also on q in F and B, and on the uniform data of $\mathcal{T}_1,\mathcal{T}_2$, but not on the indices.

The inequality $\left(\sum_{\ell=1}^{L} a_\ell\right)^p \le L^{p-1}\sum_{\ell=1}^{L} a_\ell^p$ and a second overlap count give

$$\|u\|_{H^{s,p}_{\mathcal{T}_1}(M)} \le LM_H\|u\|_{H^{s,p}_{\mathcal{T}_2}(M)}.$$

Interchanging the atlases gives $\|u\|_{H^{s,p}_{\mathcal{T}_2}(M)} \le L'M'_H\|u\|_{H^{s,p}_{\mathcal{T}_1}(M)}$; taking $c^H_{12} := (LM_H)^{-1}$ and $C^H_{12} := L'M'_H$ yields the assertion in H. In F, the same count gives explicitly

$$c^F_{12}(q) := (LM_F(q))^{-1}, \qquad C^F_{12}(q) := L'M'_F(q).$$

For B, fix provisional endpoints $a<s<b$ and $\theta = \frac{s-a}{b-a}$. If

$$c_t\|u\|_{F^t_{p,p,\mathcal{T}_1}(M)} \le \|u\|_{F^t_{p,p,\mathcal{T}_2}(M)} \le C_t\|u\|_{F^t_{p,p,\mathcal{T}_1}(M)}, \qquad t\in\{a,b\},$$

are the inequalities just proved with $c_t := (L_tM_F(t,p))^{-1}$ and $C_t := L'_tM'_F(t,p)$, Theorem 5.3.1 gives

$$c_a^{1-\theta}c_b^{\theta}\|u\|_{B^s_{p,q}(M;a,b),\mathcal{T}_1} \le \|u\|_{B^s_{p,q}(M;a,b),\mathcal{T}_2} \le C_a^{1-\theta}C_b^{\theta}\|u\|_{B^s_{p,q}(M;a,b),\mathcal{T}_1}.$$

Thus, for these endpoints one may take $c^B_{12} := c_a^{1-\theta}c_b^{\theta}$ and $C^B_{12} := C_a^{1-\theta}C_b^{\theta}$. Subsequent independence of a,b allows them to be omitted. □

Corollary 14.4.12. (Functional connection with Amann's theory in the presence of boundary) Let M be a Riemannian manifold of bounded geometry with nonempty boundary, let $\tilde{\mathfrak{K}} = (U_\alpha,\varphi_\alpha)_{\alpha\in I}$ be the normalized atlas constructed in Corollary 14.4.7, and let $(\pi_\alpha)_\alpha$ be the new quadratic system obtained by applying Proposition 13.2.6 to $\tilde{\mathfrak{K}}$. Set

$$X_\alpha := \begin{cases} \mathbb{R}^n, & U_\alpha\cap\partial M = \varnothing,\\ \mathbb{R}^n_+, & U_\alpha\cap\partial M \neq \varnothing, \end{cases}$$

and, at a boundary index, postcompose the chart with the linear isometry

$$\tau(x_1,\dots,x_n) := (x_2,\dots,x_n,x_1),$$

identifying the model Q^n_+ with normal variable first with the half-space $\mathbb{R}^n_+ = \mathbb{R}^{n-1}\times[0,\infty)$ used in Definition 14.4.9. Retain the symbol φ_α for the postcomposed chart and write $\Omega_\alpha := \varphi_\alpha(U_\alpha)\subseteq X_\alpha$. For $s\in\mathbb{R}$ and $1<p<\infty$, define

$$\mathbb{H}^{s,p}_{\partial}(\tilde{\mathfrak{K}}) := \left\{ v=(v_\alpha)_{\alpha\in I} \,\middle|\, \sum_{\alpha\in I}\|v_\alpha\|^p_{H^{s,p}(X_\alpha)} < +\infty \right\}$$

with norm given by the pth root of the preceding sum. For $s \in \mathbb{R}$, $1 \le p < \infty$, and $1 \le q \le \infty$, likewise set

$$\mathbb{F}^{s}_{p,q,\partial}(\mathfrak{K}) := \left\{ v = (v_\alpha)_{\alpha \in I} \,\middle|\, \sum_{\alpha \in I} \|v_\alpha\|^{p}_{F^{s}_{p,q}(X_\alpha)} < +\infty \right\}.$$

Both spaces carry the norm given by the pth root of the corresponding sum. Let $\chi \in C^\infty_c(Q^n, [0,1])$ be the fixed cutoff chosen in Proposition 13.2.6. Define

$$\widehat{\chi}_\alpha := \begin{cases} \chi \restriction_{\Omega_\alpha}, & X_\alpha = \mathbb{R}^n, \\ (\chi \circ \tau^{-1}) \restriction_{\Omega_\alpha}, & X_\alpha = \mathbb{R}^n_+. \end{cases}$$

Then $\widehat{\chi}_\alpha$ equals one on a neighborhood of $\operatorname{supp}(\pi_\alpha \circ \varphi_\alpha^{-1})$ and, for each $j \in \mathbb{N}_0$,

$$\sup_{\alpha \in I} \|\widehat{\chi}_\alpha\|_{BUC^j(\Omega_\alpha)} \le \|\chi\|_{BUC^j(Q^n)} < +\infty,$$

because τ is a linear isometry. Let $\widetilde{\chi}_\alpha$ be the extension by zero of $\widehat{\chi}_\alpha$ from Ω_α to X_α. Since its support stays separated from the nongeometric faces of Ω_α, this extension belongs to $C^\infty_c(X_\alpha)$, including when $X_\alpha = \mathbb{R}^n_+$ and the support meets $t = 0$. For a component v_α of either sequence space, define $\mathcal{E}_\alpha(\widetilde{\chi}_\alpha v_\alpha)$ as the distribution whose coordinate representation on U_α is $(\widetilde{\chi}_\alpha v_\alpha) \restriction_{\Omega_\alpha}$ and which is extended by zero outside U_α. Likewise, the tilde in $\widetilde{(\pi_\alpha u) \circ \varphi_\alpha^{-1}}$ denotes extension by zero from Ω_α to X_α. This is legitimate because $\operatorname{supp}(\pi_\alpha \circ \varphi_\alpha^{-1}) \Subset \Omega_\alpha$. The operators, whose formulas do not depend on s, p, q,

$$\mathcal{S}_{\partial,\mathfrak{K}} u := \left(\widetilde{(\pi_\alpha u) \circ \varphi_\alpha^{-1}} \right)_{\alpha \in I}, \qquad \mathcal{R}_{\partial,\mathfrak{K}} v := \sum_{\alpha \in I} \pi_\alpha \, \mathcal{E}_\alpha(\widetilde{\chi}_\alpha v_\alpha)$$

are continuous in both the H and F scales, and

$$\mathcal{R}_{\partial,\mathfrak{K}} \mathcal{S}_{\partial,\mathfrak{K}} = \mathrm{id}$$

on each of these spaces. There exist constants $c^\partial_{s,p}, C^\partial_{s,p}, D^\partial_{s,p} > 0$ such that

$$c^\partial_{s,p} \|u\|_{H^{s,p}(M)} \le \|\mathcal{S}_{\partial,\mathfrak{K}} u\|_{\mathbb{H}^{s,p}_\partial(\mathfrak{K})} \le C^\partial_{s,p} \|u\|_{H^{s,p}(M)}, \tag{14.38}$$

$$\|\mathcal{R}_{\partial,\mathfrak{K}} v\|_{H^{s,p}(M)} \le D^\partial_{s,p} \|v\|_{\mathbb{H}^{s,p}_\partial(\mathfrak{K})}. \tag{14.39}$$

Moreover, there exist $c^F_{s,p,q}, C^F_{s,p,q}, D^F_{s,p,q} > 0$ such that

$$c^F_{s,p,q} \|u\|_{F^{s}_{p,q}(M)} \le \|\mathcal{S}_{\partial,\mathfrak{K}} u\|_{\mathbb{F}^{s}_{p,q,\partial}(\mathfrak{K})} \le C^F_{s,p,q} \|u\|_{F^{s}_{p,q}(M)}, \tag{14.40}$$

$$\|\mathcal{R}_{\partial,\mathfrak{K}} v\|_{F^{s}_{p,q}(M)} \le D^F_{s,p,q} \|v\|_{\mathbb{F}^{s}_{p,q,\partial}(\mathfrak{K})}. \tag{14.41}$$

For a fixed integer $k > |s| + n + 1$, the constants depend only on n, s, p, k, the two overlap bounds, q in scale F, and uniform coordinate-transition and cutoff bounds through order $k+1$; they do not depend on α, u, or v.

Proof. Denote by $\mathcal{T}_F = (V_\beta, \kappa_\beta, h_\beta)_{\beta \in J}$ the quadratic localization system fixed in Definition 14.4.9. The construction of $\mathfrak{K}$ takes place in the same Fermi and interior chart families, through the two fixed linear trans-

formations in the proof of Corollary 14.4.7. Denote the normal rescaling factor by $b_N := 2r_B$. Each support of π_α or h_β lies in a common shrunken box. The packing argument of Proposition 14.4.5, applied in both directions, gives

$$L := \max\left\{\sup_{\alpha\in I} \#\left\{\beta\in J \,\middle|\, \operatorname{supp}\pi_\alpha \cap \operatorname{supp} h_\beta \neq \varnothing\right\}, \sup_{\beta\in J} \#\left\{\alpha\in I \,\middle|\, \operatorname{supp} h_\beta \cap \operatorname{supp}\pi_\alpha \neq \varnothing\right\}\right\} < +\infty.$$

Fix $k > |s| + n + 1$. The BUC^{k+1} bounds for transitions and cutoffs, the upper and lower Jacobian bounds, and Lemma 14.4.10 provide numbers $M_{\to,\mathcal{A}}, M_{\leftarrow,\mathcal{A}} > 0$, for $\mathcal{A} = H^{s,p}$ or $F^s_{p,q}$, bounding, respectively, each localized operator passing from $\mathcal{T}_F$ to Amann's localization system and each operator in the reverse direction. For two boundary charts, the transition preserves the normal parameter within each system. Comparing $\mathcal{T}_F$ with the rescaled charts in the proof of Corollary 14.4.7 introduces the fixed normal factor b_N; thus, the transition has the form $(x', t) \mapsto (\vartheta(x'), \lambda t)$, with $\lambda \in \{1, b_N, b_N^{-1}\}$. Use item (b) with $\lambda_- := \min\{1, b_N, b_N^{-1}\}$ and $\lambda_+ := \max\{1, b_N, b_N^{-1}\}$. On a mixed overlap, the support is at uniform distance from $t = 0$ and item (c) is used; between interior charts, use Lemma 6.4.3. In particular, both bounds remain valid for $s < 0$. The numbers depend only on n, s, p, k, also on q in scale F, the Jacobian bounds, the BUC^{k+1} bounds for transitions and cutoffs, and the uniform separation of mixed overlaps.

Insert $\sum_{\beta\in J} h_\beta^2 = 1$ into every localization $\pi_\alpha u$. If A_α denotes its norm in $H^{s,p}(X_\alpha)$ and B_β the corresponding summand of (14.34), then

$$A_\alpha \le M_{\to,H} \sum_{\{\beta\in J \,|\, \operatorname{supp}\pi_\alpha\cap\operatorname{supp} h_\beta\neq\varnothing\}} B_\beta.$$

The inequality $(\sum_{j=1}^{L} a_j)^p \le L^{p-1}\sum_{j=1}^{L} a_j^p$ and the two overlap counts give

$$\|\mathcal{S}_{\partial,\mathfrak{K}} u\|_{\mathbb{H}^{s,p}_\partial(\mathfrak{K})} \le L M_{\to,H} \|u\|_{H^{s,p}(M)}.$$

In the reverse direction, insert $\sum_{\alpha\in I}\pi_\alpha^2 = 1$ into each $h_\beta u$ to obtain

$$\|u\|_{H^{s,p}(M)} \le L M_{\leftarrow,H} \|\mathcal{S}_{\partial,\mathfrak{K}} u\|_{\mathbb{H}^{s,p}_\partial(\mathfrak{K})}.$$

Consequently, in (14.38) we may take

$$c^\partial_{s,p} := (L M_{\leftarrow,H})^{-1}, \qquad C^\partial_{s,p} := L M_{\to,H}.$$

The same calculation with $F^s_{p,q}$ norms gives (14.40) with

$$c^F_{s,p,q} := (L M_{\leftarrow,F})^{-1}, \qquad C^F_{s,p,q} := L M_{\to,F}.$$

For synthesis, localizing $\mathcal{R}_{\partial,\mathfrak{K}} v$ using h_β involves at most L indices α. The same three transition cases provide uniform constants $M_{\sin,H} > 0$ and $M_{\sin,F}(q) > 0$ such that each summand has norm at most $M_{\sin,H}\|v_\alpha\|_{H^{s,p}(X_\alpha)}$ in H, and the analogous bound with $M_{\sin,F}(q)$ in F. Raising to the power p, summing

first over β, and counting overlaps in the reverse direction gives

$$\|\mathcal{R}_{\partial,\mathfrak{K}} v\|^p_{H^{s,p}(M)} \le L^p M^p_{\sin,H} \sum_{\alpha\in I} \|v_\alpha\|^p_{H^{s,p}(X_\alpha)}.$$

Thus, we may take $D^{\partial}_{s,p} := LM_{\sin,H}$ and, in (14.41), $D^{F}_{s,p,q} := LM_{\sin,F}(q)$. The sum is well defined by local finiteness.

The retraction identity is distributional and does not depend on density. Indeed, if $u \in \mathcal{D}'(M)$, then $\widetilde{\chi}_\alpha = 1$ on a neighborhood of the coordinate support of π_α implies, by definition of multiplication and extension of distributions,

$$\mathcal{E}_\alpha\left(\widetilde{\chi}_\alpha \widetilde{(\pi_\alpha u)\circ\varphi_\alpha^{-1}}\right) = \pi_\alpha u.$$

The family is locally finite and $\sum_{\alpha\in I} \pi_\alpha^2 = 1$; therefore, in $\mathcal{D}'(M)$,

$$\mathcal{R}_{\partial,\mathfrak{K}}\mathcal{S}_{\partial,\mathfrak{K}} u = \sum_{\alpha\in I} \pi_\alpha^2 u = u.$$

Finally, this retraction gives global density exactly in the dense ranges. If u belongs to $H^{s,p}(M)$, or to $F^s_{p,q}(M)$ with $q<\infty$, first truncate $\mathcal{S}_{\partial,\mathfrak{K}} u$ to finitely many indices and then approximate each component by the restriction of a Schwartz function, as proved using the quotient in Lemma 14.4.10. Synthesis of each finite family belongs to $C^\infty_c(M)$ and converges to u by (14.39) or (14.41). The case $q=\infty$ is outside the density range. □

Remark 14.4.13. (The two localization systems) Corollary 14.4.7 constructs the normalized atlas and its own cutoffs π_α; it does not identify them with the cutoffs h_β of $\mathcal{T}_F$. Corollary 14.4.12 then uses the constants L, $M_{\to,\mathcal{A}}$, and $M_{\leftarrow,\mathcal{A}}$ to prove that both systems produce the same scales H and F with norms comparable through explicit inequalities. Thus, uniform regularity provides a connection at the function-space level and does not replace the Fermi localization already used in the trace and embedding proofs.

Proposition 14.4.14. (Exactness under interpolation of the localized scale) Let M be a Riemannian manifold of bounded geometry with nonempty boundary. Let $1\le p<\infty$, $a<b$, $0<\rho<1$, and $r=(1-\rho)a+\rho b$. There exist constants $\lambda_{a,b,r}, \Lambda_{a,b,r}>0$ such that

$$\lambda_{a,b,r}\|u\|_{F^r_{p,p}(M)} \le \|u\|_{(F^a_{p,p}(M),F^b_{p,p}(M))_{\rho,p}} \le \Lambda_{a,b,r}\|u\|_{F^r_{p,p}(M)}. \tag{14.42}$$

The pair $\mathcal{S}_{\partial,\mathfrak{K}}$, $\mathcal{R}_{\partial,\mathfrak{K}}$ from the preceding corollary is the same for all values of a,b,r.

Proof. Write $Y_t := \mathbb{F}^t_{p,p,\partial}(\mathfrak{K})$. Use the identity $F^t_{p,p}(\mathbb{R}^n) = B^t_{p,p}(\mathbb{R}^n)$ and the Besov analysis and synthesis of Lemma 6.3.8. This synthesis is bounded for every $1\le p<\infty$, including $p=1$, and its formulas do not depend on t. The two operators realize $F^t_{p,p}(\mathbb{R}^n)$ as a retract of

$$b^t_p := \left\{ w=(w_j)_{j\ge0} \in \left(L^p(\mathbb{R}^n)\right)^{\mathbb{N}_0} \,\middle|\, \sum_{j\in\mathbb{N}_0} 2^{jtp}\|w_j\|^p_{L^p(\mathbb{R}^n)} < +\infty \right\}.$$

More precisely, there exist operators $\mathfrak{a}, \mathfrak{r}$, independent of t, such that, for each $t \in \mathbb{R}$,

$$\mathfrak{a}\colon F^t_{p,p}(\mathbb{R}^n) \longrightarrow b^t_p, \qquad \mathfrak{r}\colon b^t_p \longrightarrow F^t_{p,p}(\mathbb{R}^n), \qquad \mathfrak{r}\mathfrak{a} = I_{F^t_{p,p}(\mathbb{R}^n)}.$$

There also exist $A_t, B_t > 0$, depending only on n, p, t and the fixed resolution, such that

$$\|\mathfrak{a}u\|_{b^t_p} \le A_t \|u\|_{F^t_{p,p}(\mathbb{R}^n)}, \qquad \|\mathfrak{r}w\|_{F^t_{p,p}(\mathbb{R}^n)} \le B_t \|w\|_{b^t_p}.$$

In particular, $B_t^{-1}\|u\|_{F^t_{p,p}(\mathbb{R}^n)} \le \|\mathfrak{a}u\|_{b^t_p} \le A_t\|u\|_{F^t_{p,p}(\mathbb{R}^n)}$; no isometric equality between Triebel–Lizorkin and Besov norms is used. In a coordinate j,

$$K\big(\tau, w_j; 2^{ja}L^p(\mathbb{R}^n), 2^{jb}L^p(\mathbb{R}^n)\big) = \min\{2^{ja}, \tau 2^{jb}\}\|w_j\|_{L^p(\mathbb{R}^n)}.$$

If $k(\tau, w)$ is the ℓ^p norm of these coordinate functionals, the definitions give

$$k(\tau, w) \le K(\tau, w; b^a_p, b^b_p) \le 2k(\tau, w).$$

Moreover,

$$\int_0^\infty \Big[\tau^{-\rho}\min\{2^{ja}, \tau 2^{jb}\}\Big]^p \frac{d\tau}{\tau} = c^p_{\rho,p} 2^{jrp}, \qquad c^p_{\rho,p} := \frac{1}{p\rho} + \frac{1}{p(1-\rho)}.$$

This equality follows by integrating separately before and after $\tau = 2^{j(a-b)}$. Tonelli applies because the interpolation index is precisely p. Interpolating the same dyadic analysis–synthesis pair gives $m_{\mathbb{R}}, M_{\mathbb{R}} > 0$ such that

$$m_{\mathbb{R}}\|w\|_{F^r_{p,p}(\mathbb{R}^n)} \le \|w\|_{(F^a_{p,p}(\mathbb{R}^n), F^b_{p,p}(\mathbb{R}^n))_{\rho,p}} \le M_{\mathbb{R}}\|w\|_{F^r_{p,p}(\mathbb{R}^n)}.$$

On the half-space, r_+ has norm at most one and the same $\mathbf{E}_+$ satisfies $r_+\mathbf{E}_+ = I$ at orders a, b. If e_a, e_b are its norms, interpolation of $\mathbf{E}_+$ gives the following lower inequality. For the upper inequality, choose $U \in F^r_{p,p}(\mathbb{R}^n)$ with $r_+U = w$, apply the full-space inequality to U, and then take the infimum over all such extensions. Thus, the quotient definition gives

$$m_{\mathbb{R}} e_a^{-(1-\rho)} e_b^{-\rho}\|w\|_{F^r_{p,p}(\mathbb{R}^n_+)} \le \|w\|_{(F^a_{p,p}(\mathbb{R}^n_+), F^b_{p,p}(\mathbb{R}^n_+))_{\rho,p}} \le M_{\mathbb{R}}\|w\|_{F^r_{p,p}(\mathbb{R}^n_+)}.$$

Taking the outer ℓ^p sum and using Tonelli again gives $m_Y, M_Y > 0$ with

$$m_Y\|v\|_{Y_r} \le \|v\|_{(Y_a, Y_b)_{\rho,p}} \le M_Y\|v\|_{Y_r}. \tag{14.43}$$

One may take m_Y as the minimum of the lower constants for the two models and M_Y as twice the maximum of their upper constants.

Abbreviate $C_t := C^F_{t,p,p}$ and $D_t := D^F_{t,p,p}$. Interpolating the common operators, using their retraction identity and (14.43), gives (14.42) with

$$\lambda_{a,b,r} := \frac{m_Y}{D_r C_a^{1-\rho} C_b^{\rho}}, \qquad \Lambda_{a,b,r} := M_Y C_r D_a^{1-\rho} D_b^{\rho}.$$

These constants depend only on the indices and uniform atlas data, not on u. □

Corollary 14.4.15. (Independence of the Besov endpoints) Let M be a Riemannian manifold of bounded geometry with nonempty boundary. Let $1 \le p < \infty$, $1 \le q \le \infty$, and let $P = (s_0, s_1, \theta)$, $Q = (t_0, t_1, \eta)$ be two triples such that $s_0 < s < s_1$, $t_0 < s < t_1$, $\theta, \eta \in (0,1)$, and

$$s = (1-\theta)s_0 + \theta s_1 = (1-\eta)t_0 + \eta t_1.$$

There exist constants $c_{P,Q}, C_{P,Q} > 0$ such that

$$c_{P,Q}\|u\|_{B^s_{p,q}(M;s_0,s_1)} \le \|u\|_{B^s_{p,q}(M;t_0,t_1)} \le C_{P,Q}\|u\|_{B^s_{p,q}(M;s_0,s_1)}.$$

Thus, the space and its topology are independent of the auxiliary endpoints. Henceforth, denote it simply by $B^s_{p,q}(M)$.

Proof. Choose $a < \min\{s_0, t_0\}$ and $b > \max\{s_1, t_1\}$. For $x \in \{s_0, s_1, t_0, t_1\}$, set $\rho_x = \frac{x-a}{b-a}$ and

$$Z_x := (F^a_{p,p}(M), F^b_{p,p}(M))_{\rho_x, p}.$$

The proposition provides $\lambda_x, \Lambda_x > 0$ with

$$\lambda_x\|u\|_{F^x_{p,p}(M)} \le \|u\|_{Z_x} \le \Lambda_x\|u\|_{F^x_{p,p}(M)}.$$

Let $W_s := (F^a_{p,p}(M), F^b_{p,p}(M))_{\frac{s-a}{b-a}, q}$. Theorem 5.5.2 provides $r_P, R_P, r_Q, R_Q > 0$ such that

$$r_P\|u\|_{W_s} \le \|u\|_{(Z_{s_0}, Z_{s_1})_{\theta,q}} \le R_P\|u\|_{W_s},$$

and the same inequalities with Q in place of P. Interpolating the four preceding inequalities gives

$$\alpha_P\|u\|_{W_s} \le \|u\|_{B^s_{p,q}(M;s_0,s_1)} \le \beta_P\|u\|_{W_s},$$

where

$$\alpha_P := \frac{r_P}{\Lambda_{s_0}^{1-\theta}\Lambda_{s_1}^{\theta}}, \qquad \beta_P := \frac{R_P}{\lambda_{s_0}^{1-\theta}\lambda_{s_1}^{\theta}}.$$

Define α_Q, β_Q by the same formula, with Q in place of P. Then we may take

$$c_{P,Q} := \frac{\alpha_Q}{\beta_P}, \qquad C_{P,Q} := \frac{\beta_Q}{\alpha_P}.$$

The outer ℓ^p sum was commuted with interpolation only in the intermediate step whose index is p; the arbitrary index q enters afterward through reiteration. □

Before taking traces on the half-space, we must verify that the datum does not depend on the chosen full-space representative.

Lemma 14.4.16. (The trace depends only on restriction to the half-space) Let $1 < p < \infty$, $j \in \mathbb{N}_0$, and $s > j + 1/p$. If $U \in H^{s,p}(\mathbb{R}^n)$ vanishes on $t > 0$, then $\mathrm{tr}_1(\partial_t^\ell U) = 0$ for $0 \le \ell \le j$. For $j = 0$, the same assertion holds in $F^s_{p,q}$ and $B^s_{p,q}$, $1 \le q \le \infty$, provided that $s > 1/p$.

Proof. For $h>0$, set $U_h(x',t)=U(x',t+h)$. This distribution vanishes on $t>-h$. A smooth function $\eta_h(t)$ supported in $(-h/2,h/2)$ and equal to one near zero satisfies $\eta_h\partial_t^\ell U_h=0$. Compatibility with multipliers from Lemma 14.1.2 gives $\operatorname{tr}_1(\partial_t^\ell U_h)=0$. Translations converge strongly to the identity on $H^{s,p}$; continuity of differentiation and the trace permits $h\to 0^+$. The same argument applies to $F^s_{p,q}$ and $B^s_{p,q}$ when the fine index is finite. For $q=\infty$, choose $0<\varepsilon<s-1/p$ and work in the space of order $s-\varepsilon$ and fine index 1. Compatibility of traces at different orders identifies the distributional limit with the trace at order s. $\square$

Theorem 14.4.17. (Trace and jets on the half-space) Let $1<p<\infty$, $j\in\mathbb{N}_0$, and $s>j+\frac{1}{p}$. The operator

$$\boldsymbol{\gamma}_j U:=\big(U\restriction_{t=0},\partial_t U\restriction_{t=0},\dots,\partial_t^j U\restriction_{t=0}\big)$$

extends to a retraction

$$\boldsymbol{\gamma}_j\colon H^{s,p}(\mathbb{R}^n_+)\longrightarrow\prod_{\ell=0}^{j}B^{\,s-\ell-\frac{1}{p}}_{p,p}(\mathbb{R}^{n-1}). \tag{14.44}$$

There exists a continuous linear coretraction $\boldsymbol{e}_j$ for which $\boldsymbol{\gamma}_j\boldsymbol{e}_j=I$. For $j=0$ and $1\le q\le\infty$, one may replace $H^{s,p}$ by $F^s_{p,q}$ and $B^s_{p,q}$, with target spaces $B^{s-\frac{1}{p}}_{p,p}$ and $B^{s-\frac{1}{p}}_{p,q}$, respectively.

Proof. Let $u\in H^{s,p}(\mathbb{R}^n_+)$ and choose an extension $U\in H^{s,p}(\mathbb{R}^n)$. Define $\gamma_\ell u:=\operatorname{tr}_1(\partial_t^\ell U)$. Two extensions differ by a distribution vanishing on $t>0$; Lemma 14.4.16 shows that the definition is independent of U. Continuity of differentiation, the Euclidean trace, and the infimum over extensions give, for $\ell\le j$,

$$\|\gamma_\ell u\|_{B^{\,s-\ell-\frac{1}{p}}_{p,p}(\mathbb{R}^{n-1})}\le C_\ell\inf_{\substack{U\in H^{s,p}(\mathbb{R}^n)\\ r_+U=u}}\|U\|_{H^{s,p}(\mathbb{R}^n)}=C_\ell\|u\|_{H^{s,p}(\mathbb{R}^n_+)}.$$

Summing the finitely many estimates proves continuity of $\boldsymbol{\gamma}_j$.

To prescribe the $j+1$ boundary data simultaneously, construct a normal profile for each derivative and estimate the sum of the extensions. Let $(\Delta'_k)_{k\ge0}$ be a dyadic resolution in the tangential variables. Choose $\vartheta\in\mathcal{S}(\mathbb{R})$ with compactly supported Fourier transform and $\vartheta(0)\neq0$. The finite matrix

$$\Big(\frac{d^m}{dt^m}\big(t^r\vartheta(t)\big)\Big|_{t=0}\Big)_{0\le m,r\le j}$$

is triangular with diagonal $r!\vartheta(0)$ and hence invertible. Thus, there exist linear combinations $\varphi_0,\dots,\varphi_j$ of the functions $\vartheta,t\vartheta,\dots,t^j\vartheta$ such that

$$\varphi_\ell^{(m)}(0)=\delta_{\ell m},\qquad 0\le\ell,m\le j. \tag{14.45}$$

All φ_ℓ are Schwartz functions with compactly supported Fourier transforms. For a datum g, define on the full space

$$(\mathbf{E}_\ell g)(x',t):=\sum_{k=0}^{\infty}2^{-k\ell}\varphi_\ell(2^kt)\Delta'_kg(x'). \tag{14.46}$$

We record the discrete estimate controlling superposition in the normal variable. For every $\varphi\in\mathcal{S}(\mathbb{R})$, every

nonnegative sequence $(a_k)_{k\ge 0}$, and $1<p<\infty$,

$$\int_{\mathbb{R}} \left(\sum_{k\in\mathbb{N}_0} 2^{\frac{2k}{p}} |\varphi(2^k t)|^2 a_k^2 \right)^{\frac{p}{2}} dt \le C_{\varphi,p} \sum_{k\in\mathbb{N}_0} a_k^p. \tag{14.47}$$

Indeed, decompose $\mathbb{R}\setminus\{0\}$ into the annuli $A_m := \{t\in\mathbb{R} \mid 2^{-m-1}<|t|\le 2^{-m}\}$, $m\in\mathbb{Z}$, and extend a_k by zero for $k<0$. If $t\in A_m$, boundedness of φ for $k\le m$ and its decay of order $N>\frac{1}{p}$ for $k>m$ give

$$2^{\frac{k}{p}}|\varphi(2^k t)| \le C_N 2^{\frac{m}{p}} b_{k-m}, \qquad b_r := \begin{cases} 2^{\frac{r}{p}}, & r\le 0,\\ 2^{-(N-\frac{1}{p})r}, & r>0. \end{cases}$$

The sequence b belongs to $\ell^1(\mathbb{Z})$. Since the ℓ^2 norm does not exceed the ℓ^1 norm, the integral over A_m, whose measure is comparable to 2^{-m}, is bounded by $C(\sum_{k\in\mathbb{Z}} b_{k-m}a_k)^p$. Summing over m, Young's inequality for sequences from Proposition B.8.4 proves (14.47).

For $k\ge 1$, the Fourier transform of the kth summand of (14.46) lies in an annulus of radius comparable to 2^k: the tangential frequency already lies in that annulus, and the normal frequency lies in a ball of radius $C2^k$. Finite interaction of blocks and Lemma 6.3.6 give the synthesis estimate

$$\|\mathbf{E}_\ell g\|_{F^s_{p,2}(\mathbb{R}^n)} \le C \left\| \left(\sum_{k\in\mathbb{N}_0} 2^{2k(s-\ell)} |\varphi_\ell(2^k t)\Delta'_k g(x')|^2 \right)^{\frac12} \right\|_{L^p(\mathbb{R}^{n-1}\times\mathbb{R})}.$$

Apply (14.47) for each x', with $a_k(x') = 2^{k(s-\ell-\frac{1}{p})}|\Delta'_k g(x')|$, and integrate in x'. This gives

$$\|\mathbf{E}_\ell g\|^p_{H^{s,p}(\mathbb{R}^n)} \le C \sum_{k\in\mathbb{N}_0} 2^{kp(s-\ell-\frac{1}{p})} \|\Delta'_k g\|^p_{L^p(\mathbb{R}^{n-1})} = C\|g\|^p_{B^{s-\ell-\frac{1}{p}}_{p,p}(\mathbb{R}^{n-1})}. \tag{14.48}$$

In particular, the series in (14.46) converges in $H^{s,p}(\mathbb{R}^n)$. Define

$$\boldsymbol{e}_j(g_0,\dots,g_j) := \left(\sum_{\ell=0}^{j} \mathbf{E}_\ell g_\ell \right) \restriction_{\mathbb{R}^n_+}.$$

The quotient norm of the restriction space and (14.48) show that this operator is continuous. For Schwartz data, we can differentiate termwise at (14.46); by (14.45),

$$\partial_t^m \mathbf{E}_\ell g|_{t=0} = \delta_{m\ell} \sum_{k\in\mathbb{N}_0} \Delta'_k g = \delta_{m\ell} g, \qquad 0\le m\le j.$$

Density of $\mathcal{S}$ in each $B^{s-\ell-\frac{1}{p}}_{p,p}$, together with the already proved continuity of the trace operators, extends this identity to all data. Consequently, $\boldsymbol{\gamma}_j \boldsymbol{e}_j = I$, and

$$\|\boldsymbol{e}_j(g_0,\dots,g_j)\|_{H^{s,p}(\mathbb{R}^n_+)} \le C \sum_{\ell=0}^{j} \|g_\ell\|_{B^{s-\ell-\frac{1}{p}}_{p,p}(\mathbb{R}^{n-1})}.$$

For $j = 0$, assertions F and B are those of Theorem 14.1.1 with $c = 1$, restricted to the half-space. □

Theorem 14.4.18. (Trace and normal derivatives at the boundary) Let M be a manifold of dimension n with nonempty boundary and bounded geometry, and let $1 < p < \infty$, $j \in \mathbb{N}_0$, and $s > j + \frac{1}{p}$. For $u \in C_c^\infty(M)$, define

$$\partial_{\boldsymbol{\nu}}^{\ell} u(x) := \frac{d^\ell}{dt^\ell} u(\mathcal{C}(x,t))\Big|_{t=0}, \qquad 0 \le \ell \le j.$$

Then

$$\mathbf{Tr}_{\partial M, j} u := \big(u \restriction_{\partial M}, \partial_{\boldsymbol{\nu}} u, \dots, \partial_{\boldsymbol{\nu}}^{j} u\big)$$

extends to a retraction

$$\mathbf{Tr}_{\partial M, j} \colon H^{s,p}(M) \longrightarrow \prod_{\ell=0}^{j} B_{p,p}^{s-\ell-\frac{1}{p}}(\partial M). \tag{14.49}$$

In particular,

$$\mathrm{Tr}_{\partial M} \colon H^{s,p}(M) \longrightarrow B_{p,p}^{s-\frac{1}{p}}(\partial M)$$

is surjective and has a continuous linear right extension.

Proof. Let $(U_i^\partial, \kappa_i^\partial, h_i)_{i \in I_\partial}$ be the boundary part of the system in Proposition 14.4.5, and write

$$\kappa_i^{\partial,0}(u) := \kappa_i^\partial(u, 0), \qquad h_i^\partial := h_i \restriction_{\partial M}.$$

By (14.31), on a neighborhood of $t = 0$,

$$\partial_t^\ell \big((h_i u) \circ \kappa_i^\partial\big) \restriction_{t=0} = (h_i^\partial \circ \kappa_i^{\partial,0})\big((\partial_{\boldsymbol{\nu}}^\ell u) \circ \kappa_i^{\partial,0}\big). \tag{14.50}$$

No lower-order Leibniz terms appear; this is the reason for condition (14.31).
Apply $\boldsymbol{\gamma}_j$ of Theorem 14.4.17 to each $(h_i u) \circ \kappa_i^\partial$. If $A(\beta)$ is the set of charts meeting boundary chart β, compatibility with multipliers and tangential changes gives, for $\ell \in \{0, \dots, j\}$,

$$\big\| (h_\beta^\partial\, \partial_{\boldsymbol{\nu}}^\ell u) \circ \kappa_\beta^{\partial,0} \big\|_{B_{p,p}^{s-\ell-\frac{1}{p}}(\mathbb{R}^{n-1})} \le C \sum_{i \in A(\beta)} \big\| (h_i u) \circ \kappa_i^\partial \big\|_{H^{s,p}(\mathbb{R}^n_+)}.$$

The cardinality of $A(\beta)$ is uniformly bounded. Raising to the power p, summing over β, and using the fact that each chart appears in uniformly finitely many sets $A(\beta)$ gives

$$\sum_{\ell=0}^{j} \|\partial_{\boldsymbol{\nu}}^\ell u\|_{B_{p,p}^{s-\ell-\frac{1}{p}}(\partial M)} \le C \|u\|_{H^{s,p}(M)}. \tag{14.51}$$

This defines the continuous extension of $\mathbf{Tr}_{\partial M, j}$.
For the coretraction, let $g = (g_0, \dots, g_j)$ be boundary data and set

$$g_{\ell,i} := (h_i^\partial g_\ell) \circ \kappa_i^{\partial,0}.$$

Choose $\chi_T \in C_c^\infty(B^{n-1}(0, 2r_B))$ equal to one on the tangential supports and $\chi_N \in C_c^\infty([0, 2r_B))$ equal to one

on $[0,r_0]$. Set $\psi(u,t)=\chi_T(u)\chi_N(t)$. Then $\psi \boldsymbol{e}_j(g_{0,i},\dots,g_{j,i})$ is supported in the chart, and its jet at $t=0$ is the local datum. Transport, extend by zero, and reconstruct:

$$\mathbf{Ex}_{\partial M,j} g := \sum_{i\in I_\partial} h_i \left[\psi\, \boldsymbol{e}_j(g_{0,i},\dots,g_{j,i})\right]\circ(\kappa_i^\partial)^{-1}. \tag{14.52}$$

Localizing $\mathbf{Ex}_{\partial M,j} g$ in chart β involves only the indices in $A(\beta)$. Uniform bounds for multipliers, chart transitions, and $\boldsymbol{e}_j$ bound this localization by the sum of the norms of $g_{\ell,i}$, with $i\in A(\beta)$ and $\ell\in\{0,\dots,j\}$. Raise to the power p and count overlaps again to obtain

$$\|\mathbf{Ex}_{\partial M,j} g\|_{H^{s,p}(M)} \le C \sum_{\ell=0}^{j} \|g_\ell\|_{B_{p,p}^{s-\ell-\frac{1}{p}}(\partial M)}.$$

The functions h_i are constant in the normal direction near the boundary, $\psi=1$ there, and $\boldsymbol{\gamma}_j \boldsymbol{e}_j = I$. Thus, taking the jet of (14.52) gives $\sum_{i\in I_\partial} (h_i^\partial)^2 g_\ell = g_\ell$ in each component. Hence,

$$\mathbf{Tr}_{\partial M,j}\mathbf{Ex}_{\partial M,j} = I.$$

□

Theorem 14.4.19. (F, B, and W traces at the boundary) Let M be a Riemannian manifold of dimension n with bounded geometry and nonempty boundary. Let $1<p<\infty$, $1\le q\le\infty$, and $s>\frac{1}{p}$. Then

$$\mathrm{Tr}_{\partial M}\colon F^s_{p,q}(M)\longrightarrow B^{s-\frac{1}{p}}_{p,p}(\partial M), \qquad \mathrm{Tr}_{\partial M}\colon B^s_{p,q}(M)\longrightarrow B^{s-\frac{1}{p}}_{p,q}(\partial M)$$

are retractions. If $s\notin\mathbb{N}$,

$$\mathrm{Tr}_{\partial M}\colon W^{s,p}(M)\longrightarrow B^{s-\frac{1}{p}}_{p,p}(\partial M)$$

is also a retraction; for $m\in\mathbb{N}$, $m>\frac{1}{p}$, the same holds with $W^{m,p}(M)$ and $B^{m-\frac{1}{p}}_{p,p}(\partial M)$.

Proof. Take $j=0$ in formulas (14.49) and (14.52). If $u_i=(h_i u)\circ\kappa_i^\partial$, the Euclidean half-space trace, tangential coordinate changes, and uniform overlap count give

$$\|\mathrm{Tr}_{\partial M}\, u\|^p_{B^{s-\frac{1}{p}}_{p,p}(\partial M)} \le C\sum_{i\in I_\partial}\|u_i\|^p_{F^s_{p,q}(\mathbb{R}^n_+)} \le C'\|u\|^p_{F^s_{p,q}(M)}.$$

For $g\in B^{s-\frac{1}{p}}_{p,p}(\partial M)$, the same count applied to the reconstruction formula, now with the Euclidean coretraction, gives

$$\|\mathrm{Ex}_{\partial M,0}\, g\|_{F^s_{p,q}(M)} \le C\|g\|_{B^{s-\frac{1}{p}}_{p,p}(\partial M)}.$$

Since the cutoffs are constant in the normal direction where the trace is computed, the identity $\sum_{i\in I_\partial}(h_i^\partial)^2=1$ implies $\mathrm{Tr}_{\partial M}\,\mathrm{Ex}_{\partial M,0}=I$.

For the Besov scale, choose $s_0<s<s_1$ with $s_0>\frac{1}{p}$ and apply Theorem 5.3.1 to the same operators at the

endpoints. The interpolation identities

$$(F^{s_0}_{p,p}(M), F^{s_1}_{p,p}(M))_{\theta,q} = B^{s}_{p,q}(M)$$

and

$$(B^{s_0-\frac{1}{p}}_{p,p}(\partial M), B^{s_1-\frac{1}{p}}_{p,p}(\partial M))_{\theta,q} = B^{s-\frac{1}{p}}_{p,q}(\partial M)$$

give the second retraction.

If $s \notin \mathbb{N}$, use restriction $W^{s,p}(\mathbb{R}^n_+)$ norms in boundary charts, never extension by zero across $t = 0$. Proposition 14.5.4 proves that $W^{s,p}(M) = B^{s}_{p,p}(M)$. This identification reduces the assertion to the Besov retraction with $q = p$; the target space remains $B^{s-\frac{1}{p}}_{p,p}(\partial M)$. For $m \in \mathbb{N}$, the boundary equivalence of Proposition 14.5.3, applied to the trivial bundle, reduces the assertion to Theorem 14.4.18 with $j = 0$. □

14.5 Version for vector bundles of bounded geometry

The trace of a section takes values in the restricted bundle. To construct it through components, choose frames adapted to the charts and parallel transport. Bounds on their transition matrices ensure uniform constants in the scalar estimates; compatibility with frame changes allows local traces to be assembled into a section of the restricted bundle.

We use the notion of a bundle of bounded geometry from Definition 13.3.13. If M has boundary, the same expression is understood up to ∂M: require the bound (13.44) throughout M, using the induced product connection on $\Lambda^2 T^*M \otimes \mathrm{End}(\mathbf{E})$. Uniform Fermi charts allow these bounds to be formulated with ordinary derivatives up to the boundary.

Proposition 14.5.1. (Uniform synchronous frames) Let M be a Riemannian manifold of bounded geometry, with or without boundary, and let $\mathbf{E} \to M$ be a bundle of bounded geometry.

(a) If M has no boundary, its uniform geodesic charts admit synchronous orthonormal frames $\mathbf{e}_i = (\mathbf{e}_{i,1}, \dots, \mathbf{e}_{i,r})$ such that the transition matrices, their inverses, and all their derivatives are bounded by constants independent of the indices.

(b) If (M, N) is a pair of bounded geometry consisting of manifolds without boundary, the frames can be constructed in the Fermi charts of Proposition 14.2.6: first transport a basis of $\mathbf{E}_{p_i}$ along radial geodesics of N, then along normal geodesics of N in M. Their restrictions to N are uniform synchronous frames of $\mathbf{E}\restriction_N$.

(c) If M has nonempty boundary, in a boundary chart $\kappa^{\partial}_i(u,t)$ the frame may be chosen parallel along the curves $t \mapsto \kappa^{\partial}_i(u,t)$. If $\nabla^{\mathbf{E}} = d + \mathbf{A}_i$ in this frame, then

$$\mathbf{A}_i(\partial_t) = 0. \tag{14.53}$$

In all three cases, the components of $\mathbf{A}_i$ and all their ordinary derivatives are uniformly bounded.

Proof. Item (a), including the bounds on transition matrices and connection coefficients, is Proposition 8.2.26. The radial formula producing these bounds was established in the chapter on connections, in Proposition 8.2.25.

For (b), first apply Proposition 8.2.26 to the restricted bundle $\mathbf{E}\restriction_N$. Its curvature is

$$\mathbf{R}^{\mathbf{E}\restriction_N}(X,Y) = \mathbf{R}^{\mathbf{E}}(X,Y), \qquad X, Y \in TN,$$

, and derivatives for the product connection of N are finite sums of restrictions of derivatives of $\mathbf{R}^{\mathbf{E}}$ and contractions with $\mathbf{II}$. Lemma 14.2.3 and the pair hypotheses therefore provide the required bounds.

From the frame obtained over N, extend each vector by parallel transport along

$$s \longmapsto \exp^{\perp}_{x_i(u)}\Big(s \sum_{a=1}^{n-k} z^a \boldsymbol{\nu}_{i,a}(x_i(u))\Big).$$

Write frames as columns and use the convention

$$\nabla^{\mathbf{E}} \mathbf{e}_i = \mathbf{e}_i \boldsymbol{\Omega}_i, \qquad \mathscr{F}_i = d\boldsymbol{\Omega}_i + \boldsymbol{\Omega}_i \wedge \boldsymbol{\Omega}_i.$$

Transport imposes the normal radial gauge

$$\sum_{a=1}^{n-k} z^a \Omega_{i,a}(z,u) = 0.$$

Contracting the curvature equation with the radial field gives the exact identities

$$\Omega_{i,b}(z,u) = \int_0^1 s \sum_{a=1}^{n-k} z^a \mathscr{F}_{i,ab}(sz,u)\, ds, \tag{14.54}$$

$$\Omega_{i,\mu}(z,u) = \Omega_{i,\mu}(0,u) + \int_0^1 \sum_{a=1}^{n-k} z^a \mathscr{F}_{i,a\mu}(sz,u)\, ds. \tag{14.55}$$

Here $k = \dim N$, normal indices a, b belong to $\{1,\dots,n-k\}$, and $\mu \in \{1,\dots,k\}$ is tangential. The first identity follows by integrating

$$\sum_{a=1}^{n-k} z^a \mathscr{F}_{i,ab} = \sum_{a=1}^{n-k} z^a \partial_a \Omega_{i,b} + \Omega_{i,b}$$

along the radius; the second follows from

$$\sum_{a=1}^{n-k} z^a \mathscr{F}_{i,a\mu} = \sum_{a=1}^{n-k} z^a \partial_a \Omega_{i,\mu}.$$

Commutators containing $\displaystyle\sum_{a=1}^{n-k} z^a \Omega_{i,a}$ vanish by radial gauge.

We prove the connection and curvature-component bounds simultaneously. Denote by A_m and F_m common bounds for the supremum norms of partial derivatives of order at most m of $\Omega_{i,A}$ and $\mathscr{F}_{i,AB}$, respectively, where $i \in I$ and $A, B \in \{1,\dots,n\}$. At order zero, F_0 is controlled by $\|\mathbf{R}^{\mathbf{E}}\|_{\infty}$, uniform comparison of coordinate

bases, and orthonormality of the frame. The two integral formulas then give A_0, using the frame bounds over N.

Suppose A_{m-1} and F_{m-1} have been obtained, with $m \in \mathbb{N}$. Apply Lemma 9.1.28 to the tensor $\mathbf{R}^{\mathbf{E}}$ taking values in $\mathrm{End}(\mathbf{E})$. Solving for its leading term expresses each partial derivative of order m as the corresponding component of $\nabla^m \mathbf{R}^{\mathbf{E}}$ plus a finite sum of partial derivatives of curvature of order less than m. The coefficients of this sum use only derivatives of Ω_i and the Christoffel symbols of order at most $m-1$. The former are controlled by A_{m-1} and the latter by Proposition 14.2.6. This gives F_m from A_{m-1}, F_{m-1} and $\|\nabla^m \mathbf{R}^{\mathbf{E}}\|_\infty$.

Now differentiate the integral formulas. For $\alpha = (\alpha_z, \alpha_u) \in \mathbb{N}_0^n$ and $|\alpha| = m$, applying the Leibniz rule to the integrand without the outer factor s gives

$$D^\alpha \left(z^a \mathscr{F}_{i,aB}(sz,u) \right) = z^a s^{|\alpha_z|} (D^\alpha \mathscr{F}_{i,aB})(sz,u) + \alpha_a s^{|\alpha_z|-1} (D^{\alpha - e_a} \mathscr{F}_{i,aB})(sz,u).$$

Omit the second term if $\alpha_a = 0$; thus, no negative power of s is ever integrated. If $r_\perp$ is the common normal radius and A_m^N bounds derivatives of the initial frame over N, then

$$A_m \le A_m^N + C_{n,m}\left(r_\perp F_m + m F_{m-1} \right) + A_{m-1}.$$

We have obtained F_m before using it to compute A_m. The recurrence starts from A_0, F_0 and provides bounds at every order, without requiring an order-m connection bound in the step establishing it.

In a boundary chart, the same construction along $t \mapsto \kappa_i^\partial(u,t)$ gives

$$\mathbf{\Omega}_i(\partial_t) = 0.$$

The curvature equation reduces exactly to

$$\partial_t \Omega_{i,\mu} = \mathscr{F}_{i,t\mu}, \qquad \Omega_{i,\mu}(u,t) = \Omega_{i,\mu}(u,0) + \int_0^t \mathscr{F}_{i,t\mu}(u,\tau)\, d\tau.$$

For purely tangential derivatives of order m, differentiate this integral m times in u; the order-m bound for $\mathscr{F}$ is obtained first by the lemma of Chapter 9, exactly as above. If at least one normal derivative occurs, use $\partial_t \Omega_{i,\mu} = \mathscr{F}_{i,t\mu}$: a total derivative of order m of the connection is expressed through a derivative of order $m-1$ of curvature. The initial case is the order-zero integral and the frame value at $t = 0$. These two cases cover every multi-index $\alpha \in \mathbb{N}_0^n$ and complete the recurrence in boundary charts.

It remains to control the transition matrices. On an overlap, after expressing both frames in the same coordinates, write

$$\mathbf{e}_i = \mathbf{e}_j G_{ji}.$$

Since the frames are orthonormal, $G_{ji} \in O(r)$ in the real case and $G_{ji} \in U(r)$ in the complex case; thus, $G_{ji}^{-1} = G_{ji}^{\mathsf{T}}$ in the former and $G_{ji}^{-1} = G_{ji}^{*}$ in the latter. If $\widetilde{\Omega}_j$ is the pullback of Ω_j under the chart transition, compatibility of connections gives the exact equation

$$dG_{ji} = G_{ji}\mathbf{\Omega}_i - \widetilde{\Omega}_j G_{ji}. \tag{14.56}$$

The operator norm of G_{ji} is one. To pass from order m to order $m+1$, let $\alpha \in \mathbb{N}_0^n$, $|\alpha| = m$, and $A \in \{1, \dots, n\}$.

The Leibniz rule gives

$$D^\alpha \partial_A G_{ji} = \sum_{\substack{\beta\in\mathbb{N}_0^n \\ \beta\le\alpha}} \binom{\alpha}{\beta} \left[(D^\beta G_{ji})(D^{\alpha-\beta}\Omega_{i,A}) - (D^\beta \widetilde{\Omega}_{j,A})(D^{\alpha-\beta} G_{ji}) \right].$$

Every derivative of G_{ji} on the right has order at most m. Derivatives of the connection forms are bounded by the preceding step, and those of the pullback by Faà di Bruno and the chart-transition bounds. If G_m is a common bound through order m and D_m controls these forms, we may take $G_{m+1} = G_m + 2^{m+1} D_m G_m$ after incorporating the matrix-norm constants into D_m. Starting from $G_0 = 1$, this bounds every derivative. The identity $G_{ji}^{-1} = G_{ji}^*$, or the transpose in the real case, gives the same bounds for the inverse. At $z = 0$, we recover the synchronous frame constructed over N, also proving the restriction assertion. This concludes the proof. □

Definition 14.5.2. (Function spaces of sections) Let M be a Riemannian manifold of bounded geometry, with or without boundary, and let $\mathbf{E} \to M$ be a bundle of bounded geometry. Fix an admissible quadratic localization system

$$\mathcal{Q} = (U_i, \varphi_i, h_i)_{i\in I}$$

and, on each U_i, one of the synchronous frames $\mathbf{e}_i = (\mathbf{e}_{i,1}, \dots, \mathbf{e}_{i,r})$ constructed in Proposition 14.5.1. Let $\mathbf{u} \in \mathcal{D}'(M, \mathbf{E})$; when there is a boundary, this means $\mathcal{D}'(\operatorname{Int} M, \mathbf{E}|_{\operatorname{Int} M})$, as in the scalar definition. In chart i, denote by u_i^a the distributional components of $\mathbf{u}$ in frame $\mathbf{e}_i$, defined by Proposition 10.2.34. Thus, the component of $h_i\mathbf{u}$ is $h_i u_i^a$. Set $\mathbb{X}_i = \mathbb{R}^n$ in an interior chart and $\mathbb{X}_i = \mathbb{R}^n_+$ in a boundary chart.
For $s \in \mathbb{R}$ and $1 < p < \infty$, define

$$H^{s,p}(M, \mathbf{E}) := \left\{ \mathbf{u} \in \mathcal{D}'(M, \mathbf{E}) \,\middle|\, \|\mathbf{u}\|_{H^{s,p}(M,\mathbf{E})} < \infty \right\},$$

where

$$\|\mathbf{u}\|_{H^{s,p}(M,\mathbf{E})} := \left(\sum_{i\in I} \sum_{a=1}^{r} \left\| (h_i u_i^a) \circ \varphi_i^{-1} \right\|_{H^{s,p}(\mathbb{X}_i)}^p \right)^{\frac{1}{p}}. \tag{14.57}$$

For $1 \le p < \infty$ and $1 \le q \le \infty$, define $F^s_{p,q}(M, \mathbf{E})$ analogously using the norm

$$\left(\sum_{i\in I} \sum_{a=1}^{r} \left\| (h_i u_i^a) \circ \varphi_i^{-1} \right\|_{F^s_{p,q}(\mathbb{X}_i)}^p \right)^{\frac{1}{p}}.$$

Finally, if $s = (1-\theta)s_0 + \theta s_1$, with $s_0 < s < s_1$, define

$$B^s_{p,q}(M, \mathbf{E}) := \left(F^{s_0}_{p,p}(M, \mathbf{E}), F^{s_1}_{p,p}(M, \mathbf{E}) \right)_{\theta,q}.$$

On the half-space, always use the restriction quotient norms of Definition 14.4.9. Definitions on N and ∂M use the restricted frames and constructions without boundary.

In boundary charts, extensions by zero are taken only across artificial faces. The face representing ∂M belongs to the model $\mathbb{R}^n_+$ and is treated by the extension operator of Chapter 6. Fixed coordinate cutoffs leave a common margin from these artificial faces; thus, multiplication and extension constants are the same throughout the

family. In an interior chart, apply Lemma 13.1.15.

Proposition 14.5.3. (Intrinsic character and integer-order equivalence) Let M be a Riemannian manifold of bounded geometry, with or without boundary, and let $\mathbf{E} \to M$ be a bundle of bounded geometry. Let $\mathcal{Q}$ and $\widetilde{\mathcal{Q}}$ be two admissible quadratic localization systems equipped with the synchronous frames of Proposition 14.5.1. For each scale $A \in \{H, F, B\}$, write $\|\mathbf{u}\|_{A_{\mathcal{Q}}}$ for the localized norm constructed with $\mathcal{Q}$. For every admissible set of indices, there exist $c_A, C_A > 0$, independent of $\mathbf{u}$, such that

$$c_A \|\mathbf{u}\|_{A_{\mathcal{Q}}} \le \|\mathbf{u}\|_{A_{\widetilde{\mathcal{Q}}}} \le C_A \|\mathbf{u}\|_{A_{\mathcal{Q}}}.$$

The constants depend on the function-space indices, multiplicity, and uniform transition, cutoff, and frame bounds, but not on the charts. For $m \in \mathbb{N}_0$ and $1 < p < \infty$, $H^{m,p}(M, \mathbf{E}) = W^{m,p}(M, \mathbf{E})$ and there exist $c_{m,p}, C_{m,p} > 0$, independent of $\mathbf{u}$, such that

$$c_{m,p} \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \le \|\mathbf{u}\|_{H^{m,p}(M,\mathbf{E})} \le C_{m,p} \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

More precisely, if $N_{m,p}(\mathbf{u})$ denotes the localized norm of (14.57), there exist $c'_{m,p}, C'_{m,p} > 0$ such that

$$c'_{m,p} \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \le N_{m,p}(\mathbf{u}) \le C'_{m,p} \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})},$$

where the covariant norm is

$$\left(\sum_{\ell=0}^{m} \|(\nabla^{\mathbf{E}})^{\ell} \mathbf{u}\|^{p}_{L^p(M, T^{(0,\ell)}(TM) \otimes \mathbf{E})} \right)^{\frac{1}{p}}. \tag{14.58}$$

Comparison of covariant and partial derivatives holds more generally for $1 \le p < \infty$. If $\mathbf{u} = \sum_{a=1}^{r_{\mathbf{E}}} u_i^a \mathbf{e}_{i,a}$ on U_i, set

$$N^W_{m,p}(\mathbf{u}) := \left(\sum_{i \in I} \sum_{a=1}^{r_{\mathbf{E}}} \|(h_i u_i^a) \circ \varphi_i^{-1}\|^{p}_{W^{m,p}(\mathbb{X}_i)} \right)^{1/p}. \tag{14.59}$$

There exist $c^W_{m,p}, C^W_{m,p} > 0$ such that

$$c^W_{m,p} \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \le N^W_{m,p}(\mathbf{u}) \le C^W_{m,p} \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

Smooth sections with compact support in M, which may meet the boundary, are dense in these spaces for every $1 \le p < \infty$. Identification with $H^{m,p}$ holds in the range $1 < p < \infty$.

Proof. On an overlap, component vectors are related by $u_i = G_{ij} u_j$. Proposition 14.5.1 bounds all derivatives of G_{ij}, and Lemma 6.4.3 controls matrix multiplication and coordinate change simultaneously. Uniform multiplicity and the finite-sum inequality used in Proposition 14.4.11 produce the constants c_A, C_A in the stated inequalities. The argument holds in F, and real interpolation transfers it to B.

For the integer-order comparison, use Lemma 9.1.28 in each regular chart. If $q \in \mathbb{N}$, $a \in \{1, \dots, r_{\mathbf{E}}\}$, and

$(i_1,\dots,i_q)\in\{1,\dots,n\}^q$, its formula is

$$((\nabla^{\mathbf{E}})^q\mathbf{u})^a_{i_1\cdots i_q}=\partial_{i_1}\cdots\partial_{i_q}u^a+\sum_{b=1}^{r_{\mathbf{E}}}\sum_{\substack{\beta\in\mathbb{N}_0^n\\|\beta|\le q-1}}(B_\beta)^a_{b,i_1\cdots i_q}\partial^\beta u^b.$$

The coefficients in that lemma use connection derivatives through order $q-1$; their supremum norms are uniform by the frame proposition. Let P_q be the sum of the L^p norms of partial derivatives of all components through order q, and let V_q be the sum of the L^p norms of covariant derivatives through that order in the chart considered. Uniform comparison of metrics and density gives $P_0\le K_0V_0$. If $P_{q-1}\le K_{q-1}V_{q-1}$, solving for the leading term in the preceding formula gives

$$P_q\le P_{q-1}+C_qV_q+C_qP_{q-1}\le\big(C_q+(1+C_q)K_{q-1}\big)V_q.$$

Thus, $K_q=C_q+(1+C_q)K_{q-1}$ can be chosen independently of the chart. The reverse inequality follows from the same formula without solving for the leading term: $V_q\le C_q'P_q$. Coefficients in both comparisons are those in the lemma of Chapter 9, whose bounds are uniform in the trivializations considered.
Apply the comparisons to $h_i\mathbf{u}$. The Leibniz rule for the product connection controls its derivatives by

$$|\nabla^q(h_i\mathbf{u})|\le C_q\sum_{b=0}^{q}|\nabla^{q-b}h_i||\nabla^b\mathbf{u}|,\qquad q\in\{0,\dots,m\}.$$

The supremum norms of cutoff derivatives and uniform multiplicity allow raising to the power p, summing over $i\in I$, and integrating. For the reverse inequality, use $\mathbf{u}=\sum_{i\in I}h_i(h_i\mathbf{u})$ and the same Leibniz rule; uniformly finitely many summands contribute at each point. Equivalence between a sum of finitely many norms and their ℓ^p sum adds only factors depending on $m,n,r_{\mathbf{E}},p$. All these steps hold for $1\le p<\infty$: only triangle inequalities, the Leibniz rule, and sums of bounded multiplicity were used. They prove both bounds in $N^W_{m,p}$, including $p=1$. For $1<p<\infty$, Theorem 6.3.10 identifies Euclidean integer-order norms with Bessel norms; on the half-space, apply it after the extension and restriction of Chapter 6. This provides the two asserted global constants. These triangular formulas also hold for weak derivatives by Lemma 9.1.44. Thus, the comparisons apply directly to each given section without presupposing an approximation already satisfying trace conditions.
We specify the density used later. The series $\mathbf{u}=\sum_{i\in I}h_i(h_i\mathbf{u})$ converges in $W^{m,p}$: its tail norms are controlled by tails of the localized ℓ^p sum. In each of the finitely many charts of a partial sum, extend components to the full space (using $\mathcal{E}_m$ from Theorem 3.6.4 in a boundary chart), regularize, and multiply by a fixed auxiliary cutoff. Restriction to the half-space gives approximations smooth up to $t=0$. Reconstruction yields sections in $\Gamma_c(M,\mathbf{E})$ converging in $W^{m,p}$. Their supports are not required to avoid the boundary. This approximation holds for every $1\le p<\infty$ by continuity of translation and regularization in L^p, applied to the finitely many derivatives. For $1<p<\infty$, the same construction works in $H^{m,p}$ and, together with the preceding comparisons, proves equality of the two spaces as subspaces of distributions on $\operatorname{Int}M$. □

The integer-order comparison identifies the derivatives entering the norm. At a noninteger order, we still need to compare values in different fibers. The error between parallel transport and component differences is first order in the distance and is therefore integrable in the fractional seminorm.

Proposition 14.5.4. (Uniform Slobodeckij localization) Let M and $\mathbf{E} \to M$ have bounded geometry, with or without boundary, let $1 < p < \infty$ and $s = m + \sigma$, where $m \in \mathbb{N}_0$ and $0 < \sigma < 1$. In a uniform quadratic system with synchronous frames, set

$$\|\mathbf{u}\|_{W^{s,p}_{\mathcal{Q}}(M,\mathbf{E})} := \left(\sum_{i \in I} \sum_{a=1}^{r_{\mathbf{E}}} \left\| (h_i u_i^a) \circ \varphi_i^{-1} \right\|^p_{W^{s,p}(\mathbb{X}_i)} \right)^{1/p}.$$

In interior charts, extend by zero outside the chart; in boundary charts, extend by zero only across artificial faces and take the restriction norm on the half-space. These norms define a space $W^{s,p}(M,\mathbf{E})$ independently of the chosen system, and

$$W^{s,p}(M,\mathbf{E}) = B^s_{p,p}(M,\mathbf{E}) \quad \text{con normas equivalentes.}$$

If M has no boundary, this space agrees with the one defined using $\mathbf{u} \in W^{m,p}(M,\mathbf{E})$ and the seminorm

$$[\nabla^m_w \mathbf{u}]^p_{\sigma,p;r} := \int_M \int_{0<d_{\mathbf{g}}(x,y)<r} \frac{|\nabla^m_w \mathbf{u}(x) - P^{\mathbf{E}_m}_{y\to x} \nabla^m_w \mathbf{u}(y)|^p}{d_{\mathbf{g}}(x,y)^{n+\sigma p}} \, d\lambda_{\mathbf{g}}(y) \, d\lambda_{\mathbf{g}}(x), \tag{14.60}$$

where $\mathbf{E}_m = T^{(0,m)}(TM) \otimes \mathbf{E}$, transport is taken along the unique short geodesic, and $r > 0$ is a sufficiently small uniform radius. Replacing r by another positive radius below the uniform radius gives an equivalent norm.

Proof. In each Euclidean model, the identification $W^{s,p} = B^s_{p,p} = F^s_{p,p}$ has constants depending only on n, s, p. It also holds for restriction norms on the half-space, by Euclidean extension and the comparisons of Chapter 6. Proposition 14.4.14 and its version without boundary in the preceding chapter show that the localized space $F^s_{p,p}$ agrees with $B^s_{p,p}$. For sections, use the same analysis and synthesis on every component: the rank is finite, matrix transitions are uniform multipliers, and the sums over charts, components, and blocks here have the same exponent p. Tonelli and the estimates in those proofs apply without changing their order. This gives equivalence with $B^s_{p,p}$ and, by Proposition 14.5.3, independence of the system. This part of the argument includes the boundary case.

Now suppose $\partial M = \varnothing$. Fix normal charts larger than those used by the cutoffs, and choose r smaller than their uniform margin. If one point lies in the support of h_i and its distance from the other is less than r, the short geodesic remains inside the larger chart. In the synchronous frame, the transport matrix $G_i(x,y)$ satisfies

$$\|G_i(x,y) - I\| + \|G_i(x,y)^{-1} - I\| \le C d_{\mathbf{g}}(x,y).$$

Indeed, integrate the transport equation; its coefficients are the bounded connection matrices evaluated on the curve velocity. Coordinate length does not exceed a constant times Riemannian length. Grönwall gives the inequality with C independent of i. The same proof applies to each tensor bundle $\mathbf{E}_m$.

Fix one of these bundles $\mathbf{E}_m$ and a section $\mathbf{v}$ of it; write v_i for its component vector. In both directions we obtain

$$|\mathbf{v}(x) - P_{y\to x}\mathbf{v}(y)| \le C\big(|v_i(x) - v_i(y)| + d_{\mathbf{g}}(x,y)|v_i(y)|\big),$$
$$|v_i(x) - v_i(y)| \le C\big(|\mathbf{v}(x) - P_{y\to x}\mathbf{v}(y)| + d_{\mathbf{g}}(x,y)|\mathbf{v}(y)|\big).$$

Distances and measures are uniformly comparable to their coordinate counterparts. The contribution of

the error terms is bounded by $C\|\mathbf{v}\|^p_{L^p(M,\mathbf{E}_m)}$, since

$$\sup_{y\in M}\int_{d_{\mathbf{g}}(x,y)<r} d_{\mathbf{g}}(x,y)^{-n+p(1-\sigma)}\,d\lambda_{\mathbf{g}}(x)\le C\int_0^r t^{p(1-\sigma)-1}\,dt<\infty.$$

This is the local comparison between the intrinsic seminorm and the component seminorm, now with a uniform constant.

To localize, we use the identity

$$h_i(x)\mathbf{v}(x)-h_i(y)P_{y\to x}\mathbf{v}(y)=h_i(x)\big(\mathbf{v}(x)-P_{y\to x}\mathbf{v}(y)\big)+(h_i(x)-h_i(y))P_{y\to x}\mathbf{v}(y).$$

We have $|h_i(x)-h_i(y)|\le Cd_{\mathbf{g}}(x,y)$, and at most $2L$ supports contribute to each pair. We raise to the power p, sum, and apply the preceding integral estimate. Conversely, we reconstruct $\mathbf{v}=\sum_{i\in I}h_i(h_i\mathbf{v})$ and use the same finite-sum estimate. The parts of the extension by zero lying outside the chart are separated from the support by a uniform distance $\delta>0$; their contribution is bounded by $C\delta^{-\sigma p}\|\mathbf{v}\|^p_{L^p(M,\mathbf{E}_m)}$. Thus the local norms and the $\|\mathbf{v}\|_{L^p(M,\mathbf{E}_m)}+[\mathbf{v}]_{\sigma,p;r}$ norm are equivalent.

For $s=m+\sigma$, we use the triangular expression for covariant derivatives in Lemma 9.1.28, both directly and to solve for the partial derivatives of order m. Each lower-order term contains a derivative of order at most $m-1$ and a uniformly smooth coefficient. It is controlled in $W^{\sigma,p}$ by $W^{1,p}\hookrightarrow W^{\sigma,p}$ and the multiplier estimate of Lemma 9.4.15. These terms can therefore be absorbed into $\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}$. The comparison at order σ applied to $\nabla^m_w\mathbf{u}$, together with the Leibniz rule for the cutoffs, proves equivalence with $\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}+[\nabla^m_w\mathbf{u}]_{\sigma,p;r}$. The local formulas hold for weak derivatives; density in the fractional norm has not been assumed.

Finally, if $0<r_1<r_2$ are two admissible radii, the difference between the integrals is taken over $r_1\le d_{\mathbf{g}}(x,y)<r_2$. The isometry of parallel transport and the uniform bound on the volume of $B_{\mathbf{g}}(y,r_2)$ bound this difference by $C_{r_1,r_2}\|\nabla^m_w\mathbf{u}\|^p_{L^p(M,\mathbf{E}_m)}$. This proves independence of the radius without requiring M to have finite total volume. □

Proposition 14.5.5. (Interpolation and complex Sobolev duality for bundles) Let $(M,\mathbf{g})$ be a manifold without boundary of bounded geometry, and let $(\mathbf{E},\mathbf{h}_{\mathbf{E}},\nabla^{\mathbf{E}})\to M$ be a complex Hermitian bundle of bounded geometry; we adopt the convention that $\mathbf{h}_{\mathbf{E}}$ is linear in the first variable. If $s_0<s_1$, $0<\theta<1$, $s_\theta=(1-\theta)s_0+\theta s_1$, and $1<p<\infty$, then

$$[H^{s_0,p}(M,\mathbf{E}),H^{s_1,p}(M,\mathbf{E})]_\theta=H^{s_\theta,p}(M,\mathbf{E}) \tag{14.61}$$

with equivalent norms. These identifications are induced by the identity on test sections and are independent of the admissible quadratic localization system and synchronous frames used to define the norms.

If $s\in\mathbb{R}$, $1<p<\infty$, and $p'=\frac{p}{p-1}$, the complex-bilinear pairing

$$\mathbf{E}_x\times\overline{\mathbf{E}}_x\longrightarrow\mathbb{C},\qquad (e,\overline{f})\longmapsto\mathbf{h}_{\mathbf{E}}(e,f),$$

followed by integration extends uniquely to a continuous bilinear pairing

$$\langle\cdot,\cdot\rangle_{s,p;\mathbf{E}}\colon H^{s,p}(M,\mathbf{E})\times H^{-s,p'}(M,\overline{\mathbf{E}})\longrightarrow\mathbb{C}. \tag{14.62}$$

The map

$$\mathcal{J}_{s,p,\mathbf{E}}\colon H^{-s,p'}(M,\overline{\mathbf{E}}) \longrightarrow (H^{s,p}(M,\mathbf{E}))', \qquad \mathcal{J}_{s,p,\mathbf{E}}(\mathbf{v})(\mathbf{u}) := \langle \mathbf{u},\mathbf{v}\rangle_{s,p;\mathbf{E}}, \tag{14.63}$$

is a complex-linear topological isomorphism. Pointwise conjugation also induces a complex-linear isometric isomorphism

$$\mathcal{C}_{s,p,\mathbf{E}}\colon \overline{H^{s,p}(M,\mathbf{E})} \longrightarrow H^{s,p}(M,\overline{\mathbf{E}}), \qquad \mathcal{C}_{s,p,\mathbf{E}}(\overline{\mathbf{u}}) := \overline{\mathbf{u}}. \tag{14.64}$$

Thus, equivalently,

$$\overline{H^{-s,p'}(M,\mathbf{E})} \cong (H^{s,p}(M,\mathbf{E}))'.$$

In the real case all bars are omitted.

These identifications are compatible with (14.61): when the orders s_0, s_1 are interpolated, the spaces in the second entry interpolate between orders $-s_0, -s_1$ and yield order $-s_\theta$ (interchanging the endpoints if necessary); the resulting pairing is the unique extension of the same integral pairing on $\Gamma_c(\mathbf{E})\times\Gamma_c(\overline{\mathbf{E}})$. Pointwise conjugation likewise commutes with these identifications.

Proof. Fix an admissible quadratic localization system $\mathcal{Q} = (U_i, \varphi_i, h_i)_{i\in I}$, with $\sum_{i\in I} h_i^2 = 1$, and unitary synchronous frames $\mathbf{e}_i = (\mathbf{e}_{i,1},\dots,\mathbf{e}_{i,r})$. Choose cutoffs $\chi_i \in C_c^\infty(U_i)$ equal to one on a neighborhood of $\operatorname{supp} h_i$, and use the conjugate frame $\overline{\mathbf{e}}_i$ in $\overline{\mathbf{E}}$. If

$$\mathbf{u} = \sum_{a=1}^{r} u_i^a \mathbf{e}_{i,a}, \qquad \mathbf{v} = \sum_{a=1}^{r} v_i^a \overline{\mathbf{e}}_{i,a},$$

and $\mathbf{v} = \overline{\mathbf{w}}$ is smooth, then $v_i^a = \overline{w_i^a}$ and $\mathbf{h}_{\mathbf{E}}(\mathbf{u},\mathbf{w}) = \sum_{a=1}^{r} u_i^a v_i^a$. Set

$$a_i(x) := \sqrt{\det\big((\varphi_i^{-1})^*\mathbf{g}\big)(x)}.$$

The functions a_i and a_i^{-1} and the cutoffs involved satisfy uniform multiplier bounds of every order.

Let $\langle z,\varphi\rangle_{\mathbb{R}^n}$ denote the Euclidean *bilinear* duality between $H^{-s,p'}(\mathbb{R}^n)$ and $H^{s,p}(\mathbb{R}^n)$. For $\mathbf{u}\in H^{s,p}(M,\mathbf{E})$ and $\mathbf{v}\in H^{-s,p'}(M,\overline{\mathbf{E}})$, define

$$\langle \mathbf{u},\mathbf{v}\rangle_{s,p;\mathbf{E}} := \sum_{i\in I}\sum_{a=1}^{r} \Big\langle (h_i v_i^a)\circ\varphi_i^{-1}, a_i\,(h_i u_i^a)\circ\varphi_i^{-1}\Big\rangle_{\mathbb{R}^n}. \tag{14.65}$$

Since multiplication by a_i is uniformly bounded on $H^{s,p}$, Euclidean duality and Hölder's inequality for sequences give

$$|\langle \mathbf{u},\mathbf{v}\rangle_{s,p;\mathbf{E}}| \le C\|\mathbf{u}\|_{H^{s,p}(M,\mathbf{E})}\|\mathbf{v}\|_{H^{-s,p'}(M,\overline{\mathbf{E}})}.$$

The series in (14.65) is therefore absolutely convergent. If $\mathbf{u},\mathbf{w}\in\Gamma_c(\mathbf{E})$ and $\mathbf{v}=\overline{\mathbf{w}}$, change of variables and $\sum_{i\in I} h_i^2 = 1$ give

$$\langle \mathbf{u},\overline{\mathbf{w}}\rangle_{s,p;\mathbf{E}} = \sum_{i\in I}\int_M h_i^2\,\mathbf{h}_{\mathbf{E}}(\mathbf{u},\mathbf{w})\,d\lambda_{\mathbf{g}} = \int_M \mathbf{h}_{\mathbf{E}}(\mathbf{u},\mathbf{w})\,d\lambda_{\mathbf{g}}.$$

Smooth compactly supported sections are dense in both spaces: this follows by approximation with finitely supported sequences having Schwartz components in the retraction–coretraction used below. Thus the extension is unique.

Conjugation changes the components u_i^a into $\overline{u_i^a}$ and commutes with the cutoffs and real coordinate changes. Since conjugation is an isometry on each Euclidean space $H^{s,p}(\mathbb{R}^n,\mathbb{C}^r)$, the rule (14.64) is a linear isometric isomorphism; its linearity uses $\lambda\overline{\mathbf{u}}=\overline{\overline{\lambda}\mathbf{u}}$ in the conjugate domain.

We now construct a retraction that will prove interpolation and then the surjectivity of (14.63) without presupposing global duality itself. For each $r_0\in\mathbb{R}$, write

$$\mathbb{H}_{\mathbf{E}}^{r_0,p}:=\ell^p\bigl(I;H^{r_0,p}(\mathbb{R}^n,\mathbb{C}^r)\bigr)$$

and define, using the same formulas for every r_0,

$$\mathsf{A}_{\mathbf{E}}\mathbf{u}:=\bigl((h_i\mathbf{u}_i)\circ\varphi_i^{-1}\bigr)_{i\in I},$$

$$\mathsf{B}_{\mathbf{E}}(Z_i):=\sum_{i\in I}h_i\sum_{a=1}^{r}\Bigl[\bigl((\chi_i\circ\varphi_i^{-1})Z_i\bigr)\circ\varphi_i\Bigr]^a\mathbf{e}_{i,a},$$

where each summand is extended by zero. The uniform multiplier and coordinate-change theorems and finite multiplicity show that

$$\mathsf{A}_{\mathbf{E}}\colon H^{r_0,p}(M,\mathbf{E})\longrightarrow\mathbb{H}_{\mathbf{E}}^{r_0,p},\qquad \mathsf{B}_{\mathbf{E}}\colon\mathbb{H}_{\mathbf{E}}^{r_0,p}\longrightarrow H^{r_0,p}(M,\mathbf{E})$$

are continuous; moreover, $\mathsf{B}_{\mathbf{E}}\mathsf{A}_{\mathbf{E}}\mathbf{u}=\sum_{i\in I}h_i^2\mathbf{u}=\mathbf{u}$.

Apply these bounds with $r_0=s_0,s_1$. Theorem 6.3.11, applied to the r components, and Proposition 5.7.12 identify

$$[\mathbb{H}_{\mathbf{E}}^{s_0,p},\mathbb{H}_{\mathbf{E}}^{s_1,p}]_\theta=\mathbb{H}_{\mathbf{E}}^{s_\theta,p}$$

with equivalent norms. The complex interpolation theorem for operators 5.7.5, applied to $\mathsf{A}_{\mathbf{E}}$ and $\mathsf{B}_{\mathbf{E}}$, preserves the identity $\mathsf{B}_{\mathbf{E}}\mathsf{A}_{\mathbf{E}}=I$ and proves (14.61). Since the formulas for both operators are independent of r_0, this identification is the identity on test sections. Independence of the quadratic localization system also follows from Proposition 14.5.3.

Let $\Lambda\in(H^{s,p}(M,\mathbf{E}))'$. Euclidean bilinear duality and $(\ell^p(X_i))'=\ell^{p'}(X_i')$ provide

$$W=(W_i)_{i\in I}\in\ell^{p'}\Bigl(I;H^{-s,p'}(\mathbb{R}^n,\mathbb{C}^r)\Bigr)$$

such that

$$(\Lambda\circ\mathsf{B}_{\mathbf{E}})(Z)=\sum_{i\in I}\langle W_i,Z_i\rangle_{\mathbb{R}^n},\qquad \|W\|_{\ell^{p'}(I;H^{-s,p'}(\mathbb{R}^n,\mathbb{C}^r))}\le\|\Lambda\|_{(H^{s,p}(M,\mathbf{E}))'}\|\mathsf{B}_{\mathbf{E}}\|_{\mathcal{L}(\mathbb{H}_{\mathbf{E}}^{s,p},H^{s,p}(M,\mathbf{E}))}.\tag{14.66}$$

Define an $\overline{\mathbf{E}}$-valued distribution $\mathbf{v}$ by

$$\langle\mathbf{u},\mathbf{v}\rangle:=\sum_{i\in I}\Bigl\langle W_i,(h_i\mathbf{u}_i)\circ\varphi_i^{-1}\Bigr\rangle_{\mathbb{R}^n},\qquad\mathbf{u}\in\Gamma_c(\mathbf{E}).\tag{14.67}$$

The sum is finite for each $\mathbf{u}$.

We verify directly, without using the duality being proved, that $\mathbf{v}\in H^{-s,p'}(M,\overline{\mathbf{E}})$. For each j, let L_{ij} be the

local operator that sends the components of a section $\mathbf{u}$ in the frame $\mathbf{e}_j$ to

$$\mathsf{L}_{ij}(\mathbf{u}_j) := \big(h_i h_j \mathbf{u}_i\big) \circ \varphi_i^{-1}, \qquad U_i \cap U_j \neq \varnothing,$$

inserting χ_j before extending by zero. It is a composition of a uniform coordinate change, a uniform transition matrix, and a uniform multiplier. Thus

$$\mathsf{L}_{ij} \colon H^{s,p}(\mathbb{R}^n, \mathbb{C}^r) \longrightarrow H^{s,p}(\mathbb{R}^n, \mathbb{C}^r)$$

has norm bounded independently of i, j. Its bilinear transpose $\mathsf{L}_{ij}^{\mathsf{T}}$ satisfies the same bound between the spaces of order $-s$ and exponent p'. If v_j denotes the component vector of $\mathbf{v}$ in the frame $\overline{\mathbf{e}}_j$, definition (14.67) gives, in $\mathcal{D}'(\mathbb{R}^n, \mathbb{C}^r)$,

$$a_j\,(h_j v_j) \circ \varphi_j^{-1} = \sum_{\substack{i \in I \\ U_i \cap U_j \neq \varnothing}} \mathsf{L}_{ij}^{\mathsf{T}} W_i. \tag{14.68}$$

Indeed, both sides have the same action on every test function: this equality is precisely (14.67) applied to $h_j \mathbf{u}$ and written in the chart j. Uniform multiplicity, the bound on the transposes, and multiplication by a_j^{-1} give

$$\|\mathbf{v}\|_{H^{-s,p'}(M,\overline{\mathbf{E}})}^{p'} \leq C \sum_{j \in I} \left(\sum_{\substack{i \in I \\ U_i \cap U_j \neq \varnothing}} \|W_i\|_{H^{-s,p'}(\mathbb{R}^n, \mathbb{C}^r)} \right)^{p'} \leq C' \sum_{i \in I} \|W_i\|_{H^{-s,p'}(\mathbb{R}^n, \mathbb{C}^r)}^{p'}.$$

Thus $\mathbf{v}$ belongs to the asserted space, and its norm is bounded by a multiple of $\|\Lambda\|_{(H^{s,p}(M,\mathbf{E}))'}$.
Finally, for $\mathbf{u} \in H^{s,p}(M, \mathbf{E})$,

$$\Lambda(\mathbf{u}) = \Lambda(\mathsf{B}_{\mathbf{E}} \mathsf{A}_{\mathbf{E}} \mathbf{u}) = \sum_{i \in I} \langle W_i, (h_i \mathbf{u}_i) \circ \varphi_i^{-1} \rangle_{\mathbb{R}^n} = \langle \mathbf{u}, \mathbf{v} \rangle_{s,p;\mathbf{E}}.$$

Therefore $\mathsf{J}_{s,p,\mathbf{E}}$ is surjective, and the preceding construction proves continuity of its inverse. If $\mathsf{J}_{s,p,\mathbf{E}}(\mathbf{v}) = 0$, then $\mathbf{v}$ vanishes on $\Gamma_c(\mathbf{E})$; since $\mathbf{h}_{\mathbf{E}}$ identifies $\mathbf{E}$ linearly with $(\overline{\mathbf{E}})^*$, this means that $\mathbf{v}$ is the zero distribution. Thus the map is also injective. Its continuity has already been proved using (14.65).
Finally, the local formulas defining the pairing, conjugation, $\mathsf{A}_{\mathbf{E}}$, and $\mathsf{B}_{\mathbf{E}}$ are the same at every order. Density of $\Gamma_c(\mathbf{E})$ and $\Gamma_c(\overline{\mathbf{E}})$ and uniqueness of the continuous extension identify the pairing at the interpolated order with (14.62). This proves the asserted compatibility with interpolation and conjugation. The representative has been constructed using local duality and the analysis and synthesis operators. □

Theorem 14.5.6. (Identification of heat potentials with the local spaces) Let $(M, \mathbf{g})$ be a manifold without boundary of bounded geometry, and let $(\mathbf{E}, \mathbf{h}_{\mathbf{E}}, \nabla^{\mathbf{E}}) \to M$ be a finite-rank bundle of bounded geometry. For $s \in \mathbb{R}$ and $1 < p < \infty$, the identity on test sections induces the identifications

$$H_{L_{\mathbf{E}}}^{s,p}(M, \mathbf{E}) = H^{s,p}(M, \mathbf{E}) = F_{p,2}^{s}(M, \mathbf{E}). \tag{14.69}$$

In particular, for any admissible quadratic system $\mathcal{Q} = (U_i, \varphi_i, h_i)_{i \in I}$ with synchronous frames, there exist

$c, C > 0$ such that

$$c\|\mathbf{u}\|_{H^{s,p}_{L^{\mathbf{E}}}(M,\mathbf{E})} \le \left(\sum_{i\in I} \sum_{a=1}^{r_{\mathbf{E}}} \left\| \widetilde{(h_i u_i^a) \circ \varphi_i^{-1}} \right\|^p_{F^s_{p,2}(\mathbb{R}^n)} \right)^{1/p} \le C\|\mathbf{u}\|_{H^{s,p}_{L^{\mathbf{E}}}(M,\mathbf{E})}. \tag{14.70}$$

The constants depend on $n, r_{\mathbf{E}}, s, p$, the uniform bounds of the localization system, and finitely many bounded-geometry bounds for M and $\mathbf{E}$. They do not depend on the chart index, the number of charts, or the section $\mathbf{u}$. For $s < 0$, the first equality also gives a canonical injective realization of the completion defined by heat potentials as a space of $\mathbf{E}$-valued distributions.

Proof. The Euclidean identification $H^{s,p}(\mathbb{R}^n) = F^s_{p,2}(\mathbb{R}^n)$ in Theorem 6.3.10 has constants depending only on n, s, p. Apply it to each component and sum the pth powers over $i \in I$ and $a \in \{1, \dots, r_{\mathbf{E}}\}$. This proves the second equality in (14.69) and its two norm comparisons for every real order.

First consider $s \ge 0$. For $s = 0$, all three norms are equivalent to the $L^p(M, \mathbf{E})$ norm, by uniform comparison of the measures and fiber norms. If $s = m$ is a positive integer, Theorem 13.3.25 and Proposition 14.5.3 give

$$H^{m,p}_{L^{\mathbf{E}}}(M, \mathbf{E}) = W^{m,p}(M, \mathbf{E}) = H^{m,p}(M, \mathbf{E}).$$

Both equalities preserve the section as a distribution, and the corresponding norms are bounded by one another.

For a positive noninteger order, choose $m \in \mathbb{N}$ with $m > s$ and set $\theta = s/m \in (0, 1)$. At the endpoints $0, m$ we have the same compatible pair of spaces, with equivalent norms. Complex interpolation of the identity and its inverse, by Theorem 5.7.5, preserves this equivalence. On the one hand, Theorem 13.3.27 gives

$$[L^p(M, \mathbf{E}), H^{m,p}_{L^{\mathbf{E}}}(M, \mathbf{E})]_\theta = H^{s,p}_{L^{\mathbf{E}}}(M, \mathbf{E}).$$

On the other hand, Proposition 14.5.5 identifies the same interpolated space with $H^{s,p}(M, \mathbf{E})$. The identity of the initial spaces therefore yields the first equality sought. The imaginary-power bound that makes this step possible is the one in Lemma 13.3.26, applied to the connection Laplacian of $\mathbf{E}$.

Negative order remains. Write $s = -a$, with $a > 0$, and $p' = p/(p-1)$. The conjugate bundle $\overline{\mathbf{E}}$ has the same geometric bounds as $\mathbf{E}$. The positive-order result already proved identifies

$$H^{a,p'}_{L^{\overline{\mathbf{E}}}}(M, \overline{\mathbf{E}}) = H^{a,p'}(M, \overline{\mathbf{E}})$$

with equivalent norms. Take the complex-linear duals of both sides and use Theorem 12.4.9 and Proposition 14.5.5, respectively. We obtain an isomorphism between $H^{-a,p}_{L^{\mathbf{E}}}(M, \mathbf{E})$ and $H^{-a,p}(M, \mathbf{E})$. On test sections this isomorphism is the identity: both dualities agree with the same bilinear integral pairing, using the metric to pair $\mathbf{E}$ with $\overline{\mathbf{E}}$. Density of test sections in the localized positive-order space uniquely determines the corresponding distribution. It also proves injectivity of this realization. In the real case conjugations are omitted.

Let us make the uniformity precise. Integer-order equivalence uses bounds on the metric, its inverse, the connection coefficients, and the cutoffs in the larger charts, together with the overlap multiplicity. The internal power estimate for the Bochner chain adds bounds on the potentials $\mathbf{V}_\ell$ and $\mathbf{W}_\ell$ of the finite chain corresponding to the integer m. These bounds are expressed in terms of the supremum norms of finitely many derivatives of the curvatures. Interpolation adds the constants of the two endpoint norms and those for imaginary powers; the latter depend only on p and the rank. For $s < 0$, the same data are used with $a = -s$

and p'. None of these steps introduces a sum of constants over all charts: overlaps are always counted using the same uniform bound. This gives the constants in (14.70). □

Remark 14.5.7. (Choice of operator in the presence of a boundary) The hypothesis $\partial M = \varnothing$ in the preceding theorem is necessary to identify the operator without imposing additional conditions. On a manifold with boundary, the localized space $H^{s,p}(M,\mathbf{E})$ is defined by restriction in boundary charts. Powers of a Dirichlet or Neumann realization incorporate the conditions of that realization. For example, on the half-space, for the scalar Dirichlet Laplacian on L^2,

$$\mathcal{D}(I + L_D) = H^{2,2}(\mathbb{R}^n_+) \cap H^{1,2}_0(\mathbb{R}^n_+),$$

whereas the localized norm of order two admits functions in $H^{2,2}(\mathbb{R}^n_+)$ with nonzero trace. Thus, before comparing a heat scale with the spaces of this chapter in the presence of a boundary, one must fix the realization and describe its trace conditions.

Theorem 14.5.8. (Trace of sections on a submanifold) Let (M,N) be a bounded-geometry pair of smooth manifolds without boundary, where M has dimension n and N has dimension k, $c = n-k$, and let $\mathbf{E} \to M$ be a vector bundle of bounded geometry. If $1 < p < \infty$ and $s > \frac{c}{p}$, restriction of smooth sections extends to a retraction

$$\mathbf{Tr}^{\mathbf{E}}_N : H^{s,p}(M,\mathbf{E}) \longrightarrow B^{s-\frac{c}{p}}_{p,p}(N, \mathbf{E}\restriction_N). \tag{14.71}$$

Moreover, for $1 \le q \le \infty$, there are retractions

$$\mathbf{Tr}^{\mathbf{E}}_N : F^s_{p,q}(M,\mathbf{E}) \longrightarrow B^{s-\frac{c}{p}}_{p,p}(N, \mathbf{E}\restriction_N), \qquad \mathbf{Tr}^{\mathbf{E}}_N : B^s_{p,q}(M,\mathbf{E}) \longrightarrow B^{s-\frac{c}{p}}_{p,q}(N, \mathbf{E}\restriction_N). \tag{14.72}$$

Each operator has a continuous linear right inverse.

Proof. In the Fermi frame $\mathbf{e}_i$, write $h_i \mathbf{u} = \sum_{a=1}^{r} u_i^a \mathbf{e}_{i,a}$ and apply tr_c to each component. By part (c) of Lemma 14.1.2, the local estimate is the finite sum of the scalar estimates in Theorem 14.1.1. On an overlap, parts (a) and (b) of the same lemma give

$$\mathrm{tr}_c(G_{ij} u_j \circ \Phi_{ji}) = (G_{ij}\restriction_{z=0})(\mathrm{tr}_c\, u_j) \circ (\Phi_{ji}\restriction_{z=0}). \tag{14.73}$$

This is the transformation law for the components of a section of $\mathbf{E}\restriction_N$; hence the local traces define an intrinsic operator. The overlap count in (14.26) proves its continuity.

To construct the right inverse, write $h_i^N \mathbf{f} = \sum_{a=1}^{r} f_i^a \mathbf{e}_{i,a}\restriction_N$ locally, apply ex_c componentwise, and reconstruct by

$$\mathbf{Ex}^{\mathbf{E}}_{M,N} \mathbf{f} = \sum_{i \in I_N} \sum_{a=1}^{r} h_i \left[\psi\, \mathrm{ex}_c\, f_i^a\right] \circ \kappa_i^{-1}\, \mathbf{e}_{i,a}. \tag{14.74}$$

The uniform bounds on the transition matrices prove continuity as in (14.28). Upon restriction, $\mathrm{tr}_c \mathrm{ex}_c = I$ and $\sum_{i \in I_N} (h_i^N)^2 = 1$, so $\mathbf{Tr}^{\mathbf{E}}_N \mathbf{Ex}^{\mathbf{E}}_{M,N} = I$. For $F^s_{p,q}$, use the same formulas with the corresponding Euclidean bounds and sum in ℓ^p over the charts. For $q = \infty$, the local formula defines the operator on the entire space,

and the compatibility relations are understood in the sense of distributions.
For $B^{s}_{p,q}$, choose $s_0 < s < s_1$, with $s_0 > c/p$, and apply the common operators to the two spaces $F^{s_i}_{p,p}(M,\mathbf{E})$. We interpolate these operators, rather than the norms of each chart separately:

$$(F^{s_0}_{p,p}(M,\mathbf{E}), F^{s_1}_{p,p}(M,\mathbf{E}))_{\theta,q} = B^{s}_{p,q}(M,\mathbf{E}),$$
$$(B^{s_0-c/p}_{p,p}(N,\mathbf{E}|_N), B^{s_1-c/p}_{p,p}(N,\mathbf{E}|_N))_{\theta,q} = B^{s-c/p}_{p,q}(N,\mathbf{E}|_N).$$

The second equality follows by reiteration of the $F_{p,p}$ scale. Continuity and the retraction identity are preserved. In particular, $B^{s}_{p,q}(M,\mathbf{E})$ is not identified with an ℓ^p sum of local Besov norms when $q \neq p$. □

Theorem 14.5.9. (Trace of sections on a manifold with boundary) Let M be a manifold with nonempty boundary of bounded geometry, and let $\mathbf{E} \to M$ be a vector bundle of bounded geometry. If $j \in \mathbb{N}_0$, $1 < p < \infty$, and $s > j + \frac{1}{p}$, let $\widetilde{\boldsymbol{\nu}}$ denote the collar vector field determined by $\widetilde{\boldsymbol{\nu}}_{\mathcal{C}(x,t)} = \partial_t \mathcal{C}(x,t)$. Then

$$\mathbf{Tr}^{\mathbf{E}}_{\partial M,j}\mathbf{u} := \big(\mathbf{u}\restriction_{\partial M}, \nabla^{\mathbf{E}}_{\widetilde{\boldsymbol{\nu}}}\mathbf{u}\restriction_{\partial M}, \dots, (\nabla^{\mathbf{E}}_{\widetilde{\boldsymbol{\nu}}})^{j}\mathbf{u}\restriction_{\partial M}\big) \tag{14.75}$$

extends to a retraction

$$\mathbf{Tr}^{\mathbf{E}}_{\partial M,j} \colon H^{s,p}(M,\mathbf{E}) \longrightarrow \prod_{\ell=0}^{j} B^{s-\ell-\frac{1}{p}}_{p,p}(\partial M, \mathbf{E}\restriction_{\partial M}). \tag{14.76}$$

For $j = 0$ and $1 \le q \le \infty$, one also obtains the retractions

$$\mathbf{Tr}^{\mathbf{E}}_{\partial M,0} \colon F^{s}_{p,q}(M,\mathbf{E}) \longrightarrow B^{s-\frac{1}{p}}_{p,p}(\partial M, \mathbf{E}\restriction_{\partial M}), \qquad \mathbf{Tr}^{\mathbf{E}}_{\partial M,0} \colon B^{s}_{p,q}(M,\mathbf{E}) \longrightarrow B^{s-\frac{1}{p}}_{p,q}(\partial M, \mathbf{E}\restriction_{\partial M}). \tag{14.77}$$

All these operators have continuous linear right inverses.

Proof. Choose the frames in part (c) of Proposition 14.5.1. By (14.53), if $\mathbf{u} = \sum_{a=1}^{r} u_i^a \mathbf{e}_{i,a}$, then

$$(\nabla^{\mathbf{E}}_{\widetilde{\boldsymbol{\nu}}})^{\ell}\mathbf{u} = \sum_{a=1}^{r} (\partial_t^{\ell} u_i^a)\mathbf{e}_{i,a} \quad \text{in the boundary chart.} \tag{14.78}$$

On an overlap of two such frames, the connection transformation formula gives $\partial_t G_{ij} = 0$, since both normal connection matrices vanish. Consequently, the jet components transform by $G_{ij}|_{t=0}$ without lower-order terms. Moreover, the cutoffs h_i are constant in t near the boundary by (14.31); hence no Leibniz terms appear when localizing the jets. Applying the retraction $\boldsymbol{\gamma}_j$ of Theorem 14.4.17 componentwise, summing over the overlaps, and using the bounds on the matrices $G_{ij}\restriction_{\partial M}$ yields

$$\sum_{\ell=0}^{j} \|(\nabla^{\mathbf{E}}_{\widetilde{\boldsymbol{\nu}}})^{\ell}\mathbf{u}\restriction_{\partial M}\|_{B^{s-\ell-\frac{1}{p}}_{p,p}(\partial M, \mathbf{E}\restriction_{\partial M})} \le C\|\mathbf{u}\|_{H^{s,p}(M,\mathbf{E})}.$$

The coretraction is obtained by applying $\boldsymbol{e}_j$ to the component vectors of the data, multiplying by the fixed cutoff ψ, and summing with factors h_i using formula (14.52). The cutoff ψ equals one in the region where the jets are computed and allows each summand to be extended by zero outside its chart. The identities

(14.78), $\boldsymbol{\gamma}_j \boldsymbol{e}_j = I$, and $\sum_{i \in I_\partial} (h_i^\partial)^2 = 1$ show that the jet of the extension is the prescribed datum. The continuity estimates are the scalar estimates summed over finitely many components and a cover of uniform multiplicity. For $j = 0$, the estimate in $F^s_{p,q}$ follows directly from the Euclidean trace and the same counting argument in ℓ^p. The formula remains valid for $q = \infty$ by the distributional interpretation of the trace. For Besov spaces, fix $s_0 < s < s_1$ with $s_0 > 1/p$ and interpolate the same operators between the global spaces $F^{s_i}_{p,p}(M, \mathbf{E})$ and $B^{s_i - 1/p}_{p,p}(\partial M, \mathbf{E}|_{\partial M})$. The definition of Besov spaces and reiteration, exactly as in the preceding theorem, give (14.77) without interchanging an ℓ^p sum over charts with the fine index q. Independence of the frames follows from Proposition 14.5.3 and (14.73). □

Remark 14.5.10. (Covariant traces and normal jets) The full covariant trace $\mathbf{Tr}_\ell \mathbf{u} = ((\nabla^{\mathbf{E}})^\ell \mathbf{u}) \restriction_{\partial M}$ takes values in $\big(T^{(0,\ell)}(TM) \otimes \mathbf{E}\big) \restriction_{\partial M}$. Write $\widetilde{\boldsymbol{\nu}}$ for the unit normal field extended along the collar geodesics. Since $\nabla^M_{\widetilde{\boldsymbol{\nu}}} \widetilde{\boldsymbol{\nu}} = 0$, the tensor differentiation rule of Chapter 9 gives, for $\ell \in \mathbb{N}_0$,

$$(\nabla^{\ell+1}\mathbf{u})(\widetilde{\boldsymbol{\nu}}^{\otimes(\ell+1)}) = \nabla^{\mathbf{E}}_{\widetilde{\boldsymbol{\nu}}}\big((\nabla^\ell \mathbf{u})(\widetilde{\boldsymbol{\nu}}^{\otimes \ell})\big) - \sum_{a=1}^{\ell} (\nabla^\ell \mathbf{u})(\widetilde{\boldsymbol{\nu}}, \dots, \underbrace{\nabla^M_{\widetilde{\boldsymbol{\nu}}} \widetilde{\boldsymbol{\nu}}}_{\text{position } a}, \dots, \widetilde{\boldsymbol{\nu}}).$$

The sum vanishes. The case $\ell = 0$ is the definition of $\nabla^{\mathbf{E}}_{\widetilde{\boldsymbol{\nu}}} \mathbf{u}$; if the contraction of order ℓ agrees with the iterated normal derivative, the preceding equality proves the same at order $\ell + 1$. Thus

$$(\nabla^\ell \mathbf{u})(\widetilde{\boldsymbol{\nu}}^{\otimes \ell}) = (\nabla^{\mathbf{E}}_{\widetilde{\boldsymbol{\nu}}})^\ell \mathbf{u}, \qquad \ell \in \mathbb{N}_0.$$

The normal jet is therefore the contraction of the full trace with $\boldsymbol{\nu}^{\otimes \ell}$.

Let us make the converse assertion precise. If $\mathbf{S}$ is an $\mathbf{E}$-valued covariant tensor field, the induced connections satisfy

$$\begin{aligned} &\big[(\nabla_{\mathbf{X}} \nabla_{\mathbf{Y}} - \nabla_{\mathbf{Y}} \nabla_{\mathbf{X}} - \nabla_{[\mathbf{X},\mathbf{Y}]})\mathbf{S}\big](\mathbf{V}_1, \dots, \mathbf{V}_r) \\ &\quad = \mathbf{R}^{\mathbf{E}}(\mathbf{X}, \mathbf{Y})\big(\mathbf{S}(\mathbf{V}_1, \dots, \mathbf{V}_r)\big) \\ &\qquad - \sum_{a=1}^{r} \mathbf{S}(\mathbf{V}_1, \dots, \mathbf{R}^M(\mathbf{X}, \mathbf{Y})\mathbf{V}_a, \dots, \mathbf{V}_r). \end{aligned} \tag{14.79}$$

This identity follows directly from the definitions of the induced connections and from $\mathbf{R}^M, \mathbf{R}^{\mathbf{E}}$. Moreover, for $\mathbf{X}$ tangent to the boundary, the Gauss and Weingarten formulas in Proposition 2.11.3 give

$$\nabla^M_{\mathbf{X}} \mathbf{Y} = \nabla^{\partial M}_{\mathbf{X}} \mathbf{Y} + \mathbf{II}(\mathbf{X}, \mathbf{Y}), \qquad \nabla^M_{\mathbf{X}} \boldsymbol{\nu} = -\mathbf{A}_{\boldsymbol{\nu}} \mathbf{X}.$$

Now suppose that the normal jets of orders $\ell \in \{0, \dots, m-1\}$ vanish. At order zero this says that $\mathbf{u} \restriction_{\partial M} = 0$. Let $\ell \in \{1, \dots, m-1\}$, and suppose that all covariant traces of orders less than ℓ vanish. The component of $\nabla^\ell \mathbf{u}$ with all arguments normal is zero by the preceding identity. In any other component, choose a tangential argument $\mathbf{X}$ and move it to the first position by finitely many adjacent transpositions.

For each transposition, apply (14.79) to the corresponding lower-order tensor. The outer derivatives are distributed over its products by Proposition 9.1.40. The added terms are contractions of the form

$$\nabla^a \mathbf{R}^M * \nabla^{\ell-2-a} \mathbf{u} \quad \text{or} \quad \nabla^a \mathbf{R}^{\mathbf{E}} * \nabla^{\ell-2-a} \mathbf{u}, \qquad a \in \{0, \dots, \ell-2\}.$$

For $\ell = 1$ there are no transpositions or curvature terms. For $\ell \geq 2$, all factors containing $\mathbf{u}$ have order less than ℓ, and their traces vanish by the induction hypothesis. In the remaining component, the tangential derivative is in the first position. Evaluating the derivative of this tensor gives the tangential derivative of a trace of order $\ell - 1$ and terms obtained by differentiating its arguments. The former is zero; the latter, described by Gauss and Weingarten, are components of the same trace of order $\ell - 1$ and also vanish. Thus all components vanish at order ℓ, completing the induction up to $m - 1$. The reverse implication follows by contracting each full trace with $\boldsymbol{\nu}^{\otimes \ell}$.

To pass to $\mathbf{u} \in W^{m,p}(M, \mathbf{E})$, with $1 \leq p < \infty$, first observe that Theorem 3.7.1, applied to the components of $\nabla^{\ell}\mathbf{u}$ in the boundary models, and comparison (14.59) give, on setting $\mathbf{E}_{\ell} := T^{(0,\ell)}(TM) \otimes \mathbf{E}$,

$$\|\mathbf{Tr}_{\ell}\mathbf{u}\|_{L^p(\partial M, \mathbf{E}_{\ell}|_{\partial M})} \leq C_{m,p}\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}, \qquad 0 \leq \ell < m. \tag{14.80}$$

Indeed, each tensor $\nabla^{\ell}\mathbf{u}$ belongs to $W^{1,p}$, the charts and cutoffs satisfy uniform bounds, and the sum of the pth powers of the local estimates is controlled by the multiplicity of the cover. The constant depends on m, p, the dimension and rank, and the uniform bounds on the geometry, frames, and cutoffs up to the orders used; it does not depend on the section. This argument includes $p = 1$ and, in dimension one, counting measure on the boundary. Contraction with $\boldsymbol{\nu}^{\otimes \ell}$ yields continuous normal jets taking values in $L^p(\partial M, \mathbf{E}|_{\partial M})$. For $p > 1$, they agree with the Besov jets already constructed, since they agree on smooth sections and both operators are continuous.

Now approximate the localizations of $\mathbf{u}$ by sections smooth up to the boundary. The approximations need not have vanishing jets. The commutation and tangential differentiation identities are written before imposing this condition; each side is a finite combination of tangential derivatives of traces and multiplication by uniformly smooth coefficients. The traces are continuous in the L^p spaces of (14.80), and tangential derivatives are continuous in distributions. The identities therefore pass to the limit, after which the preceding induction applies to the jets of $\mathbf{u}$. Thus vanishing of the normal jets of orders less than m is equivalent to vanishing of all covariant traces of those orders.

This equivalence describes the boundary conditions. To identify $W_0^{m,p}$, it remains to check that there is no obstruction to approximation at infinity either. Summability of the localizations and the uniform cutoffs also reduce this question to the half-space.

Theorem 14.5.11. (Characterization of $W_0^{m,p}$ in bounded geometry) Let M be a manifold of bounded geometry with nonempty boundary, and let $\mathbf{E} \to M$ be a vector bundle of bounded geometry equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$; in the complex case the metric is Hermitian. If $m \in \mathbb{N}$ and $1 \leq p < \infty$, then

$$W_0^{m,p}(M, \mathbf{E}) = \ker \mathbf{Tr}^{\mathbf{E}}_{\partial M, m-1} = \{\mathbf{u} \in W^{m,p}(M, \mathbf{E}) | \mathbf{Tr}_{\ell}\mathbf{u} = 0,\ 0 \leq \ell < m\}.$$

Here $W_0^{m,p}(M, \mathbf{E})$ is the closure, in the $W^{m,p}$ norm, of smooth sections whose support is a compact subset of $\operatorname{Int} M$. For $p = 1$, traces and jets are interpreted using the L^1-valued operators of the preceding remark; no identification with the Bessel scale is required.

Proof. Smooth sections compactly supported in the interior have all traces equal to zero. Continuity of the jet operator established in (14.80) proves the inclusion of $W_0^{m,p}$ in the kernel. The last equality in the

statement is the preceding remark. It therefore suffices to show that a section $\mathbf{u}$ whose normal jets of all orders less than m vanish belongs to $W_0^{m,p}$.

Take the quadratic partition (h_i) and the normally parallel frames used in the trace theorem. Write $h_i\mathbf{u} = \sum_{a=1}^{r_{\mathbf{E}}} v_i^a \mathbf{e}_{i,a}$ and extend each $v_i^a \circ \varphi_i^{-1}$ by zero across the artificial faces of the chart. In a boundary chart this yields a function in $W^{m,p}(\mathbb{R}^n_+)$ with bounded support. Since the cutoff is constant in the normal variable near the boundary and the frame is parallel in that direction, its traces satisfy

$$\gamma_0 \partial_t^\ell (v_i^a \circ \varphi_i^{-1}) = 0, \qquad 0 \le \ell < m.$$

The trace commutes with tangential derivatives: the identity is proved for smooth functions and passes to the limit in distributions by continuity of the traces. Consequently, we also have $\gamma_0 D^\beta (v_i^a \circ \varphi_i^{-1}) = 0$ for every $|\beta| \le m-1$.

The half-space criterion in Theorem 3.7.1 implies that each component belongs to $W_0^{m,p}(\mathbb{R}^n_+)$. We can approximate it in $W^{m,p}$ by functions in $C_c^\infty(\mathbb{R}^n_+)$. Multiply these approximations by a fixed cutoff equal to one on the component's support and supported inside the artificial faces of the chart. This multiplication preserves convergence and allows the functions to be reconstructed on M. Each reconstructed approximation is compactly supported in the interior. In interior charts, proceed in the same way using Euclidean regularization. Local equivalence of norms and finite rank thus show that $h_i\mathbf{u} \in W_0^{m,p}(M,\mathbf{E})$ for each i.

To combine the approximations, exhaust the countable index set by finite sets I_J and define

$$\mathbf{u}_J := \sum_{i \in I_J} h_i (h_i \mathbf{u}).$$

Each summand belongs to $W_0^{m,p}$, since multiplication by h_i is continuous and preserves the interior support of the approximations. By the synthesis estimate and integer-order equivalence of norms,

$$\|\mathbf{u} - \mathbf{u}_J\|_{W^{m,p}(M,\mathbf{E})} \le C \left(\sum_{i \in I \setminus I_J} \sum_{a=1}^{r_{\mathbf{E}}} \|v_i^a \circ \varphi_i^{-1}\|^p_{W^{m,p}(\mathbb{X}_i)} \right)^{1/p} \longrightarrow 0.$$

The right-hand side is the tail of a convergent series. Since $W_0^{m,p}$ is closed, it follows that $\mathbf{u} \in W_0^{m,p}$. This proof does not use compactness of M. □

14.6 Sobolev embeddings in bounded geometry

Without boundary, Corollary 13.3.12 formulates the local transfer using a uniformly regular atlas, with constants $c_{s,p}, C_{s,p}, D_{s,p}$. With boundary, Corollary 14.4.12 gives the analysis–synthesis pair on the mixed models $\mathbb{R}^n$ and $\mathbb{R}^n_+$, with constants $c^\partial_{s,p}, C^\partial_{s,p}, D^\partial_{s,p}$. The arguments in this section retain the admissible quadratic localization system fixed when defining the global spaces—with geodesic charts when there is no boundary, and geodesic and Fermi charts when the boundary is nonempty—because it simultaneously incorporates the bundle frames and control of the boundary face. Amann's language thus provides a functional bridge without replacing the covariant estimates already established.

On a compact manifold, local Sobolev estimates are combined using a finite cover. On a noncompact manifold, finiteness must be replaced by three uniform controls: the charts have a common model and radius, the constants

of the local operators are independent of the chart, and the cover has bounded multiplicity. The outer sum defining the global spaces also retains the spatial exponent. Thus, when the integrability exponent increases from p_0 to p_1, the inclusion $\ell^{p_0} \hookrightarrow \ell^{p_1}$ appears and $p_0 \le p_1$ is required. This restriction does not occur on a compact manifold, which has finite measure.

Lemma 14.6.1. (Uniform transfer of a local embedding) Let M be a Riemannian manifold of bounded geometry, with or without boundary, and let $\mathbf{E} \to M$ be a bundle of bounded geometry. Let $1 < p_0 \le p_1 < \infty$ and, for $\nu \in \{0,1\}$, let $A_\nu(\mathbb{R}^n)$ be one of the spaces

$$H^{s_\nu,p_\nu}(\mathbb{R}^n) \qquad \text{or} \qquad F^{s_\nu}_{p_\nu,q_\nu}(\mathbb{R}^n),$$

, with $1 \le q_\nu \le \infty$ in the second case. Suppose that the identity inclusion satisfies

$$\|v\|_{A_1(\mathbb{R}^n)} \le C_{\mathrm{euc}} \|v\|_{A_0(\mathbb{R}^n)}. \tag{14.81}$$

Then the corresponding continuous embedding holds:

$$A_0(M,\mathbf{E}) \hookrightarrow A_1(M,\mathbf{E}).$$

The global constant depends on C_{euc}, the rank of $\mathbf{E}$, and the constants c_A, C_A of Proposition 14.5.3, but not on the section.

Proof. We begin with the boundary model. The spaces on $\mathbb{R}^n_+$ carry the quotient norm of restriction. If $v \in A_0(\mathbb{R}^n_+)$ and $V \in A_0(\mathbb{R}^n)$ is an extension of v, then

$$\|v\|_{A_1(\mathbb{R}^n_+)} \le \|V\|_{A_1(\mathbb{R}^n)} \le C_{\mathrm{euc}} \|V\|_{A_0(\mathbb{R}^n)}.$$

Taking the infimum over all extensions proves

$$\|v\|_{A_1(\mathbb{R}^n_+)} \le C_{\mathrm{euc}} \|v\|_{A_0(\mathbb{R}^n_+)}. \tag{14.82}$$

The constant is the same as on the full space.
Now fix an admissible quadratic localization system $\mathcal{Q} = (U_i, \varphi_i, h_i)_{i\in I}$ and the synchronous frames used in Definition 14.5.2. If $\mathbf{u} = \sum_{a=1}^{r} u_i^a \mathbf{e}_{i,a}$ in U_i, set

$$a_{i,a} := \|(h_i u_i^a) \circ \varphi_i^{-1}\|_{A_0(\mathbb{X}_i)}, \qquad b_{i,a} := \|(h_i u_i^a) \circ \varphi_i^{-1}\|_{A_1(\mathbb{X}_i)}.$$

Estimate (14.81), or (14.82), gives $b_{i,a} \le C_{\mathrm{euc}} a_{i,a}$ with the same constant for all indices. Since $p_0 \le p_1$, the elementary inclusion $\ell^{p_0}(I \times \{1,\dots,r\}) \hookrightarrow \ell^{p_1}(I \times \{1,\dots,r\})$ yields

$$\|\mathbf{u}\|_{A_1(M,\mathbf{E})} = \left(\sum_{i\in I} \sum_{a=1}^{r} b_{i,a}^{p_1} \right)^{\frac{1}{p_1}} \le C_{\mathrm{euc}} \left(\sum_{i\in I} \sum_{a=1}^{r} a_{i,a}^{p_1} \right)^{\frac{1}{p_1}} \le C_{\mathrm{euc}} \left(\sum_{i\in I} \sum_{a=1}^{r} a_{i,a}^{p_0} \right)^{\frac{1}{p_0}} = C_{\mathrm{euc}} \|\mathbf{u}\|_{A_0(M,\mathbf{E})}.$$

This calculation has been carried out in a fixed system. Its intrinsic nature follows from Proposition 14.5.3. Recall where the geometric hypotheses enter there. On an overlap, insert the quadratic partition, multiply

each component by an auxiliary cutoff equal to one on the support being transported, and compose with the coordinate change. Uniform derivative bounds for the cutoffs, transition matrices, and coordinate changes control multipliers and compositions; Jacobian bounds compare the measures. Finally, uniform multiplicity bounds both the number of summands entering a chart and the number of times a localization appears in the global sum. Thus c_A and C_A are also independent of i. □

Theorem 14.6.2. (Embeddings between the real-order scales) Let M be an n-dimensional Riemannian manifold of bounded geometry, with or without boundary, and let $\mathbf{E} \to M$ be a bundle of bounded geometry. Let $s_0, s_1 \in \mathbb{R}$ and $1 < p_0 \le p_1 < \infty$.

(a) If

$$s_0 - \frac{n}{p_0} > s_1 - \frac{n}{p_1}, \tag{14.83}$$

then, for all $1 \le q_0, q_1 \le \infty$,

$$F^{s_0}_{p_0,q_0}(M,\mathbf{E}) \hookrightarrow F^{s_1}_{p_1,q_1}(M,\mathbf{E})$$

and

$$B^{s_0}_{p_0,q_0}(M,\mathbf{E}) \hookrightarrow B^{s_1}_{p_1,q_1}(M,\mathbf{E}).$$

(b) If

$$s_0 - \frac{n}{p_0} = s_1 - \frac{n}{p_1} \tag{14.84}$$

and $1 \le q_0 \le q_1 \le \infty$, then the same embeddings hold in the scales F and B.

(c) If

$$s_0 - \frac{n}{p_0} \ge s_1 - \frac{n}{p_1},$$

then

$$H^{s_0,p_0}(M,\mathbf{E}) \hookrightarrow H^{s_1,p_1}(M,\mathbf{E}).$$

All embeddings hold both without boundary and with boundary.

Proof. First suppose that (14.84). Part (a) of Theorem 6.6.1, applied with fine index q_0, gives

$$F^{s_0}_{p_0,q_0}(\mathbb{R}^n) \hookrightarrow F^{s_1}_{p_1,q_0}(\mathbb{R}^n).$$

Part (c) of the same theorem and $q_0 \le q_1$ then give

$$F^{s_1}_{p_1,q_0}(\mathbb{R}^n) \hookrightarrow F^{s_1}_{p_1,q_1}(\mathbb{R}^n).$$

Lemma 14.6.1 transfers the composition to M.
If (14.83) holds, define

$$\sigma_1 := s_0 - \frac{n}{p_0} + \frac{n}{p_1}.$$

Then $\sigma_1 > s_1$. The result already proved, with the same fine index q_0, and part (b) of Theorem 6.6.1 yield

$$F^{s_0}_{p_0,q_0}(M,\mathbf{E}) \hookrightarrow F^{\sigma_1}_{p_1,q_0}(M,\mathbf{E}) \hookrightarrow F^{s_1}_{p_1,q_1}(M,\mathbf{E}).$$

This proves the assertions for the Triebel–Lizorkin scale. Taking $q_0 = q_1 = 2$ and using the Euclidean identification $H^{s,p} = F^s_{p,2}$ in Theorem 6.3.10, summed over the charts as in the proof of the lemma, proves part (c).

We turn to Besov spaces. When the indices are equal, choose $\delta > 0$. The F result already proved, applied at both endpoints, gives the continuous operators

$$F^{s_0-\delta}_{p_0,p_0}(M,\mathbf{E}) \hookrightarrow F^{s_1-\delta}_{p_1,p_1}(M,\mathbf{E}), \qquad F^{s_0+\delta}_{p_0,p_0}(M,\mathbf{E}) \hookrightarrow F^{s_1+\delta}_{p_1,p_1}(M,\mathbf{E}),$$

since $p_0 \le p_1$ is also the inequality between the fine indices of these pairs. Interpolate the identity by Theorem 5.3.1. The definition of the Besov scale gives

$$B^{s_0}_{p_0,q_0}(M,\mathbf{E}) \hookrightarrow B^{s_1}_{p_1,q_0}(M,\mathbf{E}).$$

Monotonicity of the second index for the real method, Corollary 5.2.6, allows q_0 to be replaced by $q_1 \ge q_0$ in the target space. If the differential indices satisfy the strict inequality, factor once again through $B^{\sigma_1}_{p_1,q_0}(M,\mathbf{E})$. Fix $a < s_1 < \sigma_1 < b$ and write, using Theorem 5.5.2 for independence of the auxiliary endpoints in the definition of the scale,

$$B^{\sigma_1}_{p_1,q_0}(M,\mathbf{E}) = (X_0,X_1)_{\theta_\sigma,q_0}, \qquad B^{s_1}_{p_1,q_1}(M,\mathbf{E}) = (X_0,X_1)_{\theta_s,q_1},$$

where $X_0 = F^a_{p_1,p_1}(M,\mathbf{E})$, $X_1 = F^b_{p_1,p_1}(M,\mathbf{E})$, and $0 < \theta_s < \theta_\sigma < 1$. The F result already proved gives $X_1 \hookrightarrow X_0$. Lemma 5.2.5, separating positive and negative dyadic indices, shows that

$$(X_0,X_1)_{\theta_\sigma,q_0} \hookrightarrow (X_0,X_1)_{\theta_s,q_1}$$

for all q_0, q_1: the geometric factor $t^{\theta_\sigma-\theta_s}$ appears in the tail corresponding to $t \le 1$, whereas for $t \ge 1$ we use the bound of the X_0 norm by the interpolation norm, proved together with completeness of the K method. This completes the proof. □

Corollary 14.6.3. (Integer-order Sobolev embeddings) Let M be an n-dimensional Riemannian manifold of bounded geometry, with or without boundary, and let $\mathbf{E} \to M$ be a bundle of bounded geometry. Let $m_0, m_1 \in \mathbb{N}_0$ and $1 < p_0 \le p_1 < \infty$. If

$$m_0 - \frac{n}{p_0} \ge m_1 - \frac{n}{p_1},$$

then

$$W^{m_0,p_0}(M,\mathbf{E}) \hookrightarrow W^{m_1,p_1}(M,\mathbf{E}). \tag{14.85}$$

In particular, let $j \in \mathbb{N}_0$, $m \in \mathbb{N}$, and $1 < p < \infty$.

(a) If $mp < n$ and $p^*_m := \frac{np}{n-mp}$, then

$$W^{j+m,p}(M,\mathbf{E}) \hookrightarrow W^{j,q}(M,\mathbf{E}) \qquad \text{for } p \le q \le p^*_m.$$

(b) If $mp = n$, the same embedding holds for every $p \le q < \infty$.

(c) If $mp > n$, the same embedding holds for every $p \le q < \infty$.

Proof. Proposition 14.5.3 identifies $H^{m_\nu,p_\nu}(M,\mathbf{E})$ with $W^{m_\nu,p_\nu}(M,\mathbf{E})$ and provides constants $c_{m_\nu,p_\nu}, C_{m_\nu,p_\nu} > 0$ such that, for every $\mathbf{u} \in W^{m_\nu,p_\nu}(M,\mathbf{E})$ and $\nu \in \{0,1\}$,

$$c_{m_\nu,p_\nu}\|\mathbf{u}\|_{W^{m_\nu,p_\nu}(M,\mathbf{E})} \le \|\mathbf{u}\|_{H^{m_\nu,p_\nu}(M,\mathbf{E})} \le C_{m_\nu,p_\nu}\|\mathbf{u}\|_{W^{m_\nu,p_\nu}(M,\mathbf{E})}.$$

Thus (14.85) is part (c) of Theorem 14.6.2. The remaining three assertions follow by writing

$$j + m - \frac{n}{p} \ge j - \frac{n}{q}.$$

In the subcritical case this inequality is equivalent to $q \le p_m^*$; in the critical and supercritical cases it holds for every finite exponent $q \ge p$. □

Corollary 14.6.4. (Subcritical and critical cases) Let M be an n-dimensional Riemannian manifold of bounded geometry, with or without boundary, and let $\mathbf{E} \to M$ be a bundle of bounded geometry. Let $s > 0$ and $1 < p < \infty$.

(a) If $sp < n$ and $p_s^* := \frac{np}{n-sp}$, then

$$H^{s,p}(M,\mathbf{E}) \hookrightarrow L^q(M,\mathbf{E}) \qquad \text{for } p \le q \le p_s^*.$$

(b) If $sp = n$, then

$$H^{s,p}(M,\mathbf{E}) \hookrightarrow L^q(M,\mathbf{E}) \qquad \text{for every } p \le q < \infty.$$

Proof. Apply part (c) of Theorem 14.6.2 with $s_1 = 0$ and $p_1 = q$. Proposition 14.5.3, at order zero, identifies $H^{0,q}(M,\mathbf{E})$ with $L^q(M,\mathbf{E})$. If $sp < n$, the condition on the indices is equivalent to $q \le p_s^*$; if $sp = n$, it is strict for every $q < \infty$. □

To treat the supercritical case, we need a uniform formulation of Hölder sections. In the absence of a boundary, the intrinsic norm of Definition 9.2.6 is already available. Near the boundary, we use the localized formulation of Definition 9.4.32, replacing the finite sum by a uniform supremum.

Definition 14.6.5. (Uniform Hölder sections up to the boundary) Let M be a Riemannian manifold of bounded geometry, with or without boundary, and let $\mathbf{E} \to M$ be a bundle of bounded geometry. Let $k \in \mathbb{N}_0$ and $0 < \alpha \le 1$. Fix an admissible quadratic localization system $\mathcal{Q} = (U_i, \varphi_i, h_i)_{i\in I}$ and synchronous frames $\mathbf{e}_i$. Let $\mathbf{\Omega}_i := \varphi_i(U_i)$ denote the bounded coordinate domain; in a boundary chart it is contained in $\mathbb{R}^n_+$. If

$$h_i\mathbf{u} = \sum_{a=1}^{r} u_i^a \mathbf{e}_{i,a},$$

, set

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\mathcal{Q}}(\mathbf{E})} := \sup_{i\in I} \sum_{a=1}^{r} \|u_i^a \circ \varphi_i^{-1}\|_{C^{k,\alpha}(\overline{\mathbf{\Omega}_i})}. \tag{14.86}$$

Here we use the extension norm of $C^{k,\alpha}(\overline{\mathbf{\Omega}_i})$ from Definition 3.5.1. Define $\Gamma^{k,\alpha}(\mathbf{E})$ to be the space of sections of class C^k up to the boundary for which (14.86) is finite.

Proposition 14.6.6. (Independence and characterization of the uniform Hölder norm) Let M be a Riemannian manifold of bounded geometry, with or without boundary, and let $\mathbf{E} \to M$ be a bundle of bounded geometry. If $\mathcal{Q}$ and $\widetilde{\mathcal{Q}}$ are two admissible quadratic localization systems equipped with synchronous frames, there exist $c_{\mathcal{Q},\widetilde{\mathcal{Q}}}, C_{\mathcal{Q},\widetilde{\mathcal{Q}}} > 0$, independent of $\mathbf{u}$, such that

$$c_{\mathcal{Q},\widetilde{\mathcal{Q}}} \|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\mathcal{Q}}(\mathbf{E})} \le \|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\widetilde{\mathcal{Q}}}(\mathbf{E})} \le C_{\mathcal{Q},\widetilde{\mathcal{Q}}} \|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\mathcal{Q}}(\mathbf{E})}.$$

The constants depend on k, α, the multiplicity, and the uniform bounds on coordinate changes, cutoffs, and frames, but not on the chart indices. If M has no boundary, there exist $c_{\mathrm{int}}, C_{\mathrm{int}} > 0$ such that

$$c_{\mathrm{int}} \|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le \|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\mathcal{Q}}(\mathbf{E})} \le C_{\mathrm{int}} \|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})},$$

where the first norm is the intrinsic norm of (9.48). If M is compact with boundary and $\mathcal{A}$ are the finite data of Definition 9.4.32, there exist $c_\partial, C_\partial > 0$ such that

$$c_\partial \|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\mathcal{A}}(\mathbf{E})} \le \|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\mathcal{Q}}(\mathbf{E})} \le C_\partial \|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\mathcal{A}}(\mathbf{E})}.$$

Proof. Let $\mathcal{Q} = (U_i, \varphi_i, h_i)_{i\in I}$ and $\widetilde{\mathcal{Q}} = (\widetilde{U}_j, \widetilde{\varphi}_j, \widetilde{h}_j)_{j\in J}$ be two admissible quadratic localization systems equipped with synchronous frames $\mathbf{e}_i$ and $\widetilde{\mathbf{e}}_j$. Insert $\sum_{i\in I} h_i^2 = 1$ into each localization of the second system:

$$\widetilde{h}_j \mathbf{u} = \sum_{\substack{i\in I \\ U_i \cap \widetilde{U}_j \neq \varnothing}} \widetilde{h}_j h_i (h_i \mathbf{u}). \tag{14.87}$$

There are at most L summands, with L independent of j. On an overlap, the component of each summand in the frame $\widetilde{\mathbf{e}}_j$ is obtained from a component of $h_i\mathbf{u}$ by three operations: composition with the coordinate change, multiplication by an entry of the frame transition matrix, and multiplication by the two cutoffs. Also insert auxiliary cutoff functions equal to one on the supports that occur, so that all expressions are compactly supported in the exact domain of the coordinate change.

Proposition 14.4.5 and Proposition 14.5.1 bound the derivatives of the coordinate changes, their inverses, the cutoffs, and the transition matrices uniformly in i, j. The Faà di Bruno formula in Theorem 1.1.19 and the Leibniz rule then give, for each local component f, if D_{ij} is the exact coordinate domain of the term under consideration and $D_i := \Phi_{ij}(D_{ij})$,

$$\|b_{ij}(f \circ \Phi_{ij})\|_{C^{k,\alpha}(\overline{D_{ij}})} \le C_{k,\alpha} \|f\|_{C^{k,\alpha}(\overline{D_i})}, \tag{14.88}$$

where b_{ij} contains the preceding multipliers and Φ_{ij} is the coordinate change. For the seminorm of order k, use

$$[fg]_{C^{0,\alpha}(\overline{D_{ij}})} \le \|f\|_{C^0(\overline{D_{ij}})} [g]_{C^{0,\alpha}(\overline{D_{ij}})} + \|g\|_{C^0(\overline{D_{ij}})} [f]_{C^{0,\alpha}(\overline{D_{ij}})}$$

and the uniform Lipschitz bound on Φ_{ij} over the cutoff's support. In boundary charts, the coordinate changes and multipliers extend to Euclidean neighborhoods of the corresponding compact sets; thus (14.88) descends to the extension norms upon taking the infimum over extensions.

Apply (14.88) to (14.87), sum over the r components, and use the fact that there are at most L terms. This

yields

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\widetilde{\mathcal{Q}}}(\mathbf{E})} \le LC_{k,\alpha}\|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\mathcal{Q}}(\mathbf{E})}.$$

Interchanging the two systems proves independence.

Now suppose that M has no boundary. The proof of Proposition 9.2.11, applied in geodesic charts and synchronous frames, has uniform constants: they depend only on the constants c_g, C_g in the uniform metric inequalities, the bounds on the connection coefficients, and the derivatives of the cutoffs, all independent of the chart. This gives

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\mathcal{Q}}(\mathbf{E})} \le C\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})}.$$

For the reverse inequality, use $\mathbf{u} = \sum_{i\in I} h_i(h_i\mathbf{u})$. Each section $h_i(h_i\mathbf{u})$ extends by zero outside U_i, and its intrinsic Hölder norm is bounded by the right-hand side of (14.86) with a uniform constant. At any point, at most L summands contribute. When comparing two points, only indices whose terms are nonzero at one of them contribute, giving at most $2L$ summands. The triangle inequality for parallel transport then controls the Hölder seminorm, while the Leibniz rule controls the uniform norms of the derivatives. Thus

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le C'\|\mathbf{u}\|_{\Gamma^{k,\alpha}_{\mathcal{Q}}(\mathbf{E})}.$$

If M is compact with boundary and the index set has N elements, the maximum norm and the sum of the local norms satisfy

$$\max_{i\in\{1,\dots,N\}} a_i \le \sum_{i=1}^{N} a_i \le N \max_{i\in\{1,\dots,N\}} a_i, \qquad a_i \ge 0.$$

The independence already proved allows the same data to be chosen in both definitions. □

Theorem 14.6.7. (Sobolev–Morrey embeddings in bounded geometry) Let M be an n-dimensional Riemannian manifold of bounded geometry, with or without boundary, and let $\mathbf{E} \to M$ be a bundle of bounded geometry. Let $1 < p < \infty$, $k \in \mathbb{N}_0$, and $0 < \alpha < 1$.

(a) If $s > 0$ and

$$k + \alpha < s - \frac{n}{p},$$

, then

$$H^{s,p}(M,\mathbf{E}) \hookrightarrow \Gamma^{k,\alpha}(\mathbf{E}).$$

(b) If $m \in \mathbb{N}$ and

$$k + \alpha \le m - \frac{n}{p}, \tag{14.89}$$

, then

$$W^{m,p}(M,\mathbf{E}) \hookrightarrow \Gamma^{k,\alpha}(\mathbf{E}).$$

(c) If $0 < s < 1$, $sp > n$, and $\alpha = s - \frac{n}{p}$, then

$$B^{s}_{p,p}(M,\mathbf{E}) \hookrightarrow \Gamma^{0,\alpha}(\mathbf{E}).$$

In each case, elements of the source space have a unique representative in the target space. If M has

boundary, the restriction of the representative in part (b) agrees with the trace of the section.

Proof. Fix the quadratic localization system and synchronous frames of the preceding proposition. For a section $\mathbf{u}$ of the source space, write

$$h_i\mathbf{u} = \sum_{a=1}^{r} u_i^a \mathbf{e}_{i,a}, \qquad f_i^a := u_i^a \circ \varphi_i^{-1}.$$

Thus f_i^a is the ath component of the already localized section $h_i\mathbf{u}$; no second factor h_i is introduced. In an interior chart, Theorem 6.6.3 gives, under the strict hypothesis in part (a),

$$\|f_i^a\|_{C^{k,\alpha}(\overline{\mathbf{\Omega}_i})} \le C\|f_i^a\|_{H^{s,p}(\mathbb{R}^n)}. \tag{14.90}$$

The constant depends only on n, s, p, k, α. In a boundary chart, choose an extension $F_i^a \in H^{s,p}(\mathbb{R}^n)$ of $f_i^a \in H^{s,p}(\mathbb{R}^n_+)$. The same theorem controls the Hölder norm of F_i^a; restricting to $\overline{\mathbf{\Omega}_i}$ and taking the infimum over extensions gives (14.90) with the quotient norm on the right-hand side. By Proposition 14.6.6,

$$\begin{aligned}\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} &\le C \sup_{\substack{i\in I\\ a\in\{1,\dots,r_{\mathbf{E}}\}}} \|f_i^a\|_{C^{k,\alpha}(\overline{\mathbf{\Omega}_i})} \\ &\le C'\left(\sum_{i\in I}\sum_{a=1}^{r}\|f_i^a\|^p_{H^{s,p}(\mathbb{X}_i)}\right)^{\frac{1}{p}} = C'\|\mathbf{u}\|_{H^{s,p}(M,\mathbf{E})}.\end{aligned}$$

This proves (a).

For (b), use the limiting exponent in Theorem 3.5.7. In an interior chart, f_i^a is supported in a compact subset of a fixed model, and its extension by zero belongs to $W^{m,p}(\mathbb{R}^n)$. In a boundary chart, two different extensions are required. First extend f_i^a by zero from the coordinate region to $\mathbb{R}^n_+$; this crosses only the lateral part, since the support of h_i is separated from it, and Lemma 3.6.8 preserves the Sobolev norm. Then apply the operator $\mathcal{E}_m\colon W^{m,p}(\mathbb{R}^n_+) \longrightarrow W^{m,p}(\mathbb{R}^n)$ of Theorem 3.6.4. Finally, multiply by a fixed cutoff equal to one on the compact set where the original function may be nonzero. The result belongs to $W_0^{m,p}(B_{\mathrm{euc}}(0,R))$, agrees with f_i^a on the coordinate region, and satisfies

$$\|T_i f_i^a\|_{W^{m,p}(B_{\mathrm{euc}}(0,R))} \le C\|f_i^a\|_{W^{m,p}(\mathbb{R}^n_+)}. \tag{14.91}$$

The radius R, cutoff, and constant can be chosen independently of i: Proposition 14.4.5 uses domains of a common radius, the cutoff supports lie in a common smaller coordinate region, and the operator $\mathcal{E}_m$ is always the same. The Euclidean theorem and (14.91) give

$$\|f_i^a\|_{C^{k,\alpha}(\overline{\mathbf{\Omega}_i})} \le C'\|f_i^a\|_{W^{m,p}(\mathbb{X}_i)}$$

in both types of charts. Take the supremum, bound it by the ℓ^p sum, and use the inequalities with constants $c_{m,p}, C_{m,p}$ in Proposition 14.5.3. This yields

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le C\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

For (c), the Euclidean identification $B^s_{p,p} = W^{s,p}$ in Theorem 6.3.14 and Lemma 6.6.2 give, in each chart,

$$\|f_i^a\|_{C^{0,\alpha}(\overline{\mathbf{\Omega}_i})} \le C\|f_i^a\|_{B^s_{p,p}(\mathbb{X}_i)}.$$

On the half-space, proceed with quotient norms as in (a). The definition of $B^s_{p,p}(M,\mathbf{E})$ by real interpolation, the retraction and coretraction argument of Proposition 14.5.3, and the Euclidean identification $B^s_{p,p} = F^s_{p,p}$ imply

$$B^s_{p,p}(M,\mathbf{E}) = F^s_{p,p}(M,\mathbf{E})$$

and provide constants $c_{BF}, C_{BF} > 0$ such that

$$c_{BF}\|\mathbf{u}\|_{F^s_{p,p}(M,\mathbf{E})} \le \|\mathbf{u}\|_{B^s_{p,p}(M,\mathbf{E})} \le C_{BF}\|\mathbf{u}\|_{F^s_{p,p}(M,\mathbf{E})}.$$

By the localized definition of the F norm, if

$$N_{\mathrm{loc}}(\mathbf{u}) := \left(\sum_{i\in I}\sum_{a=1}^{r}\|f_i^a\|^p_{F^s_{p,p}(\mathbb{X}_i)}\right)^{\frac{1}{p}},$$

, the same constants satisfy

$$c_{BF}N_{\mathrm{loc}}(\mathbf{u}) \le \|\mathbf{u}\|_{B^s_{p,p}(M,\mathbf{E})} \le C_{BF}N_{\mathrm{loc}}(\mathbf{u}).$$

The estimate using the supremum proves (c).
For each i, the representatives of $f_i^1,\dots,f_i^r$ reconstruct a section $\mathbf{s}_i$ in U_i that agrees almost everywhere with $h_i\mathbf{u}$. Since the support of h_i lies in a smaller coordinate region, the section $h_i\mathbf{s}_i$ extends by zero outside U_i. The sum

$$\widetilde{\mathbf{u}} := \sum_{i\in I} h_i\mathbf{s}_i$$

is locally finite, defines a section of class C^k up to the boundary, and agrees with $\sum_{i\in I} h_i^2\mathbf{u} = \mathbf{u}$ as a distribution. The preceding uniform estimates and bounded multiplicity of the cover show that $\widetilde{\mathbf{u}} \in \Gamma^{k,\alpha}(\mathbf{E})$ with the bound already obtained. If two continuous representatives agree almost everywhere, the open set where they differ must be empty, since every nonempty relative ball or half-ball has positive Riemannian measure. This proves uniqueness. In the presence of a boundary, compatibility with the trace follows by approximation in $W^{m,p}(M,\mathbf{E})$ by smooth sections: the estimate just proved gives convergence in $\Gamma^{k,\alpha}(\mathbf{E})$, while Theorem 14.5.9 gives convergence of the restrictions in the Besov space on the boundary. The two distributional limits agree. □

Proposition 14.6.8. (Compactness after localization) Let M be an n-dimensional Riemannian manifold of bounded geometry, with or without boundary, and let $\mathbf{E} \to M$ be a bundle of bounded geometry. Let $m_0, m_1 \in \mathbb{N}_0$ and $1 \le p_0, p_1 < \infty$, and suppose that

$$m_0 > m_1, \qquad m_0 - \frac{n}{p_0} > m_1 - \frac{n}{p_1}.$$

. For each $\chi \in C_c^\infty(M)$, the operator

$$\mathbf{u} \longmapsto \chi\mathbf{u}$$

is compact from $W^{m_0,p_0}(M,\mathbf{E})$ to $W^{m_1,p_1}(M,\mathbf{E})$.

Proof. The support of χ meets only finitely many members of a uniformly locally finite cover. If $(\mathbf{u}_j)_{j\in\mathbb{N}}$ is bounded in $W^{m_0,p_0}(M,\mathbf{E})$, the inequalities with constants $c^W_{m_0,p_0}, C^W_{m_0,p_0}$ in Proposition 14.5.3 show that, in each of these charts and for each component, the localizations of $\chi\mathbf{u}_j$ are bounded in a Euclidean space W^{m_0,p_0} and supported in a fixed compact set. In an interior chart, Theorem 3.4.2, applied to a ball containing this support, provides a subsequence converging in W^{m_1,p_1}. The localized functions belong to $W_0^{m_0,p_0}$ of the ball, since their support is separated from its boundary. Multiplying by a cutoff equal to one on the common support and extending by zero gives convergence on all of $\mathbb{R}^n$. In a boundary chart, extend by zero only across the artificial faces to the half-space. The support remains in a compact subset of the closed half-space, possibly meeting $t = 0$; Theorem 3.6.6 gives a convergent subsequence there. Both theorems apply precisely because of the two hypotheses $m_0 > m_1$ and the strict inequality between the indices, and both allow all finite exponents in the statement.

In the range $1 < p_0 \le p_1 < \infty$, one also obtains the following factorization through Bessel spaces. The strict inequality between the differential indices allows us to define

$$\sigma_1 := m_0 - \frac{n}{p_0} + \frac{n}{p_1} > m_1.$$

Theorem 6.6.1 gives the continuous embedding $H^{m_0,p_0} \hookrightarrow H^{\sigma_1,p_1}$, while Theorem 6.6.4, applied on a bounded open set containing the fixed support, gives the compact embedding $H^{\sigma_1,p_1} \hookrightarrow H^{m_1,p_1}$. The integer-order identifications thus provide a subsequence converging in W^{m_1,p_1} in an interior chart. Since all functions are supported in a fixed compact set, multiplying by a cutoff equal to one there and extending by zero turns this local convergence into convergence in the full Euclidean space. In a boundary chart, first apply lateral extension by zero and then the half-space operator, as in (14.91); the same factorization argument applies to the extensions supported in a fixed compact set.

Only finitely many charts and components are involved. Successive extractions yield a single subsequence converging in all of them. The synthesis estimate, which uses multipliers, coordinate changes, and uniform multiplicity, reconstructs convergence in $W^{m_1,p_1}(M,\mathbf{E})$. Thus the operator is compact. □

Proposition 14.6.9. (Interpolation inequality with a small parameter) Let M be an n-dimensional Riemannian manifold of bounded geometry, with or without boundary, and let $\mathbf{E} \to M$ be a bundle of bounded geometry. Let $t, s, s_0 \in \mathbb{N}_0$ and $p_0, p, q \in (1,\infty)$ satisfy

$$t < s < s_0, \qquad \max\{p_0, q\} \le p,$$

and

$$t - \frac{n}{q} \le s - \frac{n}{p} < s_0 - \frac{n}{p_0}. \tag{14.92}$$

. For every $\varepsilon > 0$ there exists $C_\varepsilon > 0$ such that

$$\|\mathbf{u}\|_{W^{s,p}(M,\mathbf{E})} \le \varepsilon \|\mathbf{u}\|_{W^{s_0,p_0}(M,\mathbf{E})} + C_\varepsilon \|\mathbf{u}\|_{W^{t,q}(M,\mathbf{E})} \tag{14.93}$$

for every $\mathbf{u} \in W^{s_0,p_0}(M,\mathbf{E}) \cap W^{t,q}(M,\mathbf{E})$.

Proof. First establish an inequality on the fixed local model. Let K denote the common compact set containing the supports of the localization functions. The strict inequality on the right in (14.92) allows us to set

$$\sigma := s_0 - \frac{n}{p_0} + \frac{n}{p} > s.$$

Theorem 6.6.1 gives

$$H^{s_0,p_0}(\mathbb{R}^n) \hookrightarrow H^{\sigma,p}(\mathbb{R}^n).$$

. Choose a bounded Lipschitz domain Ω and a cutoff $\eta \in C_c^\infty(\Omega)$ equal to one on a neighborhood of K. Theorem 6.6.4 shows that the restriction of a bounded family in $H^{\sigma,p}(\mathbb{R}^n)$ has a subsequence converging in $H^{s,p}(\Omega)$. Since each function under consideration is supported in K, it agrees on the whole space with the extension by zero of $\eta v \restriction_\Omega$. Continuity of multiplication by η and of this extension, whose support remains separated from $\partial\Omega$, proves that

$$\{v \in W^{s_0,p_0}(\mathbb{R}^n) \mid \operatorname{supp} v \subseteq K\} \hookrightarrow W^{s,p}(\mathbb{R}^n)$$

is compact. Here the identifications $H^{s_0,p_0} = W^{s_0,p_0}$ and $H^{s,p} = W^{s,p}$ are at integer orders. On the other hand, since $t < s$ and $q \le p$, first lose regularity while keeping the exponent p fixed and then apply Hölder's inequality on the bounded domain containing K; this gives the continuous embedding into $W^{t,q}(\mathbb{R}^n)$ of the subspace of functions in $W^{s,p}(\mathbb{R}^n)$ supported in K.
We claim that, for each $\delta > 0$, there exists $C_\delta > 0$ such that

$$\|v\|_{W^{s,p}(\mathbb{R}^n)} \le \delta \|v\|_{W^{s_0,p_0}(\mathbb{R}^n)} + C_\delta \|v\|_{W^{t,q}(\mathbb{R}^n)} \tag{14.94}$$

for every $v \in W^{s_0,p_0}(\mathbb{R}^n)$ supported in K. If this failed for some δ, there would be a sequence $(v_j) \subset W^{s_0,p_0}(\mathbb{R}^n)$ supported in K which, after normalization, would satisfy

$$\|v_j\|_{W^{s,p}(\mathbb{R}^n)} = 1, \qquad \|v_j\|_{W^{s_0,p_0}(\mathbb{R}^n)} \le \delta^{-1}, \qquad \|v_j\|_{W^{t,q}(\mathbb{R}^n)} \longrightarrow 0.$$

By compactness, a subsequence would converge in $W^{s,p}$ to a limit of norm one. By continuity of $W^{s,p}_K \hookrightarrow W^{t,q}$, the same limit would be zero in $W^{t,q}$ and hence the zero distribution. This contradiction proves (14.94).
In a boundary chart, the compact inclusion used in the contradiction is obtained by first extending by zero from the half-ball to the half-space, only across the lateral part, then applying $\mathcal{E}_{s_0}$ and multiplying by a fixed cutoff. The continuous inclusion of the space of order s into that of order t is proved directly on the half-space by Hölder's inequality, since all functions are supported in K. Thus the same contradiction gives (14.94) with half-space norms. Since the domains, compact set K, cutoffs, and extension operator are common to the entire family, C_δ is independent of the chart. Apply the inequality to each localized component and take the ℓ^p norm. The triangle inequality in ℓ^p gives

$$\|(b_{i,a})\|_{\ell^p} \le \delta \|(a_{i,a})\|_{\ell^p} + C_\delta \|(c_{i,a})\|_{\ell^p},$$

where a, b, c are the local norms of orders and exponents (s_0, p_0), (s, p), and (t, q), respectively. The hypotheses $p_0 \le p$ and $q \le p$ imply

$$\|(a_{i,a})\|_{\ell^p} \le \|(a_{i,a})\|_{\ell^{p_0}}, \qquad \|(c_{i,a})\|_{\ell^p} \le \|(c_{i,a})\|_{\ell^q}.$$

Proposition 14.5.3 compares these three sums with the global covariant norms. Choose δ so that the first coefficient, after incorporating the constants c_A, C_A of Proposition 14.5.3, is ε. This gives (14.93). □

Remark 14.6.10. (Local compactness and loss of global compactness) Proposition 14.6.8 does not imply compactness of the global embedding. Even on $M = \mathbb{R}^n$, if $0 \neq v \in C_c^\infty(\mathbb{R}^n)$ and $v_j(x) := v(x - je_1)$, the sequence (v_j) is bounded in all Sobolev spaces of a fixed order. Choosing a subsequence with disjoint supports gives, for $j \neq \ell$,

$$\|v_j - v_\ell\|_{W^{m,p}(\mathbb{R}^n)}^p = 2\|v\|_{W^{m,p}(\mathbb{R}^n)}^p.$$

Thus there is no convergent subsequence. Bounded geometry prevents the local constants from degenerating, but does not prevent a sequence from escaping to infinity. Inequality (14.93) is compatible with this phenomenon: it is a global estimate with a small parameter, not a statement of global compactness.

Remark 14.6.11. (Completeness and weighted embeddings) Completeness alone does not provide a uniform coordinate radius or the preceding unweighted embeddings. Fix $0 < \varepsilon < 1$. A ball $B_{\mathbf{g}}(x, R)$ is called $(1, \varepsilon)$-admissible if it has a chart $\varphi\colon B_{\mathbf{g}}(x, R) \longrightarrow \Omega \subseteq \mathbb{R}^n$ whose metric coefficients $g_{ij}(z)$ satisfy

$$(1-\varepsilon)\sum_{i=1}^n (\xi^i)^2 \le \sum_{i,j=1}^n g_{ij}(z)\xi^i\xi^j \le (1+\varepsilon)\sum_{i=1}^n (\xi^i)^2 \qquad (z \in \Omega,\ \xi \in \mathbb{R}^n)$$

and

$$R \max_{\substack{\beta \in \mathbb{N}_0^n \\ |\beta|=1}} \max_{i,j \in \{1,\dots,n\}} \|\partial^\beta g_{ij}\|_{L^\infty(\varphi(B_{\mathbf{g}}(x,R)))} \le \varepsilon.$$

In the first condition, ξ represents the components of a tangent vector in the chart; hence this condition is equivalent to

$$\sqrt{1-\varepsilon}\,\|d\varphi_p(v)\| \le |v|_{\mathbf{g}} \le \sqrt{1+\varepsilon}\,\|d\varphi_p(v)\| \qquad (p \in B_{\mathbf{g}}(x,R),\ v \in T_pM).$$

The second condition additionally controls the first coordinate derivatives of the metric. If $R'(x)$ is the supremum of these radii, set $R_\varepsilon(x) := \min\left\{1, \dfrac{R'(x)}{2}\right\}$. The local constants can be retained inside the integral through weights formed from powers of R_ε. With the convention

$$\|\mathbf{u}\|_{L^a(M,\mathbf{E};w)} := \left(\int_M |\mathbf{u}|_{\mathbf{h}_\mathbf{E}}^a\, w\, d\lambda_{\mathbf{g}}\right)^{\frac{1}{a}},$$

for $1 < r < n$ and $r^* = \frac{nr}{n-r}$, one obtains an estimate of the form

$$\|\mathbf{u}\|_{L^{r^*}(M,\mathbf{E};R_\varepsilon^{2r^*})} \le C\|\mathbf{u}\|_{W^{1,r}(M,\mathbf{E})}$$

on a complete manifold, under the local control of the connection needed for sections; see [7, Theorem 7.5]. When R_ε is uniformly bounded away from zero, there exists $\rho > 0$ such that $\rho \le R_\varepsilon(x) \le 1$ for every $x \in M$, and hence

$$\rho^{2r^*} \le R_\varepsilon(x)^{2r^*} \le 1.$$

These inequalities recover the unweighted mechanism of this section.

Part IV

Index theory

Introduction to Part IV

One of the deepest questions in elliptic theory is how much can be known about an operator without knowing all its coefficients. For an elliptic operator on a closed manifold, lower-order terms influence the particular solutions but do not alter certain fundamental global information. Among this information is the index, defined as the difference between the dimension of the kernel and the dimension of the cokernel.

The first step will be to extend the differential calculus to the pseudodifferential calculus. Its symbols allow parametrices to be constructed and the regularity and singularities of solutions to be described precisely. Fredholm theory turns a parametrix modulo compact operators into a stable integer. This integer still has an analytic origin, but the principal symbol has an interpretation independent of the full operator: it determines a K-theory class on the cotangent bundle.

The second half of this part develops the topological tools needed to interpret that class. Bott periodicity, the Thom isomorphism, and the morphisms associated with embeddings allow the problem to be transported to Euclidean space. The Atiyah–Singer theorem finally asserts that the index obtained by this procedure agrees with the analytic index. The question uniting these chapters is simple to state, although its answer requires several languages: how can a differential equation retain, in its leading term, topological information about the entire manifold?

From elliptic analysis to the index

Fredholm discovered that certain integral equations on function spaces retained an essentially finite-dimensional structure. With the development of elliptic theory and the pseudodifferential calculus, a similar idea emerged for differential operators. In the 1960s, Atiyah and Singer proved that the analytic index could be calculated from topological data of the principal symbol. The result brought together ideas from Hodge, Hirzebruch, Thom, Bott, Grothendieck, and operator theory. Since then, the index has become one of the most fruitful bridges between analysis, geometry, and topology.

15

Pseudodifferential operators

The starting point of the pseudodifferential calculus is a difficulty that already arises when one tries to invert a constant-coefficient elliptic operator. If

$$P(D) = \sum_{|\alpha| \le m} c_\alpha D^\alpha,$$

, the Fourier transform turns the equation $P(D)u = f$ into $p(\xi)\widehat{u}(\xi) = \widehat{f}(\xi)$. When $p(\xi)$ is invertible, the formal solution is obtained by multiplication by $p(\xi)^{-1}$; this inverse, however, is almost never a polynomial and therefore does not correspond to a differential operator. Variable coefficients introduce a further difficulty: the symbol depends on both the point x and the frequency ξ, and composition no longer reduces to the ordinary product of functions.

Pseudodifferential operators enlarge the class of differential operators just enough to solve this problem. Their symbols allow separate control of variation in the base and behavior at high frequencies. Composition is described by an asymptotic expansion, the adjoint remains in the same class, and ellipticity leads to an inverse modulo operators with smooth kernels. This last property turns symbolic inversion into elliptic regularity and, on a closed manifold, into a Fredholm statement.

The analytic ingredients were prepared in earlier chapters. The Fourier transform and tempered distributions of Chapter 4 provide the local model; the Bessel potentials of Chapter 6 show that natural multipliers need not be polynomial; the principal symbol and ellipticity of Chapter 11 identify the part to be inverted. For example,

$$J^s = (I - \Delta)^{\frac{s}{2}}, \qquad \widehat{J^s u}(\xi) = \langle \xi \rangle^s \widehat{u}(\xi),$$

is an operator of order s, whereas $J^{-2} = (I - \Delta)^{-1}$ gains two derivatives without being differential. The calculus we construct explains this phenomenon within a stable theory and then transfers it to manifolds and vector bundles.

We begin on $\mathbb{R}^n$ with symbol classes, oscillatory integrals, and Kohn–Nirenberg quantization. The study of kernels will distinguish locality, pseudolocality, and proper support, and yield the composition and adjoint formulas. We then globalize the calculus, identify the kernels as distributions conormal to the diagonal, and compare local quantization with a Riemannian quantization based on the exponential map. Parametrices will then lead to microlocal regularity and the wavefront set.

The last part of the chapter separates two global situations. On manifolds of bounded geometry, we construct a uniform calculus with finite propagation that preserves Sobolev estimates over an infinite cover. On a closed manifold, smoothing remainders are compact and the parametrix yields Fredholm operators. Finally, the parameter-dependent calculus will allow us to construct Seeley's complex powers, compare them with the spectral calculus, and relate the heat kernel to the McKean–Singer formula.

The symbolic and microlocal theory will rely primarily on Hörmander [84], Taylor [140], and Shubin [135]. For geometric quantization we follow the idea of Bokobza–Haggiag [23]; the construction of complex powers is due to Seeley [132], and the transition to the analytic index uses the exposition of Bleecker and Booß–Bavnbek [21]. The proof of the Atiyah–Singer theorem is left to later chapters.

Hörmander, Seeley, and the maturation of the symbolic calculus

The pseudodifferential calculus emerged by enlarging Fourier multipliers to a class stable under composition and capable of constructing approximate inverses for elliptic operators. Hörmander organized microlocal analysis around symbols, kernels, and wavefront sets; Seeley showed how the same language constructs complex powers of elliptic operators. The strength of the theory lies in its simultaneous treatment of three scales: local behavior in the base variable, homogeneity in frequency, and global regularity of solutions.

15.1 From the Fourier inverse to symbol classes

15.1.1 Conventions and the first model

With the unitary normalization of the Fourier transform fixed in Definition 4.11.1,

$$\widehat{u}(\xi) = (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} e^{-ix\cdot\xi} u(x)\, dx, \qquad u(x) = (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} e^{ix\cdot\xi} \widehat{u}(\xi)\, d\xi.$$

Moreover, D_j denotes the partial derivative ∂_j, not the operator $-i\partial_j$. By Proposition 4.11.3, $\mathcal{F}(D^\alpha u)(\xi) = (i\xi)^\alpha \widehat{u}(\xi)$. These conventions determine all factors that will appear in quantization.

First consider $P(D) = \sum_{|\alpha|\le m} c_\alpha D^\alpha$. If $u, f \in \mathcal{S}(\mathbb{R}^n)$ and $P(D)u = f$, then

$$p(\xi)\widehat{u}(\xi) = \widehat{f}(\xi), \qquad p(\xi) := \sum_{|\alpha|\le m} c_\alpha (i\xi)^\alpha.$$

When $p(\xi) \neq 0$, formal inversion uses $p(\xi)^{-1}$. The polynomial p comes from a differential operator, but its inverse is not polynomial. If the coefficients now depend on x, the function $p(x,\xi)^{-1}$ depends simultaneously on position and frequency. The symbol class must control derivatives in both variables while allowing each derivative with respect to ξ to lower the order.

We write $\langle \xi \rangle = (1 + \|\xi\|^2)^{\frac{1}{2}}$. All real bundles and vector spaces will be complexified during the Fourier calculus; at the end, operators preserving the real structure will be restricted back to it.

15.1.2 Symbols of type $(1,0)$

The preceding heuristic suggests the two estimates a symbol must satisfy. Derivatives in x measure variation of the coefficients, while each derivative in ξ should lower the order. The class of type $(1,0)$ formalizes both controls

simultaneously.

Definition 15.1.1. (Symbol class) Let $n, r, s \in \mathbb{N}$ and $m \in \mathbb{R}$. The global uniform class

$$S^m_{1,0}(\mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s))$$

consists of smooth maps $a\colon \mathbb{R}^n_x \times \mathbb{R}^n_\xi \longrightarrow \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s)$ such that, for all multi-indices α, β, there exists $C_{\alpha,\beta} > 0$ with

$$\|D_x^\alpha D_\xi^\beta a(x,\xi)\| \le C_{\alpha,\beta} \langle \xi \rangle^{m-|\beta|}$$

for every $(x,\xi) \in \mathbb{R}^n \times \mathbb{R}^n$. If $r = s = 1$, we simply write $S^m_{1,0}(\mathbb{R}^n)$.
For an open set $U \subseteq \mathbb{R}^n$, the local class

$$S^m_{1,0}(U \times \mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s))$$

consists of smooth maps with the same target such that, for every compact set $K \Subset U$ and all multi-indices α, β, there exists $C_{K,\alpha,\beta} > 0$ satisfying

$$\|D_x^\alpha D_\xi^\beta a(x,\xi)\| \le C_{K,\alpha,\beta} \langle \xi \rangle^{m-|\beta|}, \qquad (x,\xi) \in K \times \mathbb{R}^n.$$

We abbreviate this class as $S^m_{1,0}(U; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s))$ and omit the target space only in the scalar case. When the order and all spaces are fixed within a block of text, the subscript $(1,0)$ may be abbreviated.

For $n, r, s \in \mathbb{N}$ and $m \in \mathbb{R}$, the natural topology on $S^m_{1,0}(\mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s))$ is the Fréchet topology defined by the seminorms

$$q_{N,m}(a) := \max_{|\alpha|+|\beta| \le N} \sup_{(x,\xi) \in \mathbb{R}^{2n}} \langle \xi \rangle^{-m+|\beta|} \|D_x^\alpha D_\xi^\beta a(x,\xi)\|, \qquad N \in \mathbb{N}_0.$$

On an open set U, use a compact exhaustion (K_j) and the seminorms obtained by restricting x to K_j. For $U \subseteq \mathbb{R}^n$ open, define the class of **smoothing symbols** by

$$\begin{aligned} &S^{-\infty}(U \times \mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s)) \\ &\quad := \bigcap_{\mu \in \mathbb{R}} S^\mu_{1,0}(U \times \mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s)). \end{aligned} \tag{15.1}$$

Equivalently, a belongs to this intersection if, for every compact set $K \Subset U$, all multi-indices α, β, and every $N \in \mathbb{N}_0$, there exists $C_{K,\alpha,\beta,N} > 0$ such that

$$\|D_x^\alpha D_\xi^\beta a(x,\xi)\| \le C_{K,\alpha,\beta,N} \langle \xi \rangle^{-N}, \qquad (x,\xi) \in K \times \mathbb{R}^n. \tag{15.2}$$

For the global uniform class, the same estimate is required for every $x \in \mathbb{R}^n$, with a constant independent of x, and we write

$$S^{-\infty}(\mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s)) := \bigcap_{\mu \in \mathbb{R}} S^\mu_{1,0}(\mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s)). \tag{15.3}$$

In any of the global or local spaces just defined, the inclusions from order m_1 into order m_2 are continuous when $m_1 \le m_2$, differentiation $D_x^\alpha D_\xi^\beta$ takes order m to $m - |\beta|$, and matrix multiplication adds orders whenever the target spaces allow composition.

The reason for privileging $(\rho,\delta)=(1,0)$ can already be seen in these three properties: frequency differentiation lowers the order, position differentiation does not increase it, and the Taylor expansions appearing in composition produce strictly decreasing orders. The general classes $S^m_{\rho,\delta}(U\times\mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$ replace $m-|\beta|$ by $m-\rho|\beta|+\delta|\alpha|$; they will not be needed here.

Definition 15.1.2. (Euclidean elliptic symbol) Let $U\subseteq\mathbb{R}^n$ be open, and let $r\in\mathbb{N}$ and $m\in\mathbb{R}$. A matrix-valued symbol $a\in S^m_{1,0}(U;\mathrm{End}(\mathbb{C}^r))$ is **elliptic** if, for every compact set $K\Subset U$, there exist $R_K,C_K>0$ such that $a(x,\xi)$ is invertible and

$$\|a(x,\xi)^{-1}\|\le C_K\langle\xi\rangle^{-m}$$

when $x\in K$ and $\|\xi\|\ge R_K$. It is **uniformly elliptic** if R_K and C_K can be chosen independently of K.

15.1.3 Classical symbols and asymptotic expansions

The class $S^m_{1,0}$ controls the size of a symbol but does not distinguish successive contributions from its different degrees. To construct a parametrix, we first need to separate the leading term and correct it order by order. Classical symbols provide precisely this homogeneous expansion at high frequencies.

Definition 15.1.3. (Classical symbol) Let $U\subseteq\mathbb{R}^n$ be open, and let $r,s\in\mathbb{N}$ and $m\in\mathbb{R}$. A symbol $a\in S^m_{1,0}(U;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$ is **classical** or **polyhomogeneous** if there exist smooth maps

$$a_{m-j}\colon U\times(\mathbb{R}^n\setminus\{0\})\longrightarrow\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s),\qquad j\in\mathbb{N}_0,$$

, homogeneous in the sense that $a_{m-j}(x,t\xi)=t^{m-j}a_{m-j}(x,\xi)$ for $t>0$, and a function $\vartheta\in C^\infty(\mathbb{R}^n)$ that vanishes near 0 and equals one for $\|\xi\|\ge1$, such that, for every $N\ge1$,

$$a-\sum_{j=0}^{N-1}\vartheta a_{m-j}\in S^{m-N}_{1,0}(U;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s)).$$

We write $a\in S^m_{\mathrm{cl}}(U;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$ and call a_m the **principal homogeneous component**.

The presence of ϑ does not alter the homogeneous information: two cutoffs yield symbols whose difference is compactly supported in ξ and belongs to $S^{-\infty}(U\times\mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$. The component a_m is unique. If b_m is another principal component, then $a_m-b_m\in S^{m-1}_{1,0}(U;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$ for $\|\xi\|\ge1$. For $\omega\in\mathbb{S}^{n-1}$ and $t\ge1$, homogeneity gives

$$t^m\|a_m(x,\omega)-b_m(x,\omega)\|\le C_K\,t^{m-1}.$$

Dividing by t^m and letting $t\to\infty$ gives $a_m=b_m$. The same inductive argument proves uniqueness of all homogeneous components.

Definition 15.1.4. (Asymptotic expansion) Let $U\subseteq\mathbb{R}^n$ be open, let $r,s\in\mathbb{N}$, and let $m_0\ge m_1\ge\cdots$ be real numbers with $m_j\to-\infty$ and

$$a_j\in S^{m_j}_{1,0}(U;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s)).$$

For $a \in S^{m_0}_{1,0}(U;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$, we write

$$a \sim \sum_{j=0}^{\infty} a_j$$

if, for every $N \geq 1$,

$$a - \sum_{j=0}^{N-1} a_j \in S^{m_N}_{1,0}(U;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s)).$$

When several m_j coincide, the conclusion is understood after grouping terms of equal order.

Differentiation may be performed term by term: if $a \sim \sum_{j=0}^{\infty} a_j$, then $D_x^\alpha D_\xi^\beta a \sim \sum_{j=0}^{\infty} D_x^\alpha D_\xi^\beta a_j$, with orders $m_j - |\beta|$. The coefficients of a general expansion are not unique as functions; what is determined is the class of the term of order m_j modulo symbols of the next order. For classical symbols, homogeneity removes this ambiguity.

Lemma 15.1.5. (Asymptotic summation of symbols) Let $U \subseteq \mathbb{R}^n$ be open and let $r,s \in \mathbb{N}$. In the setting of Definition 15.1.4, there exists

$$a \in S^{m_0}_{1,0}(U;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$$

with $a \sim \sum_{j=0}^{\infty} a_j$. In particular, if h_{m_0-j} is smooth on $U\times(\mathbb{R}^n\setminus\{0\})$ with values in $\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s)$ and homogeneous of degree $m_0 - j$ for each $j \in \mathbb{N}_0$, then, for a radial cutoff ϑ as in Definition 15.1.3, one can choose $a \in S^{m_0}_{\mathrm{cl}}(U;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$ with

$$a \sim \sum_{j=0}^{\infty} \vartheta h_{m_0-j}.$$

The lattice of degrees $m_0 - j$ in the last clause is essential to the notion in Definition 15.1.3. A homogeneous family of merely decreasing real degrees admits a general asymptotic sum, but defines only a homogeneous expansion with that set of degrees; it is classical in the sense adopted here when those degrees belong to $m_0 - \mathbb{N}_0$, inserting zero components at the missing degrees.

Proof. Throughout this proof, U, r, s remain fixed, and we write

$$S^q := S^q_{1,0}\big(U \times \mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s)\big).$$

Since $m_j \to -\infty$ and the sequence is nonincreasing, each order can occur only finitely many times. For each value μ that occurs, the set

$$I_\mu := \{j \in \mathbb{N}_0 \mid m_j = \mu\}$$

is finite. Group the terms corresponding to I_μ and replace the group by the finite sum $\sum_{j\in I_\mu} a_j$. This is exactly the convention fixed after Definition 15.1.4. It suffices to treat the case

$$m_0 > m_1 > m_2 > \cdots.$$

Fix an exhaustion $K_1 \Subset K_2 \Subset \cdots$ of U and a function $\chi \in C^\infty(\mathbb{R}^n)$ vanishing on $\{\|\xi\| \leq 1\}$ and equal to one on

$\{\|\xi\| \geq 2\}$. For a compact set $K \Subset U$, write

$$q^K_{L,\mu}(c) := \max_{|\alpha|+|\beta|\leq L} \sup_{x\in K,\,\xi\in\mathbb{R}^n} \langle\xi\rangle^{-\mu+|\beta|} \|D_x^\alpha D_\xi^\beta c(x,\xi)\|.$$

We will choose a sequence $\varepsilon_j \to 0^+$ and set

$$b_j(x,\xi) := \chi(\varepsilon_j\xi)a_j(x,\xi).$$

If $N < j$, then $m_j < m_N$. The Leibniz rule and the fact that $\chi(\varepsilon\xi)$ is supported where $\|\xi\| \geq \varepsilon^{-1}$ show that, for fixed K, L, N, j with $N < j$,

$$q^K_{L,m_N}\big(\chi(\varepsilon\,\cdot)a_j\big) \longrightarrow 0 \qquad (\varepsilon \longrightarrow 0^+). \tag{15.4}$$

Indeed, each Leibniz term contains, besides a seminorm of a_j, the factor $\langle\xi\rangle^{m_j-m_N}$; when a derivative hits the cutoff, powers of ε appear, and on its support $\|\xi\|$ is comparable to ε^{-1}, giving the same power of $\varepsilon^{m_N-m_j}$ or a better one.

For each $j \geq 1$, there are only finitely many conditions

$$q^{K_p}_{p,m_N}(b_j) \leq 2^{-j}, \qquad 0 \leq N < j, \qquad 1 \leq p \leq j.$$

Convergence (15.4) allows ε_j to be chosen so that all of them hold and, by decreasing it if necessary, so that $\varepsilon_j < \varepsilon_{j-1}$. Choose $\varepsilon_0 > 0$ arbitrarily.

For every compact set $K \Subset U$ and every L, the conditions with $N = 0$, applied on a K_p containing K and with $p \geq L$, show that $\displaystyle\sum_{j=0}^{\infty} b_j$ converges in the seminorm q^K_{L,m_0}. Consequently,

$$a := \sum_{j=0}^{\infty} b_j$$

belongs to S^{m_0}. Now fix N. The term b_N belongs to S^{m_N}, and the preceding conditions, this time with target order m_N, show that $\displaystyle\sum_{j>N} b_j$ converges in all seminorms of S^{m_N}. Thus, for each N,

$$a - \sum_{j=0}^{N-1} a_j = \sum_{j=N}^{\infty} b_j + \sum_{j=0}^{N-1} (b_j - a_j).$$

The first sum belongs to S^{m_N}. Each difference $b_j - a_j$ has bounded support in ξ and therefore belongs to $S^{-\infty}(U\times\mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$; this proves the asymptotic expansion. Ungrouping the finite groups recovers the interpretation specified in the definition. For the last clause, apply the same construction with radial cutoffs to $a_j = \vartheta h_{m_0-j}$; the remainder after the first N terms belongs to S^{m_0-N}, which is exactly the expansion in Definition 15.1.3. □

15.1.4 Oscillatory integrals and quantization

So far we have worked with symbol functions. To turn them into operators, we must give meaning to an integral that, except at very negative orders, is not absolutely convergent. Oscillation of the phase will compensate for

growth of the symbol.

Let $n, r, s \in \mathbb{N}$, $m < -n$, $a \in S^m_{1,0}(\mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s))$, and $u \in \mathcal{S}(\mathbb{R}^n, \mathbb{C}^r)$. Then the integral

$$(2\pi)^{-n} \int_{\mathbb{R}^n_\xi} \int_{\mathbb{R}^n_y} e^{i(x-y)\cdot\xi} a(x,\xi) u(y)\, dy\, d\xi$$

is absolutely convergent. At higher orders, oscillation of the exponential takes the place of absolute integrability. We make this replacement precise by regularization, rather than by an implicit convention.

Let $c \in C^\infty_c(\mathbb{R}^{2n})$ equal one near $(0,0)$. If $q(x,y,\xi)$ is smooth and all its derivatives have polynomial growth in (y,ξ), define, whenever the limit exists,

$$\mathrm{Os} \iint_{\mathbb{R}^n_y \times \mathbb{R}^n_\xi} e^{i(x-y)\cdot\xi} q(x,y,\xi)\, dy\, d\xi := \lim_{\varepsilon \to 0^+} \iint_{\mathbb{R}^n_y \times \mathbb{R}^n_\xi} e^{i(x-y)\cdot\xi} c(\varepsilon y, \varepsilon\xi) q(x,y,\xi)\, dy\, d\xi.$$

Existence will be proved under growth bounds of fixed order. Specifically, suppose there exist $\mu, \tau \in \mathbb{R}$ such that, for each compact set K in the variable x and all multi-indices γ, α, β,

$$\|D_x^\gamma D_y^\alpha D_\xi^\beta q(x,y,\xi)\| \le C_{K,\gamma,\alpha,\beta} \langle y\rangle^\tau \langle \xi\rangle^{\mu-|\beta|}, \qquad x \in K.$$

The exponents μ and τ do not depend on the number of derivatives. The phase is the real function $(x-y)\cdot\xi$. The identities

$$e^{i(x-y)\cdot\xi} = \langle \xi\rangle^{-2N} (1-\Delta_y)^N e^{i(x-y)\cdot\xi}$$

and

$$e^{i(x-y)\cdot\xi} = \langle x-y\rangle^{-2L} (1-\Delta_\xi)^L e^{i(x-y)\cdot\xi}$$

transfer derivatives to the amplitude. Write $c_\varepsilon(y,\xi) = c(\varepsilon y, \varepsilon\xi)$. Integrating by parts first in y and then in ξ shows that the regularized integral equals the integral of $e^{i(x-y)\cdot\xi} R_\varepsilon(x,y,\xi)$, where

$$R_\varepsilon = \langle x-y\rangle^{-2L} (1-\Delta_\xi)^L \big[\langle \xi\rangle^{-2N} (1-\Delta_y)^N (c_\varepsilon q) \big].$$

These operations are valid before taking the limit because the cutoff has compact support. For $0 < \varepsilon \le 1$, its derivatives satisfy

$$|D_y^\alpha D_\xi^\beta c_\varepsilon(y,\xi)| \le C_{\alpha,\beta} \langle \xi\rangle^{-|\beta|}.$$

Indeed, each derivative contributes a factor of ε, and on the support of the corresponding term, $\varepsilon\langle\xi\rangle$ is bounded independently of ε. The Leibniz rule and the bounds on q give, for $x \in K$,

$$\|R_\varepsilon(x,y,\xi)\| \le C_K \langle y\rangle^{\tau-2L} \langle \xi\rangle^{\mu-2N}.$$

Here we use that $\langle x-y\rangle$ and $\langle y\rangle$ are uniformly comparable as x ranges over K. Choose $2N > \mu + n$ and $2L > \tau + n$; the last expression is then integrable in (y,ξ). For each fixed (y,ξ), the cutoff equals one and all its positive-order derivatives vanish when ε is sufficiently small. By dominated convergence, the limit is the absolutely convergent integral obtained by replacing $c_\varepsilon q$ with q in R_ε. This expression is independent of the cutoff c.

Differentiating with respect to x up to order d also produces powers of ξ of degree at most d. The same proof, with $2N > \mu + d + n$, gives an integrable majorant for all these derivatives, uniformly on K. Convergence of the integrand and its derivatives is also uniform in $x \in K$ for fixed (y,ξ). This yields convergence in every $C^d(K)$ norm

and smooth dependence of the oscillatory integral on x.

For the following quantization, $q(x,y,\xi) = a(x,\xi)u(y)$ satisfies these bounds with $\mu = m$ and $\tau = 0$, since u is a Schwartz function. The same holds for $b(x,y,\xi)u(y)$ for the fixed-order amplitudes introduced below. In the composition and reduction formulas, apply the argument to the integration variables, leaving the remaining variables as parameters; symbol estimates and Peetre's inequality control the weights appearing there. The bounds are local in the parameter variables. Polynomial growth of each derivative, without common control of the exponents, will not be used as a sufficient hypothesis for existence.

Together with asymptotic summation, regularization allows us to pass from formal expansions to well-defined operators. An equivalent construction, with remainders estimated seminorm by seminorm, can be found in [135, Sections 1 and 3].

Definition 15.1.6. (Kohn–Nirenberg quantization) Let $n, r, s \in \mathbb{N}$, $m \in \mathbb{R}$, and $a \in S^m_{1,0}(\mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s))$. Define

$$\mathrm{Op}(a)u(x) := (2\pi)^{-n} \operatorname{Os} \iint_{\mathbb{R}^n_y \times \mathbb{R}^n_\xi} e^{i(x-y)\cdot\xi} a(x,\xi)u(y)\, dy\, d\xi, \qquad u \in \mathcal{S}(\mathbb{R}^n, \mathbb{C}^r).$$

Equivalently,

$$\mathrm{Op}(a)u(x) = (2\pi)^{-\frac{n}{2}} \operatorname{Os} \int_{\mathbb{R}^n_\xi} e^{ix\cdot\xi} a(x,\xi)\widehat{u}(\xi)\, d\xi.$$

The second formula is first obtained when the integrals are absolutely convergent, using Fourier inversion and Fubini's theorem, and then by regularization. The factor $(2\pi)^{-n}$ in the first formula results from the two occurrences of the unitary normalization; it cannot be replaced by $(2\pi)^{-\frac{n}{2}}$.

Proposition 15.1.7. (Continuity of quantization) Let $n, r, s \in \mathbb{N}$, $m \in \mathbb{R}$, and

$$a \in S^m_{1,0}(\mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s)).$$

. Then $\mathrm{Op}(a)$ is continuous from $\mathcal{S}(\mathbb{R}^n, \mathbb{C}^r)$ to $\mathcal{S}(\mathbb{R}^n, \mathbb{C}^s)$. By transposition it extends uniquely to a continuous operator

$$\mathrm{Op}(a)\colon \mathcal{S}'(\mathbb{R}^n, \mathbb{C}^r) \longrightarrow \mathcal{S}'(\mathbb{R}^n, \mathbb{C}^s).$$

If $a \in S^{-\infty}(\mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s))$, it maps $\mathcal{S}'(\mathbb{R}^n, \mathbb{C}^r)$ into $C^\infty(\mathbb{R}^n, \mathbb{C}^s)$; if, in addition, a decays rapidly also in x, it maps $\mathcal{S}'(\mathbb{R}^n, \mathbb{C}^r)$ into $\mathcal{S}(\mathbb{R}^n, \mathbb{C}^s)$.

Proof. Differentiating the second formula with respect to x produces sums of terms with factors $\xi^\gamma D_x^{\alpha-\gamma} a(x,\xi)$. To control a power x^β, use $x_j e^{ix\cdot\xi} = -iD_{\xi_j} e^{ix\cdot\xi}$ and integrate by parts in ξ. After expanding by the Leibniz rule, each Schwartz seminorm of $\mathrm{Op}(a)u$ is bounded by a finite sum of symbol seminorms of a and Schwartz seminorms of u. Choose the number of integrations by parts greater than $m + n$ to make the variable ξ integrable. This proves existence, membership in $\mathcal{S}(\mathbb{R}^n, \mathbb{C}^s)$, and continuity simultaneously. The transposed operator is defined by $\langle \mathrm{Op}(a)u, \varphi\rangle := \langle u, \mathrm{Op}(a)^t\varphi\rangle$, where the transpose on the right-hand side is obtained by interchanging the kernel variables; the proposition on amplitudes proved below shows that it too preserves the corresponding Schwartz spaces. If $a \in S^{-\infty}(\mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s))$, the decay in ξ can be chosen arbitrarily large, allowing differentiation under the integral against a tempered distribution and yielding smoothness. Additional decay in x gives all Schwartz seminorms. □

15.1.5 Amplitudes and reduction to symbols

Kohn–Nirenberg quantization uses a symbol evaluated at the output variable x. Composing operators, taking adjoints, or changing coordinates naturally introduces coefficients that also depend on the input variable y. Before closing the calculus under these operations, we must show that such amplitudes can be reduced back to symbols.

Definition 15.1.8. (Amplitude) Let $n, r, s \in \mathbb{N}$ and $m \in \mathbb{R}$. An **amplitude of order** m is a smooth map

$$b\colon \mathbb{R}^n_x \times \mathbb{R}^n_y \times \mathbb{R}^n_\xi \longrightarrow \operatorname{Hom}(\mathbb{C}^r, \mathbb{C}^s)$$

such that, for all multi-indices α, γ, β, there exists $C_{\alpha,\gamma,\beta} > 0$ with

$$\|D_x^\alpha D_y^\gamma D_\xi^\beta b(x,y,\xi)\| \le C_{\alpha,\gamma,\beta} \langle \xi \rangle^{m-|\beta|}.$$

Its operator, initially on $\mathcal{S}(\mathbb{R}^n, \mathbb{C}^r)$, is defined by

$$I(b)u(x) := (2\pi)^{-n} \operatorname{Os} \iint_{\mathbb{R}^n_y \times \mathbb{R}^n_\xi} e^{i(x-y)\cdot\xi} b(x,y,\xi) u(y)\, dy\, d\xi.$$

A symbol is the special amplitude independent of y. The reverse direction contains the argument that will recur in composition, adjoints, and coordinate changes.

Theorem 15.1.9. (Amplitude reduction) Let $n, r, s \in \mathbb{N}$ and $m \in \mathbb{R}$. For each amplitude b of order m with values in $\operatorname{Hom}(\mathbb{C}^r, \mathbb{C}^s)$, there exists

$$a \in S^m_{1,0}(\mathbb{R}^n; \operatorname{Hom}(\mathbb{C}^r, \mathbb{C}^s))$$

such that $I(b) = \operatorname{Op}(a)$. The symbol can be chosen with expansion

$$a(x,\xi) \sim \sum_{\alpha \in \mathbb{N}_0^n} \frac{i^{-|\alpha|}}{\alpha!} D_\xi^\alpha D_y^\alpha b(x,y,\xi)\big|_{y=x}.$$

The operator determines the symbol modulo $S^{-\infty}(\mathbb{R}^n; \operatorname{Hom}(\mathbb{C}^r, \mathbb{C}^s))$.

Proof. Throughout this proof, n, r, s, m remain fixed, and we write

$$S^q := S^q_{1,0}\big(\mathbb{R}^n; \operatorname{Hom}(\mathbb{C}^r, \mathbb{C}^s)\big).$$

Exact reduction is obtained through the partial Fourier transform of the kernel in the variable $x - y$. With this chapter's normalization, define

$$a(x,\xi) := (2\pi)^{-n} \operatorname{Os} \iint_{\mathbb{R}^n_y \times \mathbb{R}^n_\eta} e^{-iy\cdot\eta} b(x, x+y, \xi+\eta)\, dy\, d\eta. \tag{15.5}$$

This oscillatory integral exists. To see this, use, with $L, K \in \mathbb{N}$,

$$e^{-iy\cdot\eta} = \langle \eta \rangle^{-2K} (1 - \Delta_y)^K e^{-iy\cdot\eta}, \qquad e^{-iy\cdot\eta} = \langle y \rangle^{-2L} (1 - \Delta_\eta)^L e^{-iy\cdot\eta},$$

applying the first identity first, and then the second to each resulting term. After integration by parts, the

derivatives fall on the amplitude and the weight in η. Peetre's inequality in Lemma 6.1.1 gives, for every $\mu \in \mathbb{R}$,

$$\langle \xi+\eta\rangle^{\mu} \le 2^{\frac{|\mu|}{2}} \langle \xi\rangle^{\mu}\langle \eta\rangle^{|\mu|}.$$

Choosing $L > \frac{n}{2}$ and $2K > n+\big|m-|\beta|\big|$ makes the resulting integrand absolutely integrable, and after applying $D_x^{\alpha}D_{\xi}^{\beta}$ it is bounded by

$$C_{\alpha,\beta}\langle \xi\rangle^{m-|\beta|}.$$

The same argument for any number of derivatives proves that $a \in S^m$. Inserting compactly supported cutoffs before applying Fubini's theorem, the kernel formula and the changes $y-x \mapsto y$ and $\eta-\xi \mapsto \eta$ give $I(b) = \mathrm{Op}(a)$; the preceding estimates allow the cutoffs to be removed. Thus (15.5) directly constructs the symbol associated with the amplitude.

Now fix $N \ge 1$ and expand the amplitude in y about x:

$$b(x,y,\xi) = \sum_{|\alpha|<N} \frac{(y-x)^{\alpha}}{\alpha!} D_y^{\alpha} b(x,x,\xi) + \sum_{|\alpha|=N} (y-x)^{\alpha} r_{\alpha}(x,y,\xi),$$

where

$$r_{\alpha}(x,y,\xi) = \frac{N}{\alpha!}\int_0^1 (1-t)^{N-1} D_y^{\alpha} b(x,x+t(y-x),\xi)\,dt.$$

Since $(y-x)^{\alpha}e^{i(x-y)\cdot\xi} = i^{|\alpha|}D_{\xi}^{\alpha}e^{i(x-y)\cdot\xi}$, integration by parts in ξ turns each term of the finite sum into

$$\frac{i^{-|\alpha|}}{\alpha!} D_{\xi}^{\alpha} D_y^{\alpha} b(x,x,\xi).$$

Equivalently, inserting this Taylor expansion into (15.5), the identity

$$y^{\alpha}e^{-iy\cdot\eta} = i^{|\alpha|}D_{\eta}^{\alpha}e^{-iy\cdot\eta}$$

produces the same terms. In the remainder, the N integrations by parts make D_{η}^{α} act on $r_{\alpha}(x,x+y,\xi+\eta)$. Each derivative in η is a derivative in the covariable of b and lowers the order by one. The estimate used for (15.5), now applied to these derivatives, shows directly that the reduced remainder belongs to S^{m-N}. Since N is arbitrary, this gives the asserted expansion without a second appeal to amplitude reduction.

In the global model, the partial transform defining (15.5) recovers the symbol from the kernel. After localization on an open set, two choices may differ by a part of the kernel separated from the diagonal; integration by parts in the covariable shows that its transform belongs to $S^{-\infty}(\mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$. Thus the operator determines the symbol modulo this global smoothing class. □

15.1.6 Fundamental examples

Before developing the algebraic calculus, it is useful to recognize some familiar operators within the new class. The following examples show how symbol order records loss or gain of derivatives while distinguishing locality, nonlocality, and smoothing.

Example 15.1.10. (Differential operators) Let $U \subseteq \mathbb{R}^n$ be open, and let $r,s \in \mathbb{N}$ and $A_{\alpha} \in$

$C^\infty(U;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$. For

$$P=\sum_{|\alpha|\le m}A_\alpha(x)D^\alpha$$

, the Fourier symbol is

$$p(x,\xi)=\sum_{|\alpha|\le m}A_\alpha(x)(i\xi)^\alpha,\qquad P=\mathrm{Op}(p).$$

If $U=\mathbb{R}^n$ and the coefficients and all their derivatives are bounded,

$$p\in S^m_{1,0}(\mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s));$$

; locally it always belongs to $S^m_{1,0}(U;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$. The principal Fourier component is

$$p_m(x,\xi)=i^m\sum_{|\alpha|=m}A_\alpha(x)\xi^\alpha=i^m\sigma_m(P)(x,\xi),$$

where $\sigma_m(P)$ is exactly the intrinsic symbol of Definition 11.1.1. This reconciles the previously fixed differential convention with Fourier quantization. Multiplication by i^m does not change ellipticity.
The operator is local: its kernel is a finite sum of transverse derivatives of the delta distribution on the diagonal,

$$\mathbf{K}_P(x,y)=\sum_{|\alpha|\le m}A_\alpha(x)D_x^\alpha\delta(x-y).$$

Its support is therefore contained in the diagonal, where all its singularities are concentrated. The Fourier and localization estimates already proved in the Sobolev chapters give $P\colon H^{t+m}_{\mathrm{loc}}(U,\mathbb{C}^r)\longrightarrow H^t_{\mathrm{loc}}(U,\mathbb{C}^s)$; if $U=\mathbb{R}^n$ and the coefficients and their derivatives are globally bounded, one obtains $P\colon H^{t+m}(\mathbb{R}^n,\mathbb{C}^r)\longrightarrow H^t(\mathbb{R}^n,\mathbb{C}^s)$.

Example 15.1.11. (Multipliers and Bessel potentials) If a depends only on ξ, then $\mathrm{Op}(a)u=\mathcal{F}^{-1}(a\widehat{u})$. For $s\in\mathbb{R}$, the estimates preceding Definition 6.1.2 show that $\langle\xi\rangle^s\in S^s_{\mathrm{cl}}(\mathbb{R}^n)$, with principal component $\|\xi\|^s$ for $\xi\neq0$. Thus

$$J^s=\mathrm{Op}(\langle\xi\rangle^s),\qquad J^{-s}=\mathrm{Op}(\langle\xi\rangle^{-s}).$$

The first has order s and the second order $-s$; neither is local unless its symbol is a polynomial. When $s>0$, the kernel of J^{-s} is the Bessel kernel in Proposition 6.1.4.
Their principal symbols are $\|\xi\|^s$ and $\|\xi\|^{-s}$, respectively. Directly from the Fourier definition, for every $t\in\mathbb{R}$,

$$J^s\colon H^{t+s}(\mathbb{R}^n)\longrightarrow H^t(\mathbb{R}^n),\qquad J^{-s}\colon H^t(\mathbb{R}^n)\longrightarrow H^{t+s}(\mathbb{R}^n)\quad(s>0)$$

are isomorphisms. The kernels are smooth when $x\neq y$ and, except in the local polynomial cases, have a conormal singularity at $x=y$; for $s>0$, the kernel of J^{-s} progressively loses this singularity as s increases, but does not become C^∞ at a general finite order.

Example 15.1.12. (The fractional Laplacian and low frequencies) Let $s>0$. The multiplier of $(-\Delta)^{\frac{s}{2}}$ is $\|\xi\|^s$. If s is not an even integer, it is not smooth at $\xi=0$ and therefore does not belong to the global inhomogeneous class $S^s_{1,0}(\mathbb{R}^n)$ just defined. If ϑ vanishes near zero and equals one for $\|\xi\|\ge1$, then $\vartheta(\xi)\|\xi\|^s\in S^s_{\mathrm{cl}}(\mathbb{R}^n)$. The remaining part has compact frequency support and maps compactly supported distributions to smooth

functions. Thus the fractional Laplacian is microlocally a classical pseudodifferential operator of order s, although its global homogeneous treatment retains additional information at frequency zero. This distinction disappears for $(I-\Delta)^{\frac{s}{2}}$, whose symbol $\langle\xi\rangle^s$ is smooth on all of $\mathbb{R}^n$.
For $s>0$, the multiplier $\|\xi\|^s$ maps $H^{t+s}(\mathbb{R}^n)$ continuously into $H^t(\mathbb{R}^n)$ and has principal symbol $\|\xi\|^s$. It is nonlocal when s is not an even integer. If $0<s<2$, its kernel off the diagonal is represented, up to a dimensional constant, by $\|x-y\|^{-n-s}$, and its action is interpreted in the principal-value sense through the difference $u(x)-u(y)$. Thus the kernel's singularity lies on the diagonal, but its support does not: this is the distinction between nonlocality and pseudolocality.

Example 15.1.13. (Riesz and Hilbert transforms) The Riesz transform $R_j = D_j(-\Delta)^{-\frac{1}{2}}$ has symbol $\frac{i\xi_j}{\|\xi\|}$ away from $\xi=0$, homogeneous of degree zero. In dimension one, the Hilbert transform with principal-value kernel $\pi^{-1}(x-y)^{-1}$ has multiplier $-i\operatorname{sign}(\xi)$. Both are nonlocal operators of order zero at high frequencies; a cutoff at frequency zero produces representatives in $S^0_{\mathrm{cl}}(\mathbb{R}^n)$ with the same microlocal behavior.
These multipliers are also their principal symbols. Since they are bounded, both operators act continuously on every $H^t(\mathbb{R}^n)$. Away from the diagonal, the Riesz kernel is a multiple of $\frac{x_j-y_j}{\|x-y\|^{n+1}}$, and the Hilbert kernel is $\pi^{-1}\operatorname{pv}(x-y)^{-1}$. They are smooth away from $x=y$, singular on the diagonal, and not supported there.

Example 15.1.14. (Smoothing operators and exact inverses) The symbol $e^{-\|\xi\|^2}$ belongs to $S^{-\infty}(\mathbb{R}^n;\operatorname{Hom}(\mathbb{C},\mathbb{C}))$, and its operator is convolution with a Gaussian; it maps $\mathcal{S}'(\mathbb{R}^n)$ into $C^\infty(\mathbb{R}^n)$. On the other hand, $I-\Delta$ has multiplier $1+\|\xi\|^2$, and its exact inverse on $\mathcal{S}'(\mathbb{R}^n)$ is $\operatorname{Op}(\langle\xi\rangle^{-2})$. This last example contains the general mechanism of elliptic symbolic inversion without error terms.
The Gaussian operator has order $-\infty$, zero principal symbol in every finite-order quotient, and a smooth nonlocal kernel, and it maps $H^t(\mathbb{R}^n)$ into $H^N(\mathbb{R}^n)$ for all $t,N\in\mathbb{R}$. The inverse $(I-\Delta)^{-1}$ has order -2 and principal symbol $\|\xi\|^{-2}$ and is an isomorphism $H^t(\mathbb{R}^n)\longrightarrow H^{t+2}(\mathbb{R}^n)$. Its Bessel kernel is smooth off the diagonal and has the singularity there corresponding to order -2; it is an exact inverse and, in particular, a parametrix without a remainder.

15.2 Kernels, proper support, and symbolic calculus

The symbol describes the operator in frequency, whereas the kernel shows how two points in space interact. This second description is essential for distinguishing local and nonlocal operators, formulating proper support, and proving pseudolocality. It also explains why composition, adjoints, and coordinate changes remain within the calculus.

15.2.1 The kernel and the diagonal

The Schwartz kernel theorem for vector bundles, Theorem 10.2.57, represents a continuous operator by a distribution on the product. In the Euclidean scalar model, Definition 15.1.6 gives

$$\mathbf{K}_{\operatorname{Op}(a)}(x,y) = (2\pi)^{-n}\operatorname{Os}\int_{\mathbb{R}^n} e^{i(x-y)\cdot\xi}a(x,\xi)\,d\xi.$$

The possible singularity is concentrated at $x = y$. If $x \neq y$, the operator

$$L_{x,y} := \frac{1}{i\|x-y\|^2}(x-y)\cdot D_\xi$$

satisfies $L_{x,y}e^{i(x-y)\cdot\xi} = e^{i(x-y)\cdot\xi}$. After integrating by parts N times, derivatives of order N with respect to ξ reduce the symbol to order $m-N$. For $N > m+n$, the resulting integral is absolutely convergent. The same procedure may be repeated after differentiating in x and y. Thus $\mathbf{K}_{\mathrm{Op}(a)}$ is smooth off the diagonal

$$\Delta_{\mathbb{R}^n} := \{(x,x) \mid x \in \mathbb{R}^n\}.$$

An operator A is called **pseudolocal** if, for every distribution u on which it is defined,

$$\operatorname{sing\,supp}(Au) \subseteq \operatorname{sing\,supp}(u).$$

This property does not say that A is local: it only prevents it from creating singularities at points where the datum is smooth.

Thus a pseudodifferential operator can be nonlocal because its kernel is not supported on the diagonal, while remaining pseudolocal because that kernel is smooth off the diagonal. Extending the operator to general distributions and controlling supports also requires a global condition on the projections of its kernel.

Definition 15.2.1. (Proper support) Let N and M be smooth manifolds without boundary, let $\mathbf{E} \to N$ and $\mathbf{F} \to M$ be smooth vector bundles of finite rank, let

$$A\colon \Gamma_c(N,\mathbf{E}) \longrightarrow \Gamma(M,\mathbf{F})$$

be a continuous operator, also regarded as taking values in $\mathcal{D}'(M,\mathbf{F})$, and let $\mathbf{K}_A$ be its kernel on $M\times N$. We say that A is **properly supported** if both projections

$$\mathrm{pr}_M\colon \operatorname{supp}\mathbf{K}_A \longrightarrow M, \qquad \mathrm{pr}_N\colon \operatorname{supp}\mathbf{K}_A \longrightarrow N$$

are proper maps. Equivalently, for every compact subset K of either factor, the intersection of $\operatorname{supp}\mathbf{K}_A$ with the preimage of K has compact projection onto the other factor.

In this chapter's pseudodifferential calculus we take $N = M$; the formulation with two manifolds simply records that proper support is a condition on the kernel and its two projections.

This condition has two distinct consequences. Projection onto the source, pr_N, controls the support of Au when u has compact support. Projection onto the target, pr_M, allows Au to be defined for a distribution without compact support: local evaluation against a test function involves only a compact part of the distribution. In particular, a properly supported operator extends continuously

$$A\colon \Gamma_c(\mathbf{E}) \longrightarrow \Gamma_c(\mathbf{F}), \qquad A\colon \mathcal{D}'(N,\mathbf{E}) \longrightarrow \mathcal{D}'(M,\mathbf{F}),$$

if its local expression is pseudodifferential. The second extension is defined by duality with the properly supported transpose.

Proposition 15.2.2. (Decomposition with proper support) Let $U \subseteq \mathbb{R}^n$ be open, and let $r, s \in \mathbb{N}$ and $a \in S^m_{1,0}(U; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s))$. For the local operator $A = \mathrm{Op}(a)$, there exist a properly supported pseudodifferential operator A_0 of the same order and an operator R with smooth kernel such that $A = A_0 + R$. Moreover, A_0 has the same principal symbol as A.

Proof. Choose a function $\chi(x, y)$ equal to one on a neighborhood of the diagonal and supported in a properly supported neighborhood of it. Define $\mathbf{K}_{A_0} := \chi \mathbf{K}_A$. Then A_0 is properly supported. The amplitude $\chi(x, y)a(x, \xi)$ reduces to a symbol by Theorem 15.1.9. In its expansion, the term with $\alpha = 0$ is $a(x, \xi)$, and for $|\alpha| \geq 1$,

$$D_\xi^\alpha D_y^\alpha \left(\chi(x, y)a(x, \xi)\right)\big|_{y=x} = 0,$$

since χ is identically one on a neighborhood of the diagonal. Thus the reduced symbol differs from a by an element of $S^{-\infty}(U \times \mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s))$ and, in particular, has the same principal symbol. On the other hand, $(1 - \chi)\mathbf{K}_A$ is supported outside a neighborhood of the diagonal. The integrations by parts at the beginning of this section show that it is smooth. Thus $R = A - A_0$ has the asserted kernel. □

Definition 15.2.3. (Smoothing operator) Let $U \subseteq \mathbb{R}^n$ be open and let $r, s \in \mathbb{N}$. The class

$$\Psi^{-\infty}_{\mathrm{loc}}(U; \mathbb{C}^r, \mathbb{C}^s)$$

consists of continuous linear operators

$$A \colon C^\infty_c(U, \mathbb{C}^r) \longrightarrow C^\infty(U, \mathbb{C}^s)$$

whose Schwartz kernel, written relative to Lebesgue measure in the input variable, belongs to

$$C^\infty(U \times U; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s)).$$

Its elements are called **local smoothing operators**. Define

$$\Psi^{-\infty}(U; \mathbb{C}^r, \mathbb{C}^s) := \left\{ A \in \Psi^{-\infty}_{\mathrm{loc}}(U; \mathbb{C}^r, \mathbb{C}^s) \;\middle|\; \mathbf{K}_A \text{ is properly supported} \right\}. \tag{15.6}$$

Thus the notation without the subscript loc includes proper support.
On all of $\mathbb{R}^n$, if

$$a \in S^{-\infty}(\mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s)),$$

, the global Kohn–Nirenberg operator $\mathrm{Op}(a)$ has smooth kernel and, by Proposition 15.1.7, acts continuously from $\mathcal{S}'(\mathbb{R}^n, \mathbb{C}^r)$ to $C^\infty(\mathbb{R}^n, \mathbb{C}^s)$. This global statement imposes no proper-support condition; the operator belongs to $\Psi^{-\infty}(\mathbb{R}^n; \mathbb{C}^r, \mathbb{C}^s)$ only if its kernel also satisfies that condition.

Proposition 15.2.4. (Smoothing symbols and kernels) Let $U \subseteq \mathbb{R}^n$ be open, let $r, s \in \mathbb{N}$, and let A be a local pseudodifferential operator from $C^\infty_c(U, \mathbb{C}^r)$ to $C^\infty(U, \mathbb{C}^s)$. The following conditions are equivalent:

(a) every localization of A has a symbol in $S^{-\infty}(U \times \mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^r, \mathbb{C}^s))$;

(b) $\mathbf{K}_A$ is smooth near the diagonal;

(c) $\mathbf{K}_A$ belongs to $C^\infty(U\times U;\operatorname{Hom}(\mathbb{C}^r,\mathbb{C}^s))$, that is, $A\in\Psi^{-\infty}_{\mathrm{loc}}(U;\mathbb{C}^r,\mathbb{C}^s)$.

If A is properly supported, these conditions are also equivalent to $A\in\Psi^{-\infty}(U;\mathbb{C}^r,\mathbb{C}^s)$.

Proof. If a localization has symbol in $S^{-\infty}(U\times\mathbb{R}^n;\operatorname{Hom}(\mathbb{C}^r,\mathbb{C}^s))$, applying a total of q derivatives in x and y to the kernel produces only polynomial factors in ξ of degree at most q. Estimate (15.2) with $N>n+q$ yields an integrable majorant in $\mathbb{R}^n_\xi$; differentiation under the integral is therefore allowed, and the kernel is smooth near the diagonal. Every pseudodifferential kernel is smooth off the diagonal, as proved at the beginning of this section, so (b) implies (c).
Conversely, suppose (c) holds and choose $\chi(x,y)$ equal to one on a neighborhood of the diagonal, with properly supported support inside a coordinate localization. The partial transform

$$a_\chi(x,\xi):=\int_U e^{-i(x-y)\cdot\xi}\chi(x,y)\mathbf{K}_A(x,y)\,dy$$

is a rapidly decaying symbol. For multi-indices α,β, first use $(D_x+D_y)e^{-i(x-y)\cdot\xi}=0$ and integration by parts in y to obtain

$$D_x^\alpha D_\xi^\beta a_\chi(x,\xi)=(-i)^{|\beta|}\int_U e^{-i(x-y)\cdot\xi}(D_x+D_y)^\alpha\big((x-y)^\beta\chi(x,y)\mathbf{K}_A(x,y)\big)\,dy.$$

Since $(1-\Delta_y)^L e^{-i(x-y)\cdot\xi}=\langle\xi\rangle^{2L}e^{-i(x-y)\cdot\xi}$, a second integration by parts gives, for each compact set K in the variable x,

$$\sup_{x\in K}\|D_x^\alpha D_\xi^\beta a_\chi(x,\xi)\|\le C_{K,\alpha,\beta,L}\langle\xi\rangle^{-2L}.$$

Proper support of χ ensures that the variable y ranges over a compact set when $x\in K$. Since L is arbitrary, $a_\chi\in S^{-\infty}(U\times\mathbb{R}^n;\operatorname{Hom}(\mathbb{C}^r,\mathbb{C}^s))$. The corresponding operator has kernel $\chi\mathbf{K}_A$. The part $(1-\chi)\mathbf{K}_A$ is smooth for every pseudodifferential operator by the off-diagonal smoothness proved above. Thus every localization has a smoothing symbol, giving (a). The last assertion follows directly from Definition 15.2.3 upon adding proper support. □

Theorem 15.2.5. (Pseudolocality) If A is pseudodifferential and properly supported, then

$$\operatorname{sing\,supp}(Au)\subseteq\operatorname{sing\,supp}(u)$$

for every distribution u.

Proof. Let $x_0\notin\operatorname{sing\,supp}(u)$. Choose $\chi\in C_c^\infty$ equal to one on a neighborhood of the closure of an open set $W\ni x_0$ and supported in a region where u is smooth. Write $u=\chi u+(1-\chi)u$. The first term is a smooth compactly supported function, and $A(\chi u)$ is smooth by continuity of quantization. If $x\in W$ and $y\in\operatorname{supp}(1-\chi)$, then $x\neq y$; hence the pairs involved in $A((1-\chi)u)$ remain off the diagonal, where the kernel is smooth. Proper support allows y to be restricted to a compact set when evaluating locally, so pairing this smooth kernel with $(1-\chi)u$ depends smoothly on x. Thus Au is smooth on W. □

15.2.2 Composition

Amplitude reduction now closes the calculus under composition. The ordinary product of the symbols gives the leading term; mixed derivatives in x and ξ describe lower-order corrections.

Let $r_0, r_1, r_2 \in \mathbb{N}$, $A = \operatorname{Op}(a)$, and $B = \operatorname{Op}(b)$, with

$$a \in S^m_{1,0}(\mathbb{R}^n; \operatorname{Hom}(\mathbb{C}^{r_1}, \mathbb{C}^{r_2})), \qquad b \in S^\ell_{1,0}(\mathbb{R}^n; \operatorname{Hom}(\mathbb{C}^{r_0}, \mathbb{C}^{r_1})).$$

As operators on the Schwartz class, A and B can be composed without additional hypotheses. Substituting the integral formulas, first inserting compactly supported cutoffs and regrouping the phases, yields an oscillatory integral with an amplitude. After the change $z = x + y$ and $\eta = \zeta - \xi$, the composition symbol can be written as

$$(a\#b)(x,\xi) = (2\pi)^{-n} \operatorname{Os} \iint_{\mathbb{R}^n_y \times \mathbb{R}^n_\eta} e^{-iy\cdot\eta} a(x, \xi+\eta) b(x+y, \xi)\, dy\, d\eta.$$

The Taylor expansion of $b(x+y,\xi)$ in $y = 0$, followed by integration by parts in η, gives the following result.

Theorem 15.2.6. (Symbolic composition) Let $n, r_0, r_1, r_2 \in \mathbb{N}$ and $m, \ell \in \mathbb{R}$, and let

$$a \in S^m_{1,0}(\mathbb{R}^n; \operatorname{Hom}(\mathbb{C}^{r_1}, \mathbb{C}^{r_2})), \qquad b \in S^\ell_{1,0}(\mathbb{R}^n; \operatorname{Hom}(\mathbb{C}^{r_0}, \mathbb{C}^{r_1})).$$

As operators from $\mathcal{S}(\mathbb{R}^n, \mathbb{C}^{r_0})$ to $\mathcal{S}(\mathbb{R}^n, \mathbb{C}^{r_2})$,

$$\operatorname{Op}(a)\operatorname{Op}(b) = \operatorname{Op}(a\#b), \qquad a\#b \in S^{m+\ell}_{1,0}(\mathbb{R}^n; \operatorname{Hom}(\mathbb{C}^{r_0}, \mathbb{C}^{r_2})),$$

and

$$a\#b \sim \sum_{\alpha \in \mathbb{N}_0^n} \frac{i^{-|\alpha|}}{\alpha!} (D_\xi^\alpha a)(D_x^\alpha b).$$

In particular, $(a\#b)_{m+\ell} = a_m b_\ell$ for classical symbols. The same formulas apply to operators localized on an open set and to their extensions to distributions whenever proper support ensures that the composition is defined.

Proof. The preceding integral formula is first obtained with compactly supported cutoffs, where Fubini's theorem applies, and the cutoffs are then removed using oscillatory integral estimates. For $N \geq 1$, write

$$b(x+y,\xi) = \sum_{|\alpha|<N} \frac{y^\alpha}{\alpha!} D_x^\alpha b(x,\xi) + \sum_{|\alpha|=N} y^\alpha r_\alpha(x,y,\xi).$$

Here we use the integral Taylor remainder

$$r_\alpha(x,y,\xi) = \frac{N}{\alpha!} \int_0^1 (1-t)^{N-1} D_x^\alpha b(x+ty,\xi)\, dt, \qquad |\alpha| = N.$$

Since $y^\alpha e^{-iy\cdot\eta} = i^{|\alpha|} D_\eta^\alpha e^{-iy\cdot\eta}$, integration by parts makes $i^{-|\alpha|} D_\eta^\alpha$ act on $a(x,\xi+\eta)$. Integrating $e^{-iy\cdot\eta}$ against a function independent of y recovers evaluation at $\eta = 0$, producing the displayed terms.
The remaining part is a finite sum, for $|\alpha| = N$, of integrals in $t \in [0,1]$ whose amplitudes are

$$\frac{N i^{-N}}{\alpha!} (1-t)^{N-1} (D_\xi^\alpha a)(x,\xi+\eta)(D_x^\alpha b)(x+ty,\xi).$$

These amplitudes have order $m + \ell - N$ uniformly in t. The reduction estimate proved in Theorem 15.1.9

provides, for each seminorm of order P, another of finite order P' and a constant independent of t such that

$$q_{P,m+\ell-N}(r_N^{\#}) \le C_{P,N,m,\ell}\, q_{P',m}(a) q_{P',\ell}(b).$$

On an open set, use the same inequality on $K \Subset U$, replacing K on the right-hand side by a slightly larger compact set. Thus $r_N^{\#} \in S^{m+\ell-N}_{1,0}(\mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^{r_0}, \mathbb{C}^{r_2}))$. Since N is arbitrary, Lemma 15.1.5 completes the expansion. □

Corollary 15.2.7. (Commutators) Let $a \in S^m_{1,0}(\mathbb{R}^n)$ and $b \in S^\ell_{1,0}(\mathbb{R}^n)$ be scalar symbols, and suppose composition is defined in both orders. Then $[\mathrm{Op}(a), \mathrm{Op}(b)]$ has order at most $m+\ell-1$. More precisely,

$$a\#b - b\#a = \frac{1}{i}\{a,b\} + r, \qquad r \in S^{m+\ell-2}_{1,0}(\mathbb{R}^n),$$

where

$$\{a,b\} := \sum_{j=1}^{n} \left(\frac{\partial a}{\partial \xi_j}\frac{\partial b}{\partial x_j} - \frac{\partial a}{\partial x_j}\frac{\partial b}{\partial \xi_j} \right).$$

If, in addition, a and b are classical, the commutator is classical and its homogeneous component of order $m+\ell-1$ is

$$\frac{1}{i}\{a_m, b_\ell\} := \frac{1}{i}\sum_{j=1}^{n} \left(\frac{\partial a_m}{\partial \xi_j}\frac{\partial b_\ell}{\partial x_j} - \frac{\partial a_m}{\partial x_j}\frac{\partial b_\ell}{\partial \xi_j} \right).$$

If $r \in \mathbb{N}$,

$$a \in S^m_{\mathrm{cl}}\big(\mathbb{R}^n; M_{r\times r}(\mathbb{C})\big), \qquad b \in S^\ell_{\mathrm{cl}}\big(\mathbb{R}^n; M_{r\times r}(\mathbb{C})\big),$$

then the term of order $m+\ell$ is $[a_m, b_\ell]$. If it vanishes, the commutator has order at most $m+\ell-1$, and its homogeneous component of that degree is

$$[a_m, b_{\ell-1}] + [a_{m-1}, b_\ell] + \frac{1}{i}\sum_{j=1}^{n} \left(\frac{\partial a_m}{\partial \xi_j}\frac{\partial b_\ell}{\partial x_j} - \frac{\partial b_\ell}{\partial \xi_j}\frac{\partial a_m}{\partial x_j} \right).$$

In particular, if a_m and b_ℓ are scalar multiples of the identity, the two algebraic commutators in this formula vanish, leaving only the Poisson term.

Proof. The composition theorem gives

$$a\#b \sim \sum_{\alpha\in\mathbb{N}_0^n} \frac{i^{-|\alpha|}}{\alpha!}(D_\xi^\alpha a)(D_x^\alpha b), \qquad b\#a \sim \sum_{\alpha\in\mathbb{N}_0^n} \frac{i^{-|\alpha|}}{\alpha!}(D_\xi^\alpha b)(D_x^\alpha a).$$

In the scalar case, take the terms with $|\alpha| < 2$ in both expansions. The remainders belong to $S^{m+\ell-2}_{1,0}$, and the products without derivatives cancel because $ab = ba$. Thus

$$a\#b - b\#a = \frac{1}{i}\sum_{j=1}^{n}\big[(D_{\xi_j}a)(D_{x_j}b) - (D_{\xi_j}b)(D_{x_j}a)\big] + r = \frac{1}{i}\{a,b\} + r,$$

with $r \in S^{m+\ell-2}_{1,0}$. Each term in the sum has order at most $m+\ell-1$, proving the assertion without assuming

classicality.

If the scalar symbols are classical, at high frequencies we may write $a = a_m + a_{<m}$ and $b = b_\ell + b_{<\ell}$, where the remainders have orders $m-1$ and $\ell-1$. Poisson terms containing either remainder have order at most $m+\ell-2$. Thus the homogeneous component of order $m+\ell-1$ is $\frac{1}{i}\{a_m, b_\ell\}$. Composition of the classical expansions likewise gives the homogeneous components of lower orders.

For matrix-valued symbols, the same grouping must preserve the order of the factors. Degree $m+\ell$ is $a_m b_\ell - b_\ell a_m = [a_m, b_\ell]$. If it vanishes, the next degree is the sum of the derivative-free terms

$$[a_m, b_{\ell-1}] + [a_{m-1}, b_\ell]$$

and the terms with one derivative displayed in the statement. If both principal symbols are scalar multiples of the identity, these algebraic commutators vanish. □

15.2.3 Transpose and formal adjoint

Composition shows that the calculus is stable under chaining operators. The second operation needed for elliptic theory is the adjoint. At the kernel level, transposition interchanges x and y; in the Hermitian case one also takes the fiberwise adjoint. The resulting amplitude depends on y and is reduced by Theorem 15.1.9. We denote by $\operatorname{Op}(a)_h^*$ the formal Hermitian adjoint determined by the pairing of Schwartz sections.

Theorem 15.2.8. (Symbol of the adjoint) Let $n, r, s \in \mathbb{N}$, $m \in \mathbb{R}$, and

$$a \in S^m_{1,0}(\mathbb{R}^n; \operatorname{Hom}(\mathbb{C}^r, \mathbb{C}^s)).$$

. With respect to the inner products on $L^2(\mathbb{R}^n, \mathbb{C}^r)$ and $L^2(\mathbb{R}^n, \mathbb{C}^s)$ defined by Lebesgue measure and the standard Hermitian products,

$$\operatorname{Op}(a)_h^* = \operatorname{Op}(a^{(*)}),$$

where

$$a^{(*)} \in S^m_{1,0}(\mathbb{R}^n; \operatorname{Hom}(\mathbb{C}^s, \mathbb{C}^r))$$

and

$$a^{(*)}(x,\xi) \sim \sum_{\alpha \in \mathbb{N}_0^n} \frac{i^{-|\alpha|}}{\alpha!} D_\xi^\alpha D_x^\alpha \big(a(x,\xi)^*\big).$$

In particular,

$$a^{(*)} - a^* \in S^{m-1}_{1,0}(\mathbb{R}^n; \operatorname{Hom}(\mathbb{C}^s, \mathbb{C}^r)).$$

If a is classical, then so is $a^{(*)}$, and $(a^{(*)})_m = a_m^*$.

Proof. For $u \in \mathcal{S}(\mathbb{R}^n, \mathbb{C}^r)$ and $v \in \mathcal{S}(\mathbb{R}^n, \mathbb{C}^s)$, the kernel formula and regularized Fubini theorem give

$$\langle \operatorname{Op}(a)u, v\rangle = (2\pi)^{-n} \operatorname{Os} \iiint_{\mathbb{R}^n_x \times \mathbb{R}^n_y \times \mathbb{R}^n_\xi} \Big\langle u(y), e^{i(y-x)\cdot\xi} a(x,\xi)^* v(x) \Big\rangle \, dx\, dy\, d\xi.$$

Thus the adjoint amplitude is $a(y,\xi)^*$ after renaming the variables. Its reduction to a symbol is exactly the asserted expansion. The term with $\alpha = 0$ is a^*, and the remainder has order at most $m-1$. If a is classical,

substituting its homogeneous expansion and grouping terms of equal degree yields a classical expansion for $a^{(*)}$: each derivative in ξ lowers the degree by one, and at degree m only a^*_m remains. □

For a differential operator of integer order m, the principal Fourier component is $a_m = i^m \sigma_m(P)$. Thus

$$(a_m)^* = (-i)^m \sigma_m(P)^* = i^m \big((-1)^m \sigma_m(P)^*\big).$$

Removing the conversion factor i^m gives exactly

$$\sigma_m(P_h^*) = (-1)^m \sigma_m(P)^*$$

in Proposition 11.1.6. The apparent sign difference comes solely from the convention $D_j = \partial_j$ fixed at the beginning of the chapter.

Corollary 15.2.9. (The ideal of smoothing operators) Let $U \subseteq \mathbb{R}^n$ be open. If $R \in \Psi^{-\infty}(U;\mathbb{C}^r,\mathbb{C}^s)$, then $R_h^* \in \Psi^{-\infty}(U;\mathbb{C}^s,\mathbb{C}^r)$. If $A\colon C_c^\infty(U,\mathbb{C}^s) \to C^\infty(U,\mathbb{C}^q)$ and $B\colon C_c^\infty(U,\mathbb{C}^p) \to C^\infty(U,\mathbb{C}^r)$ are pseudodifferential operators with support conditions making the compositions well defined, then

$$AR \in \Psi^{-\infty}_{\mathrm{loc}}(U;\mathbb{C}^r,\mathbb{C}^q), \qquad RB \in \Psi^{-\infty}_{\mathrm{loc}}(U;\mathbb{C}^p,\mathbb{C}^s).$$

The compositions belong to the classes without the subscript loc when their kernels are properly supported; this holds, in particular, when the factors are properly supported.

Proof. At the symbol level, each term in the composition and adjoint expansions contains derivatives of a symbol of arbitrarily negative order. It therefore remains in $S^{-\infty}(U\times\mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^p,\mathbb{C}^q))$, with target spaces adjusted in each composition. The kernel formulation gives the same conclusion: composition integrates a smooth kernel against a kernel singular only on the diagonal, and proper support allows the integral to be taken and differentiated. □

15.2.4 Coordinate changes

The preceding formulas were obtained in Euclidean coordinates. For them to define a theory on manifolds, we must check that a change of chart transforms a pseudodifferential operator into another of the same order and that the principal component follows the expected cotangent rule. Let $\kappa\colon U \longrightarrow V$ be a diffeomorphism between Euclidean open sets, and let $T_\kappa u := u \circ \kappa$. If $A = \mathrm{Op}(a)$ acts on V, consider

$$\widetilde{A} := T_\kappa A T_\kappa^{-1}.$$

For $x, y \in U$ sufficiently close, define

$$B(x,y) := \int_0^1 D\kappa\big(y + t(x-y)\big)\, dt.$$

Hadamard's lemma 1.4.10, with base point y, gives the exact identity $\kappa(x) - \kappa(y) = B(x,y)(x-y)$ and also $B(x,x) = D\kappa(x)$. After the change of variables $z = \kappa(y)$ and $\xi = B(x,y)^T \eta$, the transformed operator has amplitude

$$\widetilde{b}(x,y,\xi) = a\big(\kappa(x), B(x,y)^{-T}\xi\big)\, \frac{|\det D\kappa(y)|}{|\det B(x,y)|}.$$

Away from the diagonal the kernel is smooth, so we may insert a cutoff and assume that $B(x,y)$ is invertible.

Theorem 15.2.10. (Invariance under coordinate changes) The operator $\widetilde{A}$ is pseudodifferential of the same order as A. If a is classical of order m, the transformed principal symbol is

$$\widetilde{a}_m(x,\xi) = a_m\big(\kappa(x), D\kappa(x)^{-T}\xi\big).$$

The full symbol is obtained by reducing $\widetilde{b}$ using Theorem 15.1.9 and depends on higher derivatives of κ.

Proof. The preceding formula shows that $\widetilde{b}$ is an amplitude of order m on each pair of compact coordinate sets. This follows from the chain rule: each derivative in ξ produces a factor B^{-T} and a derivative in the covariable of a, hence lowers the order; derivatives in x and y produce only smooth coefficients and spatial derivatives of a. Theorem 15.1.9 produces the full symbol; weights in that reduction are controlled by Peetre's inequality in Lemma 6.1.1. At $y = x$, the ratio of determinants equals one and $B(x,x) = D\kappa(x)$. The $\alpha = 0$ term of the reduction gives the principal formula, while each term with $|\alpha| \geq 1$ contains a derivative in ξ and has order at most $m-1$. □

This formula proves the two assertions needed globally. The full symbol is not an intrinsic function, because it changes by terms involving higher derivatives of the diffeomorphism. The principal component, however, transforms exactly by the cotangent action: if $\eta \in T^*_{\kappa(x)}V$ and $\xi = D\kappa(x)^T\eta$, then $\eta = D\kappa(x)^{-T}\xi$. It therefore defines a global object on the cotangent bundle.

Amplitude reduction controls the composition and adjoint remainders, while coordinate changes distinguish the chart-dependent full symbol from its cotangent principal component. This organization is presented in detail in [140, Chapter II, Sections 3–5] and, in a later, more compact treatment, in [141, Sections 0.2–0.4].

15.3 Pseudodifferential operators on manifolds

Invariance under coordinate changes allows us to leave the Euclidean model. The global definition will be local near the diagonal, supplemented by a proper-support condition when we wish to act on distributions without compact support.

Throughout this section, M is a finite-dimensional smooth manifold without boundary. It is not assumed compact, complete, or Riemannian until the subsection on geometric quantization. Let $\mathbf{E}, \mathbf{F} \to M$ be smooth complex vector bundles of finite rank. The real case follows by complexification and restriction.

15.3.1 Local definition and independence of choices

Let (U,κ) be a chart, and let $\mathbf{e} = (\mathbf{e}_1,\dots,\mathbf{e}_r)$ and $\mathbf{f} = (\mathbf{f}_1,\dots,\mathbf{f}_s)$ be local frames of $\mathbf{E}$ and $\mathbf{F}$. If $\chi, \psi \in C^\infty_c(U)$, the localized operator $\chi A \psi$ is represented, using the chart and frames, by a matrix of operators between functions compactly supported in $\kappa(U)$. Extension by zero after shrinking the supports allows it to be regarded on $\mathbb{R}^n$.

Definition 15.3.1. (Pseudodifferential operator on a manifold) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E}, \mathbf{F} \to M$ be smooth complex vector bundles of finite rank. For $m \in \mathbb{R}$, a continuous linear operator

$$A : \Gamma_c(M,\mathbf{E}) \longrightarrow \Gamma(M,\mathbf{F})$$

belongs to $\Psi^m_{\mathrm{loc}}(M;\mathbf{E},\mathbf{F})$ if the following two conditions hold:

(a) the kernel $\mathbf{K}_A$ is smooth off Δ_M;

(b) for every chart (U,κ), every pair of local frames of $\mathbf{E}$ and $\mathbf{F}$ over U, and all $\chi,\psi\in C_c^\infty(U)$, each entry of the Euclidean representation of $\chi A\psi$ is $\mathrm{Op}(a_{ba})$ with $a_{ba}\in S^m_{1,0}(\kappa(U))$, modulo an operator with smooth kernel.

If the representations can be chosen classical, write $\Psi^m_{\mathrm{cl,loc}}(M;\mathbf{E},\mathbf{F})$. Denote by

$$\Psi^m(M;\mathbf{E},\mathbf{F})\subseteq\Psi^m_{\mathrm{loc}}(M;\mathbf{E},\mathbf{F})$$

the subclass of properly supported operators. This latter notation will be used for composition and global action on distributions.

Definition 15.3.2. (Smoothing operators on a manifold) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E},\mathbf{F}\to M$ be smooth complex vector bundles of finite rank. Define

$$\Psi^{-\infty}_{\mathrm{loc}}(M;\mathbf{E},\mathbf{F}):=\left\{A\in\Psi^m_{\mathrm{loc}}(M;\mathbf{E},\mathbf{F})\text{ for some }m\in\mathbb{R}\;\middle|\;\mathbf{K}_A\text{ is smooth on }M\times M\right\}.$$

Proposition 15.2.4, applied in charts and frames, shows that an element of this class locally belongs to every order. The properly supported class is

$$\Psi^{-\infty}(M;\mathbf{E},\mathbf{F}):=\left\{A\in\Psi^{-\infty}_{\mathrm{loc}}(M;\mathbf{E},\mathbf{F})\;\middle|\;\mathbf{K}_A\text{ is properly supported}\right\}. \tag{15.7}$$

If M is closed, the two classes coincide. If M is noncompact, smoothness of the kernel implies neither proper support nor, after a Riemannian metric and Hermitian bundle metrics are chosen, compactness of the operator $L^2(M,\mathbf{E})\longrightarrow L^2(M,\mathbf{F})$.

The definition uses charts, frames, and cutoffs, but these choices merely express the kernel locally. The following result shows that it suffices to verify the definition in a trivializing atlas and that the resulting class is intrinsic.

Theorem 15.3.3. (Independence of charts, frames, and cutoffs) Let M be a finite-dimensional smooth manifold without boundary, let $\mathbf{E},\mathbf{F}\to M$ be smooth complex vector bundles of finite rank, and let $m\in\mathbb{R}$. Definition 15.3.1 is independent of the atlas, local frames, and cutoffs. Moreover, every $A\in\Psi^m_{\mathrm{loc}}(M;\mathbf{E},\mathbf{F})$ can be written as $A=A_0+R$, where $A_0\in\Psi^m(M;\mathbf{E},\mathbf{F})$ and $R\in\Psi^{-\infty}_{\mathrm{loc}}(M;\mathbf{E},\mathbf{F})$.

Proof. Consider two overlapping charts. After inserting cutoffs whose supports remain inside the overlap, the representations are conjugate by the transition diffeomorphism. Theorem 15.2.10 shows that conjugation preserves the order and the classical class. A change of frame in $\mathbf{E}$ or $\mathbf{F}$ multiplies the operator on the right or left by a smooth matrix. Theorem 15.2.6, applied to symbols independent of ξ, again shows that the order is preserved. Changing a cutoff yields a difference supported where the two variables are distinct, or another smooth multiplication; in the first case the kernel is smooth, and in the second the composition calculus applies.

For the last assertion, choose a properly supported neighborhood $\mathcal{U}$ of the diagonal and a cutoff $\rho\in C^\infty(M\times$

M) equal to one near Δ_M with $\operatorname{supp}\rho \subseteq \mathcal{U}$. Existence follows from a locally finite cover by relatively compact open sets and a partition of unity. The kernel $\rho\mathbf{K}_A$ defines A_0 and is properly supported; $(1-\rho)\mathbf{K}_A$ is smooth because it is separated from the diagonal. □

The distinction between the two classes is not merely typographical. On a noncompact manifold, the purely local definition does not control kernel behavior when both variables leave every compact set. Without proper support, a composition may be undefined even when both factors are locally pseudodifferential. On a closed manifold, every projection of a closed subset of $M \times M$ is proper, so the distinction disappears.

15.3.2 The global principal symbol

Once independence of local choices has been established, the principal homogeneous components can be glued over the cotangent bundle. The result is the global object that will preserve composition, adjoints, and ellipticity.

Let $\pi\colon T^*M \longrightarrow M$ be the projection and 0_M the zero section. In a chart and local frames, a classical operator $A \in \Psi^m_{\mathrm{cl,loc}}(M;\mathbf{E},\mathbf{F})$ has a principal component $a_m(x,\xi)$. Theorem 15.2.10 and the frame transformation show that, on overlaps, these components satisfy exactly the transformation rule for a bundle homomorphism

$$\pi^*\mathbf{E} \longrightarrow \pi^*\mathbf{F}$$

over $T^*M \setminus 0_M$.

Definition 15.3.4. (Pseudodifferential principal symbol) Let M be a finite-dimensional smooth manifold without boundary, let $\mathbf{E},\mathbf{F} \to M$ be smooth complex vector bundles of finite rank, and let $\pi\colon T^*M \to M$. For $A \in \Psi^m_{\mathrm{cl,loc}}(M;\mathbf{E},\mathbf{F})$, the **principal Fourier symbol** of A is the smooth section

$$\sigma^{\Psi}_m(A) \in \Gamma\big(T^*M \setminus 0_M, \operatorname{Hom}(\pi^*\mathbf{E},\pi^*\mathbf{F})\big)$$

whose local expression is a_m. It satisfies

$$\sigma^{\Psi}_m(A)(x,t\xi) = t^m \sigma^{\Psi}_m(A)(x,\xi), \qquad t>0.$$

For a differential operator P of order m, the exact compatibility with Chapter 11 is

$$\sigma^{\Psi}_m(P)(x,\xi) = i^m \sigma_m(P)(x,\xi). \tag{15.8}$$

The factor i^m must not be omitted from this equality, because the convention $D_j = \partial_j$ was fixed. Since this factor is a nonzero scalar, the two notions of ellipticity coincide. The earlier composition and adjoint rules are also recovered exactly, as checked after Theorem 15.2.8.

Example 15.3.5. (The Dirac operator as a pseudodifferential operator) Let M be a Riemannian manifold without boundary, and let $D = c \circ \nabla^{\mathbf{S}}$ be a Dirac-type operator constructed in Section 8.3. Every differential operator of order one is a properly supported classical pseudodifferential operator; thus

$$D \in \Psi^1_{\mathrm{cl}}(M;\mathbf{S},\mathbf{S}).$$

Combining (15.8) with (11.2) gives, with this chapter's Fourier convention,

$$\sigma_1^{\Psi}(D)(x,\xi) = i\,c(\xi). \tag{15.9}$$

For $\xi \neq 0$, this homomorphism is invertible and

$$\big(\sigma_1^{\Psi}(D)(x,\xi)\big)^{-1} = \frac{i\,c(\xi)}{|\xi|_{\mathbf{g}}^2},$$

since $(i\,c(\xi))^2 = |\xi|_{\mathbf{g}}^2 I$. If $\mathbf{S}$ is graded, the same formula restricted to $\mathbf{S}_x^+ \to \mathbf{S}_x^-$ is the pseudodifferential symbol of D^+.

Definition 15.3.6. (Space of principal symbols) Let M be a finite-dimensional smooth manifold without boundary, let $\mathbf{E},\mathbf{F} \to M$ be smooth complex vector bundles of finite rank, and let $\pi\colon T^*M \to M$. Let $\mathcal{S}^m_{\mathrm{hom}}(T^*M;\mathrm{Hom}(\mathbf{E},\mathbf{F}))$ be the space of smooth sections of $\mathrm{Hom}(\pi^*\mathbf{E},\pi^*\mathbf{F})$ over $T^*M \setminus 0_M$ that are homogeneous of degree m under positive fiber dilations.

Theorem 15.3.7. (Exact sequence of the principal symbol) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E},\mathbf{F},\mathbf{G} \to M$ be smooth complex vector bundles of finite rank. For every $m \in \mathbb{R}$, there is an exact sequence

$$0 \longrightarrow \Psi^{m-1}_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F}) \longrightarrow \Psi^{m}_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F}) \xrightarrow{\sigma^{\Psi}_m} \mathcal{S}^m_{\mathrm{hom}}(T^*M;\mathrm{Hom}(\mathbf{E},\mathbf{F})) \longrightarrow 0.$$

Moreover, for every $\ell \in \mathbb{R}$, if $A \in \Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$ and $B \in \Psi^{\ell}_{\mathrm{cl}}(M;\mathbf{G},\mathbf{E})$, then

$$\sigma^{\Psi}_{m+\ell}(AB) = \sigma^{\Psi}_m(A) \circ \sigma^{\Psi}_{\ell}(B)$$

and, when Hermitian bundle metrics and a density have been fixed to define the adjoint,

$$\sigma^{\Psi}_m(A_h^*) = \sigma^{\Psi}_m(A)^*.$$

Proof. Well-definedness and the two compatibility statements follow from Theorems 15.2.10, 15.2.6, and 15.2.8. If A has order at most $m-1$, its homogeneous component of degree m vanishes. Conversely, if this component vanishes in every chart, the definition of a classical symbol shows that each local representative satisfies estimates of order $m-1$; hence $A \in \Psi^{m-1}_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$.

For surjectivity, choose an auxiliary metric on T^*M, a cutoff vanishing on a neighborhood of 0_M, a locally finite trivializing cover, and a partition of unity. In each chart, quantize the given homogeneous component multiplied by the cutoff, and sum using a quadratic system of localization functions. The sum is locally finite and can be made properly supported by inserting a cutoff near the diagonal. On overlaps, Theorem 15.2.10 shows that the terms of degree m glue to the original section; discrepancies have order at most $m-1$. The resulting global operator has the prescribed symbol. □

15.3.3 The conormal bundle of the diagonal

The definition by symbols still depends on a local quantization. There is an equivalent description using only the kernel: classical pseudodifferential operators are exactly those whose kernels are conormal to the diagonal. To formulate this equivalence, we first fix the order and density conventions for a general submanifold.

Let X be a smooth manifold without boundary of dimension d, let $Y \subseteq X$ be an embedded submanifold without boundary of codimension k, and let $\mathbf{G} \to X$ be a smooth complex vector bundle of finite rank $r_{\mathbf{G}}$. Its normal and conormal bundles are

$$NY := \operatorname{coker}\big(TY \hookrightarrow TX|_Y\big), \qquad N^*Y := \{(y,\eta) \in T^*X|_Y \mid \eta|_{T_yY} = 0\}.$$

Let $\pi_Y \colon N^*Y \to Y$ denote the projection and $\boldsymbol{\mathcal{D}}_1(Y)$ the bundle of weight-one densities from Definition 2.14.14. A chart $(y,z) \in \mathbb{R}^{d-k} \times \mathbb{R}^k$ is **adapted to** Y if Y is given by $z = 0$. In this chart, conormal covectors are precisely $(y,0;0,\theta)$.

Definition 15.3.8. (Conormal distribution) A distribution $u \in \mathcal{D}'(X,\mathbf{G})$ is **classical conormal to** Y **of order** m, written

$$u \in I^m(X,Y;\mathbf{G}),$$

if it is smooth on $X \setminus Y$ and, in every localization in an adapted chart and a trivialization of G, can be written modulo a smooth section as

$$u = \left[(2\pi)^{-k} \operatorname{Os}\int_{\mathbb{R}^k_\theta} e^{iz\cdot\theta} b(y,z,\theta)\, d\theta\right] |dy\, dz|, \qquad b \in S^{m+\frac{d-2k}{4}}_{\mathrm{cl}}\big(\mathbb{R}^d_{(y,z)} \times \mathbb{R}^k_\theta; \mathbb{C}^{r_{\mathbf{G}}}\big). \tag{15.10}$$

Here $|dy\,dz|$ records the coordinate density implicit in the convention defining distributions as functionals on test sections of the dual bundle. This factor is suppressed in Euclidean formulas but must be retained when analyzing coordinate changes. After localization, the amplitude is taken compactly supported in the spatial variables. The number m is the **conormal order**; the shift $\frac{d-2k}{4}$ adapts Hörmander's convention to the operator order used on the diagonal.

The definition is independent of adapted coordinates, as the following calculation shows. Let

$$\widetilde{y} = \varphi(y,z), \qquad \widetilde{z} = \psi(y,z)$$

be two adapted systems related by the diffeomorphism $\Phi = (\varphi,\psi)$. The identity $\psi(y,0) = 0$ and Hadamard's lemma 1.4.10, applied with y as parameter, give the exact factorization

$$\psi_a(y,z) = \sum_{b=1}^{k} C_{ab}(y,z) z_b, \qquad C_{ab}(y,z) := \int_0^1 \partial_{z_b}\psi_a(y,tz)\, dt. \tag{15.11}$$

In particular, $C(y,0) = D_z\psi(y,0)$. Since

$$D\Phi(y,0) = \begin{pmatrix} D_y\varphi(y,0) & D_z\varphi(y,0) \\ 0 & C(y,0) \end{pmatrix}$$

is invertible, so are $A(y) := D_y\varphi(y,0)$ and $C(y,0)$. After shrinking the chart, $C(y,z)$ remains invertible. For each

fixed (y,z), the linear substitution

$$\theta = C(y,z)^{T}\widetilde{\theta}, \qquad d\theta = |\det C(y,z)|\, d\widetilde{\theta} \tag{15.12}$$

is exact and satisfies $z\cdot\theta = \widetilde{z}\cdot\widetilde{\theta}$. If $T(y,z)$ denotes the matrix taking the components of G in the original frame to those in the new frame, the transformed amplitude is

$$\widetilde{b}(\widetilde{y},\widetilde{z},\widetilde{\theta}) := T(y,z)\,b\big(y,z,C(y,z)^{T}\widetilde{\theta}\big)\,|\det C(y,z)|\,|\det D\Phi(y,z)|^{-1}, \qquad (y,z)=\Phi^{-1}(\widetilde{y},\widetilde{z}). \tag{15.13}$$

Indeed, the last determinant is exactly the one that converts $|dy\,dz|$ into $|d\widetilde{y}\,d\widetilde{z}|$. To check the order, first apply derivatives in $\widetilde{\theta}$ and then spatial derivatives. The Leibniz and chain rules express each derivative of $b\big(\Phi^{-1}(\widetilde{y},\widetilde{z}),C^{T}\widetilde{\theta}\big)$ as a finite sum of terms

$$A_{\alpha,\beta,\gamma;\delta,\nu,\rho}(\widetilde{y},\widetilde{z})\,\widetilde{\theta}^{\rho}\,(D_{y,z}^{\delta}D_{\theta}^{\nu}b)\big(y,z,C(y,z)^{T}\widetilde{\theta}\big),$$

where $(y,z)=\Phi^{-1}(\widetilde{y},\widetilde{z})$ and

$$|\nu| = |\gamma| + |\rho|, \qquad |\delta| + |\rho| \le |\alpha| + |\beta|.$$

Indeed, a spatial derivative hitting b increases $|\delta|$; if it hits $C^{T}\widetilde{\theta}$, it creates both a linear factor in $\widetilde{\theta}$ and a derivative in θ; if it hits a coefficient, it merely differentiates that coefficient. This proves both relations by induction on $|\alpha|+|\beta|$. Uniform invertibility of C on each localized compact set gives $c\langle\widetilde{\theta}\rangle \le \langle C^{T}\widetilde{\theta}\rangle \le C\langle\widetilde{\theta}\rangle$. The factor $\widetilde{\theta}^{\rho}$ is offset by the $|\rho|$ additional derivatives in θ. Since the remaining factors in (15.13) are smooth, for all multi-indices α,β,γ there is a constant $C_{\alpha,\beta,\gamma}>0$ such that

$$\big\| D_{\widetilde{y}}^{\alpha} D_{\widetilde{z}}^{\beta} D_{\widetilde{\theta}}^{\gamma}\widetilde{b}\big\| \le C_{\alpha,\beta,\gamma}\langle\widetilde{\theta}\rangle^{m+\frac{d-2k}{4}-|\gamma|}.$$

Each homogeneous component transforms by the same formula; thus (15.13) belongs to the same classical class. Applying the calculation to Φ^{-1} proves the reverse implication.

The principal coefficient alone is not a canonical function. If $\mu = m+\frac{d-2k}{4}$ and b_{μ} is the principal homogeneous component, then

$$b_{\mu}(y,0,\theta)|dy| \tag{15.14}$$

defines a homogeneous section of degree μ of

$$\pi_{Y}^{*}\big(G\restriction_{Y}\otimes\boldsymbol{\mathcal{D}}_{1}(Y)\big) \quad \text{on } N^{*}Y\setminus 0_{Y},$$

modulo the next degree. This is the **principal conormal symbol** in the density convention fixed above. To verify invariance, restrict (15.13) to $z=0$. The triangular form of $D\Phi(y,0)$ implies

$$|\det D\Phi(y,0)| = |\det A(y)|\,|\det C(y,0)|,$$

and hence

$$\widetilde{b}_{\mu}\big(\varphi(y,0),0,\widetilde{\theta}\big) = T(y,0)\,b_{\mu}\big(y,0,C(y,0)^{T}\widetilde{\theta}\big)\,|\det A(y)|^{-1} \quad \bmod \{\text{conormal symbols of degree at most } \mu-1\}. \tag{15.15}$$

Since $|d\widetilde{y}| = |\det A(y)|\,|dy|$ on Y, multiplying (15.15) by $|d\widetilde{y}|$ cancels the sole remaining determinant. In turn,

$\theta = C(y,0)^{T}\widetilde{\theta}$ is exactly the coordinate transformation rule in $N^{*}Y$. Thus $b_{\mu}(y,0,\theta)|dy|$ defines the asserted global section. This verification explains why omitting the density line would produce a noncanonical object.

The normal phases used in adapted charts are related by the homogeneous linear substitution (15.12). Since no additional phase variables are introduced, the changes are fully described by the cotangent rule and the preceding densities. With this convention, the normalization agrees with [84, Theorems 18.2.8–18.2.11]: in ambient dimension d and codimension k, a conormal distribution of order m is represented by an amplitude of order $m + \frac{d-2k}{4}$.

For $X = M \times M$ and $Y = \Delta_M$, the tangent space at (x,x) consists of pairs (v,v). A covector (ξ,η) annihilates it if and only if $\xi(v) + \eta(v) = 0$ for every $v \in T_x M$. Thus

$$N^{*}\Delta_M = \{(x,\xi;x,-\xi) \mid x \in M,\ \xi \in T_x^{*}M\}. \tag{15.16}$$

This is the geometric reason that the cotangent bundle, rather than the tangent bundle, parametrizes the kernel's oscillations.

In this case $d = 2n$ and $k = n$, so the shift in Definition 15.3.8 is $\frac{2n-2n}{4} = 0$. A distribution $\mathbf{K} \in I^{m}(M \times M, \Delta_M; \mathbf{F} \boxtimes \mathbf{E}^{*})$ therefore has the local expression, modulo a smooth section,

$$(2\pi)^{-n}\,\mathrm{Os}\int_{\mathbb{R}^n_\xi} e^{i(x-y)\cdot\xi}\, b(x,y,\xi)\, d\xi, \qquad b \text{ classical amplitude of order } m.$$

The bundle $\boldsymbol{\mathcal{D}}_1$ of Definition 2.14.14 supplies the required density factor. To relate it to an operator kernel, temporarily fix a positive density ν on M and use ν both to identify smooth sections with distributions and to write integration in the input variable. The principal conormal symbol of the kernel on the diagonal then takes values in

$$\mathrm{Hom}(\mathbf{E},\mathbf{F}) \otimes \boldsymbol{\mathcal{D}}_1(\Delta_M).$$

The identification $\Delta_M \cong M$ and division by ν produce a section of $\mathrm{Hom}(\pi^{*}\mathbf{E}, \pi^{*}\mathbf{F})$. If $\widetilde{\nu} = f\nu$, the kernel coefficient relative to integration in the input variable acquires $f(y)^{-1}$, which cancels with the new integration density $f(y)\nu(y)$. Pairing in the output variable, in contrast, multiplies the kernel distribution by $f(x)$; its conormal symbol on the diagonal therefore acquires $f \restriction_{\Delta_M}$, and the final division by $\widetilde{\nu} = f\nu$ cancels exactly this factor. The normalized section is consequently independent of ν. In a chart, taking the coordinate density, this section is precisely the homogeneous component of the Kohn–Nirenberg amplitude. Thus normalization by the density preserves the operator order and produces an intrinsic principal conormal symbol.

Theorem 15.3.9. (Characterization by conormal kernels) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E}, \mathbf{F} \to M$ be smooth complex vector bundles of finite rank. Let

$$A \colon \Gamma_c(M,\mathbf{E}) \longrightarrow \Gamma(M,\mathbf{F})$$

be a continuous properly supported operator. The following conditions are equivalent:

(a) $A \in \Psi^{m}_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$;

(b) $\mathbf{K}_A \in I^{m}(M \times M, \Delta_M; \mathbf{F} \boxtimes \mathbf{E}^{*})$.

The equivalence preserves the principal symbol: the homogeneous component of the conormal amplitude, restricted to $N^{*}\Delta_M$ by (15.16) and normalized by the density as explained above, is $\sigma^{\Psi}_{m}(A)$.

Proof. Suppose (a) holds. In a chart and local frames, the kernel formula for $\mathrm{Op}(a)$ is an oscillatory representation with amplitude $a(x,\xi)$. Chart changes transform the phase and amplitude as in the proof of Theorem 15.2.10; the principal component follows the cotangent rule. Off the diagonal, the integrations by parts in the first subsection of 15.2 yield smoothness. Thus (b) holds.
Conversely, suppose (b) holds. Each local conormal representation defines an operator with amplitude of order m. Theorem 15.1.9 reduces it to a classical symbol of that order. The remaining smooth term is smoothing by Proposition 15.2.4. This gives (a). In both directions, the $\alpha = 0$ term of amplitude reduction preserves the principal homogeneous component; the other terms contain at least one derivative in ξ and lower the order. This proves the last assertion. □

Combining the preceding theorem with Theorem 15.1.9 gives a precise equivalence among the three descriptions:

$$\begin{aligned} \text{classical symbol of order } m &\iff \text{classical amplitude of order } m,\\ \text{classical amplitude of order } m &\iff \text{conormal kernel of order } m \text{ to } \Delta_M. \end{aligned}$$

The first equivalence is exact at the operator level and determines the full symbols, in each chart and frames, modulo the corresponding class $S^{-\infty}(U\times\mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$; the second is exact modulo smooth kernels. The principal symbol is exactly the same global object in all three formulations.

15.4 Riemannian quantization via the exponential map

The preceding global definition is obtained by localizing Kohn–Nirenberg quantization. Once a metric and bundle connections are fixed, one can also construct a geometric quantization: the difference $x-y$ is replaced by the vector $\exp_x^{-1}(y)$, and fibers are compared by parallel transport. This formulation does not remove coordinates from the proofs, but clearly separates the geometric choices from the symbolic part.

Now suppose that $(M,\mathbf{g})$ is Riemannian and without boundary, but not necessarily complete or compact. Let $\mathbf{E},\mathbf{F}$ be complex vector bundles with Hermitian bundle metrics and compatible connections. There is an open neighborhood $\mathcal{V}$ of the zero section of TM on which

$$(x,v)\longmapsto(x,\exp_x v)$$

is a diffeomorphism onto a neighborhood $\mathcal{U}$ of Δ_M. This assertion is local around each $(x,0)$ and is globalized by shrinking a locally finite cover; it requires no uniform injectivity radius. Write

$$\ell(x,y):=\exp_x^{-1}(y)\in T_xM,\qquad (x,y)\in\mathcal{U}.$$

Let $\tau^{\mathbf{E}}_{x\leftarrow y}\colon \mathbf{E}_y\longrightarrow\mathbf{E}_x$ be parallel transport along the radial geodesic $t\mapsto\exp_x(t\ell(x,y))$. Choose a properly supported $\chi\in C^\infty(M\times M)$, supported in $\mathcal{U}$ and equal to one near the diagonal. The metric induces Lebesgue measures dv_x on T_xM and $d\xi_x$ on T_x^*M.

By the construction in Subsection 2.7.1, the Levi–Civita connection determines the horizontal–vertical decomposition of $T(T^*M)$, while the connections on $\mathbf{E}$ and $\mathbf{F}$ induce the pullback connection on $\pi^*\mathrm{Hom}(\mathbf{E},\mathbf{F})\to T^*M$. Differentiating with this connection in horizontal and vertical directions gives the derivatives ∇^{H} and ∇^{V} defined in (2.67). Write $\langle\xi\rangle_{\mathbf{g}}=(1+\|\xi\|_{\mathbf{g}}^2)^{\frac12}$.

Fix a chart $(U,x^1,\dots,x^n)$, the induced coordinates (x,ξ) determined by $\xi=\xi_j dx^j$, and frames $\mathbf{e}=(\mathbf{e}_1,\dots,\mathbf{e}_r)$ and

$\mathbf{f} = (\mathbf{f}_1, \dots, \mathbf{f}_s)$ of $\mathbf{E}$ and $\mathbf{F}$. Adopt the conventions

$$\nabla^{\mathbf{E}}_{\partial_i} \mathbf{e}_\alpha = \sum_{\gamma=1}^{r} \mathbf{e}_\gamma (\omega_i^{\mathbf{E}})_{\gamma\alpha}, \qquad \nabla^{\mathbf{F}}_{\partial_i} \mathbf{f}_b = \sum_{c=1}^{s} \mathbf{f}_c (\omega_i^{\mathbf{F}})_{cb}, \qquad \nabla_{\partial_i} \partial_j = \Gamma_{ij}^k \partial_k.$$

Proposition 2.7.27 derived the sign in the formula

$$H_i = D_{x^i} + \sum_{j,k=1}^{n} \Gamma_{ij}^k(x) \xi_k D_{\xi_j};$$

from the covector parallel-transport equation; this is identity (2.65). In particular, if $\mathbf{a} \in \Gamma(\pi^* \operatorname{Hom}(\mathbf{E}, \mathbf{F})|_{T^*U})$ and we also denote its local matrix by $\mathbf{a}(x, \xi)$, Proposition 2.7.28 gives

$$\nabla^{\mathrm{V}}_j \mathbf{a} = D_{\xi_j} \mathbf{a}, \qquad \nabla^{\mathrm{H}}_i \mathbf{a} = H_i \mathbf{a} + \omega_i^{\mathbf{F}} \mathbf{a} - \mathbf{a} \omega_i^{\mathbf{E}};$$

these are identities (2.68).

To iterate these operations intrinsically, introduce the bundles

$$\mathscr{T}^{p,q} := \pi^* \left((T^*M)^{\otimes p} \otimes (TM)^{\otimes q} \otimes \operatorname{Hom}(\mathbf{E}, \mathbf{F}) \right).$$

The Levi–Civita connection on the tensor factors, the connection on $\operatorname{Hom}(\mathbf{E}, \mathbf{F})$, and the horizontal–vertical decomposition induce

$$\nabla^{\mathrm{H}} \colon \Gamma(\mathscr{T}^{p,q}) \longrightarrow \Gamma(\mathscr{T}^{p+1,q}), \qquad \nabla^{\mathrm{V}} \colon \Gamma(\mathscr{T}^{p,q}) \longrightarrow \Gamma(\mathscr{T}^{p,q+1}).$$

As in Chapter 9, the new index is added at the beginning of the corresponding horizontal or vertical block. If T has components $T_{i_1 \cdots i_p;}{}^{j_1 \cdots j_q}$, then

$$\begin{aligned} \left((\nabla^{\mathrm{H}} T)_{i i_1 \cdots i_p;} \right)^{j_1 \cdots j_q} &= H_i T_{i_1 \cdots i_p;}{}^{j_1 \cdots j_q} + \omega_i^{\mathbf{F}} T_{i_1 \cdots i_p;}{}^{j_1 \cdots j_q} - T_{i_1 \cdots i_p;}{}^{j_1 \cdots j_q} \omega_i^{\mathbf{E}} \\ &\quad - \sum_{a=1}^{p} \Gamma_{i i_a}^k T_{i_1 \cdots k \cdots i_p;}{}^{j_1 \cdots j_q} + \sum_{b=1}^{q} \Gamma_{ik}^{j_b} T_{i_1 \cdots i_p;}{}^{j_1 \cdots k \cdots j_q}, \end{aligned} \tag{15.17}$$

$$\left((\nabla^{\mathrm{V}} T)_{i_1 \cdots i_p;} \right)^{j j_1 \cdots j_q} = D_{\xi_j} T_{i_1 \cdots i_p;}{}^{j_1 \cdots j_q}. \tag{15.18}$$

In particular, $\nabla^{\mathrm{H}} a$ takes values in $\pi^* T^*M \otimes \pi^* \operatorname{Hom}(\mathbf{E}, \mathbf{F})$, whereas $\nabla^{\mathrm{V}} a$ takes values in $\pi^* TM \otimes \pi^* \operatorname{Hom}(\mathbf{E}, \mathbf{F})$. The subscript on ∇^{V}_j in the preceding directional formula labels the vertical direction $\mathbf{d}x^j$; it is not a covariant index of the vertical tensor. Define

$$(\nabla^{\mathrm{H}})^p (\nabla^{\mathrm{V}})^q a \in \Gamma(\mathscr{T}^{p,q})$$

by applying first the q vertical derivatives and then the p horizontal derivatives, always using the preceding tensorial recurrence.

To record the order of differentiation without assuming commutativity, let $\mathfrak{W}_p := \{1, \dots, n\}^p$, with $\mathfrak{W}_0 := \{\varnothing\}$. For words $I = (i_1, \dots, i_p) \in \mathfrak{W}_p$ and $J = (j_1, \dots, j_q) \in \mathfrak{W}_q$, set

$$\nabla^{\mathrm{H}}_I := \nabla^{\mathrm{H}}_{i_1} \cdots \nabla^{\mathrm{H}}_{i_p}, \qquad \nabla^{\mathrm{V}}_J := \nabla^{\mathrm{V}}_{j_1} \cdots \nabla^{\mathrm{V}}_{j_q}. \tag{15.19}$$

These expressions are deliberately directional compositions, not components of a tensorial derivative. The word

preserves the order; in particular, I is not replaced by a multi-index, nor are letters commuted. Only to count the vertical derivatives do we write $\beta(J) := e_{j_1} + \cdots + e_{j_q} \in \mathbb{N}_0^n$.

Proposition 15.4.1. (Horizontal–vertical commutators) In a coordinate chart and the preceding local frames, the directional compositions satisfy

$$[\nabla_j^{\mathrm{V}}, \nabla_\ell^{\mathrm{V}}]a = 0, \tag{15.20}$$

$$[\nabla_i^{\mathrm{H}}, \nabla_j^{\mathrm{V}}]a = -\Gamma_{ik}^{j} \nabla_k^{\mathrm{V}} a, \tag{15.21}$$

$$[\nabla_i^{\mathrm{H}}, \nabla_j^{\mathrm{H}}]a = \mathbf{R}^{\mathbf{F}}(\partial_i, \partial_j)a - a\mathbf{R}^{\mathbf{E}}(\partial_i, \partial_j) + R_{ij\ell}{}^{k} \xi_k \nabla_\ell^{\mathrm{V}} a. \tag{15.22}$$

In particular, the order of a word can be changed only at the cost of the curvature and vertical-order terms displayed here.

Proof. The first identity follows from commutation of the derivatives D_{ξ_j}. Since $H_i = D_{x^i} + \Gamma_{i\ell}^{k} \xi_k D_{\xi_\ell}$,

$$[H_i, D_{\xi_j}] = -\Gamma_{i\ell}^{j} D_{\xi_\ell}, \qquad [H_i, H_j] = R_{ij\ell}{}^{k} \xi_k D_{\xi_\ell}.$$

Adding the connection matrices gives curvature $\mathbf{R}^{\mathbf{F}}(\partial_i, \partial_j)a - a\mathbf{R}^{\mathbf{E}}(\partial_i, \partial_j)$ on $\operatorname{Hom}(\mathbf{E}, \mathbf{F})$. These three identities yield (15.20)–(15.22). □

The following result follows the triangular scheme of Lemma 9.1.28; here we must also record the vertical derivatives created by (2.65).

Lemma 15.4.2. (Local expression for iterated geometric derivatives) Let $(M, \mathbf{g})$ be a smooth Riemannian manifold of dimension n without boundary, not necessarily complete or compact, and let $\pi\colon T^*M \to M$. Let $\mathbf{E}, \mathbf{F} \to M$ be complex vector bundles of ranks r, s equipped with bundle metrics and compatible connections. The horizontal decomposition of $T(T^*M)$ is determined by the Levi–Civita connection, and the derivatives on $\pi^* \operatorname{Hom}(\mathbf{E}, \mathbf{F})$ are those in (2.67). Fix a chart $(U, x^1, \dots, x^n)$ and local frames of $\mathbf{E}$ and $\mathbf{F}$, and let

$$\mathbf{a} \in \Gamma(\pi^* \operatorname{Hom}(\mathbf{E}, \mathbf{F})|_{T^*U}).$$

Regard the coefficients as elements of $\operatorname{End}_{\mathbb{C}}(M_{s\times r}(\mathbb{C}))$. For $I \in \mathfrak{W}_p$ and $J \in \mathfrak{W}_q$, there exist coefficients $C_{\mu,\nu}^{I,J}(x, \xi)$ indexed by the explicit finite set

$$\mathcal{A}_{I,J} := \big\{ (\mu, \beta(J) + \gamma) \in \mathbb{N}_0^n \times \mathbb{N}_0^n \;\big|\; |\mu| + |\gamma| \le p \big\}, \tag{15.23}$$

such that

$$\nabla_I^{\mathrm{H}} \nabla_J^{\mathrm{V}} \mathbf{a} = \sum_{(\mu,\nu) \in \mathcal{A}_{I,J}} C_{\mu,\nu}^{I,J}(x, \xi) \big(D_x^{\mu} D_\xi^{\nu} \mathbf{a}(x, \xi) \big). \tag{15.24}$$

If $\nu = \beta(J) + \gamma$, the coefficient $C_{\mu,\nu}^{I,J}$ is polynomial in ξ of degree at most $|\gamma|$. For $p \ge 1$, its coefficients are finite sums of products and compositions formed from $D_x^{\delta} \Gamma_{ij}^{k}$, $D_x^{\delta} \omega_i^{\mathbf{E}}$, and $D_x^{\delta} \omega_i^{\mathbf{F}}$, where $|\delta| \le p - 1$; for $p = 0$ none of these data occur.

More precisely, let $L_B(T) := BT$, $R_D(T) := TD$, and

$$\mathcal{H}_i C := D_{x^i} C + \sum_{j,k=1}^{n} \Gamma_{ij}^{k} \xi_k D_{\xi_j} C$$

for a coefficient taking values in $\mathrm{End}_{\mathbb{C}}(M_{s\times r}(\mathbb{C}))$. With the convention that a coefficient whose index does not belong to $\mathcal{A}_{I,J}$ is zero, the coefficients are determined by

$$C_{0,\beta(J)}^{\varnothing,J} = \mathrm{Id}_{M_{s\times r}(\mathbb{C})} \tag{15.25}$$

and, if $I^+ = (i, i_1, \dots, i_p)$,

$$C_{\mu,\nu}^{I^+,J} = \mathcal{H}_i C_{\mu,\nu}^{I,J} + L_{\omega_i^{\mathrm{F}}} \circ C_{\mu,\nu}^{I,J} - R_{\omega_i^{\mathrm{E}}} \circ C_{\mu,\nu}^{I,J} + \mathbf{1}_{\{\mu_i \geq 1\}} C_{\mu-e_i,\nu}^{I,J} + \sum_{j,k=1}^{n} \mathbf{1}_{\{\nu_j \geq 1\}} \Gamma_{ij}^{k} \xi_k C_{\mu,\nu-e_j}^{I,J}. \tag{15.26}$$

Proof. If $|I| + |J| = 1$, the two possibilities are, by (2.68),

$$\nabla_j^{\mathrm{V}} \mathbf{a} = D_{\xi_j} \mathbf{a}$$

and

$$\nabla_i^{\mathrm{H}} \mathbf{a} = D_{x^i} \mathbf{a} + \sum_{j,k=1}^{n} \Gamma_{ij}^{k} \xi_k D_{\xi_j} \mathbf{a} + L_{\omega_i^{\mathrm{F}}}(\mathbf{a}) - R_{\omega_i^{\mathrm{E}}}(\mathbf{a}).$$

In the first case the only coefficient is the identity with $(\mu, \nu) = (0, e_j)$. In the second, the coefficients are the identity for $(e_i, 0)$, the endomorphism $(\sum_{k=1}^{n} \Gamma_{ij}^{k} \xi_k)\,\mathrm{Id}_{M_{s\times r}(\mathbb{C})}$ for $(0, e_j)$, and $L_{\omega_i^{\mathrm{F}}} - R_{\omega_i^{\mathrm{E}}}$ for $(0,0)$. Their respective degrees are 0, 1, and 0, and no derivatives of the connection data appear.

Begin with the vertical induction. For $q = 1$, we have already obtained $\nabla_j^{\mathrm{V}} \mathbf{a} = D_{\xi_j} \mathbf{a}$. If $\nabla_J^{\mathrm{V}} \mathbf{a} = D_\xi^{\beta(J)} \mathbf{a}$ and $J^+ = (j, j_1, \dots, j_q)$, the first identity in (2.68) gives

$$\nabla_{J^+}^{\mathrm{V}} \mathbf{a} = D_{\xi_j} \left(D_\xi^{\beta(J)} \mathbf{a} \right) = D_\xi^{\beta(J)+e_j} \mathbf{a}.$$

No additional coefficient appears because the linear coordinates on each fiber have trivial vertical connection. This proves (15.25) for every word J. If a vertical letter is added to J while keeping a horizontal word I, the convention (15.19) places that differentiation before the horizontal ones: replace the initial datum $C_{0,\beta(J)}^{\varnothing,J}$ by $C_{0,\beta(J)+e_j}^{\varnothing,J^+}$, then apply, in the same order, the horizontal recurrences corresponding to the letters of I. This gives the vertical step for any I, with differentiation ∇_j^{V} applied before the horizontal derivatives.

Now fix J and assume (15.24) for a word I of length p. For brevity, let $A_{\mu,\nu} := D_x^\mu D_\xi^\nu \mathbf{a}$. Applying an additional horizontal derivative to each summand and using the Leibniz rule gives the terms

$$\begin{aligned} \nabla_i^{\mathrm{H}} \left(C_{\mu,\nu}^{I,J} A_{\mu,\nu} \right) &= (D_{x^i} C_{\mu,\nu}^{I,J}) A_{\mu,\nu} + \sum_{j,k=1}^{n} \Gamma_{ij}^{k} \xi_k (D_{\xi_j} C_{\mu,\nu}^{I,J}) A_{\mu,\nu} \\ &\quad + C_{\mu,\nu}^{I,J} D_x^{\mu+e_i} D_\xi^\nu \mathbf{a} + \sum_{j,k=1}^{n} \Gamma_{ij}^{k} \xi_k C_{\mu,\nu}^{I,J} D_x^\mu D_\xi^{\nu+e_j} \mathbf{a} \end{aligned}$$

$$+ L_{\omega_i^{\mathbf{F}}}\big(C^{I,J}_{\mu,\nu}A_{\mu,\nu}\big) - R_{\omega_i^{\mathbf{E}}}\big(C^{I,J}_{\mu,\nu}A_{\mu,\nu}\big).$$

The first two expressions differentiate the coefficient, the third differentiates $\mathbf{a}$ spatially, the fourth comes from the vertical part of the horizontal lift, and the last two are left and right connection multiplication, respectively. Regrouping by the derivative $D_x^{\mu}D_\xi^{\nu}\mathbf{a}$ gives exactly (15.26).

Let us verify the four inductive properties. The first three terms of the recurrence preserve (μ,ν); the fourth replaces μ by $\mu+e_i$; the last replaces $\nu=\beta(J)+\gamma$ by $\nu+e_j$. In all three cases, $|\mu|+|\gamma|\le p+1$. Differentiation in x preserves the degree in ξ; the operator $\xi_k D_{\xi_j}$ does not increase it either; connection multiplication preserves it; and the term creating D_{ξ_j} multiplies by a function linear in ξ, so the new degree is at most $|\gamma|+1$. Differentiating an earlier coefficient in x may introduce derivatives of order p of Γ, $\omega^{\mathbf{E}}$, or $\omega^{\mathbf{F}}$; the other terms introduce only undifferentiated data. This is precisely the bound $(p+1)-1$. Finally, (15.23) is finite, and each sum in (15.26) contains finitely many terms. This proves the step $p\longmapsto p+1$ and hence the lemma. The inductions $q\longmapsto q+1$ for the vertical datum and $p\longmapsto p+1$ for the horizontal letters cover, in particular, each total level $p+q=N+1$ from earlier levels. □

The preceding relation is triangular and can be inverted without losing control of the indices.

Lemma 15.4.3. (Inverse local triangular formula) Let $(M,\mathbf{g})$ be a smooth Riemannian manifold of dimension n without boundary, not necessarily complete or compact. Let $\mathbf{E},\mathbf{F}\to M$ be complex vector bundles of finite rank with bundle metrics and compatible connections; use the Levi–Civita connection for the horizontal lift. Fix a chart U, frames of $\mathbf{E}$ and $\mathbf{F}$ over U, and $\mathbf{a}\in\Gamma(\pi^*\mathrm{Hom}(\mathbf{E},\mathbf{F})|_{T^*U})$. For each $\alpha,\beta\in\mathbb{N}_0^n$, there exist coefficients $\widetilde{C}^{\alpha,\beta}_{I,J}(x,\xi)$ such that

$$D_x^{\alpha}D_\xi^{\beta}\mathbf{a} = \sum_{(I,J)\in\widetilde{\mathcal{A}}_{\alpha,\beta}} \widetilde{C}^{\alpha,\beta}_{I,J}(x,\xi)\big(\nabla^{\mathrm{H}}_I\nabla^{\mathrm{V}}_J\mathbf{a}\big), \tag{15.27}$$

where the admissible finite set is

$$\widetilde{\mathcal{A}}_{\alpha,\beta} := \bigcup_{h=0}^{|\alpha|}\ \bigcup_{q=|\beta|}^{|\beta|+|\alpha|-h} \mathfrak{W}_h\times\mathfrak{W}_q. \tag{15.28}$$

For $I\in\mathfrak{W}_h$ and $J\in\mathfrak{W}_q$, the coefficient can be chosen polynomial in ξ of degree at most $q-|\beta|$ and formed from derivatives in x of Γ, $\omega^{\mathbf{E}}$, and $\omega^{\mathbf{F}}$ of order at most $|\alpha|-1$ when $|\alpha|\ge 1$.

Proof. Order partial derivatives by their *horizontal complexity* $|\alpha|$; the number of vertical derivatives does not enter the first component of this ordering. If $|\alpha|=0$, choose a word J_β containing each index j exactly β_j times. The vertical induction in the preceding proof gives $D_\xi^{\beta}\mathbf{a}=\nabla^{\mathrm{V}}_{J_\beta}\mathbf{a}$, which is (15.27).

Suppose the inverse formula has been constructed for every derivative of horizontal complexity less than p and every vertical multi-index. Let $|\alpha|=p$ and choose a word I_α containing i exactly α_i times. In (15.24), applied to (I_α,J_β), there is a unique term with $|\mu|=p$: to obtain it, each of the p horizontal derivatives must choose D_{x^i} acting on $\mathbf{a}$. Its coefficient is the identity, its index is (α,β), and all other terms have $|\mu|\le p-1$. Thus

$$D_x^{\alpha}D_\xi^{\beta}\mathbf{a} = \nabla^{\mathrm{H}}_{I_\alpha}\nabla^{\mathrm{V}}_{J_\beta}\mathbf{a} - \sum_{(\mu,\nu)\in\mathcal{A}_{I_\alpha,J_\beta}\setminus\{(\alpha,\beta)\}} C^{I_\alpha,J_\beta}_{\mu,\nu}D_x^{\mu}D_\xi^{\nu}\mathbf{a}. \tag{15.29}$$

In each summand substitute the induction hypothesis corresponding to (μ,ν). After summing coefficients

with the same words, this defines the exact recurrence

$$\widetilde{C}^{\alpha,\beta}_{I,J} = \mathbf{1}_{\{(I,J)=(I_\alpha,J_\beta)\}}\,\mathrm{Id}_{M_{s\times r}(\mathbb{C})} - \sum_{(\mu,\nu)\in\mathcal{A}_{I_\alpha,J_\beta}\setminus\{(\alpha,\beta)\}} C^{I_\alpha,J_\beta}_{\mu,\nu}\circ\widetilde{C}^{\mu,\nu}_{I,J}, \tag{15.30}$$

where the sum is restricted to $\mathcal{A}_{I_\alpha,J_\beta}$ and an undefined coefficient is interpreted as zero.
It remains to check the bounds. Write $\nu=\beta+\gamma$; the preceding lemma gives $|\mu|+|\gamma|\le p$. If a word produced by substituting $D_x^\mu D_\xi^\nu\mathbf{a}$ has lengths h and q, the induction hypothesis gives $h\le|\mu|$ and

$$|\nu|\le q\le|\nu|+|\mu|-h\le|\beta|+p-h.$$

This is exactly (15.28). The degree of the product of coefficients is at most $|\gamma|+(q-|\nu|)=q-|\beta|$. Its connection jets have order at most $p-1$, since the first factor has this bound and the inductive coefficients use at most $|\mu|-1$. The sums are finite. This proves the step from horizontal complexity $p-1$ to p. □

Lemma 15.4.4. (Tensorial derivatives and ordered words) In a chart and local frames, each component of $(\nabla^{\mathrm{H}})^p(\nabla^{\mathrm{V}})^q a$ is the directional word with the same indices plus a finite sum of words with fewer than p horizontal letters. The coefficients are universal polynomials in the Christoffel symbols and their derivatives of order at most $p-1$. Conversely, each word of lengths (p,q) is the corresponding component of the iterated tensor plus a sum of the same type. On each compact set, the two families of components are therefore equivalent without loss of order.

Proof. For $(p,q)=(1,0)$ or $(0,1)$ there is no correction. The first nontrivial identities are

$$\big((\nabla^{\mathrm{H}})^2 a\big)_{ij} = \nabla^{\mathrm{H}}_i(\nabla^{\mathrm{H}}_j a) - \Gamma^k_{ij}\nabla^{\mathrm{H}}_k a$$

and

$$\big(\nabla^{\mathrm{H}}\nabla^{\mathrm{V}} a\big)_{i;}{}^{j} = \nabla^{\mathrm{H}}_i(\nabla^{\mathrm{V}}_j a) + \Gamma^j_{ik}\nabla^{\mathrm{V}}_k a.$$

Formulas (15.17)–(15.18) show inductively that adding an index leaves as leading term the word obtained by adding the same letter, and that all corrections have smaller horizontal length. The triangular matrix has identity diagonal; solving inductively gives the converse assertion. Uniform bounds on compact sets follow from bounds on the Christoffel jets. □

Definition 15.4.5. (Full geometric symbol) Let $(M,\mathbf{g})$ be a smooth Riemannian manifold without boundary, not necessarily complete or compact, let $\pi\colon T^*M\to M$, and let $\mathbf{E},\mathbf{F}\to M$ be complex vector bundles of respective finite ranks $r_{\mathbf{E}},r_{\mathbf{F}}$, with bundle metrics $\mathbf{h}_{\mathbf{E}},\mathbf{h}_{\mathbf{F}}$ and compatible connections. On T^*M use the Levi–Civita horizontal lift, and on $\pi^*\mathrm{Hom}(\mathbf{E},\mathbf{F})$ the pullback connection induced by the connections on $\mathbf{E}$ and $\mathbf{F}$. A **geometric symbol of order** m is a section

$$\mathbf{a}\in\Gamma\big(\pi^*\mathrm{Hom}(\mathbf{E},\mathbf{F})\big)$$

such that, for every compact set $K\Subset M$ and all $p,q\in\mathbb{N}_0$, there exists $C_{K,p,q}>0$ with

$$\big\|(\nabla^{\mathrm{H}})^p(\nabla^{\mathrm{V}})^q\mathbf{a}(x,\xi)\big\|_{\mathbf{g},\mathbf{h}_{\mathbf{E}},\mathbf{h}_{\mathbf{F}}}\le C_{K,p,q}\langle\xi\rangle_{\mathbf{g}}^{m-q},\qquad x\in K,\quad \xi\in T^*_xM. \tag{15.31}$$

The class is denoted by $S^m_{\mathbf{g},\nabla}(T^*M;\mathrm{Hom}(\mathbf{E},\mathbf{F}))$.
In (15.31), the notation $(\nabla^{\mathrm{H}})^p(\nabla^{\mathrm{V}})^q\mathbf{a}$ denotes the tensor in $\mathscr{T}^{p,q}$ defined by the preceding intrinsic recurrence, and the norm is induced by $\mathbf{g}$ and the bundle metrics. The words (15.19) are retained only as auxiliary compositions for the local inductions.
The symbol is **classical** if there exist sections $\mathbf{a}_{m-j}$ on $T^*M\setminus 0_M$, homogeneous of degree $m-j$, such that, for a radial cutoff ϑ vanishing near 0_M and equal to one at high frequencies,

$$\mathbf{a}-\sum_{j=0}^{N-1}\vartheta\mathbf{a}_{m-j}\in S^{m-N}_{\mathbf{g},\nabla}(T^*M;\mathrm{Hom}(\mathbf{E},\mathbf{F}))\qquad(N\geq 1).$$

We then write $\mathbf{a}\in S^m_{\mathrm{cl},\mathbf{g},\nabla}(T^*M;\mathrm{Hom}(\mathbf{E},\mathbf{F}))$.

The comparison with local classes is quantitative. Fix a matrix norm $\|\cdot\|_0$ in the chosen frames, and denote by $\|\cdot\|_{\mathrm{op},0}$ the induced norm on the corresponding endomorphism spaces. For a tensor $T\in\mathscr{T}^{p,q}$, let $\|T\|_{0,\mathrm{comp}}$ denote the Euclidean product norm of the matrix norms of its components in the fixed chart and frames; for $(p,q)=(0,0)$ it agrees with $\|\cdot\|_0$. For $K\Subset U$, $N\in\mathbb{N}_0$, and $m\in\mathbb{R}$, define

$$p^{\mathrm{loc}}_{K,N,m}(a):=\max_{|\alpha|+|\beta|\leq N}\sup_{x\in K,\,\xi\in\mathbb{R}^n}\langle\xi\rangle^{-m+|\beta|}\|D_x^\alpha D_\xi^\beta a(x,\xi)\|_0,\tag{15.32}$$

$$p^{\mathrm{geom}}_{K,N,m}(a):=\max_{p+q\leq N}\sup_{x\in K,\,\xi\in T^*_xM}\langle\xi\rangle_{\mathbf{g}}^{-m+q}\|(\nabla^{\mathrm{H}})^p(\nabla^{\mathrm{V}})^q a(x,\xi)\|_{\mathbf{g},\mathbf{h}_{\mathbf{E}},\mathbf{h}_{\mathbf{F}}},\tag{15.33}$$

$$p^{\mathrm{word}}_{K,N,m}(a):=\max_{\substack{p+q\leq N\\ I\in\mathfrak{W}_p,\,J\in\mathfrak{W}_q}}\sup_{x\in K,\,\xi\in T^*_xM}\langle\xi\rangle_{\mathbf{g}}^{-m+q}\|\nabla^{\mathrm{H}}_I\nabla^{\mathrm{V}}_J a(x,\xi)\|_{\mathbf{g},\mathbf{h}_{\mathbf{E}},\mathbf{h}_{\mathbf{F}}}.\tag{15.34}$$

The tensor norms are induced by $\mathbf{g}$ and the bundle metrics.

Proposition 15.4.6. (Quantitative equivalence of symbol seminorms) Let $(M,\mathbf{g})$ be a smooth Riemannian manifold without boundary, not necessarily complete or compact, and let $\mathbf{E},\mathbf{F}\to M$ be complex vector bundles of finite rank with bundle metrics $\mathbf{h}_{\mathbf{E}},\mathbf{h}_{\mathbf{F}}$ and compatible connections. Fix a chart (U,x), local frames of $\mathbf{E}$ and $\mathbf{F}$, and a symbol $\mathbf{a}\in\Gamma(\pi^*\mathrm{Hom}(\mathbf{E},\mathbf{F})|_{T^*U})$. For each $K\Subset U$, $N\in\mathbb{N}_0$, and $m\in\mathbb{R}$, there exists $C_{K,N,m}\geq 1$ such that

$$C^{-1}_{K,N,m}p^{\mathrm{loc}}_{K,N,m}(\mathbf{a})\leq p^{\mathrm{word}}_{K,N,m}(\mathbf{a})\leq C_{K,N,m}p^{\mathrm{loc}}_{K,N,m}(\mathbf{a}),\qquad C^{-1}_{K,N,m}p^{\mathrm{word}}_{K,N,m}(\mathbf{a})\leq p^{\mathrm{geom}}_{K,N,m}(\mathbf{a})\leq C_{K,N,m}p^{\mathrm{word}}_{K,N,m}(\mathbf{a}).\tag{15.35}$$

In particular, the same order N suffices in both inequalities: no derivatives are lost. The constants depend on K,N,m, the chart and frames, comparison of the Euclidean and Riemannian norms, the bundle metrics, and bounds on K for derivatives of Γ, $\omega^{\mathbf{E}}$, and $\omega^{\mathbf{F}}$ of order at most $N-1$; when $N=0$ they do not depend on these jets.

Proof. Compactness of K provides constants $c_K,C_K,c'_K,C'_K>0$ with

$$c_K\langle\xi\rangle\leq\langle\xi\rangle_{\mathbf{g}}\leq C_K\langle\xi\rangle,\qquad c'_K\|T\|_{0,\mathrm{comp}}\leq\|T\|_{\mathbf{g},\mathbf{h}_{\mathbf{E}},\mathbf{h}_{\mathbf{F}}}\leq C'_K\|T\|_{0,\mathrm{comp}}.$$

The polynomial and jet bounds in Lemma 15.4.2 imply that, for $p+q\le N$, there exists $B_{K,N}>0$ such that

$$\|C^{I,J}_{\mu,\beta(J)+\gamma}(x,\xi)\|_{\mathrm{op},0}\le B_{K,N}\langle\xi\rangle^{|\gamma|},\qquad x\in K,\quad \xi\in\mathbb{R}^n.$$

Since $|\mu|+|\beta(J)+\gamma|\le p+q\le N$, each partial derivative of (15.24) is included in $p^{\mathrm{loc}}_{K,N,m}$. Moreover,

$$\langle\xi\rangle^{|\gamma|}\|D_x^{\mu}D_\xi^{\beta(J)+\gamma}\mathbf{a}\|_0\le p^{\mathrm{loc}}_{K,N,m}(\mathbf{a})\langle\xi\rangle^{m-q}.$$

Summing over the finitely many indices in (15.23) and using both norm comparisons proves the bound of p^{word} by p^{loc} in (15.35).

For the reverse direction, Lemma 15.4.3 gives a constant $\widetilde{B}_{K,N}>0$ such that, if $(I,J)\in\mathfrak{W}_h\times\mathfrak{W}_q$ contributes to $D_x^\alpha D_\xi^\beta\mathbf{a}$ with $|\alpha|+|\beta|\le N$, then

$$\|\widetilde{C}^{\alpha,\beta}_{I,J}(x,\xi)\|_{\mathrm{op},0}\le\widetilde{B}_{K,N}\langle\xi\rangle^{q-|\beta|},\qquad h+q\le|\alpha|+|\beta|\le N.$$

By definition of the word seminorm,

$$\langle\xi\rangle^{q-|\beta|}\|\nabla^{\mathrm{H}}_I\nabla^{\mathrm{V}}_J\mathbf{a}\|_{\mathbf{g},\mathbf{h}_{\mathbf{E}},\mathbf{h}_{\mathbf{F}}}\le C'_{K,N,m}p^{\mathrm{word}}_{K,N,m}(\mathbf{a})\langle\xi\rangle^{m-|\beta|}.$$

The finite sum in (15.27) bounds p^{loc} by p^{word}. Recurrences (15.26) and (15.30) show exactly the asserted dependence of the constants. Finally, Lemma 15.4.4, applied for $p+q\le N$, compares p^{geom} with p^{word} at the same orders. Increasing the constant once gives all four stated inequalities. □

Proposition 15.4.6 shows that, in every relatively compact chart (U,κ) and local bundle frames, $S^m_{\mathbf{g},\nabla}(T^*M;\mathrm{Hom}(\mathbf{E},\mathbf{F}))$ coincides with $S^m_{1,0}(\kappa(U)\times\mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^{r_{\mathbf{E}}},\mathbb{C}^{r_{\mathbf{F}}}))$, and that both families of seminorms generate the same Fréchet topology. It also shows that replacing the metric, connections, frames, or charts by other smooth data does not change the local class: apply (15.35) to each choice and compare through the local family. On a noncompact base, all constants depend on K, so this equivalence is uniform only on compact sets.

Definition 15.4.7. (Riemannian quantization) Let $(M,\mathbf{g})$ be a smooth Riemannian manifold of dimension n without boundary, not necessarily complete or compact. Let $\mathbf{E},\mathbf{F}\to M$ be complex vector bundles of finite rank with bundle metrics and compatible connections; let $\chi\in C^\infty(M\times M)$ be the properly supported cutoff fixed at the beginning of this section, and use parallel transport in $\mathbf{E}$ in the input variable. For $a\in S^m_{\mathbf{g},\nabla}(T^*M;\mathrm{Hom}(\mathbf{E},\mathbf{F}))$ and $\mathbf{u}\in\Gamma_c(M,\mathbf{E})$, define

$$\mathrm{Op}_{\mathbf{g},\nabla,\chi}(a)\mathbf{u}(x):=(2\pi)^{-n}\,\mathrm{Os}\int_{T^*_xM}\int_{T_xM}e^{-i\langle\xi,v\rangle}\chi(x,\exp_x v)\,a(x,\xi)\cdot\tau^{\mathbf{E}}_{x\leftarrow\exp_x v}\mathbf{u}(\exp_x v)\,dv_x\,d\xi_x.$$

The formula can be written using Riemannian measure. If

$$\exp_x^*(d\lambda_{\mathbf{g}})(v)=j_x(v)\,dv_x,$$

, the integrand over M contains the factor $j_x(\ell(x,y))^{-1}d\lambda_{\mathbf{g}}(y)$. Thus Definition 15.4.7 is compatible with the global convention $d\lambda_{\mathbf{g}}$: the factor $j_x(\ell(x,y))^{-1}$ is the Jacobian relating the two measures.

This construction is the pseudodifferential quantization associated with the linearization ℓ, not the geometric quantization of Hamiltonian systems. It follows the intrinsic idea of Bokobza–Haggiag [23, Chapters III–VI]: a linearization, a cutoff, and a transport turn a cotangent symbol into a kernel near the diagonal.

Theorem 15.4.8. (Equivalence of local and Riemannian quantization) Let $(M,\mathbf{g})$ be a smooth Riemannian manifold without boundary, not necessarily complete or compact. Let $\mathbf{E},\mathbf{F}\to M$ be complex vector bundles of finite rank with bundle metrics and compatible connections, and let χ be a properly supported cutoff as in Definition 15.4.7. The following two assertions hold.

(i) If $a\in S^m_{\mathrm{cl},\mathbf{g},\nabla}(T^*M;\mathrm{Hom}(\mathbf{E},\mathbf{F}))$, then

$$\mathrm{Op}_{\mathbf{g},\nabla,\chi}(a)\in\Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$$

, and its principal symbol is the homogeneous component a_m.

(ii) If $A\in\Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$, there exists a classical geometric symbol a such that

$$A-\mathrm{Op}_{\mathbf{g},\nabla,\chi}(a)\in\Psi^{-\infty}(M;\mathbf{E},\mathbf{F}).$$

If the smooth kernel of this remainder is allowed to be added to the quantization, reconstruction is exact.

Proof. Throughout this proof, $M,\mathbf{E},\mathbf{F}$ and the geometric data remain fixed; we abbreviate $\Psi^q:=\Psi^q(M;\mathbf{E},\mathbf{F})$, $\Psi^{-\infty}:=\Psi^{-\infty}(M;\mathbf{E},\mathbf{F})$, and $S^q_{\mathbf{g},\nabla}:=S^q_{\mathbf{g},\nabla}(T^*M;\mathrm{Hom}(\mathbf{E},\mathbf{F}))$. For (i), localize the operator with functions supported in a chart, choosing the chart so that the segments appearing below remain inside it. Let $\mathbf{g}_0(x):=\det(\mathbf{g}(x))$, and let $T(x,y)$ be the matrix of $\tau^{\mathbf{E}}_{x\leftarrow y}$. Since $\ell(x,x)=0$, the parameter-dependent version of Hadamard's lemma 1.4.10 gives, componentwise, the exact identity

$$\ell^a(x,y)=\sum_{b=1}^{n}C^a_b(x,y)(y^b-x^b),\qquad C^a_b(x,y):=\int_0^1\partial_{y^b}\ell^a(x,x+t(y-x))\,dt. \tag{15.36}$$

Since $D_y\ell(x,x)=\mathrm{Id}_{T_xM}$, we have $C(x,x)=I$. After shrinking the localization support, $C(x,y)$ is invertible, and C, C^{-1}, and every finite family of their derivatives are bounded.
In cotangent coordinates, $d\xi_x=\mathbf{g}_0(x)^{-\frac12}d\xi$, whereas $d\lambda_{\mathbf{g}}(y)=\mathbf{g}_0(y)^{\frac12}dy$. The formula preceding the theorem and (15.36) turn the localized operator into

$$(2\pi)^{-n}\,\mathrm{Os}\iint_{\mathbb{R}^n_y\times\mathbb{R}^n_\xi}e^{-i(y-x)\cdot C(x,y)^T\xi}h(x,y)a(x,\xi)T(x,y)u(y)\,dy\,d\xi,$$

where, including the two localization functions in h,

$$h(x,y)=\chi(x,y)j_x(\ell(x,y))^{-1}\left(\frac{\mathbf{g}_0(y)}{\mathbf{g}_0(x)}\right)^{\frac12}.$$

Now make the exact change

$$\eta=C(x,y)^T\xi,\qquad \xi=L(x,y)\eta,\qquad L(x,y):=C(x,y)^{-T}. \tag{15.37}$$

Its Jacobian is $d\xi = |\det C(x,y)|^{-1} d\eta$. Consequently, the full local amplitude is

$$b(x,y,\eta) = h(x,y)|\det C(x,y)|^{-1} a\big(x, L(x,y)\eta\big) T(x,y). \tag{15.38}$$

Let us verify its estimates. The chain rules, applying derivatives in η first and then spatial derivatives, produce a finite sum of terms

$$B_{\alpha,\beta,\gamma;\mu,\nu,\rho}(x,y)\eta^{\rho}(D_x^{\mu}D_{\xi}^{\nu}a)\big(x,L(x,y)\eta\big), \tag{15.39}$$

when computing $D_x^{\alpha}D_y^{\beta}D_{\eta}^{\gamma}[a(x,L\eta)]$. The indices in each term satisfy

$$|\nu| = |\gamma| + |\rho|, \qquad |\mu| + |\rho| \le |\alpha| + |\beta|,$$

and the coefficients $B_{\alpha,\beta,\gamma;\mu,\nu,\rho}$ are products of derivatives of L. These assertions follow inductively: a spatial derivative hitting a produces $D_x a$; one hitting $L\eta$ simultaneously produces a linear factor in η and an additional derivative in ξ; and one hitting a coefficient merely differentiates that coefficient. This enumerates the three Leibniz possibilities and preserves both displayed relations.

On the spatial compact set under consideration, there exist $c, C > 0$ such that $c\langle\eta\rangle \le \langle L(x,y)\eta\rangle \le C\langle\eta\rangle$. Proposition 15.4.6 and (15.39) give, for all α,β,γ, a constant $C_{\alpha,\beta,\gamma} > 0$ with

$$\big\|D_x^{\alpha}D_y^{\beta}D_{\eta}^{\gamma}a(x,L\eta)\big\| \le C_{\alpha,\beta,\gamma}\langle\eta\rangle^{m-|\gamma|}.$$

Indeed, the factor η^{ρ} in each summand is exactly offset by the $|\rho|$ additional derivatives in ξ. All derivatives of h, $|\det C|^{-1}$, and T are bounded on the compact set, so

$$\|D_x^{\alpha}D_y^{\beta}D_{\eta}^{\gamma}b(x,y,\eta)\| \le C'_{\alpha,\beta,\gamma}\langle\eta\rangle^{m-|\gamma|}. \tag{15.40}$$

This proves, derivative by derivative, that b is an amplitude of order m. If a is classical, substituting $L\eta$ into each homogeneous component preserves its degree, and the same estimate applied to each remainder proves that b is classical. Theorem 15.1.9 reduces (15.38) to a local classical symbol of order m.

On the diagonal, $C(x,x) = L(x,x) = I$, $T(x,x) = I$, $j_x(0) = 1$, and $\mathbf{g}_0(x)^{\frac{1}{2}}\mathbf{g}_0(x)^{-\frac{1}{2}} = 1$ hold, and the localization cutoffs can be taken equal to one. Thus $b_m(x,x,\eta) = a_m(x,\eta)$. The zero-index term in amplitude-to-symbol reduction preserves this component; every remaining term contains at least one derivative in η and has order at most $m-1$. This proves (i), including the statement on the principal symbol.

For (ii), we construct all terms, not just the first. Set $R_0 := A$ and $r_m := \sigma_m^{\Psi}(R_0)$. A radial cutoff, vanishing near the zero section and equal to one for large covectors, extends r_m to a classical geometric symbol $a^{(0)}$ of order m. By (i), $\sigma_m^{\Psi}(\mathrm{Op}_{\mathbf{g},\nabla,\chi}(a^{(0)})) = r_m$; hence

$$R_1 := R_0 - \mathrm{Op}_{\mathbf{g},\nabla,\chi}(a^{(0)}) \in \Psi_{\mathrm{cl}}^{m-1}.$$

The precise induction statement is as follows: for some $N \ge 1$, we have constructed $a^{(j)} \in S_{\mathrm{cl},\mathbf{g},\nabla}^{m-j}$, $0 \le j < N$, so that

$$R_N := A - \mathrm{Op}_{\mathbf{g},\nabla,\chi}\left(\sum_{j=0}^{N-1} a^{(j)}\right) \in \Psi_{\mathrm{cl}}^{m-N}. \tag{15.41}$$

The case $N = 1$ has just been proved. Assume (15.41) and let $r_{m-N} := \sigma_{m-N}^{\Psi}(R_N)$. Extend r_{m-N} by a radial

cutoff to $a^{(N)} \in S^{m-N}_{\mathrm{cl},\mathbf{g},\nabla}$. Part (i) gives

$$\sigma^{\Psi}_{m-N}\big(\mathrm{Op}_{\mathbf{g},\nabla,\chi}(a^{(N)})\big) = r_{m-N}.$$

By exactness of the principal symbol,

$$R_{N+1} := R_N - \mathrm{Op}_{\mathbf{g},\nabla,\chi}(a^{(N)}) \in \Psi^{m-N-1}_{\mathrm{cl}},$$

which is precisely (15.41) with $N+1$. This completes the induction.
Lemma 15.1.5, applied in charts and combined using a locally finite partition, provides $a \in S^{m}_{\mathrm{cl},\mathbf{g},\nabla}$ such that, for every $N \geq 1$,

$$a - \sum_{j=0}^{N-1} a^{(j)} \in S^{m-N}_{\mathbf{g},\nabla}. \tag{15.42}$$

Part (i), now at order $m-N$, turns the left-hand side of (15.42) into an operator in Ψ^{m-N}. Adding it to R_N gives

$$A - \mathrm{Op}_{\mathbf{g},\nabla,\chi}(a) \in \Psi^{m-N} \qquad \text{for every } N \geq 1.$$

The intersection of these classes is $\Psi^{-\infty}$ by the characterization through smooth kernels. This proves (ii). □

The theorem distinguishes two levels that must not be confused: the principal component is recovered in a single step, modulo $\Psi^{m-1}(M;\mathbf{E},\mathbf{F})$; equivalence modulo $\Psi^{-\infty}(M;\mathbf{E},\mathbf{F})$ requires constructing all terms and applying asymptotic summation.

Proposition 15.4.9. (Dependence on choices) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E},\mathbf{F} \to M$ be complex vector bundles of finite rank. Consider two geometric quantization rules obtained by choosing Riemannian metrics, bundle metrics, compatible connections, linearizations, and properly supported cutoffs as in Definition 15.4.7. For a symbol of order m, changing the cutoff changes the quantization by an operator in $\Psi^{-\infty}(M;\mathbf{E},\mathbf{F})$. Changing the other data modifies the full symbol but preserves the class $\Psi^{m}(M;\mathbf{E},\mathbf{F})$, the principal symbol, and quantization modulo $\Psi^{m-1}(M;\mathbf{E},\mathbf{F})$. After successive corrections of lower-order terms, the two quantizations correspond modulo $\Psi^{-\infty}(M;\mathbf{E},\mathbf{F})$.

Proof. Throughout this proof, $M,\mathbf{E},\mathbf{F}$ remain fixed; write $\Psi^{q} := \Psi^{q}(M;\mathbf{E},\mathbf{F})$ and $\Psi^{-\infty} := \Psi^{-\infty}(M;\mathbf{E},\mathbf{F})$. Work in a relatively compact chart and write $v = y - x$. We use the exact factorizations in Hadamard's lemma 1.4.10, with x as parameter. If a smooth matrix-valued function $F(x,v)$ satisfies $F(x,0) = 0$, then

$$F(x,v) = \sum_{j=1}^{n} v_j F_j(x,v), \qquad F_j(x,v) = \int_0^1 \partial_{v_j} F(x,tv)\,dt. \tag{15.43}$$

If, in addition, $D_v F(x,0) = 0$, then

$$F(x,v) = \sum_{|\alpha|=2} v^{\alpha} F_{\alpha}(x,v), \qquad F_{\alpha}(x,v) = \frac{2}{\alpha!}\int_0^1 (1-t)\partial_v^{\alpha} F(x,tv)\,dt. \tag{15.44}$$

In general, if the vertical derivatives of orders less than L vanish at $v=0$, the same proof gives

$$F(x,v)=\sum_{|\alpha|=L} v^{\alpha}F_{\alpha,L}(x,v), \qquad F_{\alpha,L}(x,v)=\frac{L}{\alpha!}\int_0^1 (1-t)^{L-1}\partial_v^{\alpha}F(x,tv)\,dt. \tag{15.45}$$

These identities also provide the required bounds. For example, for K compact and $N\in\mathbb{N}_0$, there exists $C_{K,N,L}>0$ such that

$$\max_{|\rho|+|\sigma|\le N}\sup_{x\in K,\ v\in\overline{B}_{\mathrm{euc}}(0,\varepsilon)}\|D_x^{\rho}D_v^{\sigma}F_{\alpha,L}(x,v)\|\le C_{K,N,L}\max_{|\rho'|+|\sigma'|\le N+L}\sup_{x\in K,\ v\in\overline{B}_{\mathrm{euc}}(0,\varepsilon)}\|D_x^{\rho'}D_v^{\sigma'}F(x,v)\|.$$

Each transverse monomial translates exactly into a change of symbol order. For the normalized linear phase,

$$v^{\alpha}e^{-i\eta\cdot v}=i^{|\alpha|}D_{\eta}^{\alpha}e^{-i\eta\cdot v}, \qquad \int_{\mathbb{R}^n_{\eta}} e^{-i\eta\cdot v}v^{\alpha}c(\eta)\,d\eta=(-i)^{|\alpha|}\int_{\mathbb{R}^n_{\eta}} e^{-i\eta\cdot v}D_{\eta}^{\alpha}c(\eta)\,d\eta. \tag{15.46}$$

The second identity is understood first with a cutoff in η and then through the oscillatory procedure already established. Thus a factor v^{α} applied to an amplitude of order r produces an amplitude of order $r-|\alpha|$.

First let χ_0 and χ_1 be two admissible cutoffs. Their difference vanishes on a neighborhood of $v=0$, so all its vertical derivatives at $v=0$ are zero. For each L, formulas (15.45) and (15.46) express the difference kernel through an amplitude of order $m-L$. Given any prescribed order, choose L larger; the difference belongs to every order and therefore has smooth kernel by the characterization of smoothing operators.

Now consider two connections on $\mathbf{E}$ and their radial transports $T_0(x,x+v)$ and $T_1(x,x+v)$. Both equal the identity at $v=0$. Define

$$F(x,v):=T_1(x,x+v)-T_0(x,x+v).$$

Applied to this function F, identity (15.43) gives

$$T_1(x,x+v)-T_0(x,x+v)=\sum_{j=1}^{n} v_jT_j(x,v), \qquad T_j(x,v)=\int_0^1 \partial_{v_j}F(x,tv)\,dt. \tag{15.47}$$

The coefficients T_j satisfy the preceding bounds for each finite family of derivatives. Integration by parts in (15.46) shows that the difference between the quantizations, with all other data fixed, has amplitude of order $m-1$.

The same factorization controls Jacobian factors and measures. In the coordinates of (15.38), the scalar combination corresponding to any geometric data is

$$q(x,y)=j_x(\ell(x,y))^{-1}\left(\frac{g_0(y)}{g_0(x)}\right)^{\frac{1}{2}}|\det C(x,y)|^{-1}, \qquad q(x,x)=1.$$

For a nonexponential linearization, q denotes the exact factor obtained from the Jacobian of $y\longmapsto\ell(x,y)$ and the chosen densities; identity $D_y\ell(x,x)=I$ again gives $q(x,x)=1$. Thus, for two choices, q_1-q_0 satisfies (15.43) its coefficients and all their derivatives up to order N are bounded by a constant $C_{K,N}$ on each compact set. Each term of the difference again has order at most $m-1$ after (15.46).

It remains to compare two linearizations ℓ_0 and ℓ_1. Both satisfy

$$\ell_{\kappa}(x,x)=0, \qquad D_y\ell_{\kappa}(x,x)=I, \qquad \kappa\in\{0,1\}.$$

Consequently, $G(x,v) := \ell_1(x,x+v) - \ell_0(x,x+v)$ satisfies both hypotheses of (15.44), and

$$G(x,v) = \sum_{|\alpha|=2} v^\alpha G_\alpha(x,v), \qquad G_\alpha(x,v) = \frac{2}{\alpha!}\int_0^1 (1-t)\partial_v^\alpha G(x,tv)\,dt. \tag{15.48}$$

Define $\ell_t = \ell_0 + tG$. Shrinking the neighborhood ensures that all ℓ_t, $0 \le t \le 1$, are linearizations and that the matrices C_t in (15.36) are uniformly invertible. The fundamental theorem of calculus gives the exact identity

$$e^{-i\langle \xi,\ell_1\rangle} - e^{-i\langle \xi,\ell_0\rangle} = -i\int_0^1 e^{-i\langle \xi,\ell_t\rangle}\langle \xi, G\rangle\,dt \tag{15.49}$$

In each integrand make the change $\eta = C_t(x,y)^T\xi$. By (15.48), the factor $\langle \xi, G\rangle$ becomes a sum of monomials v^α, $|\alpha| = 2$, multiplied by a function linear in η and smooth coefficients uniformly bounded in t. Before integration by parts, the amplitude has order $m+1$; two applications of (15.46) bring it to order $m-1$. The Leibniz rules used in (15.39) give, for all ρ,σ,γ, a constant $C_{K,\rho,\sigma,\gamma} > 0$ independent of t such that the final amplitude d_t satisfies

$$\|D_x^\rho D_y^\sigma D_\eta^\gamma d_t(x,y,\eta)\| \le C_{K,\rho,\sigma,\gamma}\langle \eta\rangle^{m-1-|\gamma|}. \tag{15.50}$$

Integration in $t \in [0,1]$ preserves the estimate.

A change of metric splits into a change of its exponential linearization, already treated, and a change of the factors q; a change of connection on $\mathbf{E}$ reduces to (15.47). The connection on $\mathbf{F}$ enters the symbol seminorms, not the integral transporting the input section, and Proposition 15.4.6 shows that changing it preserves the symbol class. Combining (15.47), the factorization of q, and (15.50) gives, for each finite family of derivatives, the estimate for an amplitude of order $m-1$. Thus all the quantizations considered have the same principal symbol; this is a consequence of the factorizations, not a hypothesis.

Finally, let Q_0, Q_1 be two such quantization rules. What we have proved says that $Q_0(a) - Q_1(a) \in \Psi^{m-1}$ for every symbol of order m. Take the principal symbol of this difference, choose a correction of order $m-1$ for one of the two symbols, and subtract. If after N corrections the difference belongs to Ψ^{m-N}, its principal symbol of degree $m-N$ determines the next correction, and the new difference belongs to Ψ^{m-N-1}. An asymptotic sum of the corrections produces two corresponding symbols whose operator difference belongs to Ψ^{m-N} for every N, that is, to $\Psi^{-\infty}$. □

This separates what is canonical from what is auxiliary. The class $\Psi^m(M;\mathbf{E},\mathbf{F})$, principal symbol, ellipticity, and operator class modulo lower orders are canonical. The directional microlocal invariant will be added after it has been constructed by Fourier methods and its invariance proved. The full symbol, specific quantization, metric, connections, cutoff, and transport depend on choices. Calling the Riemannian formula *intrinsic* means that all these data are geometric and global, not that the result is independent of them term by term.

On a curved manifold, replacing partial derivatives by covariant derivatives in the flat composition formula requires additional lower-order terms. These terms contain jets of the exponential map, the connection, and curvature. The particularly simple formulas in [23, Chapter VI] require a locally affine linearization; the existence of such a linearization is equivalent to a local affine structure. For the general calculus, the local formulas in Theorems 15.2.6 and 15.2.8, together with the equivalence just proved, provide expansions containing all these geometric terms.

15.5 Elliptic inversion and microlocal analysis

The symbolic calculus was constructed to invert elliptic operators without requiring an exact inverse. We first invert the principal component and successively correct lower-order terms. The final remainder will be smoothing; this arbitrary gain of derivatives is the source of both elliptic regularity and its microlocal version.

Definition 15.5.1. (Parametrix) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E},\mathbf{F} \to M$ be smooth complex vector bundles of finite rank. Let $A \in \Psi^m(M;\mathbf{E},\mathbf{F})$. An operator $B \in \Psi^{-m}(M;\mathbf{F},\mathbf{E})$ is a **right parametrix** if $AB - I_{\mathbf{F}} \in \Psi^{-\infty}(M;\mathbf{F},\mathbf{F})$, a **left parametrix** if $BA - I_{\mathbf{E}} \in \Psi^{-\infty}(M;\mathbf{E},\mathbf{E})$, and a **two-sided parametrix** if both conditions hold. For the purely local calculus, replace all three classes by their variants with the subscript loc.

Ellipticity allows inversion of an operator at high frequencies but does not guarantee an algebraic or functional inverse. The distinction is essential: the first assertion produces a parametrix modulo smoothing operators; the second also requires control of the kernel and cokernel in a specific realization. We first develop the symbolic construction and then measure directional regularity using the wavefront set. All proofs use the convention $D_j = \partial_j$ and hence the factors $i^{-|\alpha|}$ in Theorem 15.2.6.

15.5.1 Criteria for ellipticity

We begin by collecting several formulations that will be used interchangeably. For a matrix T, let $s_{\min}(T)$ denote its smallest singular value.

Proposition 15.5.2. (Equivalent formulations of ellipticity) Let $U \subseteq \mathbb{R}^n$ be open, and let $r \in \mathbb{N}$ and $m \in \mathbb{R}$. Let

$$a \in S^m_{\mathrm{cl}}\big(U;\mathrm{End}(\mathbb{C}^r)\big), \qquad a \sim \sum_{j=0}^{\infty} a_{m-j}.$$

The following conditions are equivalent, with constants that may depend on each compact set $K \Subset U$:

(a) a is elliptic in the sense of Definition 15.1.2;

(b) there exist $c_K, R_K > 0$ such that

$$\|a(x,\xi)v\| \geq c_K \langle \xi \rangle^m \|v\|, \qquad x \in K, \quad \|\xi\| \geq R_K;$$

(c) there exist $c_K, R_K > 0$ such that

$$|\det a(x,\xi)| \geq c_K \langle \xi \rangle^{mr}, \qquad x \in K, \quad \|\xi\| \geq R_K;$$

(d) $a_m(x,\xi)$ is invertible for every $x \in U$ and every $\xi \neq 0$;

(e) there exists $b_0 \in S^{-m}_{1,0}(U;\mathrm{End}(\mathbb{C}^r))$ such that

$$ab_0 - I_r \in S^{-1}_{1,0}(U;\mathrm{End}(\mathbb{C}^r)), \qquad b_0 a - I_r \in S^{-1}_{1,0}(U;\mathrm{End}(\mathbb{C}^r)).$$

Moreover, in the high-frequency region where a is invertible, its inverse satisfies $a^{-1} \in S^{-m}_{1,0}(U;\mathrm{End}(\mathbb{C}^r))$.

Proof. Throughout this proof, U, r, m remain fixed, and we write

$$S^q := S^q_{1,0}\big(U; \mathrm{End}(\mathbb{C}^r)\big).$$

The identity

$$s_{\min}(a(x,\xi)) = \|a(x,\xi)^{-1}\|^{-1}$$

proves equivalence of (a) and (b). If (b) holds, all singular values are bounded below by $c_K\langle\xi\rangle^m$, so their product gives (c). Conversely, the estimates for S^m imply

$$\|\operatorname{adj} a(x,\xi)\| \le C_K\langle\xi\rangle^{m(r-1)}.$$

By the formula $a^{-1} = (\det a)^{-1}\operatorname{adj} a$, condition (c) yields the bound in (a).
Suppose (d) holds. On the compact set $K\times\mathbb{S}^{n-1}$, the function $s_{\min}(a_m)$ has a positive minimum. By definition of the classical expansion, there exists $C_K > 0$ such that, uniformly for $x \in K$, $\omega \in \mathbb{S}^{n-1}$, and $t \ge 1$,

$$\left\| t^{-m}a(x,t\omega) - a_m(x,\omega)\right\| \le C_K t^{-1}.$$

This inequality gives (b). Conversely, if $a_m(x_0,\omega_0)v = 0$ for some $v \neq 0$, the same convergence contradicts the lower bound in (b) applied to $(x_0, t\omega_0)$.
If (d) holds, choose a radial cutoff ϑ vanishing near the origin and equal to one at large frequencies, and set

$$b_0(x,\xi) = \vartheta(\xi)a_m(x,\xi)^{-1}.$$

Homogeneity of degree $-m$ and local compactness of the sphere show that $b_0 \in S^{-m}$. Since $a - \vartheta a_m \in S^{m-1}$ at high frequencies, both products in (e) are I_r modulo S^{-1}. If (e) holds, then $ab_0 = I_r + r$ with $r \in S^{-1}$. For large frequencies, $\|r\| < \frac{1}{2}$; thus a is invertible and

$$\|a^{-1}\| \le \|(I_r + r)^{-1}\|\,\|b_0\| \le C_K\langle\xi\rangle^{-m}.$$

Finally, in the region where a is invertible,

$$D_{x_j}(a^{-1}) = -a^{-1}(D_{x_j}a)a^{-1}, \qquad D_{\xi_j}(a^{-1}) = -a^{-1}(D_{\xi_j}a)a^{-1}.$$

Write $\gamma = (\alpha,\beta) \in \mathbb{N}_0^{2n}$ and $D^\gamma = D_x^\alpha D_\xi^\beta$. Applying D^γ to $aa^{-1} = I_r$, separating the summand in which no derivative hits a, and multiplying on the left by a^{-1} gives the exact recurrence

$$D^\gamma(a^{-1}) = -a^{-1}\sum_{0<\delta\le\gamma}\binom{\gamma}{\delta}(D^\delta a)D^{\gamma-\delta}(a^{-1}), \qquad |\gamma| \ge 1. \tag{15.51}$$

The base case $|\gamma| = 0$ is the bound $\|a^{-1}\| \le C_K\langle\xi\rangle^{-m}$ already proved. Suppose that, for every $\gamma' = (\alpha',\beta')$ with $|\gamma'| < q$,

$$\|D^{\gamma'}a^{-1}(x,\xi)\| \le C_{K,\gamma'}\langle\xi\rangle^{-m-|\beta'|}.$$

Let $|\gamma| = q$ and write $\delta = (\alpha_1,\beta_1)$. Since $0 < \delta \le \gamma$, the factor $D^{\gamma-\delta}(a^{-1})$ is covered by the induction hypothesis.

Each summand in (15.51) is then bounded by

$$C_{K,\gamma,\delta}\langle\xi\rangle^{-m}\langle\xi\rangle^{m-|\beta_1|}\langle\xi\rangle^{-m-(|\beta|-|\beta_1|)} = C_{K,\gamma,\delta}\langle\xi\rangle^{-m-|\beta|}.$$

The sum contains finitely many multi-indices δ; thus

$$\|D_x^{\alpha} D_{\xi}^{\beta} a^{-1}(x,\xi)\| \le C_{K,\alpha,\beta}\langle\xi\rangle^{-m-|\beta|},$$

which completes the induction and proves the remaining assertion. □

Definition 15.5.3. (Elliptic set and characteristic set) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E},\mathbf{F} \to M$ be smooth complex vector bundles of the same finite rank. Let $A \in \Psi^{m}_{\mathrm{cl,loc}}(M;\mathbf{E},\mathbf{F})$. Its **elliptic set** is

$$\mathrm{Ell}(A) := \big\{(x,\xi) \in T^*M \setminus 0_M \mid \sigma^{\Psi}_m(A)(x,\xi) \text{ is an isomorphism}\big\},$$

and its **characteristic set** is

$$\mathrm{Char}(A) := (T^*M \setminus 0_M) \setminus \mathrm{Ell}(A).$$

The operator is **elliptic** if $\mathrm{Char}(A) = \varnothing$.

This ellipticity is local in the base variable. On a noncompact manifold, it does not imply uniform ellipticity in the sense of Definition 15.1.2. Parameter ellipticity, which requires uniform inversion of a family $\lambda I - A$ in a sector, will be defined only when constructing complex powers.

Homogeneity of the principal symbol shows that $\mathrm{Ell}(A)$ is open and conic, whereas $\mathrm{Char}(A)$ is closed and conic. In a chart, membership in $\mathrm{Ell}(A)$ is equivalent to validity of the lower bound in Proposition 15.5.2 on a neighborhood in the base and a conic neighborhood of the covariable. For a differential operator P, identity (15.8) shows that this definition agrees with differential ellipticity despite the factor i^m.

15.5.2 Construction of a two-sided parametrix

The preceding equivalences reduce ellipticity to uniform inversion of the principal component at high frequencies. Starting from this inverse, right and left corrections are constructed recursively. We first write the recurrence in coordinates, where the order of each summand can be tracked explicitly. Let $a \sim \sum_{j=0}^{\infty} a_{m-j}$ be an elliptic classical symbol. First seek an expansion

$$b^{\mathrm{d}} \sim \sum_{k=0}^{\infty} b^{\mathrm{d}}_{-m-k}$$

such that $a \# b^{\mathrm{d}} \sim I_r$; the letter d recalls that $\mathrm{Op}(b^{\mathrm{d}})$ lies to the right of $\mathrm{Op}(a)$. The degree-zero term imposes

$$b^{\mathrm{d}}_{-m} = a_m^{-1}.$$

For $N \geq 1$, the component of degree $-N$ in $a \# b^{\mathrm{d}}$ is

$$\sum_{\substack{j,k\geq 0,\ \alpha\in\mathbb{N}_0^n \\ j+k+|\alpha|=N}} \frac{i^{-|\alpha|}}{\alpha!}(D_\xi^\alpha a_{m-j})(D_x^\alpha b^{\mathrm{d}}_{-m-k}).$$

Separating the unique summand containing the unknown b^{d}_{-m-N} gives the explicit recurrence

$$b^{\mathrm{d}}_{-m-N} = -a_m^{-1} \sum_{\substack{j,k\geq 0,\ \alpha\in\mathbb{N}_0^n \\ j+k+|\alpha|=N,\ k<N}} \frac{i^{-|\alpha|}}{\alpha!}(D_\xi^\alpha a_{m-j})(D_x^\alpha b^{\mathrm{d}}_{-m-k}). \tag{15.52}$$

To construct a left parametrix, write $b^{\mathrm{i}} \# a \sim I_r$. Now $b^{\mathrm{i}}_{-m} = a_m^{-1}$ and

$$b^{\mathrm{i}}_{-m-N} = -\left(\sum_{\substack{j,k\geq 0,\ \alpha\in\mathbb{N}_0^n \\ j+k+|\alpha|=N,\ k<N}} \frac{i^{-|\alpha|}}{\alpha!}(D_\xi^\alpha b^{\mathrm{i}}_{-m-k})(D_x^\alpha a_{m-j}) \right) a_m^{-1}. \tag{15.53}$$

In particular, the first corrections are

$$\begin{aligned} b^{\mathrm{d}}_{-m-1} &= -a_m^{-1}\left(a_{m-1}a_m^{-1} + i^{-1}\sum_{\ell=1}^{n}(D_{\xi_\ell}a_m)(D_{x_\ell}a_m^{-1}) \right), \\ b^{\mathrm{i}}_{-m-1} &= -\left(a_m^{-1}a_{m-1} + i^{-1}\sum_{\ell=1}^{n}(D_{\xi_\ell}a_m^{-1})(D_{x_\ell}a_m) \right) a_m^{-1}. \end{aligned}$$

The order of factors matters for matrix-valued symbols. The factors $i^{-|\alpha|}$ likewise cannot be omitted: they come exactly from the convention $D = \partial$ fixed at the beginning of the chapter.

Theorem 15.5.4. (Existence and equivalence of parametrices) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E}, \mathbf{F} \to M$ be smooth complex vector bundles of the same finite rank. Let $A \in \Psi^m_{\mathrm{cl}}(M; \mathbf{E}, \mathbf{F})$. The following conditions are equivalent:

(a) A is elliptic;

(b) there exists $B \in \Psi^{-m}_{\mathrm{cl}}(M; \mathbf{F}, \mathbf{E})$ such that

$$AB = I_{\mathbf{F}} - R_{\mathbf{F}}, \qquad BA = I_{\mathbf{E}} - R_{\mathbf{E}}, \qquad R_{\mathbf{E}} \in \Psi^{-\infty}(M; \mathbf{E}, \mathbf{E}), \qquad R_{\mathbf{F}} \in \Psi^{-\infty}(M; \mathbf{F}, \mathbf{F});$$

(c) the principal symbol of A has a homogeneous inverse of degree $-m$ on $T^*M \setminus 0_M$.

The operator B can be chosen properly supported and is a two-sided parametrix of A. Two two-sided parametrices differ by an operator in $\Psi^{-\infty}(M; \mathbf{F}, \mathbf{E})$.

Proof. On an open set $U \subseteq \mathbb{R}^n$ and in frames of common rank r, formulas (15.52) and (15.53) define homogeneous terms of degrees $-m-k$. Let us verify this inductively. For $k = 0$, $a_m^{-1}(x, t\xi) = t^{-m} a_m(x,\xi)^{-1}$. Suppose b^{d}_{-m-k} is homogeneous of degree $-m-k$ for $k < N$. In each summand of (15.52), $D_\xi^\alpha a_{m-j}$ has degree

$m-j-|\alpha|$ and $D_x^\alpha b^{\mathrm{d}}_{-m-k}$ retains degree $-m-k$; since $j+k+|\alpha|=N$, their product has degree $-N$. Multiplication by a_m^{-1} lowers the degree by m and gives exactly $-m-N$. The sum is finite because $j,k,|\alpha|\le N$. The same occurs in the left recurrence: the sum in parentheses has degree $-N$, and the factor a_m^{-1} on the right gives degree $-m-N$. This proves both inductive steps simultaneously. Lemma 15.1.5 produces symbols $b^{\mathrm{d}}, b^{\mathrm{i}} \in S^{-m}_{\mathrm{cl}}(U;\mathrm{End}(\mathbb{C}^r))$ with these expansions. Theorem 15.2.6 and the recurrences give

$$a\#b^{\mathrm{d}} - I_r \in S^{-\infty}(U\times\mathbb{R}^n;\mathrm{End}(\mathbb{C}^r)), \qquad b^{\mathrm{i}}\#a - I_r \in S^{-\infty}(U\times\mathbb{R}^n;\mathrm{End}(\mathbb{C}^r)).$$

Quantizing and arranging proper support yields a right parametrix B_{d} and a left parametrix B_{i}. If $AB_{\mathrm{d}} = I_{\mathbf{F}} - R_{\mathrm{d}}$ and $B_{\mathrm{i}}A = I_{\mathbf{E}} - R_{\mathrm{i}}$, then

$$B_{\mathrm{i}} - B_{\mathrm{d}} = B_{\mathrm{i}}(I_{\mathbf{F}} - AB_{\mathrm{d}}) - (I_{\mathbf{E}} - B_{\mathrm{i}}A)B_{\mathrm{d}} = B_{\mathrm{i}}R_{\mathrm{d}} - R_{\mathrm{i}}B_{\mathrm{d}}.$$

Corollary 15.2.9 shows that this difference is smoothing. Thus either parametrix is two-sided modulo $\Psi^{-\infty}(M;\mathbf{E},\mathbf{E})$ in the left defect and $\Psi^{-\infty}(M;\mathbf{F},\mathbf{F})$ in the right defect.

Globally, (c) supplies the homogeneous section $\mathbf{a}_m^{-1} := \sigma^\Psi_m(A)^{-1}$. Surjectivity of the exact sequence in Theorem 15.3.7 allows it to be quantized as an operator B_0 of order $-m$; then $AB_0 - I_{\mathbf{F}}$ and $B_0A - I_{\mathbf{E}}$ have order -1. Set $B_0^{\mathrm{d}} = B_0^{\mathrm{i}} = B_0$.

The right induction statement is

$$B^{\mathrm{d}}_{<N} := \sum_{k=0}^{N-1} B^{\mathrm{d}}_k, \qquad B^{\mathrm{d}}_k \in \Psi^{-m-k}_{\mathrm{cl}}(M;\mathbf{F},\mathbf{E}), \qquad AB^{\mathrm{d}}_{<N} - I_{\mathbf{F}} \in \Psi^{-N}_{\mathrm{cl}}(M;\mathbf{F},\mathbf{F}).$$

The base case $N=1$ is the choice of B_0. Assuming the assertion for N, define the global homogeneous section

$$\mathbf{e}^{\mathrm{d}}_N := \sigma^\Psi_{-N}\big(AB^{\mathrm{d}}_{<N} - I_{\mathbf{F}}\big) \in \mathcal{S}^{-N}_{\mathrm{hom}}\big(T^*M;\mathrm{End}(\mathbf{F})\big)$$

and

$$\mathbf{c}^{\mathrm{d}}_{-m-N} := -\mathbf{a}_m^{-1}\mathbf{e}^{\mathrm{d}}_N \in \mathcal{S}^{-m-N}_{\mathrm{hom}}\big(T^*M;\mathrm{Hom}(\mathbf{F},\mathbf{E})\big).$$

These are global sections: $\mathbf{e}^{\mathrm{d}}_N$ is the principal symbol of a global operator, and the bundle composition $\mathbf{a}_m^{-1}\circ\mathbf{e}^{\mathrm{d}}_N$ transforms $\pi^*\mathbf{F}$ into $\pi^*\mathbf{E}$. Surjectivity of the exact sequence provides $B^{\mathrm{d}}_N \in \Psi^{-m-N}_{\mathrm{cl}}(M;\mathbf{F},\mathbf{E})$ with principal symbol $\mathbf{c}^{\mathrm{d}}_{-m-N}$. The product rule for principal symbols gives

$$\begin{aligned}\sigma^\Psi_{-N}\big(A(B^{\mathrm{d}}_{<N}+B^{\mathrm{d}}_N) - I_{\mathbf{F}}\big) &= \mathbf{e}^{\mathrm{d}}_N + \sigma^\Psi_m(A)\mathbf{c}^{\mathrm{d}}_{-m-N}\\ &= \mathbf{e}^{\mathrm{d}}_N - \sigma^\Psi_m(A)\mathbf{a}_m^{-1}\mathbf{e}^{\mathrm{d}}_N = 0.\end{aligned}$$

By exactness, the new error belongs to $\Psi^{-N-1}_{\mathrm{cl}}(M;\mathbf{F},\mathbf{F})$; this completes the right step.

For the left side, suppose $B^{\mathrm{i}}_{<N}A - I_{\mathbf{E}} \in \Psi^{-N}_{\mathrm{cl}}(M;\mathbf{E},\mathbf{E})$ and set

$$\mathbf{e}^{\mathrm{i}}_N := \sigma^\Psi_{-N}\big(B^{\mathrm{i}}_{<N}A - I_{\mathbf{E}}\big) \in \mathcal{S}^{-N}_{\mathrm{hom}}\big(T^*M;\mathrm{End}(\mathbf{E})\big), \qquad \mathbf{c}^{\mathrm{i}}_{-m-N} := -\mathbf{e}^{\mathrm{i}}_N\mathbf{a}_m^{-1}.$$

Now $\mathbf{c}^{\mathrm{i}}_{-m-N}$ is a global section of $\mathrm{Hom}(\pi^*\mathbf{F},\pi^*\mathbf{E})$ and can be quantized as $B^{\mathrm{i}}_N \in \Psi^{-m-N}_{\mathrm{cl}}(M;\mathbf{F},\mathbf{E})$. In this case,

$$\sigma^\Psi_{-N}\big((B^{\mathrm{i}}_{<N}+B^{\mathrm{i}}_N)A - I_{\mathbf{E}}\big) = \mathbf{e}^{\mathrm{i}}_N + \mathbf{c}^{\mathrm{i}}_{-m-N}\sigma^\Psi_m(A) = 0,$$

so the left error also drops from $-N$ to $-N-1$. In a chart, the components of the two choices of $\mathbf{c}_{-m-N}$ are exactly the right-hand sides of (15.52) and (15.53); the preceding global formulas prove, rather than presuppose, that these expressions glue.

Lemma 15.1.5, applied over a locally finite cover and followed by adjustment of proper support, sums the two families into operators B_{d} and B_{i}. The inductive steps show that $AB_{\mathrm{d}} - I_{\mathbf{F}}$ belongs to $\Psi^{-N}(M;\mathbf{F},\mathbf{F})$ and $B_{\mathrm{i}}A - I_{\mathbf{E}}$ to $\Psi^{-N}(M;\mathbf{E},\mathbf{E})$ for each N, so both are smoothing. The algebraic identity above shows that $B_{\mathrm{i}} - B_{\mathrm{d}} \in \Psi^{-\infty}(M;\mathbf{F},\mathbf{E})$ and that either operator is two-sided. This reproduces the local recurrences globally and proves (c)⇒(b). The implication (b)⇒(c) follows by taking principal symbols in $AB = I_{\mathbf{F}} - R_{\mathbf{F}}$ and $BA = I_{\mathbf{E}} - R_{\mathbf{E}}$. Equivalence of (a) and (c) is Proposition 15.5.2 applied in charts. If B and $\widetilde{B}$ are two-sided, the same identity above, with $B_{\mathrm{i}} = B$ and $B_{\mathrm{d}} = \widetilde{B}$, shows that $B - \widetilde{B}$ is smoothing. □

Remark 15.5.5. (A parametrix need not be an inverse) The theorem's identities hold modulo smooth kernels, not exactly. A parametrix exists because of high-frequency behavior; an inverse also requires injectivity and surjectivity in the space where A is realized. For example, on a closed connected manifold, the Laplacian is elliptic and has a parametrix, but constant functions belong to its kernel. It is therefore not invertible on all of $C^{\infty}(M)$. If a realization of A has a true inverse, that inverse agrees with any parametrix modulo the correction eliminating the smoothing remainders; this additional assertion is not part of symbolic ellipticity.

Corollary 15.5.6. (Qualitative elliptic regularity) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E},\mathbf{F} \to M$ be smooth complex vector bundles of the same finite rank. Let $A \in \Psi^{m}_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$ be elliptic and properly supported. If $\mathbf{u} \in \mathcal{D}'(M,\mathbf{E})$ and $A\mathbf{u}$ is smooth on an open set $V \subseteq M$, then $\mathbf{u}$ is smooth on V. In particular,

$$\operatorname{singsupp}(A\mathbf{u}) = \operatorname{singsupp}(\mathbf{u}).$$

Proof. Let B be a two-sided parametrix. From $BA = I_{\mathbf{E}} - R_{\mathbf{E}}$ we obtain $\mathbf{u} = B(A\mathbf{u}) + R_{\mathbf{E}}\mathbf{u}$. The first summand is smooth on V by pseudolocality of B, and the second is smooth on all of M. This proves the first assertion. The reverse inclusion for singular supports is Theorem 15.2.5. □

15.5.3 The wavefront set on a Euclidean open set

Qualitative elliptic regularity detects the points where a distribution is smooth. To also record cotangent directions in which smoothness fails, we must localize in the base and examine Fourier decay within cones.

Write

$$\mathcal{E}'(\mathbb{R}^n) := \{v \in \mathcal{D}'(\mathbb{R}^n) \mid \operatorname{supp} v \text{ is compact}\}.$$

A compactly supported distribution v is tempered, and its Fourier transform is the smooth function

$$\widehat{v}(\xi) = (2\pi)^{-\frac{n}{2}} \langle v(x), e^{-ix\cdot\xi} \rangle.$$

Continuity of v on functions supported in a fixed compact set shows that $\widehat{v}$ and all its derivatives have at most polynomial growth. The wavefront set records the directions where this growth improves to rapid decay after localization in the spatial variable.

We say that two open cones $\Gamma', \Gamma \subseteq \mathbb{R}^n \setminus \{0\}$ satisfy $\Gamma' \Subset_{\mathrm{c}} \Gamma$ if

$$\overline{\Gamma' \cap \mathbb{S}^{n-1}} \subseteq \Gamma \cap \mathbb{S}^{n-1}.$$

Lemma 15.5.7. (Stability under shrinking the cone) Let $v \in \mathcal{E}'(\mathbb{R}^n)$ and suppose that, for every N, there exists C_N such that

$$|\widehat{v}(\xi)| \le C_N \langle \xi \rangle^{-N}, \qquad \xi \in \Gamma,$$

where Γ is an open cone. If $\psi \in C_c^\infty(\mathbb{R}^n)$ and $\Gamma' \Subset_{\mathrm{c}} \Gamma$, then $\widehat{\psi v}$ decays rapidly in Γ'.

Proof. With the unitary normalization,

$$\widehat{\psi v}(\xi) = (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} \widehat{\psi}(\xi - \eta)\widehat{v}(\eta)\, d\eta.$$

The function $\widehat{v}$ has polynomial growth, and $\widehat{\psi}$ is a Schwartz function. For $\xi \in \Gamma'$, split the integral into $\eta \in \Gamma$ and $\eta \notin \Gamma$. In the first region, use the arbitrary decay of $\widehat{v}$ and Peetre's inequality in Lemma 6.1.1. In the second, angular separation of the cones gives a constant $c > 0$ such that

$$|\xi - \eta| \ge c(|\xi| + |\eta|)$$

if $\xi \in \Gamma'$ and $\eta \notin \Gamma$. The decay of $\widehat{\psi}$ then offsets any power of ξ as well as the polynomial growth of $\widehat{v}$. Both integrals are bounded by $C_N' \langle \xi \rangle^{-N}$ for every N. □

Definition 15.5.8. (Euclidean wavefront set) Let $U \subseteq \mathbb{R}^n$ be open and let $u \in \mathcal{D}'(U)$. A point $(x_0, \xi_0) \in U \times (\mathbb{R}^n \setminus \{0\})$ is a **regular direction** of u if there exist $\varphi \in C_c^\infty(U)$ equal to one on a neighborhood of x_0 and an open cone Γ containing ξ_0 such that, for every $N \in \mathbb{N}_0$,

$$\sup_{\xi \in \Gamma} \langle \xi \rangle^N |\widehat{\varphi u}(\xi)| < \infty.$$

The **wavefront set** of u is the complement of the regular directions:

$$\mathrm{WF}(u) \subseteq U \times (\mathbb{R}^n \setminus \{0\}).$$

Lemma 15.5.7 shows that the definition is independent of the cutoff: if ψ is supported in the region where $\varphi = 1$, then $\psi u = \psi(\varphi u)$, and it suffices to shrink the cone.

Proposition 15.5.9. (Elementary properties of the wavefront set) Let $U \subseteq \mathbb{R}^n$ be open. For $u, v \in \mathcal{D}'(U)$ and $f \in C^\infty(U)$, the following hold:

(i) $\mathrm{WF}(u)$ is closed in $T^*U \setminus 0_U$ and conic in the covariable;

(ii)
$$\mathrm{WF}(u + v) \subseteq \mathrm{WF}(u) \cup \mathrm{WF}(v), \qquad \mathrm{WF}(f u) \subseteq \mathrm{WF}(u);$$

(iii) the projection $\pi \colon T^*U \longrightarrow U$ satisfies

$$\pi\big(\mathrm{WF}(u)\big) = \operatorname{sing\,supp}(u).$$

Proof. If a cutoff and a cone establish regularity at (x_0, ξ_0), the same function works for base points in a neighborhood of x_0, and the same cone works for directions near ξ_0. Thus the set of regular directions is open. Invariance under positive dilations is immediate and proves (i).
For a sum, choose a common cutoff and intersect two cones of regularity. For fu, take a cutoff ψ supported where the original cutoff equals one, and apply Lemma 15.5.7 to the smooth multiplier ψf. This proves (ii).
If u is smooth near x_0, a localization φu belongs to C_c^∞ and its transform is Schwartz in every direction. Thus x_0 does not belong to the projection of the wavefront set. Conversely, suppose no nonzero covariable over x_0 belongs to the wavefront set. Compactness of $\mathbb{S}^{n-1}$ allows finitely many cones of regularity to be chosen covering the sphere. Choose a single function φ equal to one near x_0 and supported in the intersection of the regions where the corresponding cutoffs equal one. The preceding lemma then shows that $\widehat{\varphi u}$ decays faster than any power in every direction. Thus $\xi^\alpha \widehat{\varphi u} \in L^1$ for every α. Fourier inversion in the distributional sense implies $\varphi u \in C^\infty$. Hence u is smooth near x_0, proving (iii). □

15.5.4 Invariance and the global definition

The Euclidean definition is expressed in frequencies, but the direction it records belongs to the cotangent bundle. We must check that a diffeomorphism transports these directions by its cotangent map and preserves rapid decay in the corresponding cones. The precise assertion is as follows.

Proposition 15.5.10. (Invariance under diffeomorphisms) Let $\kappa\colon U \longrightarrow V$ be a diffeomorphism between Euclidean open sets, and let $u \in \mathcal{D}'(U)$. For the transformed distribution $\kappa_* u \in \mathcal{D}'(V)$,

$$\mathrm{WF}(\kappa_* u) = \left\{ \left(\kappa(x), D\kappa(x)^{-T}\xi\right) \mid (x,\xi) \in \mathrm{WF}(u) \right\}.$$

Proof. Localize u on a compact set where κ is the chart under consideration. By Fourier inversion of the localized distribution, the Fourier transform of a localization of $\kappa_* u$ can be written as an integral in (x,ξ) with phase

$$x \cdot \xi - \kappa(x) \cdot \eta.$$

Its stationary points in x satisfy $\xi = D\kappa(x)^T \eta$. Suppose (x_0, ξ_0) is regular, and set $\eta_0 = D\kappa(x_0)^{-T}\xi_0$. Shrink the neighborhood of x_0 and the cones of ξ_0, η_0 so that every solution of the stationary relation remains within the cone where the localized transform of u decays rapidly. Use this decay in that region. In the complement, the gradient $\xi - D\kappa(x)^T\eta$ is bounded away from zero; repeated integration by parts with

$$L = \frac{1 - i(\xi - D\kappa(x)^T\eta)\cdot D_x}{1 + \|\xi - D\kappa(x)^T\eta\|^2}$$

produces any negative power of $\langle \eta \rangle$. Jacobians and cutoffs are smooth compactly supported amplitudes and do not change the estimates. Thus $(\kappa(x_0), \eta_0)$ is regular for $\kappa_* u$. Applying the same argument to κ^{-1} gives the reverse inclusion and proves equality. □

Definition 15.5.11. (Global wavefront set) Let M be a finite-dimensional smooth manifold without boundary, let $\mathbf{E} \to M$ be a smooth complex vector bundle of finite rank, and let $\mathbf{u} \in \mathcal{D}'(M, \mathbf{E})$. In a chart $\kappa\colon U \to \mathbb{R}^n$

and a local frame, write $\mathbf{u} = (u^1, \dots, u^r)$. Declare that $(x,\xi) \in T^*M \setminus 0_M$ does not belong to $\mathrm{WF}(\mathbf{u})$ if

$$\big(\kappa(x), D\kappa(x)^{-T}\xi\big) \notin \bigcup_{a=1}^{r} \mathrm{WF}(u^a).$$

Proposition 15.5.10 proves independence of the chart. A frame change multiplies the components by a smooth invertible matrix; Proposition 15.5.9(ii), applied in both directions, proves independence of the frame. Thus $\mathrm{WF}(\mathbf{u})$ is a closed conic subset of $T^*M \setminus 0_M$, and

$$\pi\big(\mathrm{WF}(\mathbf{u})\big) = \operatorname{sing\,supp}(\mathbf{u}).$$

The definition is also independent of the choice of a positive density for representing distributions in coordinates: two choices differ by a nonvanishing smooth function. In the Riemannian case, as elsewhere in Riemannian analysis, we use the measure $d\lambda_{\mathbf{g}}$. In this precise sense, the wavefront set is canonical: it is independent of the atlas, frame, metric, and auxiliary density.

15.5.5 Pseudodifferential action and microlocal regularity

Pseudolocality says that a pseudodifferential operator creates no singularities in the base. The wavefront set refines this assertion: the operator creates no new singular directions either. When the symbol is elliptic at a covector, a microlocal parametrix also recovers the datum's singular direction from that of its image.

Theorem 15.5.12. (Pseudodifferential operators create no wavefronts) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E}, \mathbf{F} \to M$ be smooth complex vector bundles of finite rank. Let $A \in \Psi^m(M; \mathbf{E}, \mathbf{F})$ be properly supported. Then, for every $\mathbf{u} \in \mathcal{D}'(M, \mathbf{E})$,

$$\mathrm{WF}(A\mathbf{u}) \subseteq \mathrm{WF}(\mathbf{u}).$$

In particular, for every multi-index α and every smooth function f,

$$\mathrm{WF}(D^\alpha \mathbf{u}) \subseteq \mathrm{WF}(\mathbf{u}), \qquad \mathrm{WF}(f\mathbf{u}) \subseteq \mathrm{WF}(\mathbf{u})$$

in coordinates.

Proof. The assertion is local. In coordinates, fix $(x_0, \xi_0) \notin \mathrm{WF}(\mathbf{u})$ and write $A = \mathrm{Op}(a)$ modulo a smoothing operator. Choose $\psi \in C_c^\infty$ equal to one near x_0 and supported where a cutoff establishing regularity of (x_0, ξ_0) equals one, and decompose $\mathbf{u} = \psi\mathbf{u} + (1-\psi)\mathbf{u}$. The second summand yields a smooth function near x_0 because the kernel of A is smooth off the diagonal. For $\mathbf{v} = \psi\mathbf{u} \in \mathcal{E}'$ and $\varphi \in C_c^\infty$ supported near x_0, the quantization formula gives

$$\widehat{\varphi A \mathbf{v}}(\zeta) = (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} \mathcal{F}_{x\to\theta}\big(\varphi(x) a(x,\eta)\big)(\zeta - \eta)\widehat{\mathbf{v}}(\eta)\, d\eta. \tag{15.54}$$

Integrating by parts in x gives, for every L,

$$\big\| \mathcal{F}_{x\to\theta}\big(\varphi a(\cdot,\eta)\big)(\theta) \big\| \le C_L \langle\theta\rangle^{-L} \langle\eta\rangle^m.$$

Take a cone Γ where $\widehat{\mathbf{v}}$ decays rapidly and a cone $\Gamma' \Subset_{\mathrm{c}} \Gamma$ containing ξ_0. In (15.54), separate $\eta \in \Gamma$ and $\eta \notin \Gamma$. In the first part, decay of $\widehat{\mathbf{v}}$ absorbs the order m; in the second, use $|\zeta - \eta| \geq c(|\zeta| + |\eta|)$ for $\zeta \in \Gamma'$. Since L is arbitrary and $\widehat{\mathbf{v}}$ has polynomial growth, the right-hand side decays rapidly in Γ'. This proves the inclusion. The final two assertions are special cases, since derivatives and smooth multiplication are pseudodifferential operators. □

To invert only near a covector, it is useful to fix some terminology. Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be smooth complex vector bundles of finite rank. We say that $R \in \Psi^s_{\mathrm{loc}}(M; \mathbf{E}, \mathbf{F})$ is **microlocally smoothing** at $q = (x_0, \xi_0) \in T^*M \setminus 0_M$ if, in some chart and local frames of $\mathbf{E}$ and $\mathbf{F}$, the symbol of a localization of R satisfies, on a product $V \times \Gamma$ containing q,

$$\|D_x^\alpha D_\xi^\beta r(x,\xi)\| \leq C_{N,\alpha,\beta} \langle \xi \rangle^{-N}$$

for every N and large frequencies. The proof of the preceding theorem, using these bounds in the corresponding conic part and cone separation in its complement, gives

$$q \notin \mathrm{WF}(R\mathbf{u}) \qquad \text{for every } \mathbf{u} \in \mathcal{D}'(M, \mathbf{E}). \tag{15.55}$$

Let us check that this condition is independent of the chart. Let $\kappa \colon U \to \widetilde{U}$ be a coordinate change, write

$$\mathcal{B}_\kappa(x,y) := \int_0^1 D\kappa\big(y + t(x-y)\big)\, dt$$

, and suppose r satisfies the preceding bounds near $(\kappa(x_0), \eta_0)$, where $\eta_0 = D\kappa(x_0)^{-T}\xi_0$. After inserting a cutoff $\rho(x,y)$ equal to one near the diagonal, the formula in Theorem 15.2.10 gives the transformed amplitude

$$\widetilde{b}(x,y,\xi) = \rho(x,y) r\big(\kappa(x), \mathcal{B}_\kappa(x,y)^{-T}\xi\big) \frac{|\det D\kappa(y)|}{|\det \mathcal{B}_\kappa(x,y)|}. \tag{15.56}$$

Frame changes merely add smooth matrices on the left and right of this expression.

By continuity of $\mathcal{B}_\kappa^{-T}$ on unit directions, one can choose cones $\Gamma_2 \Subset_{\mathrm{c}} \Gamma_1$ around ξ_0 and a neighborhood U_0 of x_0 such that

$$\mathcal{B}_\kappa(x,y)^{-T}\xi \in \Gamma, \qquad c\langle \xi \rangle \leq \langle \mathcal{B}_\kappa(x,y)^{-T}\xi \rangle \leq C\langle \xi \rangle$$

for $x, y \in U_0$, $\xi \in \Gamma_1$, and large frequencies. Fix an angular cutoff ϑ supported in Γ_1 and equal to one on Γ_2. The chain rule shows that each derivative of $\vartheta(\xi)\widetilde{b}(x,y,\xi)$ is a finite sum of terms

$$c_{\mu,\nu,\lambda}(x,y)\, \xi^\mu (D_z^\nu D_\eta^\lambda r)\big(\kappa(x), \mathcal{B}_\kappa(x,y)^{-T}\xi\big),$$

and terms of the same form with a derivative of ϑ. The coefficients $c_{\mu,\nu,\lambda}$ and all their derivatives are bounded after shrinking U_0. Given L, apply the bound on r with exponent $L + |\mu|$; the preceding comparability gives, for all α, γ, β,

$$\|D_x^\alpha D_y^\gamma D_\xi^\beta (\vartheta \widetilde{b})(x,y,\xi)\| \leq C_{L,\alpha,\gamma,\beta} \langle \xi \rangle^{-L} \tag{15.57}$$

on $U_0 \times U_0 \times \Gamma_2$.

When reducing (15.56), each term

$$\frac{i^{-|\delta|}}{\delta!} D_\xi^\delta D_y^\delta \widetilde{b}(x,y,\xi)\big|_{y=x}$$

satisfies (15.57) for any L. If s is a global order of r, the remainder after summing all terms with $|\delta| < J$ satisfies symbol estimates of order $s - J$ by Theorem 15.1.9. For a prescribed bound $\langle\xi\rangle^{-L}$, choose $J > s + L$; the remainder then also satisfies that bound in the smaller cone. Thus the transformed symbol satisfies estimates of order $-L$ on $U_0 \times \Gamma_2$ for every L. Applying the same calculation to κ^{-1} proves equivalence of the two conditions. The smooth frame and density factors already considered change none of the bounds. This proves independence of the chart and auxiliary trivializations.

Proposition 15.5.13. (Microlocal parametrix) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E}, \mathbf{F} \to M$ be smooth complex vector bundles of the same finite rank. If $q \in \mathrm{Ell}(A)$ for $A \in \Psi^m_{\mathrm{cl,loc}}(M; \mathbf{E}, \mathbf{F})$, there exist $B \in \Psi^{-m}_{\mathrm{cl,loc}}(M; \mathbf{F}, \mathbf{E})$ and operators $R_{\mathbf{E}}, R_{\mathbf{F}}$ microlocally smoothing at q such that

$$BA = I_{\mathbf{E}} - R_{\mathbf{E}}, \qquad AB = I_{\mathbf{F}} - R_{\mathbf{F}}$$

microlocally at q.

Proof. Choose a chart $\kappa\colon U \longrightarrow \Omega \subseteq \mathbb{R}^n$ and local frames of common rank r. In this proof write

$$S^j := S^j_{1,0}\big(\Omega; \mathrm{End}(\mathbb{C}^r)\big).$$

Choose neighborhoods $V_2 \Subset V_1 \Subset \Omega$ of the base point and cones $\Gamma_2 \Subset_{\mathrm{c}} \Gamma_1$ around the covariable of q so that a_m is invertible on $V_1 \times \Gamma_1$. Let $\chi(x,\xi)$ be a cutoff of degree zero at large frequencies, supported in $V_1 \times \Gamma_1$ and equal to one on $V_2 \times \Gamma_2$. Set

$$b^{\mathrm{d}}_{-m} = b^{\mathrm{i}}_{-m} = \chi a_m^{-1}.$$

Since all derivatives of χ vanish on the smaller product, there $a \# b^{\mathrm{d}}_{-m} - I_{\mathbf{F}} \in S^{-1}$ and $b^{\mathrm{i}}_{-m} \# a - I_{\mathbf{E}} \in S^{-1}$.
The right induction statement is that, after constructing b^{d}_{-m-k} for $0 \le k < N$,

$$a \# \sum_{k=0}^{N-1} b^{\mathrm{d}}_{-m-k} - I_{\mathbf{F}} \in S^{-N} \qquad \text{on } V_2 \times \Gamma_2.$$

Let e^{d}_N be the error's homogeneous component of degree $-N$, computed on $V_1 \times \Gamma_1$. Define

$$b^{\mathrm{d}}_{-m-N} = -\chi a_m^{-1} e^{\mathrm{d}}_N.$$

On $V_2 \times \Gamma_2$, the new component of degree $-N$ is $e^{\mathrm{d}}_N + a_m b^{\mathrm{d}}_{-m-N} = 0$; the composition formula therefore gives an error in S^{-N-1}. This is exactly the step in (15.52) and proves the right induction.
For the left side, if e^{i}_N is the component of degree $-N$ of

$$\Big(\sum_{k=0}^{N-1} b^{\mathrm{i}}_{-m-k}\Big) \# a - I_{\mathbf{E}},$$

computed on $V_1 \times \Gamma_1$, take $b^{\mathrm{i}}_{-m-N} = -\chi e^{\mathrm{i}}_N a_m^{-1}$. The equality $e^{\mathrm{i}}_N + b^{\mathrm{i}}_{-m-N} a_m = 0$ again reduces the error to S^{-N-1} and reproduces (15.53).
Lemma 15.1.5 sums both families into symbols $b^{\mathrm{d}}, b^{\mathrm{i}} \in S^{-m}$. For each N, both errors belong to S^{-N} on

$V_2 \times \Gamma_2$, so they are microlocally smoothing at q. At the operator level,

$$B_{\mathrm{i}} - B_{\mathrm{d}} = B_{\mathrm{i}}(I_{\mathbf{F}} - AB_{\mathrm{d}}) - (I_{\mathbf{E}} - B_{\mathrm{i}}A)B_{\mathrm{d}}.$$

The composition expansion shows that composing a finite-order symbol with one belonging to S^{-N} on the smaller product for every N preserves this property, after shrinking the cones once more. Thus $B_{\mathrm{i}} - B_{\mathrm{d}}$ is microlocally smoothing, and $B := B_{\mathrm{d}}$ also satisfies the left identity. Quantizing, inserting spatial cutoffs, and arranging proper support yields the two asserted identities; these changes add only smooth kernels near q. □

Theorem 15.5.14. (Microlocal elliptic regularity) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E}, \mathbf{F} \to M$ be smooth complex vector bundles of the same finite rank. Let $A \in \Psi^m_{\mathrm{cl}}(M; \mathbf{E}, \mathbf{F})$ be properly supported. For every $\mathbf{u} \in \mathcal{D}'(M, \mathbf{E})$,

$$\mathrm{WF}(A\mathbf{u}) \subseteq \mathrm{WF}(\mathbf{u}) \subseteq \mathrm{WF}(A\mathbf{u}) \cup \mathrm{Char}(A).$$

Equivalently,

$$\mathrm{WF}(A\mathbf{u}) \cap \mathrm{Ell}(A) = \mathrm{WF}(\mathbf{u}) \cap \mathrm{Ell}(A). \tag{15.58}$$

If A is elliptic, then $\mathrm{WF}(A\mathbf{u}) = \mathrm{WF}(\mathbf{u})$.

Proof. The first inclusion is Theorem 15.5.12. Now let $q \in \mathrm{Ell}(A)$ and suppose $q \notin \mathrm{WF}(A\mathbf{u})$. A microlocal parametrix gives $\mathbf{u} = B(A\mathbf{u}) + R_{\mathbf{E}}\mathbf{u}$ near q. The first summand has no wavefront at q by the preceding theorem, and neither does the second by (15.55). Thus $q \notin \mathrm{WF}(\mathbf{u})$, which is the second inclusion. The remaining assertions reformulate these two inclusions. □

The wavefront set can also be defined entirely in the language of the pseudodifferential calculus.

Theorem 15.5.15. (Characterization by operators of order zero) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E} \to M$ be a smooth complex vector bundle of finite rank. Let $\mathbf{u} \in \mathcal{D}'(M, \mathbf{E})$ and $q \in T^*M \setminus 0_M$. The following are equivalent:

(a) $q \notin \mathrm{WF}(\mathbf{u})$;

(b) there exists $Q \in \Psi^0_{\mathrm{cl}}(M; \mathbf{E}, \mathbf{E})$, properly supported and elliptic at q, such that $Q\mathbf{u} \in \Gamma(M, \mathbf{E})$.

Consequently,

$$\mathrm{WF}(\mathbf{u}) = \bigcap \big\{ \mathrm{Char}(Q) \mid Q \in \Psi^0_{\mathrm{cl}}(M; \mathbf{E}, \mathbf{E}),\ Q\mathbf{u} \in \Gamma(M, \mathbf{E}) \big\}. \tag{15.59}$$

The intersection may be restricted to operators whose principal symbol is a scalar multiple of the identity of $\mathbf{E}$.

Proof. Suppose (a) holds. In a chart and local frame, choose a function φ equal to one near the base point and a cone Γ in which $\widehat{\varphi \mathbf{u}}$ decays rapidly. Let χ be a spatial cutoff equal to one on a smaller neighborhood, and ϑ a homogeneous cutoff of degree zero, angularly supported in Γ and equal to one near the ray of q at large frequencies. Quantize

$$q_0(x, \xi) = \chi(x)\vartheta(\xi) I_{\mathbf{E}}$$

and arrange proper support. In the region where q_0 contributes, the function $\vartheta\widehat{\varphi\mathbf{u}}$ decays rapidly. Fourier inversion and estimate (15.54) show that $Q\mathbf{u}$ is smooth; the parts separated from the diagonal are also smooth. Moreover, the principal symbol of Q is the identity near q, so Q is elliptic there. This proves (b). If (b) holds, microlocal elliptic regularity applied to Q gives

$$\mathrm{WF}(\mathbf{u}) \cap \mathrm{Ell}(Q) = \mathrm{WF}(Q\mathbf{u}) \cap \mathrm{Ell}(Q) = \varnothing.$$

Since $q \in \mathrm{Ell}(Q)$, we obtain (a). Formula (15.59) is the set-theoretic expression of this equivalence. The construction in the first paragraph already uses a scalar symbol times $I_{\mathbf{E}}$, proving the last assertion. □

15.5.6 The wavefront set of the kernel

The conormal description of the kernel and the wavefront-set definition must agree on the diagonal. The following result identifies the possible directions exactly and explains, in microlocal terms, why a pseudodifferential operator relates a covector only to its negative in the input variable.

Theorem 15.5.16. (Wavefront set of a pseudodifferential kernel) Let M be a finite-dimensional smooth manifold without boundary, and let $\mathbf{E}, \mathbf{F} \to M$ be smooth complex vector bundles of finite rank. If $A \in \Psi^{m}_{\mathrm{cl,loc}}(M; \mathbf{E}, \mathbf{F})$ and $\mathbf{K}_A$ is its Schwartz kernel, then

$$\mathrm{WF}(\mathbf{K}_A) \subseteq N^{*}\Delta_M \setminus 0_{M\times M} = \big\{(x,\xi;x,-\xi) \mid (x,\xi) \in T^{*}M \setminus 0_M\big\}. \tag{15.60}$$

Proof. By Theorem 15.3.9, in a chart $\kappa\colon U \longrightarrow \Omega \subseteq \mathbb{R}^n$ and local frames of ranks $r_{\mathbf{E}}, r_{\mathbf{F}}$, the kernel has the form, modulo a smooth function,

$$K(x,y) = (2\pi)^{-n}\,\mathrm{Os}\int_{\mathbb{R}^n_\xi} e^{i(x-y)\cdot\xi}\, b(x,y,\xi)\,d\xi, \qquad b\colon \Omega\times\Omega\times\mathbb{R}^n_\xi \longrightarrow \mathrm{Hom}(\mathbb{C}^{r_{\mathbf{E}}}, \mathbb{C}^{r_{\mathbf{F}}}),$$

where b is a classical amplitude of order m. We already know that K is smooth if $x \neq y$. Now localize near a point of the diagonal with $\rho \in C_c^{\infty}$ and take the Fourier transform in (x,y). Up to a constant depending only on n,

$$\widehat{\rho K}(\zeta,\eta) = \int_{\mathbb{R}^n} \mathcal{F}_{(x,y)\to(\theta,\omega)}\big(\rho b(\cdot,\cdot,\xi)\big)(\zeta-\xi,\eta+\xi)\,d\xi. \tag{15.61}$$

Integration by parts in x and y gives, for every N,

$$\big\|\mathcal{F}_{x,y}(\rho b)(\theta,\omega,\xi)\big\| \le C_N \langle(\theta,\omega)\rangle^{-N}\langle\xi\rangle^{m}.$$

Consider a closed cone of covectors (ζ,η) disjoint from the conormal bundle, that is, one in which

$$|\zeta+\eta| \ge c\big(|\zeta|+|\eta|\big).$$

With $q = \frac{\zeta-\eta}{2}$ and $\xi = q+\tau$, we have the identity

$$|\zeta-\xi|^2 + |\eta+\xi|^2 = 2|\tau|^2 + \tfrac{1}{2}|\zeta+\eta|^2.$$

In the cone under consideration, $|q| \le C|\zeta+\eta|$. Inserting the preceding estimate into (15.61), choosing N

arbitrarily large, and integrating in τ gives, for every L,

$$|\widehat{\rho K}(\zeta,\eta)| \le C_L \langle(\zeta,\eta)\rangle^{-L}.$$

By Definition 15.5.8, no covector with $\zeta+\eta\neq 0$ belongs to the wavefront set over the diagonal. The remaining covectors are exactly $(x,\xi;x,-\xi)$, in accordance with (15.16). Invariance under coordinate changes and multiplication by the smooth factors arising from frames and a density globalize the inclusion. □

If one adopts the convention of changing sign in the input covariable,

$$\mathrm{WF}'(\mathbf{K}_A) := \big\{(x,\xi;y,\eta)\,|\,(x,\xi;y,-\eta)\in \mathrm{WF}(\mathbf{K}_A)\big\},$$

the inclusion (15.60) becomes

$$\mathrm{WF}'(\mathbf{K}_A) \subseteq \big\{(x,\xi;x,\xi)\,|\,(x,\xi)\in T^*M\setminus 0_M\big\}.$$

Thus a pseudodifferential kernel transmits a singularity only at the same point and in the same cotangent direction. This assertion contains qualitative pseudolocality and, together with the microlocal parametrix, explains the elliptic equality (15.58).

The symbolic construction of the parametrix and the conormal inclusion for the kernel's wavefront set correspond, under the translation $D=\partial$, to Theorems 18.1.9, 18.1.16, and 18.1.24 of [84]. These proofs make explicit the recurrence, control of remainders, and passage from Fourier analysis to the global formulation.

15.6 Action on Sobolev spaces, uniform calculus, and Fredholm theory

The symbolic calculus acquires analytic content when translated into estimates between Sobolev spaces. In this section we write

$$H^s(M,\mathbf{E}) := H^{s,2}(M,\mathbf{E}), \qquad s\in\mathbb{R},$$

and use the bundle metrics and measure $d\lambda_{\mathbf{g}}$ to define the inner products on $L^2(M,\mathbf{E})$ and $L^2(M,\mathbf{F})$. In the complex case, we retain the previously fixed convention: the Hermitian inner product is linear in its first variable. We first prove the Euclidean order-zero estimate, then transfer it to manifolds, carefully distinguish the uniform noncompact case from the closed case, and deduce the Fredholm property.

15.6.1 The Calderón–Vaillancourt estimate

The decisive point is that an order-zero symbol defines a bounded operator between $L^2(\mathbb{R}^n,\mathbb{C}^r)$ and $L^2(\mathbb{R}^n,\mathbb{C}^s)$ even though its kernel need not be absolutely integrable. We give a proof using wave packets, because it exhibits finitely many seminorms and uses neither interpolation nor spectral theory.

Theorem 15.6.1. (Calderón–Vaillancourt) Let $n,r,s\in\mathbb{N}$, let

$$a\in S^0_{1,0}\big(\mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s)\big)$$

, and let $N_{\mathrm{CV}} := 4n+4$. There exists a constant $C=C(n,r,s)>0$ such that

$$\|\mathrm{Op}(a)u\|_{L^2(\mathbb{R}^n,\mathbb{C}^s)} \le C\, q_{N_{\mathrm{CV}},0}(a)\,\|u\|_{L^2(\mathbb{R}^n,\mathbb{C}^r)} \tag{15.62}$$

for every $u \in \mathcal{S}(\mathbb{R}^n, \mathbb{C}^r)$. Consequently, $\mathrm{Op}(a)$ extends uniquely to a continuous operator from $L^2(\mathbb{R}^n, \mathbb{C}^r)$ to $L^2(\mathbb{R}^n, \mathbb{C}^s)$.

Proof. It suffices to treat the scalar case: in finite rank, apply the argument to each matrix entry. Fix a nonzero $g \in C_c^\infty(\mathbb{R}^n)$ and define

$$g_{z,\zeta}(x) := e^{ix\cdot\zeta} g(x-z), \qquad (Wu)(z,\zeta) := \langle u, g_{z,\zeta}\rangle_{L^2(\mathbb{R}^n)}, \qquad (z,\zeta) \in \mathbb{R}^{2n}.$$

Plancherel's identity, applied first in ζ and then in z, gives Moyal's identity

$$\|Wu\|^2_{L^2(\mathbb{R}^{2n})} = (2\pi)^n \|g\|^2_{L^2(\mathbb{R}^n)} \|u\|^2_{L^2(\mathbb{R}^n)}. \tag{15.63}$$

By polarization, $W^*W = c_g I$, where $c_g = (2\pi)^n \|g\|^2_{L^2(\mathbb{R}^n)}$.
Consider the matrix kernel of $W\,\mathrm{Op}(a)W^*$:

$$\mathcal{M}_a(z,\zeta;w,\eta) := \langle \mathrm{Op}(a) g_{w,\eta}, g_{z,\zeta}\rangle.$$

The quantization formula of Definition 15.1.6 writes it as an oscillatory integral in (x,y,θ) with phase

$$\Phi = x\cdot(\theta-\zeta) + y\cdot(\eta-\theta)$$

and amplitude

$$(2\pi)^{-n} a(x,\theta) g(y-w)\overline{g(x-z)}.$$

Set $L = n+1$. Since

$$(1-\Delta_x)^L e^{i\Phi} = \langle \theta-\zeta\rangle^{2L} e^{i\Phi}, \qquad (1-\Delta_y)^L e^{i\Phi} = \langle \theta-\eta\rangle^{2L} e^{i\Phi},$$

, integrate by parts L times in x and in y. Derivatives in x hit a and $g(x-z)$; derivatives in y hit only $g(y-w)$. On the supports of these two factors,

$$\langle z-w\rangle \le C_g \langle x-y\rangle.$$

To introduce this weight without changing the oscillatory integral, expand the polynomial $\langle z-w\rangle^{2L} = (1+|z-w|^2)^L$ using $z-w = (x-y)-(x-z)+(y-w)$. The factors in $x-z$ and $y-w$ are incorporated into the smooth compactly supported functions and their derivatives. The remaining factors are monomials $(x-y)^\gamma$ with $|\gamma| \le 2L$; use

$$(x-y)^\gamma e^{i\Phi} = i^{-|\gamma|} D_\theta^\gamma e^{i\Phi}$$

to integrate by parts in θ. Derivatives of the weights $\langle\theta-\zeta\rangle^{-2L}$ and $\langle\theta-\eta\rangle^{-2L}$ do not worsen their decay, and those hitting the symbol are controlled by $q_{4L,0}(a)$. This yields

$$|\mathcal{M}_a(z,\zeta;w,\eta)| \le C_g q_{4L,0}(a) \langle z-w\rangle^{-2L} \int_{\mathbb{R}^n} \langle\theta-\zeta\rangle^{-2L}\langle\theta-\eta\rangle^{-2L}\, d\theta.$$

Since $2L > n$, the elementary convolution inequality, together with Peetre's weight comparison in Lemma 6.1.1, gives

$$\int_{\mathbb{R}^n} \langle\theta-\zeta\rangle^{-2L}\langle\theta-\eta\rangle^{-2L}\, d\theta \le C_L \langle\zeta-\eta\rangle^{-2L}.$$

This inequality is proved by splitting the domain into the regions $\|\theta-\zeta\| \geq \frac{\|\zeta-\eta\|}{2}$ and $\|\theta-\eta\| \geq \frac{\|\zeta-\eta\|}{2}$. Thus

$$|\mathcal{M}_a(z,\zeta;w,\eta)| \leq C q_{4n+4,0}(a)\langle z-w\rangle^{-2n-2}\langle \zeta-\eta\rangle^{-2n-2}. \tag{15.64}$$

The right-hand side is integrable in (w,η) uniformly in (z,ζ), and also in (z,ζ) uniformly in (w,η). Proposition B.8.3, applied with $X = Y = \mathbb{R}^{2n}$, Lebesgue measure, and $r = s = 1$, shows that the integral operator with kernel $\mathcal{M}_a$ is bounded on $L^2(\mathbb{R}^{2n})$. Finally,

$$\operatorname{Op}(a) = c_g^{-2} W^*\big(W \operatorname{Op}(a) W^*\big) W,$$

and (15.63) yield (15.62). Density of $\mathcal{S}(\mathbb{R}^n,\mathbb{C}^r)$ in $L^2(\mathbb{R}^n,\mathbb{C}^r)$ gives the unique extension. □

The integer $4n+4$ is a sufficient choice using only finitely many derivatives. For other choices and proofs, see [140, 84, 135].

15.6.2 Action on Sobolev scales

Recall that

$$J^t = \operatorname{Op}(\langle\xi\rangle^t)\colon H^t(\mathbb{R}^n) \longrightarrow L^2(\mathbb{R}^n)$$

is an isometric isomorphism with the unitary normalization fixed in Definition 4.11.1 and Theorem 4.11.10.

Theorem 15.6.2. (Euclidean Sobolev mapping) Let $n, r, q \in \mathbb{N}$, $m, \sigma \in \mathbb{R}$, and

$$a \in S^m_{1,0}\big(\mathbb{R}^n; \operatorname{Hom}(\mathbb{C}^r,\mathbb{C}^q)\big).$$

. Then

$$\operatorname{Op}(a)\colon H^{\sigma+m}(\mathbb{R}^n,\mathbb{C}^r) \longrightarrow H^{\sigma}(\mathbb{R}^n,\mathbb{C}^q)$$

is continuous. Its norm is controlled by finitely many seminorms of a in $S^m_{1,0}(\mathbb{R}^n;\operatorname{Hom}(\mathbb{C}^r,\mathbb{C}^q))$.

Proof. The composition calculus of Theorem 15.2.6 shows that

$$B := J^{\sigma} \operatorname{Op}(a) J^{-(\sigma+m)}$$

is a pseudodifferential operator of order zero. The seminorms of a fixed number of terms in its symbol and of the remainder are controlled by finitely many seminorms of a. Theorem 15.6.1 gives

$$\|\operatorname{Op}(a)u\|_{H^{\sigma}(\mathbb{R}^n,\mathbb{C}^q)} = \|J^{\sigma}\operatorname{Op}(a)u\|_{L^2(\mathbb{R}^n,\mathbb{C}^q)} \leq C\|J^{\sigma+m}u\|_{L^2(\mathbb{R}^n,\mathbb{C}^r)} = C\|u\|_{H^{\sigma+m}(\mathbb{R}^n,\mathbb{C}^r)}.$$

□

Before passing to manifolds, it is useful to isolate the other term that appears when localizing an operator: a smooth compactly supported kernel. Unlike the pseudodifferential part, this term improves regularity by arbitrarily many derivatives. The following estimate specifies how many kernel derivatives suffice to control each Sobolev mapping.

Lemma 15.6.3. (Sobolev mapping of a smooth compactly supported kernel) Let $U, V \subseteq \mathbb{R}^n$ be bounded open sets, and let $K \Subset U \times V$, $r, s \in \mathbb{N}$, and

$$k \in C^\infty\big(U \times V; \operatorname{Hom}(\mathbb{C}^r, \mathbb{C}^s)\big), \qquad \operatorname{supp} k \subseteq K.$$

. For $\sigma, \tau \in \mathbb{R}$, define

$$a_\sigma := \max\{0, \lceil \sigma \rceil\}, \qquad b_\tau := \max\{0, \lceil -\tau \rceil\}, \qquad N(n, \sigma, \tau) := a_\sigma + b_\tau. \tag{15.65}$$

For $u \in H^\tau(V, \mathbb{C}^r)$, choose an extension $\widetilde{u} \in H^\tau(\mathbb{R}^n, \mathbb{C}^r)$ of u. For each $x \in U$, define $T_k u(x) \in \mathbb{C}^s$ by

$$\langle T_k u(x), w \rangle_{\mathbb{C}^s} := \langle \widetilde{u}, k(x, \cdot)^* w \rangle_{H^\tau(\mathbb{R}^n, \mathbb{C}^r), H^{-\tau}(\mathbb{R}^n, \mathbb{C}^r)}, \qquad w \in \mathbb{C}^s, \tag{15.66}$$

where $k(x, \cdot)^* w$ is extended by zero outside V and the pairing is linear in the first variable, in accordance with this chapter's Hermitian convention. This definition is independent of the chosen extension and determines a continuous linear operator

$$T_k \colon H^\tau(V, \mathbb{C}^r) \longrightarrow H^\sigma(U, \mathbb{C}^s).$$

The map $x \mapsto T_k u(x)$ is smooth and, for every multi-index α,

$$\big\langle D_x^\alpha (T_k u)(x), w \big\rangle_{\mathbb{C}^s} = \big\langle \widetilde{u}, \big(D_x^\alpha k\big)(x, \cdot)^* w \big\rangle_{H^\tau(\mathbb{R}^n, \mathbb{C}^r), H^{-\tau}(\mathbb{R}^n, \mathbb{C}^r)}. \tag{15.67}$$

If u has a representative in $L^1_{\mathrm{loc}}(V, \mathbb{C}^r)$, then

$$(T_k u)(x) = \int_V k(x, y) u(y)\, dy, \qquad x \in U.$$

Moreover, there is a constant $C = C(n, \sigma, \tau, U, V, K, r, s) > 0$ independent of k such that

$$\|T_k\|_{\mathcal{L}(H^\tau(V, \mathbb{C}^r), H^\sigma(U, \mathbb{C}^s))} \le C \max_{|\alpha| + |\beta| \le N(n, \sigma, \tau)} \sup_{(x, y) \in K} \|D_x^\alpha D_y^\beta k(x, y)\|. \tag{15.68}$$

The choice of N in (15.65) is sufficient; smaller values may be valid but are not needed for later applications.

Proof. Spaces on open sets are understood with the quotient restriction norm of Definition 6.1.5, applied componentwise. Let $K_U := \operatorname{pr}_1(K) \Subset U$ and $K_V := \operatorname{pr}_2(K) \Subset V$. For $x \in U$ and $w \in \mathbb{C}^s$,

$$k(x, \cdot)^* w \in C_c^\infty(V, \mathbb{C}^r), \qquad \operatorname{supp}\big(k(x, \cdot)^* w\big) \subseteq K_V.$$

Its extension by zero belongs to $C_c^\infty(\mathbb{R}^n, \mathbb{C}^r)$ and, by Proposition 6.1.6, to $H^{-\tau}(\mathbb{R}^n, \mathbb{C}^r)$. The right-hand side of (15.66) is therefore well defined. Since the Hermitian inner product is linear in its first variable, this expression is antilinear in w. If $(e_j)_{j=1}^s$ is an orthonormal basis of $\mathbb{C}^s$, the vector

$$\sum_{j=1}^{s} \big\langle \widetilde{u}, k(x, \cdot)^* e_j \big\rangle_{H^\tau(\mathbb{R}^n, \mathbb{C}^r), H^{-\tau}(\mathbb{R}^n, \mathbb{C}^r)}\, e_j$$

satisfies (15.66) for every $w \in \mathbb{C}^s$. Nondegeneracy of the Hermitian inner product shows that it is the unique vector with this property.

Let us check independence of the extension. If $\widetilde{u}_1$ and $\widetilde{u}_2$ restrict to u on V, then $d := \widetilde{u}_1 - \widetilde{u}_2$ vanishes as a distribution on V. Since $k(x,\cdot)^* w$ has compact support contained in V, the Sobolev pairing here agrees with the distributional action, and

$$\langle d, k(x,\cdot)^* w \rangle_{H^{\tau}(\mathbb{R}^n,\mathbb{C}^r),H^{-\tau}(\mathbb{R}^n,\mathbb{C}^r)} = 0.$$

Thus (15.66) is independent of $\widetilde{u}$.

For each $w \in \mathbb{C}^s$, the map

$$x \longmapsto k(x,\cdot)^* w$$

is smooth from U into the Fréchet space $C^{\infty}_{K_V}(\mathbb{R}^n,\mathbb{C}^r)$ of smooth functions supported in K_V. The inclusion of this space into $H^{-\tau}(\mathbb{R}^n,\mathbb{C}^r)$ is continuous. Composing with the pairing against $\widetilde{u}$ gives a smooth function of x and allows differentiation within the duality. Taking w successively in an orthonormal basis of $\mathbb{C}^s$ shows that $x \mapsto T_k u(x)$ is smooth and gives (15.67) for every multi-index α.

If $u \in L^1_{\mathrm{loc}}(V,\mathbb{C}^r)$, pairing with a test function recovers the Lebesgue integral. By definition of the adjoint and the Hermitian convention,

$$\begin{aligned} \langle T_k u(x), w \rangle_{\mathbb{C}^s} &= \int_V \big\langle u(y), k(x,y)^* w \big\rangle_{\mathbb{C}^r}\, dy \\ &= \int_V \big\langle k(x,y) u(y), w \big\rangle_{\mathbb{C}^s}\, dy. \end{aligned}$$

Since this holds for every $w \in \mathbb{C}^s$, the duality definition agrees with the usual integral asserted in the statement.

It remains to prove the estimate. Fix $\varepsilon > 0$ and choose the extension so that

$$\|\widetilde{u}\|_{H^{\tau}(\mathbb{R}^n,\mathbb{C}^r)} \le \|u\|_{H^{\tau}(V,\mathbb{C}^r)} + \varepsilon.$$

If $|\alpha| \le a_\sigma$ and $\|w\|_{\mathbb{C}^s} = 1$, duality, $b_\tau \ge -\tau$, and (15.67) give

$$\begin{aligned} \big|\big\langle D_x^{\alpha}(T_k u)(x), w \big\rangle_{\mathbb{C}^s}\big| &\le \|\widetilde{u}\|_{H^{\tau}(\mathbb{R}^n,\mathbb{C}^r)} \big\| \big(D_x^{\alpha} k\big)(x,\cdot)^* w \big\|_{H^{-\tau}(\mathbb{R}^n,\mathbb{C}^r)} \\ &\le \|\widetilde{u}\|_{H^{\tau}(\mathbb{R}^n,\mathbb{C}^r)} \big\| \big(D_x^{\alpha} k\big)(x,\cdot)^* w \big\|_{H^{b_\tau}(\mathbb{R}^n,\mathbb{C}^r)}. \end{aligned}$$

For $q \in \mathbb{N}_0$, the polynomial comparison

$$\langle \xi \rangle^{2q} \le C_{n,q} \sum_{|\beta| \le q} |\xi^{\beta}|^2$$

and Plancherel's theorem 4.11.10, applied componentwise, imply

$$\|f\|^2_{H^q(\mathbb{R}^n,\mathbb{C}^r)} \le C_{n,q} \sum_{|\beta| \le q} \|D^{\beta} f\|^2_{L^2(\mathbb{R}^n,\mathbb{C}^r)}.$$

Since all preceding test functions are supported in K_V, this inequality with $q = b_\tau$ gives

$$\|\big(D_x^\alpha k\big)(x,\cdot)^* w\|_{H^{b_\tau}(\mathbb{R}^n,\mathbb{C}^r)} \le C_0 \max_{|\beta|\le b_\tau} \sup_{(z,y)\in K} \|D_z^\alpha D_y^\beta k(z,y)\|. \tag{15.69}$$

Here C_0 depends on n, b_τ, r, s and the volume of K_V, but not on x, k, u or w.
Taking the supremum over unit vectors w, integrating in $x \in K_U$, summing over $|\alpha| \le a_\sigma$, and applying the same Plancherel comparison with $q = a_\sigma$ yields

$$\|T_k u\|_{H^{a_\sigma}(\mathbb{R}^n,\mathbb{C}^s)} \le C_1 \|\widetilde{u}\|_{H^\tau(\mathbb{R}^n,\mathbb{C}^r)} \max_{\substack{|\alpha|\le a_\sigma \\ |\beta|\le b_\tau}} \sup_{(x,y)\in K} \|D_x^\alpha D_y^\beta k(x,y)\|.$$

In this formula, extend $T_k u$ by zero outside U; the extension is smooth because $\operatorname{supp}(T_k u) \subseteq K_U \Subset U$. Since $a_\sigma \ge \sigma$, the inclusion $H^{a_\sigma}(\mathbb{R}^n,\mathbb{C}^s) \hookrightarrow H^\sigma(\mathbb{R}^n,\mathbb{C}^s)$ and restriction to U are continuous. Finally, $|\alpha| + |\beta| \le a_\sigma + b_\tau = N(n,\sigma,\tau)$; let $\varepsilon \to 0^+$ to obtain (15.68). □

The local version requires a distinction between compact support and local regularity. For a compact set $K \Subset M$, set

$$H^t_K(M,\mathbf{E}) := \{\mathbf{u} \in H^t_{\mathrm{loc}}(M,\mathbf{E}) \mid \operatorname{supp}\mathbf{u} \subseteq K\}, \qquad H^t_{\mathrm{comp}}(M,\mathbf{E}) := \bigcup_{K\Subset M} H^t_K(M,\mathbf{E}),$$

with the usual inductive topology. The topology of $H^t_{\mathrm{loc}}(M,\mathbf{E})$ is defined by the seminorms $\|\chi\mathbf{u}\|_{H^t(M,\mathbf{E})}$, $\chi \in C^\infty_c(M)$, in accordance with Definition 6.1.7.

Proposition 15.6.4. (Local and compact-support versions) Let $(M,\mathbf{g})$ be a finite-dimensional smooth Riemannian manifold without boundary, not necessarily complete, and let $\mathbf{E},\mathbf{F} \to M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics and metric connections. Let $m, s \in \mathbb{R}$ and $A \in \Psi^m_{\mathrm{loc}}(M;\mathbf{E},\mathbf{F})$. Then

$$A\colon H^{s+m}_{\mathrm{comp}}(M,\mathbf{E}) \longrightarrow H^s_{\mathrm{loc}}(M,\mathbf{F})$$

is continuous. If A is properly supported, there are also continuous extensions

$$A\colon H^{s+m}_{\mathrm{comp}}(M,\mathbf{E}) \longrightarrow H^s_{\mathrm{comp}}(M,\mathbf{F}), \qquad A\colon H^{s+m}_{\mathrm{loc}}(M,\mathbf{E}) \longrightarrow H^s_{\mathrm{loc}}(M,\mathbf{F}).$$

Proof. Let $\chi, \psi \in C^\infty_c(M)$. In finitely many charts and frames, $\chi A \psi$ is a matrix of Euclidean operators of order m modulo a smooth kernel. Theorem 15.6.2 controls the pseudodifferential part, while Lemma 15.6.3 controls the smooth kernel and shows that it gains arbitrarily many derivatives. This proves the first mapping after choosing $\psi = 1$ near the datum's support.
If A is properly supported, the image of a compact set has support in another compact set. For the local mapping, given χ, proper support allows $\psi \in C^\infty_c(M)$ to be chosen so that

$$\chi A = \chi A \psi$$

on a neighborhood of the support of χ. The estimate already proved applies to ψu. These estimates are precisely continuity for the stated inductive and projective topologies. □

Corollary 15.6.5. (Local Sobolev elliptic regularity) Let $(M,\mathbf{g})$ be a finite-dimensional smooth Riemannian manifold without boundary, not necessarily complete, and let $\mathbf{E},\mathbf{F}\to M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics and metric connections. Let $m,s\in\mathbb{R}$, and let $A\in\Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$ be elliptic and properly supported. If $\mathbf{u}\in\mathcal{D}'(M,\mathbf{E})$ and $A\mathbf{u}\in H^s_{\mathrm{loc}}(M,\mathbf{F})$, then $\mathbf{u}\in H^{s+m}_{\mathrm{loc}}(M,\mathbf{E})$. In particular, for every $t\in\mathbb{R}$,

$$\mathbf{u}\in H^t_{\mathrm{loc}}(M,\mathbf{E})\quad\Longleftrightarrow\quad A\mathbf{u}\in H^{t-m}_{\mathrm{loc}}(M,\mathbf{F}).$$

Proof. Let $B\in\Psi^{-m}_{\mathrm{cl}}(M;\mathbf{F},\mathbf{E})$ be a parametrix. The identity $BA=I-R$, with $R\in\Psi^{-\infty}(M;\mathbf{E},\mathbf{E})$, gives $\mathbf{u}=B(A\mathbf{u})+R\mathbf{u}$. Proposition 15.6.4 maps the first term into $H^{s+m}_{\mathrm{loc}}(M,\mathbf{E})$, and the second is smooth. This proves the first assertion. The remaining implication in the equivalence is the local mapping property of A. For differential operators, this recovers the regularity of Theorem 11.4.2; the pseudodifferential calculus adds the localization in codirections of Theorem 15.5.14. □

In particular, if M is closed, every proper-support condition is automatic and a finite cover gives the following result.

Corollary 15.6.6. (Mapping on a closed manifold) Let $(M,\mathbf{g})$ be a closed Riemannian manifold, and let $\mathbf{E},\mathbf{F}\to M$ be complex Hermitian bundles of finite rank equipped with metric connections. Let $m,s\in\mathbb{R}$ and $A\in\Psi^m(M;\mathbf{E},\mathbf{F})$. Then

$$A_s\colon H^{s+m}(M,\mathbf{E})\longrightarrow H^s(M,\mathbf{F})$$

is continuous. The norm of A_s is controlled by finitely many symbol seminorms in a finite atlas and finitely many seminorms of the smoothing kernel.

Proof. Since M is compact, the constant function 1 belongs to $C^\infty_c(M)$. In the topology of $H^t_{\mathrm{loc}}(M,\mathbf{E})$ defined before Proposition 15.6.4, the seminorm corresponding to $\chi=1$ is

$$\|1\,\mathbf{u}\|_{H^t(M,\mathbf{E})}=\|\mathbf{u}\|_{H^t(M,\mathbf{E})}.$$

Conversely, continuity of multiplication by smooth functions, obtained in coordinates using Lemma 6.1.8, shows that each seminorm $\|\chi\mathbf{u}\|_{H^t(M,\mathbf{E})}$ is bounded by a multiple of $\|\mathbf{u}\|_{H^t(M,\mathbf{E})}$. Thus

$$H^t_{\mathrm{loc}}(M,\mathbf{E})=H^t(M,\mathbf{E})$$

as topological spaces. Moreover, the support of every distribution on M is a closed subset of a compact space. In the definition of $H^t_{\mathrm{comp}}(M,\mathbf{E})$ we may take $K=M$, giving

$$H^t_{\mathrm{comp}}(M,\mathbf{E})=H^t(M,\mathbf{E})$$

also as topological spaces.
Proposition 15.6.4, with these two identifications and $t=s+m$, gives the continuous mapping

$$A_s\colon H^{s+m}(M,\mathbf{E})\longrightarrow H^s(M,\mathbf{F}).$$

For the assertion on the norm, compactness of M allows a finite atlas, unitary trivializations, and finitely

many cutoffs to be chosen. In the proof of Proposition 15.6.4, each part localized near the diagonal is estimated by Theorem 15.6.2; its constant depends on finitely many seminorms of the local symbol. The parts away from the diagonal have smooth kernel by Proposition 15.2.4, and Lemma 15.6.3 controls them through finitely many seminorms of that kernel. Since only finitely many localizations occur, the norm of A_s is controlled by the finite collection of seminorms in the statement. □

15.6.3 Uniform pseudodifferential calculus with finite propagation

The preceding results are local, and on a closed manifold a finite cover suffices to combine their constants. On a noncompact manifold, the same estimate may deteriorate as the chart changes. To prevent this, we fix a bounded-geometry localization system, require uniform symbol bounds, and also control propagation of the remainders.

On an infinite cover, requiring each local representative to be a symbol is insufficient: the constants in its estimates might grow with the chart. There is no unique extension of the pseudodifferential calculus to open manifolds. We consider the calculus with finite propagation and uniform local bounds, which suffices for later applications and is compatible with the model of [57, Section 5]. Chapter 13 already constructed geodesic charts, quadratic systems, and synchronous frames with all derivatives controlled; Chapter 14 proved independence of section norms from those choices. We develop only the new pseudodifferential information.

Fix an admissible geodesic quadratic system

$$\mathcal{Q} = (U_i, \varphi_i, h_i, \mathbf{e}_i^{\mathbf{E}}, \mathbf{e}_i^{\mathbf{F}})_{i\in I}, \qquad U_i = B_{\mathbf{g}}(p_i, 2r), \qquad \sum_{i\in I} h_i^2 = 1,$$

with the synchronous frames of Proposition 8.2.26. The radius r and separation of the centers are those of Theorem 13.1.22. For $\rho \geq 0$, set

$$I_{\mathcal{Q}}(i,\rho) := \{j \in I \mid d_{\mathbf{g}}(U_i, U_j) \leq \rho\}, \qquad N_{\mathcal{Q}}(\rho) := \sup_{i\in I} \#I_{\mathcal{Q}}(i,\rho).$$

Lemma 15.6.7. (Uniform number of interactions at bounded distance) Let $(M,\mathbf{g})$ be a complete Riemannian manifold without boundary of bounded geometry, and let $\mathcal{Q}$ be the preceding admissible geodesic quadratic system, of radius $r>0$ and finite overlap multiplicity. For every $\rho \geq 0$, we have $N_{\mathcal{Q}}(\rho) < \infty$. More precisely, if

$$L_{\mathcal{Q}} := \sup_{i\in I} \#\{j \in I \mid U_i \cap U_j \neq \varnothing\}$$

and

$$k(\rho) := \left\lceil \frac{\rho + 4r}{r} \right\rceil + 2,$$

, then

$$N_{\mathcal{Q}}(\rho) \leq 1 + L_{\mathcal{Q}} + \cdots + L_{\mathcal{Q}}^{k(\rho)}. \tag{15.70}$$

Proof. If $d_{\mathbf{g}}(U_i, U_j) \leq \rho$, then $d_{\mathbf{g}}(p_i, p_j) \leq \rho + 4r$. Completeness and Hopf–Rinow provide a minimizing geodesic between the centers. Divide it into at most $\left\lceil \frac{\rho+4r}{r} \right\rceil + 1$ segments of length at most r. Each subdivision point belongs to some ball $B_{\mathbf{g}}(p_v, r)$ of the cover. Two centers chosen at consecutive subdivision points are at distance at most $3r$, so their balls of radius $2r$ intersect. Adding i and j at the endpoints gives a chain of at most $k(\rho)$ intersections joining U_i to U_j. From any chart there are at most $L_{\mathcal{Q}}$ choices at each step. Counting all chains of lengths from zero to $k(\rho)$ gives (15.70). This count permits repetitions and therefore

remains an upper bound. □

The preceding lemma ensures that, for a fixed propagation radius, each chart interacts with only a uniformly bounded number of charts. With this control, we can choose a diagonal representation of the operator and define seminorms that separately measure its symbolic part and smooth remainder.

Set $B := B_{\mathrm{euc}}(0, 2r)$. The functions in the geodesic system can be chosen with $\operatorname{supp}(h_i \circ \varphi_i^{-1}) \subset B_{\mathrm{euc}}\left(0, \frac{3r}{2}\right)$, as in the proof of Theorem 13.1.22. If $\mathbf{u} \in \Gamma_c(\mathbf{E})$, let $\mathbf{u}_i \colon U_i \to \mathbb{C}^{r_{\mathbf{E}}}$ denote its column of components in the frame $\mathbf{e}_i^{\mathbf{E}}$, and define local analysis and synthesis by

$$\mathcal{A}_i^{\mathbf{E}} \mathbf{u} := \widetilde{(h_i \mathbf{u}_i) \circ \varphi_i^{-1}},$$
$$\mathcal{S}_i^{\mathbf{F}} v := h_i \sum_{b=1}^{r_{\mathbf{F}}} (v^b \circ \varphi_i) \mathbf{e}_{i,b}^{\mathbf{F}}.$$

The tilde denotes extension by zero; this is smooth because the support of h_i is uniformly separated from the boundary of U_i. The auxiliary cutoffs of (B3) are inserted before extending an expression that does not already contain the factor h_i.

The locally finite sum

$$w_{\mathcal{Q}}(x, y) := \sum_{i \in I} h_i(x) h_i(y)$$

has uniformly bounded derivatives near the diagonal, and $w_{\mathcal{Q}}(x, x) = 1$. Indeed, at most $L_{\mathcal{Q}}$ summands occur in each chart, and their derivatives are controlled by (B2). The mean value theorem in charts and uniform comparison of Euclidean and Riemannian distances give numbers $\delta_{\mathcal{Q}} > 0$ and $c_{\mathcal{Q}} > 0$ such that

$$w_{\mathcal{Q}}(x, y) \geq \frac{1}{2}, \qquad d_{\mathbf{g}}(x, y) \leq 2\delta_{\mathcal{Q}}, \tag{15.71}$$

and all derivatives of $w_{\mathcal{Q}}^{-1}$ are bounded in that region by constants independent of the chart. Decrease $\delta_{\mathcal{Q}}$ so that it is less than a quarter of the normal radius and the $2\delta_{\mathcal{Q}}$-neighborhood of each $\operatorname{supp}(h_i)$ remains in U_i.

Fix a function $\omega_{\mathcal{Q}} \in C^\infty(M \times M, [0, 1])$ equal to one when $d_{\mathbf{g}}(x, y) \leq \frac{\delta_{\mathcal{Q}}}{3}$ and zero when $d_{\mathbf{g}}(x, y) \geq \frac{2\delta_{\mathcal{Q}}}{3}$. It is constructed by applying a fixed cutoff to $d_{\mathbf{g}}(x, y)^2$ within the normal radius; its covariant derivatives are uniformly bounded. In the chart i, write ω_i for its representative and set

$$(\mathrm{Op}_{\omega_i}(a_i) v)(x) := (2\pi)^{-n} \operatorname{Os} \iint_{B_y \times \mathbb{R}^n_\xi} e^{i(x-y)\cdot\xi} \omega_i(x, y) a_i(x, \xi) v(y)\, dy\, d\xi, \qquad x \in B.$$

This formula uses the same chart and frames for x and y. Define

$$Q_i^{\mathcal{Q}}(a_i) := \mathcal{S}_i^{\mathbf{F}} \mathrm{Op}_{\omega_i}(a_i) \mathcal{A}_i^{\mathbf{E}}. \tag{15.72}$$

Its kernel is supported where $x, y \in \operatorname{supp}(h_i)$ and $d_{\mathbf{g}}(x, y) \leq \frac{2\delta_{\mathcal{Q}}}{3}$. In the usual abbreviated notation, (15.72) is precisely

$$h_i\, \varphi_i^* \mathrm{Op}_{\omega_i}(a_i) (\varphi_i^{-1})^* h_i,$$

with the identifications through $\mathbf{e}_i^{\mathbf{E}}, \mathbf{e}_i^{\mathbf{F}}$ written in $\mathcal{A}_i^{\mathbf{E}}$ and $\mathcal{S}_i^{\mathbf{F}}$.

For a family $(a_i)_{i\in I}$, define the symbol seminorm of the representation by

$$q^{\mathrm{u},\mathcal{Q}}_{N,m}((a_i)) := \sup_{i\in I} \max_{|\alpha|+|\beta|\le N} \sup_{x\in B,\,\xi\in\mathbb{R}^n} \langle\xi\rangle^{-m+|\beta|}\,\|D_x^\alpha D_\xi^\beta a_i(x,\xi)\|. \tag{15.73}$$

An operator with kernel $\mathbf{K}_R$ has propagation at most ρ if

$$\operatorname{supp}\mathbf{K}_R \subseteq \{(x,y)\in M\times M \mid d_{\mathbf{g}}(x,y)\le\rho\}.$$

If R has smooth kernel of propagation at most ρ, then

$$\mathbf{K}_R \in C^\infty\left(M_x\times M_y;\mathbf{F}_x\boxtimes\mathbf{E}_y^*\right) = C^\infty\left(M_x\times M_y;\operatorname{Hom}(\mathbf{E}_y,\mathbf{F}_x)\right).$$

Equip this bundle with the product connection induced by the connection of $\mathbf{F}$ in the variable x and the dual connection of $\mathbf{E}$ in the variable y. The expression $(\nabla_x)^p(\nabla_y)^q\mathbf{K}_R$ denotes iterated tensorial derivatives in each factor, with the new index first in its block; the two product connections commute. In the following expression, the norm is induced by $\mathbf{g}$, $\mathbf{h}_\mathbf{F}$, and $\mathbf{h}_\mathbf{E}$ on $(T^*_xM)^{\otimes p}\otimes(T^*_yM)^{\otimes q}\otimes\operatorname{Hom}(\mathbf{E}_y,\mathbf{F}_x)$. Set

$$s^{\mathrm{u}}_N(R) := \max_{p+q\le N}\sup_{(x,y)\in M\times M}\|(\nabla_x)^p(\nabla_y)^q\mathbf{K}_R(x,y)\|_{\mathbf{g},\mathbf{h}_\mathbf{F},\mathbf{h}_\mathbf{E}}. \tag{15.74}$$

Definition 15.6.8. (Uniform diagonal representation) Let $(M,\mathbf{g})$ be complete, without boundary, and of bounded geometry, and let $\mathbf{E},\mathbf{F}\to M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics $\mathbf{h}_\mathbf{E},\mathbf{h}_\mathbf{F}$ and compatible connections of bounded geometry. A **uniform diagonal representation of order** m **and residual radius** ρ of an operator $A\colon\Gamma_c(M,\mathbf{E})\to\Gamma(M,\mathbf{F})$ is a pair $\mathfrak{r}=((a_i)_{i\in I},R)$ such that

$$A = A_{\mathrm{near}} + R, \qquad A_{\mathrm{near}} := \sum_{i\in I} Q_i^{\mathcal{Q}}(a_i), \tag{15.75}$$

$q^{\mathrm{u},\mathcal{Q}}_{N,m}((a_i))<\infty$ for every N, and R has propagation at most ρ and satisfies $s^{\mathrm{u}}_N(R)<\infty$ for every N. Denote the set of these representations by $\operatorname{Rep}^{\mathcal{Q}}_{m,\rho}(A)$ and define their seminorms by

$$P^{\mathcal{Q}}_{m,N}(\mathfrak{r}) := q^{\mathrm{u},\mathcal{Q}}_{N,m}((a_i)) + s^{\mathrm{u}}_N(R). \tag{15.76}$$

The operator belongs to $\Psi^m_{\mathrm{u},\rho}(M;\mathbf{E},\mathbf{F})$ if this set is nonempty, and $\Psi^m_{\mathrm{u}}(M;\mathbf{E},\mathbf{F}) := \bigcup_{\rho\ge0}\Psi^m_{\mathrm{u},\rho}(M;\mathbf{E},\mathbf{F})$.

If $\mathbf{E}=\mathbf{F}$, the identity belongs to the calculus with $a_i(x,\xi)=I$ and $R=0$, since $\operatorname{Op}_{\omega_i}(I)=I$ on the support of h_i because $\omega_i=1$ on the diagonal, and

$$\sum_{i\in I} Q_i^{\mathcal{Q}}(I)u = \sum_{i\in I} h_i^2 u = u.$$

This is the reason for using the same chart in both variables and a quadratic system.

The quantities (15.76) depend on the representation. To obtain operator seminorms, fix $\rho\ge\delta_{\mathcal{Q}}$ and set

$$\|A\|^{\mathrm{u},\mathcal{Q}}_{m,N;\rho} := \inf_{\mathfrak{r}\in\operatorname{Rep}^{\mathcal{Q}}_{m,\rho}(A)} P^{\mathcal{Q}}_{m,N}(\mathfrak{r}), \tag{15.77}$$

with value $+\infty$ if no such representation exists. On $\Psi^m_{\mathrm{u},\rho}(M;\mathbf{E},\mathbf{F})$ these are seminorms: addition and scalar multi-

plication are performed componentwise in representations, and choosing representations approximating the two infima gives the triangle inequality and homogeneity. They are the quotient seminorms of the linear map

$$((a_i),R)\longmapsto \sum_{i\in I} Q_i^{\mathcal{Q}}(a_i)+R.$$

The quotient seminorms separate points. If they all vanish for an operator A, then for each $j\ge 1$ one can choose a representation of A whose first j seminorms sum to less than 2^{-j}. On any fixed pair of charts, its kernels then converge to zero distributionally: for the pseudodifferential part this follows from continuity of quantization on test functions, and for the remainder from uniform convergence of the kernel. All representations have the same distributional kernel $\mathbf{K}_A$; by uniqueness, $\mathbf{K}_A=0$ and $A=0$. Thus each stage $\Psi^m_{\mathrm{u},\rho}(M;\mathbf{E},\mathbf{F})$, with $\rho\ge\delta_{\mathcal{Q}}$, is a Hausdorff metrizable locally convex space, since the family of seminorms is indexed by $N\in\mathbb{N}_0$.

These stages are considered only as locally convex spaces; completeness, and hence the Fréchet property, would require proving that the chosen representation space is complete and that the kernel of the quotient map is closed in that realization. If $\rho_1\le\rho_2$, inclusion of the first stage into the second is continuous, since a representation of radius ρ_1 is also one of radius ρ_2; its image need not be closed. In particular, the filtered union is not identified with a strict inductive limit or an LF-space.

The global structure used here is bornological and is fixed explicitly: a family $\mathscr{B}\subset\Psi^m_{\mathrm{u}}(M;\mathbf{E},\mathbf{F})$ is called **bounded in the uniform calculus** if there exists $\rho\ge\delta_{\mathcal{Q}}$ such that $\mathscr{B}\subset\Psi^m_{\mathrm{u},\rho}(M;\mathbf{E},\mathbf{F})$ and

$$\sup_{A\in\mathscr{B}}\|A\|^{\mathrm{u},\mathcal{Q}}_{m,N;\rho}<\infty\qquad\text{for every } N\in\mathbb{N}_0.$$

This definition does not identify such families with the bounded sets of an inductive-limit topology. Only when $\mathcal{Q}$ and ρ are fixed will we omit these superscripts from q^{u}, P, and $\|\cdot\|^{\mathrm{u}}_{m,N;\rho}$.

Define $\Psi^{-\infty}_{\mathrm{u}}(M;\mathbf{E},\mathbf{F})$ to consist of finite-propagation operators $R\colon\Gamma_c(M,\mathbf{E})\to\Gamma(M,\mathbf{F})$ whose kernel

$$\mathbf{K}_R\in C^\infty\big(M\times M;\operatorname{Hom}(\mathbf{E}_y,\mathbf{F}_x)\big)$$

satisfies (15.74) for every $N\in\mathbb{N}_0$. In the synchronous frames of the system $\mathcal{Q}$, this condition is equivalent to requiring all localized kernels $h_i(x)\mathbf{K}_R(x,y)h_j(y)$ to have partial derivatives of every order bounded by constants independent of (i,j); the equivalence follows from uniform bounds on the connections, frame changes, and functions h_i. This is the required compatibility with the localization system. Finite propagation is global, not microlocal; by Hopf–Rinow, every operator in the calculus maps $\Gamma_c(M,\mathbf{E})$ into $\Gamma_c(M,\mathbf{F})$. If M is noncompact, membership in $\Psi^{-\infty}_{\mathrm{u}}(M;\mathbf{E},\mathbf{F})$ does not imply compactness of the extension $L^2(M,\mathbf{E})\to L^2(M,\mathbf{F})$; Remark 15.6.16 gives a counterexample.

Lemma 15.6.9. (Exact symbol of a uniformly smooth kernel) Let $r_{\mathbf{E}},r_{\mathbf{F}}\in\mathbb{N}$, let $B=B_{\mathrm{euc}}(0,2r)\subset\mathbb{R}^n$, and let

$$K_i\in C^\infty_c\big(B\times B;\operatorname{Hom}(\mathbb{C}^{r_{\mathbf{E}}},\mathbb{C}^{r_{\mathbf{F}}})\big),\qquad i\in I,$$

be a family of kernels supported in a fixed compact subset of $B\times B$, with uniformly bounded derivatives. Their exact symbols

$$r_i(x,\xi):=\int_{B_y}e^{-i(x-y)\cdot\xi}K_i(x,y)\,dy$$

form a bounded family in $S^{-P}_{1,0}(B\times\mathbb{R}^n;\operatorname{Hom}(\mathbb{C}^{r_{\mathbf{E}}},\mathbb{C}^{r_{\mathbf{F}}}))$ for each $P\in\mathbb{R}$. In particular, the definition of

$\Psi_{\mathrm{u}}^{-\infty}(M;\mathbf{E},\mathbf{F})$ agrees with the intersection of all orders when a common radius is fixed and the preceding diagonal representations are used.

Proof. The identity avoiding spurious terms from differentiation of the phase is, for all multi-indices α,β,

$$D_x^\alpha D_\xi^\beta r_i(x,\xi) = (-i)^{|\beta|}\int_{B_y} e^{-i(x-y)\cdot\xi}(D_x+D_y)^\alpha\left[(x-y)^\beta K_i(x,y)\right]dy. \tag{15.78}$$

To prove it, D_ξ^β produces exactly $(-i)^{|\beta|}(x-y)^\beta$. Moreover, $(D_x+D_y)e^{-i(x-y)\cdot\xi}=0$; integrating the term D_y by parts shows that differentiating the integral in x is equivalent to applying D_x+D_y to the remaining factor. Iterating this equality gives (15.78).

Now use

$$\langle\xi\rangle^{2L}e^{-i(x-y)\cdot\xi} = (1-\Delta_y)^L e^{-i(x-y)\cdot\xi}$$

and transfer $(1-\Delta_y)^L$ by integration by parts to the last factor of (15.78). Since the supports remain in a fixed compact set, this yields

$$\langle\xi\rangle^{2L}\|D_x^\alpha D_\xi^\beta r_i(x,\xi)\| \le C_{\alpha,\beta,L}\max_{|\mu|+|\nu|\le|\alpha|+|\beta|+2L}\|D_x^\mu D_y^\nu K_i\|_{L^\infty(B\times B;\mathrm{Hom}(\mathbb{C}^{r_{\mathbf{E}}},\mathbb{C}^{r_{\mathbf{F}}}))},$$

with a constant independent of i. Given P, choosing $2L \ge P+|\beta|$ proves the estimates for $S^{-P}_{1,0}(B\times\mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^{r_{\mathbf{E}}},\mathbb{C}^{r_{\mathbf{F}}}))$. Comparison of local partial and covariant derivatives, using the bounds on Christoffel symbols and connection matrices, identifies these estimates with (15.74).

If $R\in\Psi_{\mathrm{u}}^{-\infty}(M;\mathbf{E},\mathbf{F})$, take $a_i=0$ in (15.75), so the operator belongs to every order with the same radius. For the converse, we do not assume that one representation works simultaneously at all orders. Let A be a finite-propagation operator belonging to $\Psi_{\mathrm{u}}^{\mu}(M;\mathbf{E},\mathbf{F})$ for every $\mu\in\mathbb{R}$, and fix $p,q\in\mathbb{N}_0$. Choose $\mu<-n-p-q-2$ and a representation of A of that order,

$$A=\sum_{i\in I}Q_i^{\mathcal{Q}}(a_i^{(\mu)})+R_\mu.$$

After applying p derivatives in the output variable and q in the input variable to the kernel of each diagonal piece, the oscillatory integral terms are bounded by $C_{p,q}\langle\xi\rangle^{\mu+p+q}$. This function is integrable in $\mathbb{R}^n$, and uniform multiplicity of the cover gives a chart-independent bound for the sum of pieces. The kernel of R_μ is already uniformly smooth. Consequently, the same distributional kernel $\mathbf{K}_A$ is represented by a kernel of class $C^{p,q}$ with the corresponding derivatives uniformly bounded. As p,q varies, the resulting representations are compatible because they all represent the unique distributional kernel $\mathbf{K}_A$. Thus $\mathbf{K}_A$ is smooth and satisfies (15.74) for every N; together with finite propagation of A, this proves $A\in\Psi_{\mathrm{u}}^{-\infty}(M;\mathbf{E},\mathbf{F})$. □

The preceding representations control a family of symbols chart by chart. To construct parametrices, we must sum formal expansions using frequency cutoffs that can be chosen uniformly in the chart index. The following lemma is the uniform version of symbolic asymptotic summation.

Lemma 15.6.10. (Uniform asymptotic summation) Let $r_{\mathbf{E}},r_{\mathbf{F}}\in\mathbb{N}$, let $\mathcal{I}$ be an index set, and let $m_0>m_1>\cdots$

be real numbers with $m_j \to -\infty$. In this lemma, abbreviate

$$S^{\mu} := S^{\mu}_{1,0}\big(B \times \mathbb{R}^n; \mathrm{Hom}(\mathbb{C}^{r_{\mathrm{E}}}, \mathbb{C}^{r_{\mathrm{F}}})\big).$$

For each $j \in \mathbb{N}_0$, let $(a_\nu^{(j)})_{\nu \in \mathcal{I}}$ be a family in S^{m_j} such that

$$q^{\mathrm{u}}_{N,m_j}((a_\nu^{(j)})) < \infty \qquad \text{for all } N, j.$$

There is a family $(a_\nu)_{\nu\in\mathcal{I}} \subset S^{m_0}$, bounded in the seminorms of S^{m_0}, such that, for every $N \geq 1$ and every $L \in \mathbb{N}_0$,

$$q^{\mathrm{u}}_{L,m_N}\left((a_\nu) - \sum_{j=0}^{N-1} (a_\nu^{(j)})\right) < \infty. \tag{15.79}$$

If orders repeat, first group the families of equal order.

Proof. Take $\chi \in C^\infty(\mathbb{R}^n)$ vanishing for $\|\xi\| \leq 1$ and equal to one for $\|\xi\| \geq 2$. If $j > N$, the Leibniz rule and the support of the derivatives of $\chi(\varepsilon\xi)$ give

$$q^{\mathrm{u}}_{L,m_N}\big((\chi(\varepsilon\cdot)a_\nu^{(j)})_\nu\big) \leq C_{L,N,j}\,\varepsilon^{m_N - m_j} q^{\mathrm{u}}_{L,m_j}((a_\nu^{(j)})), \qquad 0 < \varepsilon \leq 1. \tag{15.80}$$

Indeed, a term in which D_ξ^γ hits the cutoff is supported in $\varepsilon^{-1} \leq \|\xi\| \leq 2\varepsilon^{-1}$ if $|\gamma| > 0$ and in $\|\xi\| \geq \varepsilon^{-1}$ if $\gamma = 0$; in either case,

$$\varepsilon^{|\gamma|}\langle\xi\rangle^{m_j - m_N + |\gamma|} \leq C_{N,j,\gamma}\,\varepsilon^{m_N - m_j}.$$

The constant is uniform in ν because the seminorm in the last expression of (15.80) is uniform.
Choose $\varepsilon_j \in (0,1]$ decreasing. Once $\varepsilon_0, \dots, \varepsilon_{j-1}$ are fixed, the positive power of (15.80) allows ε_j to be chosen so that

$$q^{\mathrm{u}}_{L,m_N}\big((\chi(\varepsilon_j\cdot)a_\nu^{(j)})_\nu\big) \leq 2^{-j} \tag{15.81}$$

for all pairs $0 \leq N < j$ and $0 \leq L \leq j$. Define

$$a_\nu(x,\xi) := \sum_{j=0}^{\infty} \chi(\varepsilon_j\xi) a_\nu^{(j)}(x,\xi).$$

For a fixed seminorm q^{u}_{L,m_0}, the terms with $j > \max\{L, 0\}$ form, by (15.81), a series dominated by $\displaystyle\sum_{j=0}^{\infty} 2^{-j}$; the remaining terms are finite in number. This proves convergence in all seminorms of S^{m_0}, uniformly in ν.
Now fix $N \geq 1$. We have the exact identity

$$a_\nu - \sum_{j=0}^{N-1} a_\nu^{(j)} = \sum_{j=0}^{N-1} (\chi(\varepsilon_j\xi) - 1) a_\nu^{(j)} + \sum_{j=N}^{\infty} \chi(\varepsilon_j\xi) a_\nu^{(j)}.$$

The first sum has uniformly bounded support in ξ and belongs to every symbol class. In the second, the terms with $N \leq j \leq \max\{N, L\}$ are finite in number and belong to S^{m_N}; the remainder converges in q^{u}_{L,m_N} by (15.81). This proves (15.79) for each L. □

Definition 15.6.11. (Uniform classicality and ellipticity) Let $(M,\mathbf{g})$ be a complete Riemannian manifold without boundary of bounded geometry; let $\mathbf{E},\mathbf{F}\to M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics and compatible connections of bounded geometry; fix an admissible system $\mathcal{Q}$ as above, set $r_{\mathbf{E}}:=\operatorname{rk}\mathbf{E}$ and $r_{\mathbf{F}}:=\operatorname{rk}\mathbf{F}$, and let $m\in\mathbb{R}$. An operator $A\in\Psi^m_{\mathrm{u}}(M;\mathbf{E},\mathbf{F})$ is **uniformly classical** if it admits a diagonal representation whose symbols have expansions

$$a_i\sim\sum_{j=0}^{\infty}a^{(i)}_{m-j}$$

whose homogeneous components, restricted to $\|\xi\|=1$, have all derivatives bounded by constants independent of i, and if the remainders after N components are uniformly bounded in

$$S^{m-N}_{1,0}\big(B\times\mathbb{R}^n;\operatorname{Hom}(\mathbb{C}^{r_{\mathbf{E}}},\mathbb{C}^{r_{\mathbf{F}}})\big).$$

We write $A\in\Psi^m_{\mathrm{u,cl}}(M;\mathbf{E},\mathbf{F})$.
Its principal symbol is the global section whose matrices in a chart are obtained from

$$\sigma^{\Psi}_m(A)(x,\xi)=\sum_{i\in I}h_i(x)^2\big[a^{(i)}_m(x,\xi)\big]_{\mathbf{e}^{\mathbf{E}}_i,\mathbf{e}^{\mathbf{F}}_i},\tag{15.82}$$

where each summand is transported to the corresponding fiber and covariable. The sum is finite at every point. Independence of the representation and system will be proved below by the exact transformation of kernels near the diagonal.
If $\mathbf{E}$ and $\mathbf{F}$ have the same rank, an operator $A\in\Psi^m_{\mathrm{u,cl}}(M;\mathbf{E},\mathbf{F})$ is **uniformly elliptic** if there exists $c>0$ such that

$$\big\|\sigma^{\Psi}_m(A)(x,\xi)v\big\|_{\mathbf{h}_{\mathbf{F}}(x)}\ge c\|v\|_{\mathbf{h}_{\mathbf{E}}(x)},\qquad x\in M,\quad \|\xi\|_{\mathbf{g}}=1,\quad v\in\mathbf{E}_x.\tag{15.83}$$

By homogeneity, for $\xi\neq 0_x$ this is equivalent to

$$\big\|\sigma^{\Psi}_m(A)(x,\xi)^{-1}\big\|_{\mathcal{L}((\mathbf{F}_x,\mathbf{h}_{\mathbf{F}}(x)),(\mathbf{E}_x,\mathbf{h}_{\mathbf{E}}(x)))}\le c^{-1}\|\xi\|_{\mathbf{g}}^{-m}.$$

The definition was formulated relative to an admissible geodesic system $\mathcal{Q}$. Before using the calculus, we must check that changing charts, frames, or cutoffs preserves the operator class and its bounded families. We therefore compare two admissible systems $\mathcal{Q}$ and $\mathcal{Q}^{\sharp}$, including their frames. The cross bounds in (B1), used in Lemma 13.3.4 and Proposition 14.5.3, provide the two finite cross multiplicities; let $L_{\times}$ denote their maximum. To specify how many derivatives are used, for $N\in\mathbb{N}_0$ and $\mu\in\mathbb{R}$ define

$$L_N:=n+N+1,\qquad K_{N,\mu}:=n+N+1+\lceil|\mu|\rceil,\qquad \nu(N,\mu,n):=N+2L_N+2K_{N,\mu}+4.$$

In the exact amplitude reduction formula (15.5), L_N integrations using $1-\Delta_\eta$ make the spatial variable integrable, and $K_{N,\mu}$ integrations using $1-\Delta_y$ make the frequency variable integrable after N derivatives are taken. Thus the order-N seminorm of the reduced symbol uses at most $\nu(N,\mu,n)$ derivatives of the amplitude. This number is not optimal, but it is fixed and independent of the chart.

Let $I^{\sharp}$ denote the index set of the system $\mathcal{Q}^{\sharp}$. Take a representation $\mathfrak{r}=((a_i),R)\in\operatorname{Rep}^{\mathcal{Q}}_{m,\rho}(A)$. Choose $0<\delta<$

$\frac{1}{4}\min\{\delta_{\mathcal{Q}}, \delta_{\mathcal{Q}^\sharp}\}$ and a uniform cutoff $\zeta(x,y)$ equal to one for $d_{\mathbf{g}}(x,y) \le \delta$ and zero for $d_{\mathbf{g}}(x,y) \ge 2\delta$. Split exactly as

$$\mathbf{K}_{A_{\mathrm{near}}} = \zeta \mathbf{K}_{A_{\mathrm{near}}} + (1-\zeta)\mathbf{K}_{A_{\mathrm{near}}}.$$

The second summand is separated from the diagonal. The integrations by parts in the covariable used in the pseudolocality proof, with the uniform seminorms of (a_i), show that it is a uniformly smooth kernel of propagation at most $\frac{2\delta_{\mathcal{Q}}}{3}$; incorporate it into R.

On the support of the first summand, $w_{\mathcal{Q}^\sharp} \ge \frac{1}{2}$ by (15.71). Thus the identity

$$\zeta \mathbf{K}_{A_{\mathrm{near}}}(x,y) = \sum_{a \in I^\sharp} h_a^\sharp(x) \frac{\zeta(x,y)\mathbf{K}_{A_{\mathrm{near}}}(x,y)}{w_{\mathcal{Q}^\sharp}(x,y)} h_a^\sharp(y) \tag{15.84}$$

redistributes the kernel exactly into pieces using the same chart $U_a^\sharp$ for x and y. For fixed a, only the indices

$$J(a) := \{i \in I \mid U_i \cap U_a^\sharp \neq \varnothing\}, \qquad \#J(a) \le L_\times.$$

contribute.

Write $\Phi_{ia} := \varphi_i \circ (\varphi_a^\sharp)^{-1}$ on the overlap and

$$B_{ia}(x,y) := \int_0^1 D\Phi_{ia}(y + t(x-y))\, dt.$$

Then $\Phi_{ia}(x) - \Phi_{ia}(y) = B_{ia}(x,y)(x-y)$, and, decreasing δ if necessary, B_{ia} is invertible with uniformly bounded inverse. Let $G_{ia}^{\mathbf{E}}(y)$ and $G_{ia}^{\mathbf{F}}(x)$ be the frame-change matrices from the new frames to the old ones. After the change $\xi = B_{ia}(x,y)^T \eta$, the contribution of index i to the term a in (15.84) has, before reduction, amplitude

$$c_{ai}(x,y,\xi) = \Theta_{ai}(x,y) G_{ia}^{\mathbf{F}}(x) a_i\big(\Phi_{ia}(x), B_{ia}(x,y)^{-T}\xi\big) G_{ia}^{\mathbf{E}}(y)^{-1} \frac{|\det D\Phi_{ia}(y)|}{|\det B_{ia}(x,y)|}, \tag{15.85}$$

where Θ_{ai} is the product of ζ, the functions h_i in both variables, the cutoff ω_i, the necessary auxiliary cutoffs, and $w_{\mathcal{Q}^\sharp}^{-1}$. All these factors are expressed in the chart a and have uniformly bounded derivatives. The formula separately includes the coordinate transition, both frame changes, and the Jacobian in the integration variable.

Exact reduction in Theorem 15.1.9, applied to $\sum_{i \in J(a)} c_{ai}$, produces a symbol $a_a^\sharp$ in the single chart a. The Leibniz rule, the Faà di Bruno formula of Theorem 1.1.19, the number of derivatives fixed by ν, and $\#J(a) \le L_\times$ give a representation $\mathfrak{r}^\sharp$ of A for which

$$P_{m,N}^{\mathcal{Q}^\sharp}(\mathfrak{r}^\sharp) \le C_{N,m} L_\times P_{m,\nu(N,m,n)}^{\mathcal{Q}}(\mathfrak{r}). \tag{15.86}$$

The constant depends on bounds up to order $\nu(N,m,n)+2$ for transitions and their inverses, frame changes and their inverses, cutoffs, bundle metrics, and densities, but not on a or i. The new remainder has propagation at most $\rho^{\mathrm{com}} := \max\{\rho, \delta_{\mathcal{Q}}, \delta_{\mathcal{Q}^\sharp}\}$.

Now take the infimum of (15.86) over all representations of radius at most ρ. This gives the intrinsic comparison

$$\|A\|_{m,N;\rho^{\mathrm{com}}}^{\mathrm{u},\mathcal{Q}^\sharp} \le C_{N,m} L_\times \|A\|_{m,\nu(N,m,n);\rho}^{\mathrm{u},\mathcal{Q}}. \tag{15.87}$$

Interchanging $\mathcal{Q}$ and $\mathcal{Q}^\sharp$ gives the reverse inequality after using the common radius ρ^{com}. This proves quantitative independence of the class, its filtration by radii, its bounded sets, and its locally convex topology. Applied to the

principal homogeneous components of (15.85), the same formula gives the exact cotangent rule and shows that (15.82) is independent of the representation and system.

Having proved independence of choices, we must verify that the uniform calculus preserves the operations that motivated its construction. Write A_h^{*} for the formal Hermitian adjoint of the pseudodifferential operator A, in accordance with the preceding local theorems. Reserve $T^{\dagger}$ for the Hilbert space adjoint of a bounded operator between two Hilbert spaces whose inner products are already fixed. For a representation of residual radius ρ, write

$$\widehat{\rho} := \max\left\{\rho, \frac{2\delta_{\mathcal{Q}}}{3}\right\};$$

this bounds propagation of the full operator, including its diagonal part. Given $N \in \mathbb{N}_0$ and $\mu, \lambda \in \mathbb{R}$, define the derivative count and interaction factor

$$\mathfrak{n}_N(\mu,\lambda) := \nu(N,\mu+\lambda,n) + \nu(N,\mu,n) + \nu(N,\lambda,n), \tag{15.88}$$

$$\mathfrak{M}_{\mathcal{Q}}(\rho,\sigma) := (1+L_{\mathcal{Q}})^{2}\big(1+N_{\mathcal{Q}}(\rho+\sigma)\big)^{2}. \tag{15.89}$$

The second factor records both overlaps of diagonal pieces and bounded-distance interactions of residual kernels; applications require only that it be finite and depend on the stated data.

Proposition 15.6.12. (Properties of the uniform calculus) Let $(M,\mathbf{g})$ be a complete Riemannian manifold without boundary of bounded geometry, and let $\mathbf{E},\mathbf{F},\mathbf{G} \to M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics and compatible connections of bounded geometry. Let $m,\ell \in \mathbb{R}$, $\rho_A, \rho_B \geq \delta_{\mathcal{Q}}$, $A \in \Psi^{m}_{\mathrm{u},\rho_A}(M;\mathbf{E},\mathbf{F})$, and $B \in \Psi^{\ell}_{\mathrm{u},\rho_B}(M;\mathbf{G},\mathbf{E})$. Then

(i) $AB \in \Psi^{m+\ell}_{\mathrm{u},\rho_{AB}}(M;\mathbf{G},\mathbf{F})$ with
$$\rho_{AB} := \rho_A + \rho_B;$$

(ii) $A_h^{*} \in \Psi^{m}_{\mathrm{u},\rho_A}(M;\mathbf{F},\mathbf{E})$;

(iii) the classes $\Psi^{-\infty}_{\mathrm{u}}(M;\mathbf{E},\mathbf{F})$ are stable under adjoints and form a two-sided ideal between the corresponding spaces within the finite-propagation calculus.

In particular, composition is the continuous bilinear map of stages

$$\begin{aligned}\Psi^{m_1}_{\mathrm{u},\rho_1}(M;\mathbf{F},\mathbf{G}) \times \Psi^{m_2}_{\mathrm{u},\rho_2}(M;\mathbf{E},\mathbf{F}) &\longrightarrow \Psi^{m_1+m_2}_{\mathrm{u},\rho_1+\rho_2}(M;\mathbf{E},\mathbf{G}),\\ (A,B) &\longmapsto A\circ B,\end{aligned} \tag{15.90}$$

for $\rho_1,\rho_2 \geq \delta_{\mathcal{Q}}$, and the adjoint is a continuous map from $\Psi^{m}_{\mathrm{u},\rho}(M;\mathbf{E},\mathbf{F})$ to $\Psi^{m}_{\mathrm{u},\rho}(M;\mathbf{F},\mathbf{E})$. For each N, there exists $C_{N,m,\ell}$ independent of local indices such that

$$\|AB\|^{\mathrm{u},\mathcal{Q}}_{m+\ell,N;\rho_{AB}} \leq C_{N,m,\ell}\,\mathfrak{M}_{\mathcal{Q}}(\rho_A,\rho_B)\,\|A\|^{\mathrm{u},\mathcal{Q}}_{m,\mathfrak{n}_N(m,\ell);\rho_A}\,\|B\|^{\mathrm{u},\mathcal{Q}}_{\ell,\mathfrak{n}_N(m,\ell);\rho_B}. \tag{15.91}$$

Moreover, with $\mathfrak{a}_N(m) := \nu(N,m,n) + N + 2$,

$$\|A_h^{*}\|^{\mathrm{u},\mathcal{Q}}_{m,N;\rho_A} \leq C_{N,m}\,\|A\|^{\mathrm{u},\mathcal{Q}}_{m,\mathfrak{a}_N(m);\rho_A}. \tag{15.92}$$

Proof. Take diagonal representations $\mathfrak{r}_A = ((a_i), R_A)$ and $\mathfrak{r}_B = ((b_j), R_B)$. Since $\rho_A, \rho_B \geq \delta_{\mathcal{Q}}$, we have $\widehat{\rho}_A = \rho_A$ and $\widehat{\rho}_B = \rho_B$. The kernel formula for composition is

$$\mathbf{K}_{AB}(x,y) = \int_{M_z} \mathbf{K}_A(x,z)\mathbf{K}_B(z,y)\, d\lambda_{\mathbf{g}}(z).$$

If the integrand is nonzero, then $d_{\mathbf{g}}(x,y) \leq \widehat{\rho}_A + \widehat{\rho}_B$, proving the propagation bound. Split as

$$AB = A_{\mathrm{near}}B_{\mathrm{near}} + A_{\mathrm{near}}R_B + R_A B_{\mathrm{near}} + R_A R_B. \tag{15.93}$$

Consider the first summand first. Its kernel is the sum of

$$K_{ij}(x,y) := \int_{M_z} \mathbf{K}_{Q_i(a_i)}(x,z)\mathbf{K}_{Q_j(b_j)}(z,y)\, d\lambda_{\mathbf{g}}(z).$$

This occurs only if $U_i \cap U_j \neq \varnothing$; hence, for fixed i, there are at most $L_{\mathcal{Q}}$ values of j. Choose a cutoff ζ vanishing outside $d_{\mathbf{g}}(x,y) < \frac{\delta_{\mathcal{Q}}}{2}$ and equal to one near the diagonal. The part $(1-\zeta)K_{ij}$ is separated from the diagonal. Integration by parts in both covariables, before and after integration in z, gives all bounds in (15.74); at most $L_{\mathcal{Q}}$ summands occur per chart. Incorporate this part into the remainder.
For ζK_{ij}, use the exact identity (15.84) again:

$$\zeta(x,y) \sum_{(i,j)\in I\times I} K_{ij}(x,y) = \sum_{a\in I} h_a(x) \frac{\zeta(x,y)\sum_{(i,j)\in I\times I} K_{ij}(x,y)}{w_{\mathcal{Q}}(x,y)} h_a(y). \tag{15.94}$$

After shrinking the support of ζ once, the choice of $\delta_{\mathcal{Q}}$ ensures that, if the summand a,i,j is nonzero, all three points x,z,y belong to U_a. Moreover, $U_i \cap U_a \neq \varnothing$ and $U_j \cap U_a \neq \varnothing$; for fixed a there are at most $L_{\mathcal{Q}}^2$ pairs (i,j).
Write $\Phi_{ia} = \varphi_i \circ \varphi_a^{-1}$ and

$$B_{ia}(x,z) = \int_0^1 D\Phi_{ia}(z + t(x-z))\, dt.$$

In the chart a, the change $\eta = B_{ia}(x,z)^{-T}\xi$ transforms the first piece into the amplitude

$$c_{ia}(x,z,\xi) = \Theta_{ia}(x,z) G_{ia}^{\mathbf{F}}(x) a_i\big(\Phi_{ia}(x), B_{ia}(x,z)^{-T}\xi\big) G_{ia}^{\mathbf{E}}(z)^{-1} \frac{|\det D\Phi_{ia}(z)|}{|\det B_{ia}(x,z)|}. \tag{15.95}$$

Here Θ_{ia} contains the corresponding cutoffs; for the second piece, with Φ_{ja}, one obtains the same formula in the variables (z,y) and with frame changes $G_{ja}^{\mathbf{E}}, G_{ja}^{\mathbf{G}}$. Both intermediate matrices take values in the same frame $\mathbf{e}_a^{\mathbf{E}}$. This transformation takes place within the single chart a; it is not a quantization with base variables in different charts. Uniform bounds on transitions, frames, and Jacobians control all derivatives of both amplitudes. Exact reduction gives symbols $\widetilde{a}_{ia}(x,\xi)$ and $\widetilde{b}_{ja}(x,\xi)$, both defined in the chart a. Theorem 15.2.6, now applied in that single chart, yields

$$\widetilde{a}_{ia} \# \widetilde{b}_{ja} \sim \sum_{\alpha\in\mathbb{N}_0^n} \frac{i^{-|\alpha|}}{\alpha!} D_\xi^\alpha \widetilde{a}_{ia}\, D_x^\alpha \widetilde{b}_{ja}.$$

Differentiating this formula up to order N, including reduction of both amplitudes, uses at most $\mathfrak{n}_N(m,\ell)$

derivatives of (a_i) and (b_j). Summing the at most $L_{\mathcal{Q}}^2$ pairs gives a symbol c_a in the same chart a and a uniformly smooth part.

The remaining three terms in (15.93) are uniformly smooth. For $R_A R_B$, this is checked by differentiation under the integral; for each output chart, the integration domain is covered by at most $N_{\mathcal{Q}}(\widehat{\rho}_A + \widehat{\rho}_B)$ charts, each of uniformly bounded volume. In $A_{\mathrm{near}} R_B$, apply the pseudodifferential piece, in its single chart, to derivatives of the smooth kernel of R_B; in $R_A B_{\mathrm{near}}$, proceed in the other variable. The same count and Calderón–Vaillancourt after conjugation by powers of $\langle D \rangle$ give, for the constructed representation,

$$P^{\mathcal{Q}}_{m+\ell,N}(\mathfrak{r}_{AB}) \le C_{N,m,\ell}\, \mathfrak{M}_{\mathcal{Q}}(\widehat{\rho}_A, \widehat{\rho}_B) P^{\mathcal{Q}}_{m,\mathfrak{n}_N(m,\ell)}(\mathfrak{r}_A) P^{\mathcal{Q}}_{\ell,\mathfrak{n}_N(m,\ell)}(\mathfrak{r}_B). \tag{15.96}$$

Its remainder has radius at most ρ_{AB}. Choosing representations separately approximating the two infima and passing to those infima proves (15.91).

The adjoint of $Q_i^{\mathcal{Q}}(a_i)$ still uses the chart i in both variables. Theorem 15.2.8 and exact reduction give a symbol $a_i^{(*)}$ with

$$a_i^{(*)}(x,\xi) \sim \sum_{\alpha \in \mathbb{N}_0^n} \frac{i^{-|\alpha|}}{\alpha!} D_\xi^\alpha D_x^\alpha (a_i(x,\xi)^*).$$

In nonunitary frames, insert the bundle metric matrices and the local density of $d\lambda_{\mathbf{g}}$. Their derivatives and those of their inverses are uniformly bounded. The difference between the exact adjoint kernel and the truncated quantization of $a_i^{(*)}$ is uniformly smooth and preserves propagation. This first proves the analogue of (15.92) for $P^{\mathcal{Q}}_{m,N}$ and then, taking the infimum, the asserted inequality. Finally, $\mathbf{K}_{R_h^*}(x,y) = \mathbf{K}_R(y,x)^*$ preserves the radius and all seminorms (15.74). The arguments for the preceding three smooth terms, with one factor already smoothing, prove the two-sided ideal property. □

Stability under composition now leads to elliptic inversion. We first invert the principal symbol in each chart, correct lower-order terms by a uniform recurrence, and sum these corrections without losing control of propagation.

Theorem 15.6.13. (Uniform parametrix) Let $(M, \mathbf{g})$ be a complete Riemannian manifold without boundary of bounded geometry, and let $\mathbf{E}, \mathbf{F} \to M$ be complex vector bundles of the same finite rank equipped with Hermitian bundle metrics and compatible connections of bounded geometry. If $m \in \mathbb{R}$ and $A \in \Psi^m_{\mathrm{u,cl}}(M; \mathbf{E}, \mathbf{F})$ is uniformly elliptic, there exists $B \in \Psi^{-m}_{\mathrm{u}}(M; \mathbf{F}, \mathbf{E})$ such that

$$BA - I \in \Psi^{-\infty}_{\mathrm{u}}(M; \mathbf{E}, \mathbf{E}), \qquad AB - I \in \Psi^{-\infty}_{\mathrm{u}}(M; \mathbf{F}, \mathbf{F}).$$

Proof. Fix a diagonal representation of A of residual radius ρ_A and use the convention $\widehat{\rho}_A$ introduced before Proposition 15.6.12. Localize the full symbol of A in one chart at a time. More precisely, apply redistribution (15.84) with two cutoffs equal to one on $\mathrm{supp}(h_i)$ and reduce the amplitude in the chart i. Let $a^{(i)}$ denote the resulting symbol. Its homogeneous families satisfy

$$a^{(i)}(x,\xi) \sim \sum_{k=0}^{\infty} a^{(i)}_{m-k}(x,\xi),$$

and $a^{(i)}_m$ is the matrix, in the frame i, of the global symbol $\sigma^{\Psi}_m(A)$. Thus inversion is applied to the local matrix of the global principal symbol and uses uniform ellipticity directly.

For $j, N \in \mathbb{N}_0$, set

$$A_{j,N} := \sup_{i \in I} \max_{|\gamma| \le N} \sup_{\substack{x \in B,\ \xi \in \mathbb{R}^n \\ \|\xi\| = 1}} \|D^\gamma a^{(i)}_{m-j}(x,\xi)\|, \qquad D^\gamma := D_x^{\gamma_x} D_\xi^{\gamma_\xi}.$$

Let I_N be the same quantity for $(a^{(i)}_m)^{-1}$. Differentiating $(a^{(i)}_m)^{-1} a^{(i)}_m = I$, isolating the term $\eta = 0$, and multiplying on the right by $(a^{(i)}_m)^{-1}$ gives, for $|\gamma| \ge 1$, the exact multi-index recurrence

$$D^\gamma (a^{(i)}_m)^{-1} = - \sum_{0 < \eta \le \gamma} \binom{\gamma}{\eta} D^{\gamma - \eta} (a^{(i)}_m)^{-1} (D^\eta a^{(i)}_m)(a^{(i)}_m)^{-1}. \tag{15.97}$$

In particular, $I_0 \le c^{-1}$ after uniform comparison of the fiber norms, and

$$I_N \le I_0 + C_N I_0 A_{0,N} \sum_{p=0}^{N-1} I_p. \tag{15.98}$$

This recurrence proves inductively that $I_N < \infty$ for every N and specifies which derivatives of the principal symbol occur.

The formal components of the left and right inverses are defined by

$$b^{\mathrm{L},(i)}_{-m} = b^{\mathrm{R},(i)}_{-m} := (a^{(i)}_m)^{-1}, \tag{15.99}$$

$$b^{\mathrm{L},(i)}_{-m-j} := - \left[\sum_{\substack{k,q \in \mathbb{N}_0,\ \alpha \in \mathbb{N}_0^n \\ k+q+|\alpha| = j,\ q<j}} \frac{i^{-|\alpha|}}{\alpha!} D_\xi^\alpha b^{\mathrm{L},(i)}_{-m-q} D_x^\alpha a^{(i)}_{m-k} \right] (a^{(i)}_m)^{-1}, \quad j \ge 1, \tag{15.100}$$

$$b^{\mathrm{R},(i)}_{-m-j} := -(a^{(i)}_m)^{-1} \left[\sum_{\substack{k,q \in \mathbb{N}_0,\ \alpha \in \mathbb{N}_0^n \\ k+q+|\alpha| = j,\ q<j}} \frac{i^{-|\alpha|}}{\alpha!} D_\xi^\alpha a^{(i)}_{m-k} D_x^\alpha b^{\mathrm{R},(i)}_{-m-q} \right]. \tag{15.101}$$

Here we have isolated $b_{-m-j} a_m$ in $b \# a$ and $a_m b_{-m-j}$ in $a \# b$, respectively; the other summands have $q < j$. Define $B^{\mathrm{L}}_{j,N}$ and $B^{\mathrm{R}}_{j,N}$ as the supremum, over i, $x \in B$, $\|\xi\| = 1$, and $|\gamma| \le N$, of the derivatives of the corresponding components. The Leibniz rule and (15.97) give the quantified bounds

$$B^{\mathrm{L}}_{j,N} \le C_{j,N} I_{N+j} \sum_{\substack{k,q \in \mathbb{N}_0,\ \alpha \in \mathbb{N}_0^n \\ k+q+|\alpha| = j,\ q<j}} B^{\mathrm{L}}_{q,N+j} A_{k,N+j}, \tag{15.102}$$

$$B^{\mathrm{R}}_{j,N} \le C_{j,N} I_{N+j} \sum_{\substack{k,q \in \mathbb{N}_0,\ \alpha \in \mathbb{N}_0^n \\ k+q+|\alpha| = j,\ q<j}} A_{k,N+j} B^{\mathrm{R}}_{q,N+j}. \tag{15.103}$$

Induction on j proves that both quantities are finite for every j, N. Each component has degree $-m-j$; homogeneity turns bounds on the sphere into uniform symbol estimates.

For the first Borel sum, fix radial cutoffs ϑ, χ vanishing on $\|\xi\| \le 1$ and equal to one on $\|\xi\| \ge 2$.

Lemma 15.6.10 chooses sequences $\varepsilon_j^{\mathrm{L}}, \varepsilon_j^{\mathrm{R}} \to 0^+$ for which

$$\widetilde{b}_{\mathrm{L}}^{(i)}(x,\xi) := \sum_{j=0}^{\infty} \chi(\varepsilon_j^{\mathrm{L}}\xi)\vartheta(\xi) b_{-m-j}^{\mathrm{L},(i)}(x,\xi), \tag{15.104}$$

$$\widetilde{b}_{\mathrm{R}}^{(i)}(x,\xi) := \sum_{j=0}^{\infty} \chi(\varepsilon_j^{\mathrm{R}}\xi)\vartheta(\xi) b_{-m-j}^{\mathrm{R},(i)}(x,\xi) \tag{15.105}$$

are families in $S^{-m}_{1,0}(B\times\mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^{r_{\mathrm{F}}},\mathbb{C}^{r_{\mathrm{E}}}))$ and, after subtracting the first N summands, belong uniformly to the analogous class of order $-m-N$. These sums fix the expansion to be realized by the global inverse. Their principal term defines, in the adopted diagonal model,

$$b_0^{(i)}(x,\xi) := \vartheta(\xi)(a_m^{(i)}(x,\xi))^{-1}, \qquad B_0 := \sum_{i\in I} Q_i^{\mathcal{Q}}(b_0^{(i)}). \tag{15.106}$$

In particular, diagonal quantization of $\widetilde{b}_{\mathrm{L}}^{(i)}$ or $\widetilde{b}_{\mathrm{R}}^{(i)}$ differs from B_0 at order $-m-1$. The equality $\sum_{i\in I} h_i^2 = 1$ shows that the principal symbol of B_0 is $\sigma_m^{\Psi}(A)^{-1}$. Take $\rho_{B_0} := \delta_{\mathcal{Q}}$ and

$$R_0 := I - B_0A \in \Psi^{-1}_{\mathrm{u},\varrho_0}(M;\mathbf{E},\mathbf{E}), \qquad S_0 := I - AB_0 \in \Psi^{-1}_{\mathrm{u},\varrho_0}(M;\mathbf{F},\mathbf{F}), \qquad \varrho_0 := \widehat{\rho}_A + \widehat{\rho}_{B_0}.$$

We now specify the bounds on powers, including their radii. Let

$$\mathfrak{C}_N(\rho,\sigma;\mu,\lambda) := C_{N,\mu,\lambda}\,\mathfrak{M}_{\mathcal{Q}}(\rho,\sigma), \tag{15.107}$$

where $C_{N,\mu,\lambda}$ is the constant in (15.91). For $j \ge 1$, set

$$r_{j,N} := \|R_0^j\|^{\mathrm{u},\mathcal{Q}}_{-j,N;j\varrho_0}, \qquad s_{j,N} := \|S_0^j\|^{\mathrm{u},\mathcal{Q}}_{-j,N;j\varrho_0},$$
$$\ell_{j,N} := \|R_0^jB_0\|^{\mathrm{u},\mathcal{Q}}_{-m-j,N;j\varrho_0+\rho_{B_0}}, \qquad d_{j,N} := \|B_0S_0^j\|^{\mathrm{u},\mathcal{Q}}_{-m-j,N;\rho_{B_0}+j\varrho_0},$$

and $b_{0,N} := \|B_0\|^{\mathrm{u},\mathcal{Q}}_{-m,N;\rho_{B_0}}$, $a_N := \|A\|^{\mathrm{u},\mathcal{Q}}_{m,N;\rho_A}$. For $j=0$, adopt $\ell_{0,N} = d_{0,N} = b_{0,N}$. Exact cancellation of the principal symbols of B_0A and AB_0, followed by amplitude reduction with one additional derivative, gives the base

$$r_{1,N} + s_{1,N} \le C_{N,m}\,\mathfrak{M}_{\mathcal{Q}}(\widehat{\rho}_A,\widehat{\rho}_{B_0})\left(1 + b_{0,\mathfrak{n}_{N+1}(-m,m)}a_{\mathfrak{n}_{N+1}(-m,m)}\right). \tag{15.108}$$

The composition construction followed by passage to the infimum gives, for $j \ge 1$,

$$r_{j+1,N} \le \mathfrak{C}_N(j\varrho_0,\varrho_0;-j,-1)\,r_{j,\mathfrak{n}_N(-j,-1)}\,r_{1,\mathfrak{n}_N(-j,-1)}, \tag{15.109}$$

$$s_{j+1,N} \le \mathfrak{C}_N(j\varrho_0,\varrho_0;-j,-1)\,s_{j,\mathfrak{n}_N(-j,-1)}\,s_{1,\mathfrak{n}_N(-j,-1)}, \tag{15.110}$$

$$\ell_{j,N} \le \mathfrak{C}_N(j\varrho_0,\rho_{B_0};-j,-m)\,r_{j,\mathfrak{n}_N(-j,-m)}\,b_{0,\mathfrak{n}_N(-j,-m)}, \tag{15.111}$$

$$d_{j,N} \le \mathfrak{C}_N(\rho_{B_0},j\varrho_0;-m,-j)\,b_{0,\mathfrak{n}_N(-m,-j)}\,s_{j,\mathfrak{n}_N(-m,-j)}. \tag{15.112}$$

In particular, all four families of quantities are finite. The formulas simultaneously show growth of the radius, the increase $N \mapsto \mathfrak{n}_N$ in the derivative count, and the explicit appearance of $N_{\mathcal{Q}}(j\varrho_0+\varrho_0)$ within $\mathfrak{M}_{\mathcal{Q}}$. For R_0^N and S_0^N, the first two recurrences, iterated from $r_{1,N}$ and $s_{1,N}$, are the required quantified bounds;

in particular,

$$R_0^N \in \Psi_{\mathrm{u},N\rho_0}^{-N}(M;\mathbf{E},\mathbf{E}), \qquad S_0^N \in \Psi_{\mathrm{u},N\rho_0}^{-N}(M;\mathbf{F},\mathbf{F}). \tag{15.113}$$

For $N \geq 1$, introduce the finite sums

$$C_N^{\mathrm{L}} := \sum_{j=0}^{N-1} R_0^j B_0, \qquad C_N^{\mathrm{R}} := B_0 \sum_{j=0}^{N-1} S_0^j. \tag{15.114}$$

The identities $B_0 A = I - R_0$ and $A B_0 = I - S_0$ give exactly

$$I - C_N^{\mathrm{L}} A = R_0^N, \qquad I - A C_N^{\mathrm{R}} = S_0^N. \tag{15.115}$$

Now use the representations produced recursively in the proof of Proposition 15.6.12. Let $(c_{j,i}^{\mathrm{L}})_i$ and $(c_{j,i}^{\mathrm{R}})_i$ be their symbol families near the diagonal for $R_0^j B_0$ and $B_0 S_0^j$. Bounds (15.111) and (15.112), before taking the infimum, verify the hypotheses of uniform asymptotic summation. With two further cutoff sequences, we obtain explicitly

$$b_{\mathrm{L}}^{(i)}(x,\xi) := \sum_{j=0}^{\infty} \chi(\delta_j^{\mathrm{L}}\xi) c_{j,i}^{\mathrm{L}}(x,\xi), \qquad B_{\mathrm{L}} := \sum_{i\in I} Q_i^{\mathcal{Q}}(b_{\mathrm{L}}^{(i)}), \tag{15.116}$$

$$b_{\mathrm{R}}^{(i)}(x,\xi) := \sum_{j=0}^{\infty} \chi(\delta_j^{\mathrm{R}}\xi) c_{j,i}^{\mathrm{R}}(x,\xi), \qquad B_{\mathrm{R}} := \sum_{i\in I} Q_i^{\mathcal{Q}}(b_{\mathrm{R}}^{(i)}). \tag{15.117}$$

Here only symbols of the parts near the diagonal are summed. The residual kernels of $R_0^j B_0$ and $B_0 S_0^j$, whose radii grow with j, are not summed; this distinction keeps propagation fixed for B_{L} and B_{R}.

For each N, the defining property of the two Borel sums and the finitely many remainders of terms with $j < N$ give

$$B_{\mathrm{L}} - C_N^{\mathrm{L}} \in \Psi_{\mathrm{u}}^{-m-N}(M;\mathbf{F},\mathbf{E}), \qquad B_{\mathrm{R}} - C_N^{\mathrm{R}} \in \Psi_{\mathrm{u}}^{-m-N}(M;\mathbf{F},\mathbf{E}). \tag{15.118}$$

The radius of a representation of these differences may depend on N; the four operators B_{L}, B_{R}, $B_{\mathrm{L}}A - I$, and $AB_{\mathrm{R}} - I$, however, have fixed propagations. Combining (15.118) with (15.115) gives, for every N,

$$B_{\mathrm{L}} A - I \in \Psi_{\mathrm{u}}^{-N}(M;\mathbf{E},\mathbf{E}), \qquad A B_{\mathrm{R}} - I \in \Psi_{\mathrm{u}}^{-N}(M;\mathbf{F},\mathbf{F}).$$

The two remainders are fixed finite-propagation operators belonging to $\Psi_{\mathrm{u}}^{-N}(M;\mathbf{E},\mathbf{E})$ and $\Psi_{\mathrm{u}}^{-N}(M;\mathbf{F},\mathbf{F})$, respectively, for every N. Apply the converse implication in Lemma 15.6.9: given p,q, choose $N > n+p+q+2$ and a representation of order $-N$ of the corresponding remainder. Absolute convergence of derivatives of its diagonal kernel and the uniformly smooth kernel of that representation provide the covariant bounds of orders p,q. Uniqueness of the distributional kernel makes these representations compatible as p,q varies; hence the two remainders belong to $\Psi_{\mathrm{u}}^{-\infty}(M;\mathbf{E},\mathbf{E})$ and $\Psi_{\mathrm{u}}^{-\infty}(M;\mathbf{F},\mathbf{F})$, respectively.

If $B_{\mathrm{L}} A = I - R_{\mathbf{E}}$ and $A B_{\mathrm{R}} = I - R_{\mathbf{F}}$, then

$$B_{\mathrm{L}} - B_{\mathrm{R}} = B_{\mathrm{L}} R_{\mathbf{F}} - R_{\mathbf{E}} B_{\mathrm{R}} \in \Psi_{\mathrm{u}}^{-\infty}(M;\mathbf{F},\mathbf{E}).$$

Taking $B = B_{\mathrm{L}}$ and using the ideal property also on the right gives

$$BA - I \in \Psi_{\mathrm{u}}^{-\infty}(M;\mathbf{E},\mathbf{E}), \qquad AB - I \in \Psi_{\mathrm{u}}^{-\infty}(M;\mathbf{F},\mathbf{F}). \tag{15.119}$$

□

The preceding parametrix remains a symbolic construction. To obtain global regularity, we must relate uniform seminorms to the Sobolev norms defined through the localization system. Lemma 15.6.3 controls the smooth remainders, while the diagonal part reduces to the Euclidean theorem.

Theorem 15.6.14. (Uniform Sobolev mapping) Let $(M,\mathbf{g})$ be a complete Riemannian manifold without boundary of dimension n and bounded geometry; let $\mathbf{E},\mathbf{F} \to M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics and compatible connections of bounded geometry, and fix the preceding admissible system $\mathcal{Q}$. If $m,s \in \mathbb{R}$, $\rho \geq \delta_{\mathcal{Q}}$, and $A \in \Psi_{\mathrm{u},\rho}^{m}(M;\mathbf{E},\mathbf{F})$, then

$$A\colon H^{s+m}(M,\mathbf{E}) \longrightarrow H^{s}(M,\mathbf{F})$$

is continuous. There exist an integer $N = N(n,m,s)$ and a constant C_s, depending on the uniform data of the system but not on a chart index or on A, such that

$$\|A\|_{\mathcal{L}(H^{s+m}(M,\mathbf{E}),H^{s}(M,\mathbf{F}))} \leq C_s\bigl(1 + N_{\mathcal{Q}}(\rho)\bigr)\|A\|_{m,N;\rho}^{\mathrm{u},\mathcal{Q}}. \tag{15.120}$$

In particular, every $R \in \Psi_{\mathrm{u}}^{-\infty}(M;\mathbf{E},\mathbf{F})$ acts continuously from $H^{t}(M,\mathbf{E})$ to $H^{s}(M,\mathbf{F})$ for all $s,t \in \mathbb{R}$. All these estimates are uniform on bounded families in the calculus.

Proof. Let $\mathfrak{r} = ((a_i),R)$ be a diagonal representation of A of residual radius ρ. Introduce the analysis, diagonal block, and synthesis operators

$$\begin{aligned}
\mathbf{A}_{\mathbf{E}}\mathbf{u} &:= (\mathcal{A}_i^{\mathbf{E}}\mathbf{u})_{i\in I},\\
\mathbf{T}_{(a_i)}(v_i) &:= (\mathrm{Op}_{\omega_i}(a_i)v_i)_{i\in I},\\
\mathbf{S}_{\mathbf{F}}(v_i) &:= \sum_{i\in I} \mathcal{S}_i^{\mathbf{F}} v_i.
\end{aligned}$$

The part near the diagonal factors exactly as

$$A_{\mathrm{near}} = \mathbf{S}_{\mathbf{F}}\mathbf{T}_{(a_i)}\mathbf{A}_{\mathbf{E}}. \tag{15.121}$$

Analysis and synthesis are the retraction and coretraction operators of the preceding chapter: their continuity was established in (13.36) and their equivalence with global norms in Lemma 13.3.10. Reduction of the amplitude $\omega_i(x,y)a_i(x,\xi)$ uses finitely many derivatives, independently of i. Theorem 15.6.2, applied componentwise, therefore provides $N_0 = N_0(n,m,s)$ such that, for every $\mathbf{u} \in \Gamma_c(M,\mathbf{E})$,

$$\|A_{\mathrm{near}}\mathbf{u}\|_{H^{s}(M,\mathbf{F})} \leq C_s q_{N_0,m}^{\mathrm{u},\mathcal{Q}}((a_i))\|\mathbf{u}\|_{H^{s+m}(M,\mathbf{E})}. \tag{15.122}$$

For the remainder, localize $h_i R h_j$. This can be nonzero only if $j \in I_{\mathcal{Q}}(i,\rho)$. Apply Lemma 15.6.3, whose duality definition acts directly on restriction spaces, to the element $h_j\mathbf{u} \in H^{s+m}(U_j,\mathbf{E})$ on the fixed coordinate

rectangles, with

$$\sigma = s, \qquad \tau = s + m, \qquad N_1 := \max\{0, \lceil s \rceil\} + \max\{0, \lceil -s - m \rceil\}.$$

The supports of the localized kernels remain in a fixed compact subset of the rectangles, since the factors h_i, h_j are uniformly separated from the chart boundaries. Uniform comparison of partial and covariant derivatives up to order N_1 gives

$$\|h_i R h_j \mathbf{u}\|_{H^s(U_i,\mathbf{F})} \le C_s s^{\mathrm{u}}_{N_1}(R) \|h_j \mathbf{u}\|_{H^{s+m}(U_j,\mathbf{E})}.$$

Each sum has at most $N_Q(\rho)$ indices. Cauchy–Schwarz followed by reverse counting of the pairs (i, j) yields

$$\|R\mathbf{u}\|_{H^s(M,\mathbf{F})} \le C_s N_Q(\rho) s^{\mathrm{u}}_{N_1}(R) \|\mathbf{u}\|_{H^{s+m}(M,\mathbf{E})}. \tag{15.123}$$

With $N := \max\{N_0, N_1\}$, (15.122) and (15.123) first give

$$\|A\|_{\mathcal{L}(H^{s+m}(M,\mathbf{E}),H^s(M,\mathbf{F}))} \le C_s (1 + N_Q(\rho)) P^{\mathcal{Q}}_{m,N}(\mathfrak{r}).$$

Taking the infimum over all representations of radius ρ proves (15.120). If R is smoothing, use the representation $((0), R)$ and regard R as an operator of order $t - s$; this gives the mapping from $H^t(M,\mathbf{E})$ to $H^s(M,\mathbf{F})$. Density of $\Gamma_c(M,\mathbf{E})$, proved using the same analysis–synthesis pair in the preceding chapter, completes the extensions. □

Corollary 15.6.15. (Uniform elliptic estimate and regularity) Let $(M, \mathbf{g})$ be a complete Riemannian manifold without boundary of bounded geometry, and let $\mathbf{E}, \mathbf{F} \to M$ be complex vector bundles of the same finite rank equipped with Hermitian bundle metrics and compatible connections of bounded geometry. Let $m \in \mathbb{R}$ and let $A \in \Psi^m_{\mathrm{u,cl}}(M; \mathbf{E}, \mathbf{F})$ be uniformly elliptic. For $s, t \in \mathbb{R}$, there exists $C_{s,t} > 0$ such that

$$\|\mathbf{u}\|_{H^{s+m}(M,\mathbf{E})} \le C_{s,t} \big(\|A\mathbf{u}\|_{H^s(M,\mathbf{F})} + \|\mathbf{u}\|_{H^t(M,\mathbf{E})} \big), \qquad \mathbf{u} \in \Gamma_c(M,\mathbf{E}). \tag{15.124}$$

If $\mathbf{u} \in H^t(M,\mathbf{E})$ and $A\mathbf{u} \in H^s(M,\mathbf{F})$ in the distributional sense, then $\mathbf{u} \in H^{s+m}(M,\mathbf{E})$.

Proof. Let B be the parametrix of (15.119) and write $BA = I - R_{\mathbf{E}}$. The preceding theorem gives

$$\|\mathbf{u}\|_{H^{s+m}(M,\mathbf{E})} \le \|BA\mathbf{u}\|_{H^{s+m}(M,\mathbf{E})} + \|R_{\mathbf{E}}\mathbf{u}\|_{H^{s+m}(M,\mathbf{E})} \le C_{s,t} \big(\|A\mathbf{u}\|_{H^s(M,\mathbf{F})} + \|\mathbf{u}\|_{H^t(M,\mathbf{E})} \big),$$

since B has order $-m$ and $R_{\mathbf{E}}$ is uniformly smoothing. The same distributional identity proves the last assertion. □

Remark 15.6.16. (Uniform does not mean compact) On a noncompact manifold without boundary, an element of $\Psi^{-\infty}_{\mathrm{u}}(M; \mathbf{E}, \mathbf{F})$ need not be compact or Fredholm. On $\mathbb{R}^n$, let $0 \neq \kappa \in C^\infty_c(\mathbb{R}^n)$ and

$$Ru := \kappa * u.$$

Its symbol $(2\pi)^{\frac{n}{2}} \widehat{\kappa}(\xi)$ belongs to $S^{-\infty}(\mathbb{R}^n; \mathrm{Hom}(\mathbb{C}, \mathbb{C}))$ with the unitary normalization of Definition 4.11.1, and its kernel has finite propagation and translation-invariant bounds. Thus $R \in \Psi^{-\infty}_{\mathrm{u}}(\mathbb{R}^n; \mathbb{C}, \mathbb{C})$. Choose $u \in C^\infty_c(\mathbb{R}^n)$ with $Ru \neq 0$ and set $u_j(x) = u(x - je_1)$. Then Ru_j is the corresponding translate of Ru; a subsequence

with disjoint supports cannot converge. Thus R is not compact. Moreover, $\widehat{\kappa}(\xi) \to 0$ as $\|\xi\| \to \infty$; normalized functions with Fourier supports in disjoint balls escaping to infinity form an orthonormal sequence (v_j) with $Rv_j \to 0$. Since v_j converges weakly to zero, its distance to any finite-dimensional subspace tends to one. This contradicts the lower bound for a Fredholm operator on the orthogonal complement of its kernel; thus R is not Fredholm either.

For the same reason, existence of a parametrix with *uniformly* smoothing remainders does not prove the Fredholm property. For example, $D_1 = \partial_1 \colon H^1(\mathbb{R}) \to L^2(\mathbb{R})$ is uniformly elliptic but its range is not closed. On open manifolds, additional hypotheses at infinity are needed; they will not be introduced here.

15.6.4 Closed manifolds: compactness and Schatten classes

On a noncompact manifold, a uniformly smooth kernel can translate to infinity without producing a compact operator. On a closed manifold this possibility disappears: smooth kernels are compact and, in fact, belong to Schatten classes. This difference will allow passage from a smoothing parametrix to the Fredholm property.

First fix the functional-analytic terminology used in this subsection. Let H_1, H_2 be separable Hilbert spaces and let $T \colon H_1 \to H_2$ be compact. Its **singular values** are the eigenvalues, repeated according to multiplicity, arranged in nonincreasing order and padded with zeros when the rank is finite,

$$s_j(T) := \lambda_j\big((T^{\dagger}T)^{\frac{1}{2}}\big), \qquad j \geq 1.$$

For $1 \leq p < \infty$, the **Schatten class** $\mathfrak{S}_p(H_1, H_2)$ consists of compact operators such that

$$\|T\|_{\mathfrak{S}_p} := \left(\sum_{j=1}^{\infty} s_j(T)^p \right)^{\frac{1}{p}} < \infty.$$

In particular, $\mathfrak{S}_2$ is the Hilbert–Schmidt class and $\mathfrak{S}_1$ the trace class. If (e_j) is an orthonormal basis of H_1, then

$$\|T\|_{\mathfrak{S}_2}^2 = \sum_{j=1}^{\infty} \|Te_j\|_{H_2}^2; \tag{15.125}$$

this quantity is independent of the basis and is called the **Hilbert–Schmidt norm**. If $H_1 = H_2 = H$ and $T \in \mathfrak{S}_1(H)$, its **trace** is

$$\operatorname{Tr}(T) := \sum_{j=1}^{\infty} \langle Te_j, e_j \rangle_H. \tag{15.126}$$

The series converges absolutely, and its sum is independent of the orthonormal basis. These assertions follow first for finite-rank operators by singular value decomposition and then by completeness in the norms $\mathfrak{S}_2$ and $\mathfrak{S}_1$.

Proposition 15.6.17. (Square-integrable kernels and products of Schatten classes) Let $(M, \mathbf{g})$ be a smooth closed Riemannian manifold of dimension n, and let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics. An integral operator

$$(T_K u)(x) = \int_{M_y} K(x,y) u(y)\, d\lambda_{\mathbf{g}}(y)$$

is Hilbert–Schmidt if and only if, up to almost-everywhere equality, its kernel belongs to

$$L^2\big(M\times M;\operatorname{Hom}(\mathbf{E}_y,\mathbf{F}_x)\big).$$

Here $\|K(x,y)\|_{\mathrm{HS}}$ is the Euclidean norm of the matrix of $K(x,y)\colon \mathbf{E}_y\to\mathbf{F}_x$ in orthonormal bases, independent of those bases. In this case,

$$\|T_K\|_{\mathfrak{S}_2}^2=\int_{M_x\times M_y}\|K(x,y)\|_{\mathrm{HS}}^2\,d\lambda_{\mathbf{g}}(x)\,d\lambda_{\mathbf{g}}(y). \tag{15.127}$$

Moreover, if $C\in\mathfrak{S}_2(H_1,H_2)$ and $B\in\mathfrak{S}_2(H_2,H_3)$, then

$$BC\in\mathfrak{S}_1(H_1,H_3),\qquad \|BC\|_{\mathfrak{S}_1}\le\|B\|_{\mathfrak{S}_2}\|C\|_{\mathfrak{S}_2}. \tag{15.128}$$

Proof. The isometric identification between the Hilbert tensor product $L^2(M,\mathbf{F})\widehat{\otimes}\overline{L^2(M,\mathbf{E})}$ and Hilbert–Schmidt operators sends an elementary tensor $f\otimes\overline{e}$ to the operator $u\mapsto\langle u,e\rangle f$. In local orthonormal frames, this identification is precisely $K\mapsto T_K$; Parseval and Tonelli give (15.127). Surjectivity of the identification also proves the converse and uniqueness of the kernel in $L^2(M\times M;\operatorname{Hom}(\mathbf{E}_y,\mathbf{F}_x))$.
For the last assertion, use a singular value decomposition

$$Cu=\sum_{j=1}^{\infty}s_j(C)\langle u,e_j\rangle f_j,$$

where (e_j) is orthonormal in H_1 and (f_j) is an orthonormal system in H_2. Then

$$BCu=\sum_{j=1}^{\infty}s_j(C)\langle u,e_j\rangle Bf_j$$

is a nuclear representation. Indeed, a rank-one operator $u\mapsto\langle u,e\rangle h$ has $\mathfrak{S}_1$ norm equal to $\|e\|\|h\|$; by the triangle inequality, a series of such operators for which these quantities have finite sum converges in $\mathfrak{S}_1$. Now, by Cauchy–Schwarz and (15.125),

$$\sum_{j=1}^{\infty}s_j(C)\|Bf_j\|\le\left(\sum_{j=1}^{\infty}s_j(C)^2\right)^{\frac12}\left(\sum_{j=1}^{\infty}\|Bf_j\|^2\right)^{\frac12}\le\|C\|_{\mathfrak{S}_2}\|B\|_{\mathfrak{S}_2}.$$

In the last inequality, (f_j) was extended to an orthonormal basis of H_2. The partial sums therefore converge in trace-class norm and prove (15.128). □

Proposition 15.6.18. (Smoothing operators on a closed manifold) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold, and let $\mathbf{E},\mathbf{F}\longrightarrow M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics and Hermitian connections. If $R\in\Psi^{-\infty}(M;\mathbf{E},\mathbf{F})$, then, for all $s,t\in\mathbb{R}$,

$$R\colon H^s(M,\mathbf{E})\longrightarrow H^t(M,\mathbf{F})$$

is continuous and compact. In fact, as an operator from $L^2(M,\mathbf{E})$ to $L^2(M,\mathbf{F})$, R is trace class.

Proof. After localizing the kernel on coordinate rectangles, the duality definition of Lemma 15.6.3 applies directly to every element of $H^s(M,\mathbf{E})$ and allows differentiation within the pairing with the distribution. Thus R maps $H^s(M,\mathbf{E})$ continuously into $H^N(M,\mathbf{F})$ for every N. Choose $N > t$. The inclusion $H^N(M,\mathbf{F}) \hookrightarrow H^t(M,\mathbf{F})$ is compact by the Rellich–Kondrashov theorem, obtained from 6.6.4 using a finite atlas; factorization proves compactness.

For the last assertion, localize the kernel on finitely many coordinate rectangles and extend each piece smoothly to a torus. Its double Fourier coefficients decay faster than any power. Thus the piece is a sum of rank-one operators with absolutely summable coefficients and is trace class. A finite sum preserves this property. □

Lemma 15.6.19. (Diagonal formula for a continuous kernel) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold, and let $\mathbf{E} \longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric. If $T \in \mathfrak{S}_1(L^2(M,\mathbf{E}))$ has a continuous integral kernel $\mathbf{K}_T(x,y)$, then

$$\operatorname{Tr}(T) = \int_{M_x} \operatorname{tr}_{\mathbf{E}_x} \mathbf{K}_T(x,x)\, d\lambda_{\mathbf{g}}(x).$$

Proof. Fix a finite cover (V_i) with $\overline{V}_i$ contained in an open set U_i equipped with a unitary frame $(\mathbf{e}_{i,a})$. Take finite measurable subdivisions $\mathcal{P}_\nu$ whose positive-measure cells lie in some V_i and whose maximum diameter δ_ν tends to zero; discard null cells. For each cell $Q \subset V_i$ and each vector of the local frame, let

$$\mathbf{v}_{Q,a} := \lambda_{\mathbf{g}}(Q)^{-\frac{1}{2}} \mathbf{1}_Q \mathbf{e}_{i,a},$$

, and denote by P_ν the orthogonal projection onto the space spanned by these vectors. If $\mathbf{u} \in \Gamma(M,\mathbf{E})$ and $\mathbf{u} = \sum_{a=1}^{r_{\mathbf{E}}} u_{i,a}\mathbf{e}_{i,a}$ in U_i, then, on $Q \subset V_i$,

$$P_\nu \mathbf{u} = \sum_{a=1}^{r_{\mathbf{E}}} \left(\frac{1}{\lambda_{\mathbf{g}}(Q)} \int_{Q_y} u_{i,a}(y)\, d\lambda_{\mathbf{g}}(y) \right) \mathbf{e}_{i,a}.$$

Uniformity of the moduli of continuity of the coefficients over this finite cover gives $\|P_\nu \mathbf{u} - \mathbf{u}\|_{L^2(M,\mathbf{E})} \leq C\omega_{\mathbf{u}}(\delta_\nu)$. Density of smooth sections and $\|P_\nu\| \leq 1$ imply that $P_\nu \to I$ strongly.

Since T is trace class,

$$\|T - P_\nu T P_\nu\|_{\mathfrak{S}_1} \longrightarrow 0;$$

indeed, $T - P_\nu T P_\nu = (I - P_\nu)T + P_\nu T(I - P_\nu)$, and both terms converge to zero in trace norm, first for T of finite rank and then by approximating T and $T^\dagger$ in $\mathfrak{S}_1$. Consequently,

$$\operatorname{Tr}(T) = \lim_{\nu \to \infty} \sum_{Q \in \mathcal{P}_\nu} \sum_{a=1}^{r_{\mathbf{E}}} \frac{1}{\lambda_{\mathbf{g}}(Q)} \int_{Q_x \times Q_y} \left\langle \mathbf{K}_T(x,y)\mathbf{e}_{i,a}(y), \mathbf{e}_{i,a}(x) \right\rangle d\lambda_{\mathbf{g}}(y)\, d\lambda_{\mathbf{g}}(x).$$

On $\overline{V}_i \times \overline{V}_i$, set

$$k_{i,a}(x,y) := \left\langle \mathbf{K}_T(x,y)\mathbf{e}_{i,a}(y), \mathbf{e}_{i,a}(x) \right\rangle.$$

These functions are uniformly continuous. If ω is the maximum of their moduli of continuity, the difference

between the last sum and the diagonal integral is bounded by

$$\operatorname{rk}(\mathbf{E})\lambda_{\mathbf{g}}(M)\omega(\delta_\nu),$$

which tends to zero. Finally, $\sum_{a=1}^{r_{\mathbf{E}}} k_{i,a}(x,x) = \operatorname{tr}_{\mathbf{E}_x} \mathbf{K}_T(x,x)$, so the limit is independent of the frame and proves the formula. □

Theorem 15.6.20. (Hilbert–Schmidt and trace-class thresholds) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold of dimension n, and let $\mathbf{E},\mathbf{F} \longrightarrow M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics and Hermitian connections. Let $m \in \mathbb{R}$.

(i) If $A \in \Psi^m(M;\mathbf{E},\mathbf{F})$ and $m < -\frac{n}{2}$, then

$$A \in \mathfrak{S}_2\big(L^2(M,\mathbf{E}), L^2(M,\mathbf{F})\big),$$

that is, A is Hilbert–Schmidt.

(ii) If $m < -n$, then

$$A \in \mathfrak{S}_1\big(L^2(M,\mathbf{E}), L^2(M,\mathbf{F})\big).$$

If $\mathbf{E} = \mathbf{F}$, its trace is given by the diagonal formula

$$\operatorname{Tr}(A) = \int_{M_x} \operatorname{tr}_{\mathbf{E}_x} \mathbf{K}_A(x,x)\, d\lambda_{\mathbf{g}}(x). \tag{15.129}$$

If, with the convention of Definition 15.4.7,

$$A = \operatorname{Op}_{\mathbf{g},\nabla,\chi}(a) + R, \qquad R \in \Psi^{-\infty}(M;\mathbf{E},\mathbf{E}),$$

and $m < -n$, then

$$\operatorname{Tr}(A) = (2\pi)^{-n} \int_{M_x} \int_{T_x^*M} \operatorname{tr}_{\mathbf{E}_x} a(x,\xi)\, d\xi_x\, d\lambda_{\mathbf{g}}(x) + \int_{M_x} \operatorname{tr}_{\mathbf{E}_x} \mathbf{K}_R(x,x)\, d\lambda_{\mathbf{g}}(x). \tag{15.130}$$

Proof. First localize a piece whose symbol $a(x,\xi)$ has compact support in x. Its kernel is

$$K(x,y) = (2\pi)^{-n} \int_{\mathbb{R}^n_\xi} e^{i(x-y)\cdot\xi} a(x,\xi)\, d\xi.$$

Plancherel in the variable y gives

$$\int_{\mathbb{R}^n_y} \|K(x,y)\|_{\mathrm{HS}}^2\, dy = (2\pi)^{-n} \int_{\mathbb{R}^n_\xi} \|a(x,\xi)\|_{\mathrm{HS}}^2\, d\xi.$$

The right-hand side is integrable in x when $2m < -n$. The square of the Hilbert–Schmidt norm of an integral operator is the $L^2(M\times M;\operatorname{Hom}(\mathbf{E}_y,\mathbf{F}_x))$ norm of its kernel; a finite atlas and Proposition 15.6.18 for the remainders prove (i).

Suppose $m < -n$. Construct a scalar elliptic operator $Q_{\mathbf{E}} \in \Psi^{\frac{m}{2}}(M;\mathbf{E},\mathbf{E})$ with local full symbol $\langle\xi\rangle^{\frac{m}{2}} I_{\mathbf{E}}$ modulo lower-order terms and hence principal symbol $\|\xi\|^{\frac{m}{2}} I_{\mathbf{E}}$, and a parametrix $C_{\mathbf{E}} \in \Psi^{-\frac{m}{2}}(M;\mathbf{E},\mathbf{E})$. If $C_{\mathbf{E}} Q_{\mathbf{E}} = I - R_{\mathbf{E}}$, then

$$A = (AC_{\mathbf{E}})Q_{\mathbf{E}} + AR_{\mathbf{E}}.$$

The first two factors have order $\frac{m}{2} < -\frac{n}{2}$ and are Hilbert–Schmidt by (i); their product is trace class. The last term is smoothing and trace class by the preceding proposition. This proves (ii).

When $m < -n$, in each localized piece the integral defining the kernel has the uniform majorant $C\langle\xi\rangle^m \in L^1(\mathbb{R}^n)$. Dominated convergence shows that the kernel is jointly continuous in (x,y); a finite sum of pieces and the smooth remainder preserve this property. Lemma 15.6.19, applied to the trace-class operator already constructed, gives (15.129). In geometric quantization, $j_x(0) = 1$ and parallel transport on the diagonal is the identity; thus

$$\mathbf{K}_{\mathrm{Op}_{\mathbf{g},\nabla,\chi}(a)}(x,x) = (2\pi)^{-n} \int_{T_x^*M} a(x,\xi)\, d\xi_x.$$

Adding the term R proves (15.130). □

15.6.5 Elliptic operators and Fredholm theory

An elliptic parametrix gives inverse identities modulo smoothing operators. On a closed manifold these remainders are compact, so Atkinson's theory immediately turns symbolic inversion into a Fredholm statement. We begin with the form of this criterion suited to the two identities of a parametrix.

Lemma 15.6.21. (Compact parametrix criterion) Let X, Y be Hilbert spaces and let $T \in \mathcal{L}(X,Y)$ and $S \in \mathcal{L}(Y,X)$. If

$$ST - I_X \in \mathcal{K}(X), \qquad TS - I_Y \in \mathcal{K}(Y),$$

, then T is Fredholm in the sense of Definition B.2.40.

Proof. Let $T^\dagger\colon Y \to X$ and $S^\dagger\colon X \to Y$ denote the bounded Hilbert space adjoints. These are not formal adjoints of differential operators: they depend on the specific inner products of X and Y. If $Tu = 0$, then $u = (I_X - ST)u$; the unit ball of $\ker T$ is therefore relatively compact. A normed space with relatively compact unit ball is finite-dimensional, so $\dim\ker T < \infty$. Applying the same argument to $T^\dagger$ and $S^\dagger$ gives $\dim\ker T^\dagger < \infty$.

Let us prove that the range is closed. On $(\ker T)^\perp$, if there were no $c > 0$ with $\|Tu\|_Y \geq c\|u\|_X$, there would be a sequence $u_j \perp \ker T$, $\|u_j\|_X = 1$, and $Tu_j \to 0$. From

$$u_j = STu_j + (I_X - ST)u_j$$

and compactness of $I_X - ST$, we could extract a subsequence converging to u. Then $\|u\| = 1$, $Tu = 0$, and $u \perp \ker T$, a contradiction. The lower bound on $(\ker T)^\perp$ implies that $\mathrm{Ran}\, T$ is closed. Finally,

$$\mathrm{coker}\, T \cong (\mathrm{Ran}\, T)^\perp = \ker T^\dagger$$

is finite-dimensional. □

Theorem 15.6.22. (Elliptic Fredholm theorem on a closed manifold) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold, and let $\mathbf{E},\mathbf{F}\longrightarrow M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics and Hermitian connections. Let $m,s\in\mathbb{R}$ and let $A\in\Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$ be elliptic. Then

$$A_s\colon H^{s+m}(M,\mathbf{E})\longrightarrow H^s(M,\mathbf{F})$$

is Fredholm. Its kernel and cokernel have smooth representatives:

$$\ker A_s=\{\mathbf{u}\in\Gamma(M,\mathbf{E})\mid A\mathbf{u}=0\},\tag{15.131}$$

$$\big(\operatorname{coker}A_s\big)'\cong\{\mathbf{w}\in\Gamma(M,\overline{\mathbf{F}})\mid\overline{A_h^*}\mathbf{w}=0\}\cong\overline{\{\mathbf{v}\in\Gamma(M,\mathbf{F})\mid A_h^*\mathbf{v}=0\}}.\tag{15.132}$$

In particular,

$$\operatorname{ind}(A_s)=\dim\ker\big(A\colon\Gamma(M,\mathbf{E})\longrightarrow\Gamma(M,\mathbf{F})\big)-\dim\ker\big(A_h^*\colon\Gamma(M,\mathbf{F})\longrightarrow\Gamma(M,\mathbf{E})\big).\tag{15.133}$$

Proof. The elliptic construction provides a parametrix $B\in\Psi^{-m}_{\mathrm{cl}}(M;\mathbf{F},\mathbf{E})$ and remainders

$$BA=I-R_{\mathbf{E}},\qquad AB=I-R_{\mathbf{F}},\qquad R_{\mathbf{E}}\in\Psi^{-\infty}(M;\mathbf{E},\mathbf{E}),\qquad R_{\mathbf{F}}\in\Psi^{-\infty}(M;\mathbf{F},\mathbf{F}).$$

By Corollary 15.6.6, $B\colon H^s(M,\mathbf{F})\longrightarrow H^{s+m}(M,\mathbf{E})$ is continuous, and by Proposition 15.6.18 both remainders are compact on the corresponding spaces. Lemma 15.6.21 proves that A_s is Fredholm.
If $\mathbf{u}$ is a distribution and $A\mathbf{u}=0$, the first identity gives $\mathbf{u}=R_E\mathbf{u}$. Since $R_{\mathbf{E}}$ is smoothing, $\mathbf{u}$ is smooth. This proves (15.131) and shows that the kernel is independent of the Sobolev order. By Proposition 14.5.5, applied on the closed manifold, the complex-linear dual of $H^s(M,\mathbf{F})$ is $H^{-s}(M,\overline{\mathbf{F}})$. Define the conjugate of the Hermitian adjoint by

$$\overline{A_h^*}\colon\Gamma(M,\overline{\mathbf{F}})\longrightarrow\Gamma(M,\overline{\mathbf{E}}),\qquad\overline{A_h^*}(\overline{\mathbf{v}}):=\overline{A_h^*\mathbf{v}}.$$

It is complex-linear. In charts it is obtained by conjugating the coefficients and kernel of A_h^*; hence it belongs to $\Psi^m_{\mathrm{cl}}(M;\overline{\mathbf{F}},\overline{\mathbf{E}})$ and is elliptic. The defining identity of the Hermitian adjoint becomes the bilinear identity

$$\langle A\mathbf{u},\mathbf{w}\rangle_{\mathbf{F},\overline{\mathbf{F}}}=\langle\mathbf{u},\overline{A_h^*}\mathbf{w}\rangle_{\mathbf{E},\overline{\mathbf{E}}}.$$

Consequently, the annihilator of the range of A_s is identified with

$$\ker\left(\overline{A_h^*}\colon H^{-s}(M,\overline{\mathbf{F}})\longrightarrow H^{-s-m}(M,\overline{\mathbf{E}})\right).$$

The conjugate operator is elliptic, and the same smoothing argument makes its solutions smooth. Pointwise conjugation identifies its kernel with the conjugate space of $\ker A_h^*$. This gives (15.132) and, together with the definition of the index, yields (15.133). □

Corollary 15.6.23. (Independence of the Sobolev exponent) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold; let $\mathbf{E},\mathbf{F}\longrightarrow M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics and Hermitian connections; and let $m\in\mathbb{R}$ and let $A\in\Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$ be elliptic. Then

$$\operatorname{ind}\left(A\colon H^{s+m}(M,\mathbf{E})\longrightarrow H^s(M,\mathbf{F})\right)$$

is independent of $s \in \mathbb{R}$.

Proof. The two spaces of smooth solutions appearing in (15.133) are independent of s. □

15.6.6 Analytic stability of the index

Once the Fredholm property is established, the index can change only if the family leaves the set of Fredholm operators. Compact perturbations and continuous deformations preserve this set; applied to the pseudodifferential calculus, they show that lower-order terms do not change the index.

Theorem 15.6.24. (Compact perturbations and continuous families) Let X, Y be Hilbert spaces.

(i) If $T \in \mathcal{L}(X,Y)$ is Fredholm and $K \in \mathcal{K}(X,Y)$, then $T+K$ is Fredholm and

$$\operatorname{ind}(T+K) = \operatorname{ind}(T).$$

(ii) The set of Fredholm operators is open in $\mathcal{L}(X,Y)$, and the index is locally constant.

(iii) If Λ is connected and $\lambda \mapsto T_\lambda \in \mathcal{L}(X,Y)$ is a continuous family of Fredholm operators, then $\operatorname{ind}(T_\lambda)$ is constant on Λ.

Proof. Since T is Fredholm, there are orthogonal decompositions

$$X = \ker T \oplus X_0, \qquad Y = \operatorname{Ran} T \oplus Y_0,$$

with Y_0 finite-dimensional. The restriction $T\colon X_0 \to \operatorname{Ran} T$ is a continuous isomorphism. Define $S\colon Y \to X$ as its inverse on $\operatorname{Ran} T$ and zero on Y_0. Then $ST - I_X$ and $TS - I_Y$ have finite rank. For $T+K$, the products with S differ from the identity by compact operators, so Lemma 15.6.21 proves that $T+K$ is Fredholm.
For operators sufficiently close to T, the components between X_0 and $\operatorname{Ran} T$ remain invertible by stability of invertibility. Eliminating this block by invertible operations reduces the nearby operator to a map between $\ker T$ and Y_0. Its index is

$$\dim \ker T - \dim Y_0 = \operatorname{ind} T,$$

regardless of the rank of this finite block. This proves openness and local constancy simultaneously. Applied to the path $T+tK$, it proves equality of indices in (i). Finally, a locally constant integer-valued function is constant on a connected space, giving (iii). □

Corollary 15.6.25. (Pseudodifferential stability) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold; let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics and Hermitian connections; let $m, s \in \mathbb{R}$; and let $A \in \Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$ be elliptic.

(a) If $K\colon H^{s+m}(M,\mathbf{E}) \longrightarrow H^s(M,\mathbf{F})$ is compact, then $A+K$ is Fredholm with the same index as A.

(b) In particular, this holds if K is smoothing. It also holds for $K \in \Psi^{m-\varepsilon}(M;\mathbf{E},\mathbf{F})$ with $\varepsilon > 0$, since

$$H^{s+m}(M,\mathbf{E}) \xrightarrow{K} H^{s+\varepsilon}(M,\mathbf{F}) \hookrightarrow H^s(M,\mathbf{F})$$

and the second arrow is compact.

(c) If $(A_\lambda)_{\lambda\in\Lambda}$ is an elliptic family of order m, continuous in the pseudodifferential topology of order m, and Λ is connected, then $\operatorname{ind} A_\lambda$ is independent of λ.

Proof. The first two parts follow from Proposition 15.6.18, the preceding theorem, and Rellich. For (c), the mapping theorem shows that continuity in sufficiently many symbol seminorms implies continuity in

$$\mathcal{L}\big(H^{s+m}(M,\mathbf{E}),H^s(M,\mathbf{F})\big).$$

Each A_λ is Fredholm by Theorem 15.6.22; part (iii) of the preceding theorem then applies. □

The stability obtained here is entirely analytic: it uses parametrices, regularity, compactness, and norm continuity. On a closed manifold, these are exactly the arguments that turn ellipticity of the symbol into a well-defined stable integer.

15.7 Complex powers, heat, and the analytic index

The parametrix of an elliptic operator inverts its symbol with respect to composition. To construct noninteger powers, we must uniformly invert an entire family: the resolvent $\lambda I - A$. The variable λ does not have the same weight as the covariable ξ. If A has order $m > 0$, the natural scaling is

$$(\xi,\lambda)\longmapsto(t\xi,t^m\lambda).$$

This scaling governs the resolvent parametrix, complex powers, and their comparison with the spectral calculus.

Throughout this section, $(M,\mathbf{g})$ is a smooth closed Riemannian manifold of dimension n, and $\mathbf{E}\longrightarrow M$ is a complex vector bundle of finite rank equipped with a Hermitian bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. These data remain fixed, and within this section we abbreviate

$$\Gamma(\mathbf{E}):=\Gamma(M,\mathbf{E}),\qquad \Psi^\mu(M;\mathbf{E}):=\Psi^\mu(M;\mathbf{E},\mathbf{E}).$$

Let

$$A\in\Psi^m_{\mathrm{cl}}(M;\mathbf{E}),\qquad m>0,$$

be a classical elliptic operator. Write $a\sim\sum_{j=0}^{\infty}a_{m-j}$ for its Fourier symbol in coordinates and local frames. If A is differential, recall the conversion fixed at the beginning of the chapter:

$$a_m(x,\xi)=i^m\sigma_m(A)(x,\xi).$$

The sectorial condition is formulated for a_m, since this is the symbol entering quantization. By $\sigma(A)$ and $\rho(A)$ we mean the spectrum and resolvent of the closed realization on $L^2(M,\mathbf{E})$ with domain $H^m(M,\mathbf{E})$.

Lemma 15.7.1. (Graph norm and elliptic realization) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold; let $\mathbf{E}\longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$; and let $A\in\Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{E})$ be elliptic, with $m>0$. Then there are constants $c,C>0$

such that

$$c\|\mathbf{u}\|_{H^m(M,\mathbf{E})} \le \|\mathbf{u}\|_{L^2(M,\mathbf{E})} + \|A\mathbf{u}\|_{L^2(M,\mathbf{E})} \le C\|\mathbf{u}\|_{H^m(M,\mathbf{E})}, \qquad \mathbf{u} \in \Gamma(M,\mathbf{E}). \tag{15.134}$$

The operator $A\colon H^m(M,\mathbf{E}) \subset L^2(M,\mathbf{E}) \longrightarrow L^2(M,\mathbf{E})$ is closed, $\Gamma(M,\mathbf{E})$ is a core, and its graph norm is equivalent to the $H^m(M,\mathbf{E})$ norm.

Proof. The mapping property $A : H^m(M,\mathbf{E}) \to L^2(M,\mathbf{E})$ gives $\|\mathbf{u}\|_{L^2(M,\mathbf{E})} + \|A\mathbf{u}\|_{L^2(M,\mathbf{E})} \le C\|\mathbf{u}\|_{H^m(M,\mathbf{E})}$. Let $B \in \Psi^{-m}_{\mathrm{cl}}(M;\mathbf{E})$ and $R \in \Psi^{-\infty}(M;\mathbf{E},\mathbf{E})$ satisfy $BA = I - R$. Then

$$\|\mathbf{u}\|_{H^m(M,\mathbf{E})} \le \|BA\mathbf{u}\|_{H^m(M,\mathbf{E})} + \|R\mathbf{u}\|_{H^m(M,\mathbf{E})} \le C_1\|A\mathbf{u}\|_{L^2(M,\mathbf{E})} + C_2\|\mathbf{u}\|_{L^2(M,\mathbf{E})},$$

since $B : L^2(M,\mathbf{E}) \to H^m(M,\mathbf{E})$ and $R : L^2(M,\mathbf{E}) \to H^m(M,\mathbf{E})$ are continuous. This proves (15.134) on $\Gamma(\mathbf{E})$ and, by density, on $H^m(M,\mathbf{E})$.

If $\mathbf{u}_j \in H^m(M,\mathbf{E})$, $\mathbf{u}_j \to \mathbf{u}$ in $L^2(M,\mathbf{E})$, and $A\mathbf{u}_j \to \mathbf{f}$ in $L^2(M,\mathbf{E})$, the first inequality applied to $\mathbf{u}_j - \mathbf{u}_k$ shows that $(\mathbf{u}_j)$ is Cauchy in $H^m(M,\mathbf{E})$. Its limit in $H^m(M,\mathbf{E})$ agrees with $\mathbf{u}$, and continuity $A : H^m(M,\mathbf{E}) \to L^2(M,\mathbf{E})$ gives $A\mathbf{u} = \mathbf{f}$; hence the realization is closed. Finally, for $\mathbf{u} \in H^m(M,\mathbf{E})$ choose $\mathbf{v}_j \in \Gamma(\mathbf{E})$ with $\mathbf{v}_j \to \mathbf{u}$ in $H^m(M,\mathbf{E})$. The second inequality implies $\mathbf{v}_j \to \mathbf{u}$ in graph norm. This is exactly the assertion that $\Gamma(\mathbf{E})$ is a core. □

Proposition 15.7.2. (Compact resolvent and discrete spectrum) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold; let $\mathbf{E} \longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$; and let $A \in \Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{E})$ be elliptic, with $m > 0$, realized on $L^2(M,\mathbf{E})$ with domain $H^m(M,\mathbf{E})$. If $\rho(A) \neq \varnothing$, every resolvent of this realization is compact: for each $\lambda_0 \in \rho(A)$,

$$(\lambda_0 I - A)^{-1} : L^2(M,\mathbf{E}) \longrightarrow L^2(M,\mathbf{E})$$

is compact. Under this hypothesis, $\sigma(A)$ consists of isolated eigenvalues, each of finite algebraic multiplicity, and has no finite accumulation points. If A is self-adjoint and bounded below, then $\rho(A) \neq \varnothing$ and there is an orthonormal basis $(\boldsymbol{\varphi}_j)$ of $L^2(M,\mathbf{E})$ consisting of smooth eigensections. Repeating eigenvalues according to multiplicity,

$$A\boldsymbol{\varphi}_j = \lambda_j \boldsymbol{\varphi}_j, \qquad \lambda_j \longrightarrow +\infty.$$

Proof. A parametrix $B \in \Psi^{-m}_{\mathrm{cl}}(M;\mathbf{E})$ and a remainder $R \in \Psi^{-\infty}(M;\mathbf{E},\mathbf{E})$ give $\mathbf{u} = BAu + R\mathbf{u}$ for $\mathbf{u} \in \Gamma(M,\mathbf{E})$. The mapping properties and extension by density yield the elliptic estimate

$$\|\mathbf{u}\|_{H^m(M,\mathbf{E})} \le C\big(\|A\mathbf{u}\|_{L^2(M,\mathbf{E})} + \|\mathbf{u}\|_{L^2(M,\mathbf{E})}\big), \qquad \mathbf{u} \in H^m(M,\mathbf{E}). \tag{15.135}$$

If $\mathbf{u} = (\lambda_0 I - A)^{-1} f$, continuity of the resolvent on $L^2(M,\mathbf{E})$ and $A\mathbf{u} = \lambda_0 \mathbf{u} - f$ show, through (15.135), that $(\lambda_0 I - A)^{-1}$ is continuous from $L^2(M,\mathbf{E})$ to $H^m(M,\mathbf{E})$. The inclusion $H^m(M,\mathbf{E}) \hookrightarrow L^2(M,\mathbf{E})$ is compact by Rellich, so the resolvent viewed on $L^2(M,\mathbf{E})$ is compact.

The spectral correspondence

$$\lambda \in \sigma(A) \quad \Longleftrightarrow \quad (\lambda_0 - \lambda)^{-1} \in \sigma\big((\lambda_0 I - A)^{-1}\big), \qquad \lambda \neq \lambda_0,$$

reduces the assertions on isolation and algebraic multiplicity to the spectral theorem for compact operators.

In the self-adjoint bounded-below case, choose a real λ_0 below the spectrum. The resolvent is then compact and self-adjoint, and its spectral theorem provides an orthonormal basis of eigenvectors. The preceding correspondence and the lower bound force $\lambda_j \to +\infty$. Finally, $A\varphi_j = \lambda_j \varphi_j$ and elliptic regularity imply $\varphi_j \in \Gamma(\mathbf{E})$. □

15.7.1 Spectral cut and a minimal parameter-dependent calculus

Constructing A^z requires choosing a branch of the logarithm and controlling the resolvent along a sector avoiding both the principal spectrum and the spectrum of the closed realization. We first fix the cut, then construct the uniform parametrix of $\lambda I - A$.

For $\theta \in \mathbb{R}$, set

$$L_\theta := \{re^{i\theta} \mid r > 0\}.$$

On $\mathbb{C} \setminus (L_\theta \cup \{0\})$, fix the branch

$$\log_\theta \lambda = \log|\lambda| + i \arg_\theta \lambda, \qquad \theta - 2\pi < \arg_\theta \lambda < \theta,$$

and write $\lambda^z := e^{z \log_\theta \lambda}$.

Definition 15.7.3. (Agmon angle and spectral cut) Let $(M, \mathbf{g})$ be a smooth closed Riemannian manifold, let $(\mathbf{E}, \mathbf{h}_\mathbf{E}) \longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric, and let $A \in \Psi^m_{\mathrm{cl}}(M; \mathbf{E}, \mathbf{E})$ be elliptic, with $m > 0$ and principal Fourier symbol a_m. Let $\theta \in \mathbb{R}$. We say that θ is an **Agmon angle for the principal symbol** of A if

$$\operatorname{spec} a_m(x, \xi) \cap L_\theta = \varnothing$$

for every $(x, \xi) \in T^*M \setminus 0_M$. It is an **admissible spectral cut for** A if, in addition,

$$\sigma(A) \cap L_\theta = \varnothing.$$

To define all powers, positive and negative, we also assume $0 \in \rho(A)$, that is, invertibility of A. If 0 is an eigenvalue, reduced powers require separating the generalized eigenspace, as specified next.

If $0 \in \sigma(A)$ and A is not necessarily self-adjoint, the correct separation uses more than $\ker A$ alone. Existence of the admissible spectral cut implies $\rho(A) \neq \varnothing$; Proposition 15.7.2 then shows that 0 is isolated. Let

$$\Pi_0 := \frac{1}{2\pi i} \int_{|\lambda|=\varepsilon} (\lambda I - A)^{-1} \, d\lambda \tag{15.136}$$

be its Riesz projection, with the circle positively oriented and containing no other spectral point. Its range is the finite-dimensional generalized eigenspace of 0, and $L^2(M, \mathbf{E}) = \operatorname{ran} \Pi_0 \oplus \ker \Pi_0$ is a A-invariant decomposition. The restriction of A to $\ker \Pi_0$ is invertible; by **reduced power** we mean exclusively the power of this restriction, extended by zero on $\operatorname{ran} \Pi_0$. This convention asserts no group law on all of $L^2(M, \mathbf{E})$. If A is self-adjoint, Π_0 is the orthogonal projection onto $\ker A$, and no nilpotent part occurs.

In a cotangent chart, with the Euclidean norm fixed by this chapter's local convention, the quantity

$$\rho_m(\xi,\lambda) := \|\xi\|_{\mathbb{R}^n} + |\lambda|^{\frac{1}{m}}$$

is homogeneous of degree one under the weighted scaling fixed above. For smooth excisions, use the equivalent weight

$$\widehat{\rho}_m(\xi,\lambda) := \left(\langle\xi\rangle^{2m} + |\lambda|^2\right)^{\frac{1}{2m}}. \tag{15.137}$$

Unlike ρ_m, this weight is smooth also on the axes; the two are comparable in the region of high frequencies and large parameters.

Definition 15.7.4. (Parameter-dependent symbol and ellipticity) Let $m > 0$, let $U \subseteq \mathbb{R}^n$ be open, let $r \in \mathbb{N}$, and let $\Lambda \subseteq \mathbb{C}$ be a closed sector. Consider families with values in $\mathrm{End}(\mathbb{C}^r)$ and set

$$\Omega_m(\xi,\lambda) := |\lambda| + \langle\xi\rangle^m.$$

If

$$c \in C^\infty(U \times \mathbb{R}^n \times \Lambda; \mathrm{End}(\mathbb{C}^r))$$

is smooth up to the faces of the sector in the real variables $(x,\xi,\operatorname{Re}\lambda,\operatorname{Im}\lambda)$, for $K \Subset U$, $j \in \mathbb{N}_0$, $\alpha,\beta \in \mathbb{N}_0^n$, and $k,\ell \in \mathbb{N}_0$ define the following seminorms, where $\|\cdot\|_{\mathrm{op},\mathbb{C}^r}$ is the operator norm induced by the standard Hermitian norm:

$$\mathfrak{p}^{\mathrm{R},j}_{K,\alpha,\beta,k,\ell}(c) := \sup_{\substack{x\in K,\ \xi\in\mathbb{R}^n\\ \lambda\in\Lambda}} \langle\xi\rangle^{j+|\beta|}\Omega_m(\xi,\lambda)^{1+k+\ell}\left\|D_x^\alpha D_\xi^\beta \partial_\lambda^k \partial_{\bar\lambda}^\ell c(x,\xi,\lambda)\right\|_{\mathrm{op},\mathbb{C}^r}, \tag{15.138}$$

$$\mathfrak{p}^{\mathrm{D},j}_{K,\alpha,\beta,k,\ell}(c) := \sup_{\substack{x\in K,\ \xi\in\mathbb{R}^n\\ \lambda\in\Lambda}} \langle\xi\rangle^{j+|\beta|}\Omega_m(\xi,\lambda)^{k+\ell}\left\|D_x^\alpha D_\xi^\beta \partial_\lambda^k \partial_{\bar\lambda}^\ell c(x,\xi,\lambda)\right\|_{\mathrm{op},\mathbb{C}^r}. \tag{15.139}$$

Here $D_x^\alpha = \partial_x^\alpha$ and $D_\xi^\beta = \partial_\xi^\beta$, in accordance with this chapter's convention, while $\partial_\lambda = \frac{1}{2}(\partial_{\operatorname{Re}\lambda} - i\partial_{\operatorname{Im}\lambda})$ and $\partial_{\bar\lambda} = \frac{1}{2}(\partial_{\operatorname{Re}\lambda} + i\partial_{\operatorname{Im}\lambda})$ are the Wirtinger derivatives.

A family $q^{(j)}$, with $j \geq 0$, has **resolvent type** j if all seminorms (15.138) are finite. It has **defect type** j if all seminorms (15.139) are finite. In particular, for the first type,

$$\|D_x^\alpha D_\xi^\beta \partial_\lambda^k \partial_{\bar\lambda}^\ell q^{(j)}(x,\xi,\lambda)\|_{\mathrm{op},\mathbb{C}^r} \leq C_{K,\alpha,\beta,k,\ell,j}\langle\xi\rangle^{-j-|\beta|}\Omega_m(\xi,\lambda)^{-1-k-\ell},$$

and for the second the last factor is replaced by $\Omega_m^{-k-\ell}$. Families of resolvent type j and defect type j behave as orders $-m-j$ and $-j$, respectively, in the cone $|\lambda| \leq C\langle\xi\rangle^m$, while retaining the correct estimate when $|\lambda|$ dominates.

A family is **holomorphic in the parameter** if $\partial_{\bar\lambda} c = 0$ in the interior of Λ. It is **simultaneously smoothing in ξ and λ** if, for all $P,Q \in \mathbb{N}_0$, every compact set K, and all α,β,k,ℓ, there exists a constant $C_{K,P,Q,\alpha,\beta,k,\ell} > 0$ such that

$$\left\|D_x^\alpha D_\xi^\beta \partial_\lambda^k \partial_{\bar\lambda}^\ell c(x,\xi,\lambda)\right\|_{\mathrm{op},\mathbb{C}^r} \leq C_{K,P,Q,\alpha,\beta,k,\ell}\langle\xi\rangle^{-P}(1+|\lambda|)^{-Q}. \tag{15.140}$$

We abbreviate this condition by saying that c is smoothing with parameter. Membership in every resolvent type j imposes only arbitrary decay in ξ and the resolvent factor in λ; condition (15.140) additionally requires every power of $1+|\lambda|$ and does not follow from the former condition.

This is the weak version of the parameter-dependent calculus. The strong bound condensed into a single power of ρ_m fails for a general classical pseudodifferential operator when $|\lambda|$ dominates $\langle\xi\rangle^m$; the preceding separate bounds remain valid. At high frequencies, a family of resolvent type 0 is **classical with parameter** if its components are homogeneous under $(\xi,\lambda)\mapsto(t\xi,t^m\lambda)$ and the remainder after N components has resolvent type N for $\|\xi\|\geq 1$. The complementary bounded-frequency part is required only to be smoothing in ξ, retaining the decay factor $\Omega_m^{-1-k-\ell}$. If c_j has resolvent type j, write

$$c\sim\sum_{j=0}^{\infty}c_j\quad\Longleftrightarrow\quad c-\sum_{j=0}^{N-1}c_j\text{ has resolvent type }N\text{ for every }N\in\mathbb{N}_0. \tag{15.141}$$

The same convention, replacing *resolvent* by *defect*, is used for defect-type families.

The homogeneous principal symbol a_m is **elliptic with parameter** in Λ if $\lambda I-a_m(x,\xi)$ is invertible for $\xi\neq 0$ and $\lambda\in\Lambda$ and, for every $K\Subset U$, there exists $C_K>0$ such that its inverse satisfies

$$\|\big(\lambda I-a_m(x,\xi)\big)^{-1}\|\leq C_K\big(|\lambda|+\|\xi\|^m\big)^{-1},\qquad x\in K.$$

This condition is stronger than ellipticity of A without a parameter.

The smooth weight in (15.137) satisfies

$$2^{-\frac12}\Omega_m(\xi,\lambda)\leq\widehat{\rho}_m(\xi,\lambda)^m\leq\Omega_m(\xi,\lambda). \tag{15.142}$$

Indeed, for $a,b\geq 0$ we have $\frac{a+b}{\sqrt2}\leq(a^2+b^2)^{\frac12}\leq a+b$; it suffices to take $a=\langle\xi\rangle^m$ and $b=|\lambda|$. If $\chi\in C^\infty(\mathbb{R})$ is constant outside a compact subset of $(0,\infty)$, fix $0<c_\chi<C_\chi$ such that $\operatorname{supp}\chi'\subseteq[c_\chi,C_\chi]$. The chain rule gives, when $|\gamma|+r+s\geq 1$,

$$\big|D_\xi^\gamma\partial_\lambda^r\partial_{\bar\lambda}^s\chi(\varepsilon\widehat{\rho}_m)\big|\leq C_{\gamma,r,s}\langle\xi\rangle^{-|\gamma|}\Omega_m^{-r-s}\mathbf{1}_{\{c_\chi\varepsilon^{-1}\leq\widehat{\rho}_m\leq C_\chi\varepsilon^{-1}\}}. \tag{15.143}$$

To justify every derivative order, first differentiate $\widehat{\rho}_m^{2m}=\langle\xi\rangle^{2m}+|\lambda|^2$. A derivative in ξ of the resulting quotient is bounded by $C\langle\xi\rangle^{-1}$, and a Wirtinger derivative by $C\widehat{\rho}_m^{-m}$. Repeated use of the Leibniz rule gives terms containing $|\gamma|$ factors of the first type and $r+s$ of the second, possibly grouped into higher-order derivatives; their total exponents remain the same. Comparison (15.142) proves (15.143).

Lemma 15.7.5. (Asymptotic summation in weak parameter-dependent classes) Fix $m>0$, an open set $U\subseteq\mathbb{R}^n$, a rank $r\in\mathbb{N}$, and a closed sector $\Lambda\subseteq\mathbb{C}$ as in Definition 15.7.4. Let $(c_j)_{j\geq0}$ be a sequence of $\operatorname{End}(\mathbb{C}^r)$-valued families such that c_j has resolvent type j. There is a family c of resolvent type 0 satisfying $c\sim\sum_{j=0}^{\infty}c_j$ in the sense of (15.141). The assertion also holds for defect-type families. If all c_j are holomorphic in λ, the sum can be chosen holomorphic. Any two sums differ by a family belonging to every resolvent type N; the difference is smoothing with parameter precisely when it additionally satisfies the powers of $1+|\lambda|$ in (15.140). Finally, suppose that, for each P,Q and each finite family of derivatives, there exists J such that the terms c_j, $j\geq J$, satisfy an inequality of the form (15.140) with constants that may depend on j. Then one may use the joint cutoff $\chi(\varepsilon_j\widehat{\rho}_m)$ and choose ε_j with the following quantified property. For each

simultaneous seminorm $\mathfrak{s}_{K,P,Q,\alpha,\beta,k,\ell}$, there exists J such that, for every $N \geq J$,

$$\mathfrak{s}_{K,P,Q,\alpha,\beta,k,\ell}\left(\sum_{j=N}^{\infty} \chi(\varepsilon_j \widehat{\rho}_m) c_j\right) \leq \sum_{j=N}^{\infty} 2^{-j}.$$

This second auxiliary sum is not generally holomorphic in λ.

Proof. Choose $\chi \in C^\infty(\mathbb{R})$ with $0 \leq \chi \leq 1$, $\chi(t) = 0$ for $t \leq 1$, and $\chi(t) = 1$ for $t \geq 2$. Exhaust each chart by compact sets $K_1 \Subset K_2 \Subset \cdots$ and enumerate in a sequence $(\mathfrak{p}_\nu)_{\nu \geq 1}$ the seminorms (15.138) with $K = K_d$ and all indices $d, \alpha, \beta, k, \ell$. For $0 < \varepsilon \leq 1$, set

$$\chi_{j,\varepsilon}(\xi) := \chi(\varepsilon \langle \xi \rangle).$$

Successive applications of the chain rule give

$$|D_\xi^\gamma \chi_{j,\varepsilon}(\xi)| \leq C_\gamma \langle \xi \rangle^{-|\gamma|} \mathbf{1}_{\{\langle \xi \rangle \geq \varepsilon^{-1}\}}. \tag{15.144}$$

For $\gamma = 0$, the indicator merely expresses the cutoff support. Where a derivative of the cutoff is nonzero, $\varepsilon \langle \xi \rangle \in [1, 2]$; each derivative of $\langle \xi \rangle$ contributes a power bounded by that on the right-hand side.
The Leibniz rule, (15.144), and the defining inequality for c_j show that each term of $D_\xi^\beta(\chi_{j,\varepsilon} c_j)$ is bounded by

$$C \langle \xi \rangle^{-j-|\beta|} \Omega_m^{-1-k-\ell} \mathbf{1}_{\{\langle \xi \rangle \geq \varepsilon^{-1}\}}.$$

Thus, for each seminorm $\mathfrak{p}_\nu$ of resolvent type 0, there exists $C_{j,\nu} > 0$ such that

$$\mathfrak{p}_\nu(\chi_{j,\varepsilon} c_j) \leq C_{j,\nu} \varepsilon^j. \tag{15.145}$$

The derivatives $\partial_\lambda^k \partial_{\bar{\lambda}}^\ell$ fall only on c_j, since this cutoff depends on ξ and not on λ; hence the exponent $-1-k-\ell$ of Ω_m is preserved exactly.
Set $\varepsilon_0 = 1$ and recursively choose $\varepsilon_j \in (0, 2^{-j}]$ for $j \geq 1$. At step j, require, for the first j seminorms and every $N = 0, 1, \ldots, j-1$, that the resolvent-type N seminorm of the cutoff term not exceed 2^{-j}; for $N = 0$ this is equivalent to requiring

$$C_{j,\nu} \varepsilon_j^j \leq 2^{-j}, \qquad 1 \leq \nu \leq j. \tag{15.146}$$

There are only finitely many conditions at each step, all containing a positive power ε_j^{j-N}, so the choice is possible. Define

$$c := \sum_{j=0}^{\infty} \chi(\varepsilon_j \langle \xi \rangle) c_j. \tag{15.147}$$

The series is locally finite: for fixed ξ, $\varepsilon_j \langle \xi \rangle \leq 2^{-j} \langle \xi \rangle < 1$ holds from some index onward. For a fixed seminorm $\mathfrak{p}_\nu$, its tail from $j \geq \max\{\nu, 1\}$ is dominated by $\sum_{j=0}^{\infty} 2^{-j}$; hence it converges in every seminorm of resolvent type 0.
Fix N. For $j > N$, the preceding calculation, normalized with $\langle \xi \rangle^{N+|\beta|}$, contains $\langle \xi \rangle^{N-j} \leq \varepsilon_j^{j-N}$ on the cutoff support. The conditions imposed when choosing ε_j prove convergence of $\sum_{j=N}^{\infty} \chi(\varepsilon_j \langle \xi \rangle) c_j$ in every seminorm

of resolvent type N. Moreover,

$$c - \sum_{j=0}^{N-1} c_j = \sum_{j=N}^{\infty} \chi(\varepsilon_j\langle\xi\rangle)c_j - \sum_{j=0}^{N-1}\big(1-\chi(\varepsilon_j\langle\xi\rangle)\big)c_j. \tag{15.148}$$

The second sum is finite, and each summand has ξ in a compact set, so it belongs to every resolvent type N. This proves the remainder estimate for each N.

For defect type, repeat the same inequalities with $\Omega_m^{-k-\ell}$; no step changes that power. If the c_j are holomorphic, the locally finite sum (15.147) is also holomorphic. Subtracting two sums and using (15.148) for every N shows that their difference belongs to all the indicated types. If it additionally has the factor $(1+|\lambda|)^{-Q}$ for each Q, one obtains exactly (15.140); this is the quantified formulation of simultaneous residual decay.

To prove the last assertion, now use $\chi(\varepsilon_j\widehat{\rho}_m)$ and also enumerate the seminorms

$$\mathfrak{s}_{K,P,Q,\alpha,\beta,k,\ell}(d) := \sup_{\substack{x\in K,\,\xi\in\mathbb{R}^n\\ \lambda\in\Lambda}} \langle\xi\rangle^{P}(1+|\lambda|)^{Q}\|D_x^{\alpha}D_\xi^{\beta}\partial_\lambda^{k}\partial_{\bar\lambda}^{\ell}d\|.$$

Fix one of them and apply the hypothesis to exponents $P+L$ and $Q+L$. The Leibniz rule and (15.143) give, on the cutoff support, the bound

$$\mathfrak{s}_{K,P,Q,\alpha,\beta,k,\ell}\big(\chi(\varepsilon_j\widehat{\rho}_m)c_j\big) \le C_{j,L} \sup_{\substack{x\in K,\ \xi\in\mathbb{R}^n,\ \lambda\in\Lambda\\ \widehat{\rho}_m(\xi,\lambda)\ge\varepsilon_j^{-1}}} \langle\xi\rangle^{-L}(1+|\lambda|)^{-L}.$$

By (15.142), every point in the last supremum satisfies $\langle\xi\rangle \ge c\widehat{\rho}_m$ or $1+|\lambda| \ge c\widehat{\rho}_m^{m}$. Thus the right-hand side does not exceed $C_{j,L}\varepsilon_j^{\min\{1,m\}L}$. For a weak seminorm of resolvent or defect type, first absorb the positive powers of $\langle\xi\rangle$ and Ω_m by choosing $P+L$ and $Q+L$ still larger, obtaining the same positive power of ε_j. Recursively decrease ε_j so that the first j applicable seminorms do not exceed 2^{-j}. For a fixed seminorm, increase the index J in the hypothesis if necessary until that seminorm is among the first j for every $j \ge J$. The condition is then imposed on each summand of index $j \ge J$, and for every $N \ge J$ its tail is dominated by $\sum_{j=N}^{\infty} 2^{-j}$. Moreover, $1-\chi(\varepsilon_j\widehat{\rho}_m)$ has jointly compact support in (ξ,λ) for each fixed j. Thus the finite corrections are smoothing with parameter, and the tails satisfy (15.140). This proves the assertion without identifying simultaneous smoothing with mere membership in every resolvent type. □

The cutoff in this proof depends only on ξ and preserves holomorphy. In contrast, the global cutoffs $\chi(\varepsilon\widehat{\rho}_m)$ needed to excise the origin $(\xi,\lambda)=(0,0)$ jointly contain $|\lambda|^2$ and, unless constant, are not holomorphic. We always distinguish the auxiliary symbol family containing these cutoffs, the holomorphic homogeneous components, and the holomorphic exact resolvent.

The first condition is not a statement about the global spectrum of A. It is a uniform condition on a finite-dimensional family of matrices. Homogeneity of a_m and compactness of the cosphere bundle allow the ray to be widened: there exists $\varepsilon_{\mathrm{p}} > 0$ such that

$$\lambda I - a_m(x,\xi) \quad \text{is invertible if} \quad \xi \neq 0, \quad \lambda \in \Lambda^{\mathrm{p}}_{\theta,\varepsilon_{\mathrm{p}}},$$

where

$$\Lambda^{\mathrm{p}}_{\theta,\varepsilon_{\mathrm{p}}} := \{re^{i\varphi} \mid r>0,\ |\varphi-\theta| \le \varepsilon_{\mathrm{p}}\}$$

is understood modulo 2π. We do not yet assert that this principal sector is contained in $\rho(A)$. That conclusion is obtained first for large $|\lambda|$ using the parametrix and Neumann series. Only afterward is the sector narrowed to avoid the remaining compact spectral set; this logical order avoids using resolvent existence to construct the resolvent. Until then, all subsequent parameter seminorms and asymptotic sums are taken with $\Lambda = \Lambda^{\mathrm{p}}_{\theta,\varepsilon_{\mathrm{p}}}$.

Inversion on the normalized compact set followed by dilation gives

$$\left\|(\lambda I - a_m(x,\xi))^{-1}\right\|_{\mathcal{L}((\mathbf{E}_x,\mathbf{h}_{\mathbf{E}}(x)))} \le C\left(|\lambda| + |\xi|_{\mathbf{g}}^{m}\right)^{-1}.$$

Differentiating the identity $(\lambda I - a_m)(\lambda I - a_m)^{-1} = I$ gives, for the homogeneous terms introduced below and, in a local unitary frame, for $\|\xi\|_{\mathbb{R}^n} \ge 1$, weak estimates of the form

$$\left\|D_x^{\alpha} D_{\xi}^{\beta} \partial_{\lambda}^{k} q_{-m-j}(x,\xi,\lambda)\right\|_{\mathrm{op},\mathbb{C}^r} \le C_{\alpha,\beta,k} \langle \xi \rangle^{-j-|\beta|} \Omega_m(\xi,\lambda)^{-1-k}.$$

These bounds, together with holomorphy in λ, are the portion of the parameter-dependent calculus we use.

Proposition 15.7.6. (Resolvent parametrix) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold; let $(\mathbf{E},\mathbf{h}_{\mathbf{E}}) \longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$; and let $A \in \Psi^{m}_{\mathrm{cl}}(M;\mathbf{E},\mathbf{E})$ be elliptic, with $m > 0$ and local full symbol a. Suppose θ is an admissible spectral cut for A and $0 \in \rho(A)$. There exists a global auxiliary symbol family $\widetilde{q}$ of resolvent type 0, not necessarily holomorphic, which is a two-sided inverse of $\lambda I - a$ modulo families smoothing with parameter in the principal sector $\Lambda^{\mathrm{p}}_{\theta,\varepsilon_{\mathrm{p}}}$. At high frequencies its classical expansion is

$$\widetilde{q}(x,\xi,\lambda) \underset{\|\xi\|_{\mathbb{R}^n}\to\infty}{\sim} \sum_{j=0}^{\infty} q_{-m-j}(x,\xi,\lambda), \qquad \lambda \in \Lambda^{\mathrm{p}}_{\theta,\varepsilon_{\mathrm{p}}},$$

where the components are considered only for $\xi \neq 0$, are holomorphic in λ, satisfy

$$q_{-m-j}(x,t\xi,t^{m}\lambda) = t^{-m-j} q_{-m-j}(x,\xi,\lambda), \qquad t > 0,$$

and are determined recursively as follows. If

$$p_m := \lambda I - a_m, \qquad p_{m-k} := -a_{m-k} \quad (k \ge 1),$$

, then

$$q_{-m} = p_m^{-1}$$

and, for $j \ge 1$,

$$q_{-m-j} = -q_{-m} \sum_{\substack{k+\ell+|\alpha|=j \\ 0\le\ell<j}} \frac{i^{-|\alpha|}}{\alpha!} (D_{\xi}^{\alpha} p_{m-k})(D_x^{\alpha} q_{-m-\ell}). \tag{15.149}$$

The same component also satisfies the right recurrence

$$q_{-m-j} = -\sum_{\substack{k+\ell+|\alpha|=j \\ 0\le\ell<j}} \frac{i^{-|\alpha|}}{\alpha!} (D_{\xi}^{\alpha} q_{-m-\ell})(D_x^{\alpha} p_{m-k}) q_{-m}. \tag{15.150}$$

For every compact set K, all $\alpha, \beta \in \mathbb{N}_0^n$, and $k \in \mathbb{N}_0$, there exists $C_{K,j,\alpha,\beta,k} > 0$ such that, if $\|\xi\| \geq 1$,

$$\left\| D_x^\alpha D_\xi^\beta \partial_\lambda^k q_{-m-j}(x,\xi,\lambda) \right\| \leq C_{K,j,\alpha,\beta,k} \langle \xi \rangle^{-j-|\beta|} \Omega_m(\xi,\lambda)^{-1-k}, \qquad \partial_{\bar{\lambda}} q_{-m-j} = 0. \tag{15.151}$$

There exist $0 < \varepsilon \leq \varepsilon_{\mathrm{p}}$ and $R_0 > 0$ such that

$$\Lambda_{\theta,\varepsilon} := \{ re^{i\varphi} \mid r > 0,\ |\varphi - \theta| \leq \varepsilon \} \subseteq \rho(A).$$

The full symbol of the resolvent in this sector, $r(x,\xi,\lambda)$, taken in a fixed local quantization, is holomorphic in λ; for $|\lambda| \geq R_0$ it has the same high-frequency expansion

$$r(x,\xi,\lambda) \underset{\|\xi\| \to \infty}{\sim} \sum_{j=0}^{\infty} q_{-m-j}(x,\xi,\lambda).$$

For every $s \in \mathbb{R}$, there is a constant $C_s > 0$ such that, for $\lambda \in \Lambda_{\theta,\varepsilon}$ with $|\lambda| \geq R_0$, the resolvent satisfies

$$\|(\lambda I - A)^{-1}\mathbf{u}\|_{H^{s+m}(M,\mathbf{E})} + |\lambda| \|(\lambda I - A)^{-1}\mathbf{u}\|_{H^s(M,\mathbf{E})} \leq C_s \|\mathbf{u}\|_{H^s(M,\mathbf{E})}. \tag{15.152}$$

The constant C_s depends on s, the sector, finitely many parameter seminorms of the symbol, and the choices of a finite atlas, but not on $\mathbf{u}$ or λ in the indicated region; the estimate holds for every $\mathbf{u} \in H^s(M,\mathbf{E})$.

Proof. The symbolic composition formula gives

$$(p \# q)(x,\xi,\lambda) \sim \sum_{\alpha \in \mathbb{N}_0^n} \frac{i^{-|\alpha|}}{\alpha!} (D_\xi^\alpha p)(D_x^\alpha q).$$

Transfer of Euclidean weights in the composition estimates is governed by Peetre's inequality in Lemma 6.1.1; the weight $\Omega_m(\xi,\lambda)$ also preserves the resolvent factor recorded separately below. The term of degree zero in the total weight is $p_m q_{-m}$; imposing $p_m q_{-m} = I$ gives $q_{-m} = p_m^{-1}$. The parameter-ellipticity estimate proves (15.151) for $j = 0$, $\alpha = \beta = 0$, and $k = 0$. If $\mathscr{D}$ is one of the derivatives D_{x^r}, D_{ξ_r}, or ∂_λ, differentiating $p_m q_{-m} = I$ gives the exact identity

$$\mathscr{D} q_{-m} = -q_{-m} (\mathscr{D} p_m) q_{-m}. \tag{15.153}$$

For $\mathscr{D} = \partial_{\bar{\lambda}}$, the right-hand side is zero. To order the derivatives together, write $\mathscr{D}^\nu = D_x^\alpha D_\xi^\beta \partial_\lambda^h$ and use the componentwise order on triple multi-indices. Applying the Leibniz rule to $\mathscr{D}^\nu(p_m q_{-m}) = 0$ and then multiplying on the left by q_{-m} gives the exact recurrence

$$\mathscr{D}^\nu q_{-m} = -q_{-m} \sum_{0 < \delta \leq \nu} \binom{\nu}{\delta} (\mathscr{D}^\delta p_m)(\mathscr{D}^{\nu-\delta} q_{-m}). \tag{15.154}$$

This formula closes an induction on $|\nu|$: in each summand, the derivative of q_{-m} in the last factor has strictly smaller order. If the λ component of δ is zero, the symbol bounds on p_m and the induction hypothesis bound this summand by

$$C \Omega_m^{-1} \langle \xi \rangle^{m-|\delta_\xi|} \langle \xi \rangle^{-|\beta|+|\delta_\xi|} \Omega_m^{-1-h} \leq C \langle \xi \rangle^{-|\beta|} \Omega_m^{-1-h}.$$

If that component is one, the summand can be nonzero only when $\mathscr{D}^{\delta} p_m = I$; the induction hypothesis then gives $C\langle\xi\rangle^{-|\beta|}\Omega_m^{-1-h}$ directly. For two or more derivatives in λ, the differentiated factor of p_m is zero. The sum in (15.154) is finite, so

$$\|D_x^{\alpha} D_{\xi}^{\beta} \partial_{\lambda}^{k} q_{-m}\| \le C_{K,\alpha,\beta,k}\langle\xi\rangle^{-|\beta|}\Omega_m^{-1-k}.$$

This establishes the initial case, including holomorphy.

Now suppose the components $q_{-m},\dots,q_{-m-j+1}$ have been constructed and their homogeneity, holomorphy, and (15.151) proved. The coefficient of degree $-j$ in $p\#q$ is

$$p_m q_{-m-j} + \sum_{\substack{k+\ell+|\gamma|=j \\ 0\le\ell<j}} \frac{i^{-|\gamma|}}{\gamma!}(D_{\xi}^{\gamma} p_{m-k})(D_x^{\gamma} q_{-m-\ell}).$$

Setting it equal to zero and multiplying on the left by q_{-m} gives exactly (15.149); thus the new component is unique. Under dilation $(\xi,\lambda)\mapsto(t\xi,t^m\lambda)$, the product inside the sum has degree

$$(m-k-|\gamma|)+(-m-\ell) = -(k+\ell+|\gamma|) = -j.$$

The outer factor q_{-m} lowers the degree to $-m-j$. Every factor in the recurrence is holomorphic in λ, so the new component is also holomorphic.

To prove its estimates, now write the symbol index as κ and the number of derivatives in λ as h. Distributing $D_x^{\alpha} D_{\xi}^{\beta} \partial_{\lambda}^{h}$ among the three factors of a summand with $\kappa+\ell+|\gamma| = j$ gives Leibniz terms of the form, apart from their multinomial coefficient,

$$\left(D_x^{\alpha_0} D_{\xi}^{\beta_0} \partial_{\lambda}^{h_0} q_{-m}\right)\left(D_x^{\alpha_1} D_{\xi}^{\beta_1+\gamma} \partial_{\lambda}^{h_1} p_{m-\kappa}\right)\left(D_x^{\alpha_2+\gamma} D_{\xi}^{\beta_2} \partial_{\lambda}^{h_2} q_{-m-\ell}\right),$$

where $\alpha_0+\alpha_1+\alpha_2 = \alpha$, $\beta_0+\beta_1+\beta_2 = \beta$, and $h_0+h_1+h_2 = h$. If $h_1 = 0$, the induction hypotheses bound its norm by

$$C\langle\xi\rangle^{-j-|\beta|+m}\Omega_m^{-2-h} \le C\langle\xi\rangle^{-j-|\beta|}\Omega_m^{-1-h}.$$

If $h_1 = 1$, the term is nonzero only for $\kappa = 0$, $\gamma = 0$, and $\alpha_1 = \beta_1 = 0$; then $j = \ell$ and the two resolvent factors give exactly $C\langle\xi\rangle^{-j-|\beta|}\Omega_m^{-1-h}$. If $h_1 \ge 2$, the term is zero. There are finitely many Leibniz distributions and finitely many triples (κ,ℓ,γ) for each j, so summing proves (15.151) for the new component. This completes the induction.

For two-sided compatibility, the equation $q\#p = I$ gives, at degree $-j$, the equation

$$q_{-m-j} p_m + \sum_{\substack{k+\ell+|\alpha|=j \\ 0\le\ell<j}} \frac{i^{-|\alpha|}}{\alpha!}(D_{\xi}^{\alpha} q_{-m-\ell})(D_x^{\alpha} p_{m-k}) = 0,$$

, and multiplying on the right by q_{-m} gives (15.150). To check that this does not define different components, let q^{d} be the formal series determined by $p\#q^{\mathrm{d}} = I$ and q^{i} the one determined by $q^{\mathrm{i}}\#p = I$. Formal associativity, whose coefficient at each degree contains only finite sums, gives

$$q^{\mathrm{i}} = q^{\mathrm{i}}\#(p\#q^{\mathrm{d}}) = (q^{\mathrm{i}}\#p)\#q^{\mathrm{d}} = q^{\mathrm{d}}.$$

Thus the two recurrences determine the same series term by term. This entire construction is at high

frequency: a_{m-k} and q_{-m-j} are evaluated only for $\xi \neq 0$.
To complete the construction on the axis $\xi = 0$, use the full symbol

$$p(x,\xi,\lambda) := \lambda I - a(x,\xi),$$

, which is smooth for every ξ. There exists $R > 0$ such that p is pointwise invertible when $\widehat{\rho}_m \geq R$. To see this quantitatively, fix $C_0 > 0$. In the cone $|\lambda| \leq C_0\langle\xi\rangle^m$, the principal estimate and the bound $\|a - a_m\| \leq C_1\langle\xi\rangle^{m-1}$ imply

$$\|p_m^{-1}(a - a_m)\| \leq C_2\langle\xi\rangle^{-1}.$$

If $\langle\xi\rangle \geq 2C_2$, the matrix geometric series inverts $p = p_m - (a - a_m) = p_m[I - p_m^{-1}(a - a_m)]$. In the complementary cone, choose $C_0 \geq 2C_3$, where $\|a(x,\xi)\| \leq C_3\langle\xi\rangle^m$; then

$$\|\lambda^{-1}a(x,\xi)\| \leq \tfrac{1}{2} \quad \text{if} \quad |\lambda| \geq C_0\langle\xi\rangle^m,$$

and $p = \lambda[I - \lambda^{-1}a]$ is invertible. Comparison (15.142) allows a single R to be chosen for both cones.
Let $\chi \in C^\infty(\mathbb{R})$ vanish on $(-\infty, 1]$ and equal one on $[2,\infty)$. Extending by zero where the inverse is not used, define

$$b_0(x,\xi,\lambda) := \chi\left(\frac{\widehat{\rho}_m(\xi,\lambda)}{R}\right) p(x,\xi,\lambda)^{-1}.$$

The inverse-derivative formula (15.153), now applied to p^{-1}, the symbol bounds on a, and (15.143) show, derivative by derivative, that b_0 is a global family of resolvent type 0. It is not holomorphic, since the cutoff depends on $|\lambda|^2$. For

$$e := I - p\#b_0$$

, we have e of defect type 1: the contribution $I - \chi$ has jointly compact support in (ξ,λ), and every remaining term in the symbolic calculus contains at least one derivative in ξ. Outside that compact support, we therefore have the sharper bound

$$\left\| D_x^\alpha D_\xi^\beta \partial_\lambda^k \partial_{\bar\lambda}^\ell e \right\| \leq C_{\alpha,\beta,k,\ell}\langle\xi\rangle^{m-1-|\beta|}\Omega_m(\xi,\lambda)^{-1-k-\ell}. \tag{15.155}$$

That is, besides losing one power of $\langle\xi\rangle$, the defect contains the factor $\langle\xi\rangle^{m-1}\Omega_m^{-1}$. To obtain powers of the defect, start from $e^{\#(N+1)} = e^{\#N}\#e$. If the following bound holds for N, the composition formula distributes derivatives between $e^{\#N}$ and e; the product of the weight factors is

$$\langle\xi\rangle^{N(m-1)}\Omega_m^{-N}\langle\xi\rangle^{m-1}\Omega_m^{-1} = \langle\xi\rangle^{(N+1)(m-1)}\Omega_m^{-(N+1)}.$$

Each derivative in ξ lowers the power of $\langle\xi\rangle$, and each Wirtinger derivative lowers that of Ω_m; the Leibniz rule produces a finite sum. The case $N = 1$ is (15.155), so induction gives, modulo a family of jointly compact support,

$$\left\| D_x^\alpha D_\xi^\beta \partial_\lambda^k \partial_{\bar\lambda}^\ell e^{\#N} \right\| \leq C_{N,\alpha,\beta,k,\ell}\langle\xi\rangle^{N(m-1)-|\beta|}\Omega_m^{-N-k-\ell}.$$

Given $P, Q \in \mathbb{N}_0$, choose an integer $N \geq \max\{Q, P + mQ + 1\}$. Since $\Omega_m \geq 1 + |\lambda|$, $\Omega_m \geq \langle\xi\rangle^m$, and $N - Q \geq 0$, we have

$$\Omega_m^{-N-k-\ell} \leq (1 + |\lambda|)^{-Q-k-\ell}\langle\xi\rangle^{-m(N-Q)}.$$

Thus the preceding inequality implies

$$\left\| D_x^\alpha D_\xi^\beta \partial_\lambda^k \partial_{\bar\lambda}^\ell e^{\#N} \right\| \le C_{P,Q,N,\alpha,\beta,k,\ell} \langle \xi \rangle^{-P-|\beta|} (1+|\lambda|)^{-Q-k-\ell}. \tag{15.156}$$

Indeed, after extracting $(1+|\lambda|)^{-Q-k-\ell}$, the remaining power is $\langle \xi \rangle^{N(m-1)-m(N-Q)} = \langle \xi \rangle^{-N+mQ}$, which does not exceed $\langle \xi \rangle^{-P}$. This is quantified simultaneous smoothing. In particular, $c_k := b_0 \# e^{\#k}$ has resolvent type k, and for every P, Q and each finite family of derivatives there exists an integer $J = J(P, Q, \alpha, \beta, k, \ell)$ such that terms of index $j \ge J$ satisfy the filtered simultaneous-smoothing hypothesis. Apply the second part of Lemma 15.7.5, with the joint cutoffs $\chi(\varepsilon_k \widehat{\rho}_m)$, to sum the formal series

$$\widetilde{q} \sim b_0 \# \sum_{k=0}^{\infty} e^{\#k}$$

and obtain the nonholomorphic auxiliary family $\widetilde{q}$. If

$$T_N := b_0 \# \sum_{k=0}^{N-1} e^{\#k},$$

, the finite geometric identity gives

$$p \# T_N = (I - e) \# \sum_{k=0}^{N-1} e^{\#k} = I - e^{\#N}. \tag{15.157}$$

In the algebra of full symbols, possible corrections from the composition formula already belong to the ideal of families smoothing with parameter. Thus

$$s_1 := I - p \# \widetilde{q} = e^{\#N} - p \# (\widetilde{q} - T_N).$$

Given P, Q and a finite family of derivatives, choose N as in (15.156). The first part of the last expression satisfies the required bound there, and the diagonal choice of cutoffs in the lemma gives the same bound for the second. Thus

$$\| D_x^\alpha D_\xi^\beta \partial_\lambda^k \partial_{\bar\lambda}^\ell s_1 \| \le C_{P,Q,\alpha,\beta,k,\ell} \langle \xi \rangle^{-P} (1+|\lambda|)^{-Q}.$$

The left construction provides $\widetilde{q}_{\mathrm{i}} \# p = I - s_2$ with the same estimate. The identity

$$\widetilde{q} - \widetilde{q}_{\mathrm{i}} = s_2 \# \widetilde{q} - \widetilde{q}_{\mathrm{i}} \# s_1$$

shows that both families differ by a family smoothing with parameter. Replacing one by the other preserves its expansion and yields a two-sided inverse modulo that ideal. Expanding p and $\widetilde{q}$ for large $\|\xi\|$, uniqueness at each degree recovers exactly the components q_{-m-j} of (15.149).

The cutoffs in this full sum depend on $\widehat{\rho}_m$ and therefore need not be holomorphic. We will not use $\widetilde{q}$ as though it were: contour deformations will be performed only on each recursive component; the exact resolvent, although holomorphic on its resolvent set, will always be integrated over the fixed global contour. Quantizing $\widetilde{q}$ in charts, inserting partitions of unity, and summing gives $Q(\lambda)$ with

$$(\lambda I - A) Q(\lambda) = I - S_1(\lambda), \qquad Q(\lambda)(\lambda I - A) = I - S_2(\lambda),$$

where S_1 and S_2 are smoothing. Relative to the measure $d\lambda_{\mathbf{g}}(y)$, their kernels satisfy

$$\mathbf{K}_{S_j}(\lambda;\cdot,\cdot) \in C^\infty(M\times M;\operatorname{Hom}(\operatorname{pr}_2^*\mathbf{E},\operatorname{pr}_1^*\mathbf{E})).$$

Equip this bundle with the connection induced by the Hermitian connection of $\mathbf{E}$ and the tensor norms induced by $\mathbf{g}$ and $\mathbf{h}_{\mathbf{E}}$. For all $Q,k,\ell,a,b\in\mathbb{N}_0$ there exists $C_{Q,k,\ell,a,b}>0$ such that

$$\sup_{x,y\in M}\left|\nabla_x^a\nabla_y^b\partial_\lambda^k\partial_{\bar\lambda}^\ell\mathbf{K}_{S_j}(\lambda;x,y)\right|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\le C_{Q,k,\ell,a,b}(1+|\lambda|)^{-Q}. \tag{15.158}$$

Let $V=\operatorname{vol}_{\mathbf{g}}(M)$. Proposition B.8.3, applied fiberwise with $X=Y=M$ and $\mu=\nu=\lambda_{\mathbf{g}}$, together with (15.158) for $\alpha=\beta=k=\ell=0$, gives, for each $Q\in\mathbb{N}$,

$$\|S_j(\lambda)\|_{\mathcal{L}(L^2(M,\mathbf{E}))}\le V\sup_{x,y\in M}\|\mathbf{K}_{S_j}(\lambda;x,y)\|_{\mathcal{L}((\mathbf{E}_y,\mathbf{h}_{\mathbf{E}}(y)),(\mathbf{E}_x,\mathbf{h}_{\mathbf{E}}(x)))}\le VC_Q(1+|\lambda|)^{-Q}. \tag{15.159}$$

Choose R_1 so that the last expression is at most $\frac12$ for $j=1,2$, $\lambda\in\Lambda^{\mathrm{p}}_{\theta,\varepsilon_{\mathrm{p}}}$, and $|\lambda|\ge R_1$. The series $\displaystyle\sum_{\nu=0}^{\infty}S_j(\lambda)^\nu$ then converge in $\mathcal{L}(L^2(M,\mathbf{E}))$, their sums have norm at most two, and the two parametrix identities provide a right and a left inverse of $\lambda I-A$, respectively. They coincide and define the global resolvent. Thus

$$\{\lambda\in\Lambda^{\mathrm{p}}_{\theta,\varepsilon_{\mathrm{p}}}\mid|\lambda|\ge R_1\}\subseteq\rho(A). \tag{15.160}$$

Narrowing the sector is now justified. The set

$$\mathbf{F}:=\sigma(A)\cap\{\lambda\mid|\lambda|\le R_1\}$$

is finite: admissibility of the cut implies $L_\theta\subseteq\rho(A)$, so Proposition 15.7.2 applies. Moreover, $0\notin\mathbf{F}$ and $\mathbf{F}\cap L_\theta=\varnothing$ by the cut hypotheses. Finiteness of $\mathbf{F}$ gives $0<\varepsilon\le\varepsilon_{\mathrm{p}}$ such that $\mathbf{F}\cap\Lambda_{\theta,\varepsilon}=\varnothing$. Together with (15.160), this proves $\Lambda_{\theta,\varepsilon}\subseteq\rho(A)$. Fix $R_0\ge\max\{R_1,1\}$.
For $|\lambda|\ge R_0$, the algebraic identity

$$(\lambda I-A)^{-1}=Q(\lambda)(I-S_1(\lambda))^{-1}=(I-S_2(\lambda))^{-1}Q(\lambda)$$

shows that the result is the exact resolvent; its holomorphy follows from holomorphy of $\lambda\mapsto\lambda I-A$ and uniqueness of the inverse, not from the cutoffs used in summation. Explicitly, the resolvent identity gives

$$\frac{(\lambda+h-A)^{-1}-(\lambda-A)^{-1}}{h}=-(\lambda+h-A)^{-1}(\lambda-A)^{-1},$$

and the right-hand side converges in operator norm to $-(\lambda-A)^{-2}$ as $h\to0$. This proves operator holomorphy of the exact resolvent. The identity

$$(\lambda I-A)^{-1}-Q(\lambda)=Q(\lambda)\big[(I-S_1(\lambda))^{-1}-I\big]$$

and its left version, together with (15.158), show that the difference satisfies the same estimate for each Q and each finite family of kernel derivatives.

On the part $|\lambda| \le R_0$ of the sector, the resolvent exists by the choice just justified. Since $0 \in \rho(A)$, the closure of this part after adding the vertex is a compact subset of $\rho(A)$. The two parametrix identities give

$$(\lambda I - A)^{-1} - Q(\lambda) = (\lambda I - A)^{-1} S_1(\lambda) = S_2(\lambda)(\lambda I - A)^{-1}.$$

Elliptic regularity applied on both sides shows that this difference is smoothing; on each compact subset of the sector, all its kernel seminorms are uniform. The difference may fail to be holomorphic because Q contains cutoffs depending on $|\lambda|$.

In a fixed chart and quantization, extracting the full symbol from the kernel is a continuous linear operation. Applied directly to the exact resolvent, it produces a symbol $r(x, \xi, \lambda)$ holomorphic throughout the sector. For large parameters, $r - \widetilde{q}$ is smoothing with parameter, and on the compact part it is uniformly smoothing; thus r retains the high-frequency expansion formed by the q_{-m-j}. Bounds on its derivatives in λ follow from Cauchy inequalities in a slightly smaller sector. Finally, the weak estimates of resolvent type 0 give the first norm in (15.152); using $(\lambda I - A)(\lambda I - A)^{-1} = I$ gives the second. The construction is matrix-valued from the first step, so it is unchanged for bundle sections. □

15.7.2 Construction of complex powers

The parameter-dependent parametrix gives the high-frequency behavior of the resolvent, while the exact resolvent retains holomorphy and spectral information. Integrating them against λ^z over a contour around the cut combines both properties in an operator of complex order.

Let Γ_θ be a keyhole contour contained in $\rho(A)$, with two infinite branches in the spectrum-free sector and a small arc around zero. It is the limit, as the outer arc is removed, of positively oriented closed contours surrounding the spectrum of A in the cut plane. With this orientation and the resolvent $(\lambda I - A)^{-1}$, the scalar residue at an eigenvalue μ is $+\mu^z$. Invertibility prevents the small arc from meeting the spectrum, and estimate

$$\|(\lambda I - A)^{-1}\|_{\mathcal{L}(L^2(M,\mathbf{E}))} \le C_0 |\lambda|^{-1}, \qquad \lambda \in \Lambda_{\theta,\varepsilon}, \quad |\lambda| \ge R_0,$$

makes the following integral converge in operator norm when $\operatorname{Re} z < 0$.

Definition 15.7.7. (Complex powers) Let $(M, \mathbf{g})$ be a smooth closed Riemannian manifold; let $\mathbf{E} \longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric; let $A \in \Psi^m_{\mathrm{cl}}(M; \mathbf{E}, \mathbf{E})$ be elliptic and invertible, with $m > 0$; and let θ be an admissible spectral cut. Let $\Gamma_\theta \subset \rho(A)$ be the positively oriented keyhole contour described above, and use the branch $\log_\theta$ in λ^z. For $\operatorname{Re} z < 0$, define

$$A^z := \frac{1}{2\pi i} \int_{\Gamma_\theta} \lambda^z (\lambda I - A)^{-1} \, d\lambda. \tag{15.161}$$

For arbitrary $z \in \mathbb{C}$, choose $k \in \mathbb{N}$ with $\operatorname{Re}(z - k) < 0$ and set

$$A^z := A^k A^{z-k} \quad \text{on } \Gamma(M, \mathbf{E}). \tag{15.162}$$

The resolvent identity

$$(\lambda I - A)^{-1} - (\mu I - A)^{-1} = (\mu - \lambda)(\lambda I - A)^{-1}(\mu I - A)^{-1}$$

and two successive applications of Cauchy's formula first prove, for negative real parts, that

$$A^z A^w = A^{z+w}.$$

Let us check that the integral with $z=-1$ is the usual inverse of A. Indeed, the contour calculus for rational functions follows directly from the resolvent identity and Cauchy's formula; since $0\in\rho(A)$, applying it to $r(\lambda)=\lambda^{-1}$ gives

$$\frac{1}{2\pi i}\int_{\Gamma_\theta}\lambda^{-1}(\lambda I-A)^{-1}\,d\lambda = A^{-1}. \tag{15.163}$$

Let us give the analytic justification of this identity. Truncate the keyhole contour and apply Cauchy's formula before removing the truncation. On $\Gamma(M,\mathbf{E})$, use

$$A(\lambda I-A)^{-1}=\lambda(\lambda I-A)^{-1}-I, \qquad (\lambda I-A)^{-1}A=\lambda(\lambda I-A)^{-1}-I.$$

Moreover, for $\mathbf{u}\in\Gamma(M,\mathbf{E})$,

$$(\lambda I-A)^{-1}\mathbf{u}-\lambda^{-1}\mathbf{u}=\lambda^{-1}(\lambda I-A)^{-1}A\mathbf{u}.$$

The resolvent estimate makes the remaining boundary terms tend to zero as the outer arc is removed, while the inner arc remains inside $\rho(A)$ because $0\in\rho(A)$. The scalar Cauchy formula then gives, respectively,

$$AA^{-1}\mathbf{u}=\mathbf{u}, \qquad A^{-1}A\mathbf{u}=\mathbf{u}, \qquad \mathbf{u}\in\Gamma(M,\mathbf{E}),$$

proving (15.163) without identifying the integral with the inverse in advance.

We can now check that (15.162) is independent of k. If $\operatorname{Re}\zeta<-1$, the integrals converge after multiplication by A, and the preceding identities give

$$AA^{\zeta}=A^{\zeta}A=A^{\zeta+1};$$

the additional term $\dfrac{1}{2\pi i}\displaystyle\int_{\Gamma_\theta}\lambda^{\zeta}\,d\lambda$ is zero by Cauchy's formula and decay at infinity. If k is admissible and $\zeta:=z-k-1$, then $\operatorname{Re}\zeta<-1$ and

$$A^{k+1}A^{z-k-1}=A^k(AA^{\zeta})=A^kA^{z-k}.$$

By induction, any two admissible choices produce the same operator. The identity (15.163) gives $A^0=I$ and shows that integer powers are the usual ones.

Finally, for $z,w\in\mathbb{C}$ choose $k,\ell\in\mathbb{N}$ with $\operatorname{Re}(z-k)<0$ and $\operatorname{Re}(w-\ell)<0$. Resolvents commute with A on $\Gamma(M,\mathbf{E})$, so negative powers commute with integer powers. Using the law already proved in the negative half-plane,

$$A^zA^w=A^{k+\ell}A^{z-k}A^{w-\ell}=A^{k+\ell}A^{z+w-k-\ell}=A^{z+w}.$$

Invertibility is precisely what permits this group law for all $z\in\mathbb{C}$; without it, negative powers require a separate convention on the kernel.

For $\mu\in\mathbb{C}$, the notation $\Psi^{\mu}_{\mathrm{cl}}(M;\mathbf{E},\mathbf{E})$ means that the symbol has homogeneous components of degrees $\mu-j$ and satisfies estimates of order $\operatorname{Re}\mu$. For $t>0$, interpret $t^{\mu}=e^{\mu\log t}$ using the real logarithm.

Definition 15.7.8. (Holomorphy for a family of variable order) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold, let $\mathbf{E}\longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric, let $m>0$, and let $G\subseteq\mathbb{C}$ be open. A family $B(z)\in\Psi^{mz}_{\mathrm{cl}}(M;\mathbf{E},\mathbf{E})$ is **holomorphic of variable order** mz if the

following three levels hold.

Homogeneous components. In every chart and for $\xi \neq 0$, the components $b_{mz-j}(x,\xi;z)$ are holomorphic in G (entire when $G=\mathbb{C}$), and for each $K \Subset G$, compact subset K_x of the chart, $h \in \mathbb{N}_0$, and α, β, there exists $C>0$ such that

$$\|D_x^\alpha D_\xi^\beta \partial_z^h b_{mz-j}(x,\xi;z)\| \le C\|\xi\|^{m\operatorname{Re} z - j - |\beta|}(1+|\log\|\xi\||)^h, \quad \|\xi\| \ge 1, \quad z \in K. \tag{15.164}$$

Full symbol. With a fixed homogeneous cutoff $\chi(\xi)$, the full symbol $b(x,\xi;z)$ is holomorphic in z and, for each $N, h \in \mathbb{N}_0$, $\delta>0$, $K \Subset G$, and α, β, there exists $C>0$ such that

$$\left\| D_x^\alpha D_\xi^\beta \partial_z^h \left(b - \sum_{j=0}^{N-1} \chi\, b_{mz-j} \right)(x,\xi;z) \right\| \le C\langle\xi\rangle^{m\operatorname{Re} z - N - |\beta| + \delta}, \qquad z \in K. \tag{15.165}$$

The arbitrary loss δ absorbs the powers of $\log\langle\xi\rangle$ arising from differentiation in z. Relative to $d\lambda_{\mathbf{g}}(y)$, the smoothing remainder has a kernel

$$\mathbf{K}_R(z;\cdot,\cdot) \in C^\infty(M\times M; \operatorname{Hom}(\operatorname{pr}_2^*\mathbf{E}, \operatorname{pr}_1^*\mathbf{E}))$$

holomorphic in z. With the induced connection and tensor norm, for all $h, a, b \in \mathbb{N}_0$,

$$\sup_{\substack{z\in K\\ x,y\in M}} \left| \partial_z^h \nabla_x^a \nabla_y^b \mathbf{K}_R(z;x,y) \right|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \le C_{K,h,a,b}.$$

Operator level. The map $z \mapsto B(z)$ is holomorphic from G into $\mathcal{L}_b(\Gamma(M,\mathbf{E}),\Gamma(M,\mathbf{E}))$, where $\Gamma(M,\mathbf{E})$ carries its Fréchet topology and the subscript b denotes uniform convergence on bounded subsets. In the presence of the two preceding symbol levels, this is equivalent to the following fixed-Sobolev formulation. If $\tau_K := m\max_{z\in K}\operatorname{Re} z$, then, for every $r \in \mathbb{R}$, $h \in \mathbb{N}_0$, and $\delta>0$,

$$\sup_{z\in K} \|\partial_z^h B(z)\|_{\mathcal{L}(H^r(M,\mathbf{E}),H^{r-\tau_K-\delta}(M,\mathbf{E}))} \le C_{K,r,h,\delta}, \tag{15.166}$$

and $z \mapsto B(z)$ is holomorphic on an open neighborhood of K contained in G, with values in that bounded-operator space. Choose this neighborhood so that $m\operatorname{Re} z < \tau_K + \delta/2$; the remaining margin absorbs the logarithmic powers of the derivatives. The entire family over G need not take values in a single Sobolev pair. The fixed order $\tau_K+\delta$ allows operators whose real orders vary with z to be compared in the same Banach space.

Theorem 15.7.9. (Complex powers of an elliptic operator) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold; let $\mathbf{E} \longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric $\mathbf{h}_\mathbf{E}$ and a compatible connection $\nabla^\mathbf{E}$; let $A \in \Psi_{\mathrm{cl}}^m(M;\mathbf{E},\mathbf{E})$ be elliptic and invertible, with $m>0$ and principal Fourier symbol a_m; and fix an admissible spectral cut θ. For every $z \in \mathbb{C}$,

$$A^z \in \Psi_{\mathrm{cl}}^{mz}(M;\mathbf{E},\mathbf{E}).$$

The family is holomorphic in the sense of Definition 15.7.8 and satisfies

$$A^z A^w = A^{z+w}, \qquad \sigma_{mz}^\Psi(A^z)(x,\xi) = a_m(x,\xi)^z, \tag{15.167}$$

where the matrix power on the right uses the same spectral cut. Moreover,

$$A^z\colon H^r(M,\mathbf{E}) \longrightarrow H^{r-m\operatorname{Re} z}(M,\mathbf{E})$$

is continuous for every $r \in \mathbb{R}$ when initially considered on smooth sections.

Proof. Begin with $\operatorname{Re} z < 0$. By Proposition 15.7.6, the resolvent symbol is

$$r(x,\xi,\lambda) \underset{\|\xi\|\to\infty}{\sim} \sum_{j=0}^{\infty} q_{-m-j}(x,\xi,\lambda).$$

. Extraction of the full symbol is linear and continuous, so it commutes with the convergent integral defining A^z. Thus a symbol of A^z is

$$b(x,\xi;z) = \frac{1}{2\pi i}\int_{\Gamma_\theta} \lambda^z r(x,\xi,\lambda)\, d\lambda.$$

The following deformation is performed exclusively for homogeneous components, not for r. Indeed, compactness of the cosphere bundle, invertibility of a_m, and the principal angle give a normalized contour uniformly avoiding $\operatorname{spec} a_m(x,\omega)$ for every $\|\omega\| = 1$. Let $\Gamma_{\theta,\xi}$ denote its image under $\lambda = \|\xi\|^m\mu$. Its branches lie in the principal sector, and its curved part has radius $c\|\xi\|^m$, with $c > 0$ smaller than the modulus of every eigenvalue of $a_m(x,\omega)$. For large $\|\xi\|$, the fixed contour Γ_θ and $\Gamma_{\theta,\xi}$ are homotopic in the set where $\lambda I - a_m(x,\xi)$ is invertible. This homotopy may cross global eigenvalues of A and therefore does not apply to the exact symbol r; it does apply to each q_{-m-j}, whose only singularities in λ arise from the principal resolvent. For $\xi \neq 0$, define

$$b_{mz-j}(x,\xi;z) := \frac{1}{2\pi i}\int_{\Gamma_{\theta,\xi}} \lambda^z q_{-m-j}(x,\xi,\lambda)\, d\lambda. \tag{15.168}$$

Parameter estimates allow differentiation under the integral. Indeed, if $K \Subset \{z \mid \operatorname{Re} z < 0\}$ and $\eta := -\max_{z\in K} \operatorname{Re} z > 0$, then on the branches where $|\lambda| \geq 1$,

$$\left\|\partial_z^h\left(\lambda^z D_x^\alpha D_\xi^\beta q_{-m-j}\right)\right\| \leq C_{K,h,\alpha,\beta,j}(1+\log|\lambda|)^h|\lambda|^{-1-\eta}\langle\xi\rangle^{-j-|\beta|}. \tag{15.169}$$

The function $(1+\log r)^h r^{-1-\eta}$ is integrable in $[1,\infty)$; after normalization by $\lambda = \|\xi\|^m\mu$, the arc belongs to a compact set uniformly avoiding the principal spectrum. This justifies, in the symbol topology, both the integral and all its derivatives in z, x and ξ. Replacing ξ by $t\xi$ and making the change $\lambda = t^m\mu$, homogeneity of the symbolic resolvent gives

$$\begin{aligned} b_{mz-j}(x,t\xi;z) &= \frac{1}{2\pi i}\int_{\Gamma_{\theta,\xi}} (t^m\mu)^z t^{-m-j} q_{-m-j}(x,\xi,\mu) t^m\, d\mu \\ &= t^{mz-j} b_{mz-j}(x,\xi;z). \end{aligned}$$

Thus the terms in (15.168) have exactly the required degrees.
It remains to control the remainder without moving the global resolvent contour. Fix a cutoff $\chi_0(\xi)$ vanishing near zero and equal to one beyond a frequency for which the preceding principal homotopy is valid.

For $L \in \mathbb{N}$, set, on the fixed contour,

$$R_L(x,\xi,\lambda) := r(x,\xi,\lambda) - \sum_{j=0}^{L-1} \chi_0(\xi) q_{-m-j}(x,\xi,\lambda).$$

The parameter-dependent expansion of Proposition 15.7.6 and uniform smoothing of $r - \widetilde{q}$ give, on the two infinite branches,

$$\|D_x^\alpha D_\xi^\beta R_L(x,\xi,\lambda)\| \le C_{\alpha,\beta,L} \langle \xi \rangle^{-L-|\beta|} \Omega_m(\xi,\lambda)^{-1}. \tag{15.170}$$

On the fixed curved part of the contour, the same inequality for large $\|\xi\|$ is the ordinary estimate of order $-m-L$; the region of bounded ξ contributes only a smoothing symbol. Since each q_{-m-j} can be deformed by the principal homotopy while r remains on Γ_θ, for large $\|\xi\|$ we have exactly

$$b - \sum_{j=0}^{L-1} \chi_0 b_{mz-j} = \frac{1}{2\pi i} \int_{\Gamma_\theta} \lambda^z R_L(x,\xi,\lambda)\, d\lambda. \tag{15.171}$$

Write $X = \langle \xi \rangle^m$ and let $r_* > 0$ be the radius of the fixed curved part. If $K \Subset \{\operatorname{Re} z < 0\}$, then after ∂_z^h, (15.170) and splitting each branch into $r_* \le |\lambda| \le X$ and $|\lambda| \ge X$ give

$$\begin{aligned} &\left\| D_x^\alpha D_\xi^\beta \partial_z^h \left(b - \sum_{j=0}^{L-1} \chi_0 b_{mz-j} \right) \right\| \\ &\quad \le C_{K,\alpha,\beta,L,h} \langle \xi \rangle^{-L-|\beta|} \left[X^{-1} \int_{r_*}^{X} r^{\operatorname{Re} z} (1 + |\log r|)^h \, dr + \int_X^\infty r^{\operatorname{Re} z - 1} (1 + \log r)^h \, dr \right]. \end{aligned} \tag{15.172}$$

If $X < r_*$, absorb this region into the constant. For $X \ge r_*$, bound the first integral by separating the cases $\operatorname{Re} z > -1$, $= -1$, and < -1; integrate the second in $[X, \infty)$. Uniformly for $z \in K$ and every $\delta > 0$, the result is

$$\left\| D_x^\alpha D_\xi^\beta \partial_z^h \left(b - \sum_{j=0}^{L-1} \chi_0 b_{mz-j} \right) \right\| \le C_{K,\alpha,\beta,L,h,\delta} \left(\langle \xi \rangle^{m \operatorname{Re} z - L - |\beta| + \delta} + \langle \xi \rangle^{-m-L-|\beta|+\delta} \right). \tag{15.173}$$

Here we used $(1 + |\log \langle \xi \rangle|)^h \le C_{h,\delta} \langle \xi \rangle^\delta$; this inequality also covers the borderline case $\operatorname{Re} z = -1$.
Now given N, h, δ and K, choose $L \ge N$ so large that

$$-m - L + \frac{\delta}{2} \le m \min_{z \in K} \operatorname{Re} z - N.$$

Apply (15.173) with $\frac{\delta}{2}$. Both terms are bounded by $C \langle \xi \rangle^{m \operatorname{Re} z - N - |\beta| + \delta}$. The finite terms $\displaystyle\sum_{j=N}^{L-1} \chi_0 b_{mz-j}$ satisfy the same bound by (15.164). The identity

$$b - \sum_{j=0}^{N-1} \chi_0 b_{mz-j} = \left(b - \sum_{j=0}^{L-1} \chi_0 b_{mz-j} \right) + \sum_{j=N}^{L-1} \chi_0 b_{mz-j}$$

proves (15.165). The rescaling in (15.168) and the majorant (15.169) in turn prove (15.164). Thus

$$b(x,\xi;z)\sim\sum_{j=0}^{\infty}b_{mz-j}(x,\xi;z)$$

is a classical symbol of complex order mz and is holomorphic at the first two levels of Definition 15.7.8. The difference between the exact resolvent and the parametrix satisfies, for each Q and each finite number of kernel derivatives, the bound (15.158). Once $Q>\max_{z\in K}\operatorname{Re}z+1$ is chosen, its product with $|\lambda^z|(1+|\log\lambda|)^h$ is integrable on the infinite branches. The integral therefore has a smooth holomorphic kernel with all seminorms uniform on K and does not alter the classical symbol obtained. The symbol estimates, mapping theorem, and differentiation under the integral give the bound (15.166). To verify holomorphy in this norm, if the segment $[z,z+h]$ remains in a compact neighborhood, use Taylor's identity with integral remainder

$$b(z+h)-b(z)-h\partial_z b(z)=h^2\int_0^1(1-t)\partial_z^2 b(z+th)\,dt.$$

Each symbol seminorm of the right-hand side is at most $C|h|^2$ by the preceding bounds. Quantization is continuous from these seminorms into $\mathcal{L}(H^r(M,\mathbf{E}),H^{r-\tau_K-\delta}(M,\mathbf{E}))$, so the difference quotient converges there to $\partial_z A^z$. The same identity applied to each seminorm of $\Gamma(\mathbf{E})$ proves holomorphy on $\Gamma(\mathbf{E})$ itself. This establishes all three levels when $\operatorname{Re}z<0$.

For arbitrary z, choose k as in (15.162). The composition calculus gives

$$A^kA^{z-k}\in\Psi_{\mathrm{cl}}^{mk+m(z-k)}=\Psi_{\mathrm{cl}}^{mz}.$$

For a compact set $K\Subset\mathbb{C}$, choose a single integer k such that $\operatorname{Re}(z-k)\le-\eta<0$ for every $z\in K$. Composition with the fixed operator A^k is continuous in the symbol topologies and the operator spaces of (15.166); hence it transfers all uniform bounds already proved to A^z. The group law proves independence of k. If $w=z-k$ has negative real part, taking $j=0$ in (15.168), the holomorphic functional calculus of the matrix $a_m(x,\xi)$ gives

$$b_{mw}(x,\xi;w)=\frac{1}{2\pi i}\int_{\Gamma_{\theta,\xi}}\lambda^w(\lambda I-a_m(x,\xi))^{-1}\,d\lambda=a_m(x,\xi)^w.$$

Multiplicativity of the principal symbol under composition then yields $\sigma^{\Psi}_{mz}(A^z)=a_m^k a_m^w=a_m^z$ for every z. The mapping property is that of a pseudodifferential operator of real order $m\operatorname{Re}z$. □

Proposition 15.7.10. (Closed realizations of powers) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold; let $\mathbf{E}\longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric; let $A\in\Psi_{\mathrm{cl}}^m(M;\mathbf{E},\mathbf{E})$ be elliptic and invertible, with $m>0$ and a fixed admissible spectral cut; and let $z\in\mathbb{C}$. Let $d=m\operatorname{Re}z$. If $d>0$, the closure in $L^2(M,\mathbf{E})$ of $A^z|_{\Gamma(M,\mathbf{E})}$ has domain $H^d(M,\mathbf{E})$, and there exist $c_z,C_z>0$ such that

$$c_z\|\mathbf{u}\|_{H^d(M,\mathbf{E})}\le\|\mathbf{u}\|_{L^2(M,\mathbf{E})}+\|A^z\mathbf{u}\|_{L^2(M,\mathbf{E})}\le C_z\|\mathbf{u}\|_{H^d(M,\mathbf{E})},\qquad\mathbf{u}\in\Gamma(M,\mathbf{E}).\tag{15.174}$$

This realization is closed, and $\Gamma(M,\mathbf{E})$ is a core. If $d\le0$, $A^z|_{\Gamma(M,\mathbf{E})}$ extends uniquely to a bounded operator on $L^2(M,\mathbf{E})$; this is its realization, its domain is all of $L^2(M,\mathbf{E})$, and $\Gamma(M,\mathbf{E})$ is also a core.

Proof. Suppose $d > 0$. The preceding theorem gives continuous maps $A^z : H^d(M,\mathbf{E}) \to L^2(M,\mathbf{E})$ and $A^{-z} : L^2(M,\mathbf{E}) \to H^d(M,\mathbf{E})$. The group law, first on $\Gamma(\mathbf{E})$, provides the exact identity $\mathbf{u} = A^{-z}A^z\mathbf{u}$. Thus

$$\|\mathbf{u}\|_{H^d(M,\mathbf{E})} \le \|A^{-z}\|_{\mathcal{L}(L^2(M,\mathbf{E}),H^d(M,\mathbf{E}))}\|A^z\mathbf{u}\|_{L^2(M,\mathbf{E})}, \qquad \|A^z\mathbf{u}\|_{L^2(M,\mathbf{E})} \le \|A^z\|_{\mathcal{L}(H^d(M,\mathbf{E}),L^2(M,\mathbf{E}))}\|\mathbf{u}\|_{H^d(M,\mathbf{E})},$$

, giving (15.174). If $\mathbf{u}_j \to \mathbf{u}$ and $A^z\mathbf{u}_j \to \mathbf{f}$ in $L^2(M,\mathbf{E})$, the first inequality applied to $\mathbf{u}_j - \mathbf{u}_k$ proves that $(\mathbf{u}_j)$ converges in $H^d(M,\mathbf{E})$; continuity $A^z : H^d(M,\mathbf{E}) \to L^2(M,\mathbf{E})$ gives $A^z\mathbf{u} = \mathbf{f}$. Thus the realization with domain $H^d(M,\mathbf{E})$ is closed. For $\mathbf{u} \in H^d(M,\mathbf{E})$, a sequence of smooth sections converging to $\mathbf{u}$ in $H^d(M,\mathbf{E})$ also converges in graph norm by the second inequality. Consequently, the closure of the restriction to $\Gamma(\mathbf{E})$ is precisely this realization, and $\Gamma(\mathbf{E})$ is a core.
If $d \le 0$, the mapping property gives $A^z : L^2(M,\mathbf{E}) \to H^{-d}(M,\mathbf{E}) \hookrightarrow L^2(M,\mathbf{E})$ when $d < 0$, and $A^z : L^2(M,\mathbf{E}) \to L^2(M,\mathbf{E})$ when $d = 0$. Density of $\Gamma(\mathbf{E})$ in $L^2(M,\mathbf{E})$ proves uniqueness of the extension. If $\mathbf{u}_j \in \Gamma(\mathbf{E})$ converges to $\mathbf{u}$ in $L^2(M,\mathbf{E})$, continuity implies $A^z\mathbf{u}_j \to A^z\mathbf{u}$ in $L^2(M,\mathbf{E})$, so smooth sections are dense also in graph norm. □

This proof follows the parameter-dependent classes and sums, the resolvent, and the holomorphic families presented in [135, Chapter II, §§9.1, 9.4 and 11.1–11.4]. Historically, the result and the method of integrating the resolvent parametrix are due to Seeley [132].

15.7.3 Agreement with the spectral calculus

The contour construction also applies to non-self-adjoint operators. When A is self-adjoint and positive, each spectral projection reduces the contour to the scalar Cauchy formula. This identifies Seeley's powers with the spectral calculus used in Chapter 12.

Proposition 15.7.11. (Contour calculus, spectral calculus, and the semigroup) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold; let $\mathbf{E} \longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric; and let $A \in \Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{E})$ be elliptic and self-adjoint on $L^2(M,\mathbf{E})$, with $m > 0$ and $A \ge cI$ for some $c > 0$. Take the negative real axis as the cut. Then the powers in Definition 15.7.7 agree with the powers from the spectral theorem. As closed operators,

$$A^z = \int_{[c,\infty)} \lambda^z \, dE_A(\lambda). \tag{15.175}$$

Moreover, for $\operatorname{Re} s > 0$,

$$A^{-s} = \frac{1}{\Gamma(s)} \int_0^\infty t^{s-1} e^{-tA} \, dt, \tag{15.176}$$

where the Bochner integral converges in $\mathcal{L}(L^2(M,\mathbf{E}),L^2(M,\mathbf{E}))$.

Proof. Proposition 15.7.2 provides an orthonormal basis $(\boldsymbol{\varphi}_j)$ of smooth eigensections, with $A\boldsymbol{\varphi}_j = \lambda_j\boldsymbol{\varphi}_j$ and $\lambda_j \to \infty$. For $\operatorname{Re} z < 0$, Cauchy's formula applied to each eigenvalue gives

$$\frac{1}{2\pi i}\int_{\Gamma_\pi} \lambda^z (\lambda I - A)^{-1}\boldsymbol{\varphi}_j \, d\lambda = \left(\frac{1}{2\pi i}\int_{\Gamma_\pi} \frac{\lambda^z}{\lambda - \lambda_j}\, d\lambda\right)\boldsymbol{\varphi}_j = \lambda_j^z \boldsymbol{\varphi}_j.$$

For arbitrary z, choose $k \in \mathbb{N}$ with $\operatorname{Re}(z-k) < 0$ and use $A^z = A^k A^{z-k}$; since $A^k\boldsymbol{\varphi}_j = \lambda_j^k\boldsymbol{\varphi}_j$, this gives $A^z\boldsymbol{\varphi}_j =$

$\lambda_j^z \boldsymbol{\varphi}_j$. By linearity, both constructions agree on the space $\mathcal{F}$ of finite spectral sums.
The spectral power has domain

$$\mathcal{D}(A_{\mathrm{esp}}^z) = \left\{ \mathbf{u} = \sum_{j=1}^{\infty} u_j \boldsymbol{\varphi}_j \in L^2(M,\mathbf{E}) \;\middle|\; \sum_{j=1}^{\infty} \lambda_j^{2\operatorname{Re} z} |u_j|^2 < \infty \right\}. \tag{15.177}$$

If $\mathbf{u}$ belongs to this domain and

$$\mathbf{u}_N := \sum_{\lambda_j \le N} u_j \boldsymbol{\varphi}_j,$$

, then $\mathbf{u}_N \in \mathcal{F} \subseteq \Gamma(M,\mathbf{E})$ and

$$\|\mathbf{u} - \mathbf{u}_N\|_{L^2(M,\mathbf{E})}^2 + \|A_{\mathrm{esp}}^z(\mathbf{u} - \mathbf{u}_N)\|_{L^2(M,\mathbf{E})}^2 = \sum_{\lambda_j > N} (1 + |\lambda_j^z|^2)|u_j|^2 \longrightarrow 0.$$

Thus $\mathcal{F}$ is a core for the spectral power.
Let us prove that it is also a core for the pseudodifferential power. If $d = m \operatorname{Re} z \le 0$, this power is bounded on $L^2(M,\mathbf{E})$ by Proposition 15.7.10; density of $\mathcal{F}$ in $L^2(M,\mathbf{E})$ then implies density in graph norm. Suppose $d > 0$ and choose

$$N_0 := \max\left\{1, \left\lceil \frac{d}{m} \right\rceil \right\}, \qquad mN_0 \ge d.$$

If $\mathbf{v} = \sum_{j=1}^{\infty} v_j \boldsymbol{\varphi}_j \in \Gamma(M,\mathbf{E})$ and $\mathbf{v}_N = \sum_{\lambda_j \le N} v_j \boldsymbol{\varphi}_j$, then $A^{N_0}\mathbf{v} \in L^2(M,\mathbf{E})$. Since $\mathbf{v}$ belongs to the domain of A^{N_0} and A is self-adjoint, the coefficient of $A^{N_0}\mathbf{v}$ in $\boldsymbol{\varphi}_j$ is

$$(A^{N_0}\mathbf{v}, \boldsymbol{\varphi}_j)_{L^2(M,\mathbf{E})} = (\mathbf{v}, A^{N_0}\boldsymbol{\varphi}_j)_{L^2(M,\mathbf{E})} = \lambda_j^{N_0} v_j.$$

By Parseval,

$$\|\mathbf{v} - \mathbf{v}_N\|_{L^2(M,\mathbf{E})}^2 + \|A^{N_0}(\mathbf{v} - \mathbf{v}_N)\|_{L^2(M,\mathbf{E})}^2 = \sum_{\lambda_j > N} (1 + \lambda_j^{2N_0})|v_j|^2 \longrightarrow 0.$$

Graph-norm equivalence (15.174), applied to exponent N_0, gives $\mathbf{v}_N \to \mathbf{v}$ in $H^{mN_0}(M,\mathbf{E})$ and, by the continuous inclusion, in $H^d(M,\mathbf{E})$.
Now let $\mathbf{u} \in H^d(M,\mathbf{E})$ and $\varepsilon > 0$. By density of $\Gamma(M,\mathbf{E})$ in $H^d(M,\mathbf{E})$, choose $\mathbf{v} \in \Gamma(M,\mathbf{E})$ such that

$$\|\mathbf{u} - \mathbf{v}\|_{H^d(M,\mathbf{E})} < \frac{\varepsilon}{2}.$$

For this $\mathbf{v}$, the convergence just proved allows $N \in \mathbb{N}$ to be chosen so that

$$\|\mathbf{v} - \mathbf{v}_N\|_{H^d(M,\mathbf{E})} < \frac{\varepsilon}{2}.$$

Since $\mathbf{v}_N \in \mathcal{F}$, the triangle inequality gives

$$\|\mathbf{u} - \mathbf{v}_N\|_{H^d(M,\mathbf{E})} < \varepsilon.$$

Thus $\mathcal{F}$ is dense in $H^d(M,\mathbf{E})$. Equivalence (15.174) for z shows that this is also density in the graph norm of the pseudodifferential power. Hence $\mathcal{F}$ is a core for both closed realizations. Since they agree on $\mathcal{F}$, their

closures coincide, proving (15.175) without presupposing equality on all of $\Gamma(\mathbf{E})$.
The scalar identity

$$\lambda^{-s} = \frac{1}{\Gamma(s)} \int_0^\infty t^{s-1} e^{-t\lambda}\, dt, \qquad \lambda \geq c,$$

is transferred by the spectral theorem. Near zero, $t^{\operatorname{Re} s-1}$ is a majorant, and at infinity $t^{\operatorname{Re} s-1} e^{-ct}$ is a majorant. More precisely,

$$\|t^{s-1} e^{-tA}\|_{\mathcal{L}(L^2(M,\mathbf{E}))} \leq t^{\operatorname{Re} s-1} \quad (0 < t \leq 1), \qquad \|t^{s-1} e^{-tA}\|_{\mathcal{L}(L^2(M,\mathbf{E}))} \leq t^{\operatorname{Re} s-1} e^{-ct} \quad (t \geq 1).$$

The first function is integrable on $(0,1]$ because $\operatorname{Re} s > 0$, and the second on $[1,\infty)$. The Bochner integral therefore converges in $\mathcal{L}(L^2(M,\mathbf{E}))$. Applying both expressions to each spectral projection and using the same majorants allows the integral and spectral calculus to be interchanged, proving (15.176). □

15.7.4 Bessel potentials, the fractional Laplacian, and heat

The preceding identification returns us to the operators that motivated this chapter. Powers of the connection Laplacian, previously defined by the spectral theorem and the semigroup, now have classical symbols and can be studied within the same microlocal calculus.

Now let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold, and let $\mathbf{E} \longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. Denote its nonnegative self-adjoint realization by $L_{\mathbf{E}} = (\nabla^{\mathbf{E}})^*_h \nabla^{\mathbf{E}}$. Although the intrinsic differential symbol of $L_{\mathbf{E}}$ is $-\|\xi\|^2_{\mathbf{g}} I$, its principal Fourier symbol is $\|\xi\|^2_{\mathbf{g}} I$. Thus the operator

$$B_{\mathbf{E}} := I + L_{\mathbf{E}}$$

is elliptic, self-adjoint, satisfies $B_{\mathbf{E}} \geq I$, and admits the negative axis as a spectral cut.

Corollary 15.7.12. (Bessel powers and the fractional Laplacian) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold, and let $\mathbf{E} \longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. Let $L_{\mathbf{E}} = (\nabla^{\mathbf{E}})^*_h \nabla^{\mathbf{E}}$ and $B_{\mathbf{E}} = I + L_{\mathbf{E}}$. For every $z \in \mathbb{C}$,

$$B_{\mathbf{E}}^z \in \Psi^{2z}_{\mathrm{cl}}(M;\mathbf{E},\mathbf{E}), \qquad \sigma^{\Psi}_{2z}(B_{\mathbf{E}}^z)(x,\xi) = \|\xi\|^{2z}_{\mathbf{g}} I_{\mathbf{E}_x}.$$

If $s > 0$, the Bessel potential constructed through the semigroup satisfies

$$J^{\mathbf{E}}_{s,2} = (I + L_{\mathbf{E}})^{-\frac{s}{2}} = B_{\mathbf{E}}^{-\frac{s}{2}} \in \Psi^{-s}_{\mathrm{cl}}(M;\mathbf{E},\mathbf{E}). \tag{15.178}$$

In particular, for every $r \in \mathbb{R}$,

$$B_{\mathbf{E}}^{-\frac{s}{2}} : H^r(M,\mathbf{E}) \longrightarrow H^{r+s}(M,\mathbf{E})$$

is an isomorphism with inverse $B_{\mathbf{E}}^{\frac{s}{2}}$. More precisely, for every $s \in \mathbb{R}$ there exist constants $c_s, C_s > 0$ such that, for $\mathbf{u} \in \Gamma(M,\mathbf{E})$,

$$c_s \|\mathbf{u}\|_{H^s(M,\mathbf{E})} \leq \|B_{\mathbf{E}}^{\frac{s}{2}} \mathbf{u}\|_{L^2(M,\mathbf{E})} \leq C_s \|\mathbf{u}\|_{H^s(M,\mathbf{E})}. \tag{15.179}$$

The constants depend on s, the metric $\mathbf{g}$, the Hermitian metric and connection of $\mathbf{E}$, and the finite cover, trivializations, and partition of unity chosen for the localized Sobolev norm; once these data are fixed, they are uniform in $\mathbf{u}$.

Let Π_0 be the orthogonal projection onto $\ker L_{\mathbf{E}}$. For $s > 0$,

$$L_{\mathbf{E}}^{\frac{s}{2}} = (L_{\mathbf{E}} + \Pi_0)^{\frac{s}{2}} - \Pi_0 \in \Psi_{\mathrm{cl}}^{s}(M; \mathbf{E}, \mathbf{E}), \tag{15.180}$$

and the reduced negative power on $(\ker L_{\mathbf{E}})^{\perp}$ is

$$L_{\mathbf{E},\perp}^{-\frac{s}{2}} = (L_{\mathbf{E}} + \Pi_0)^{-\frac{s}{2}} - \Pi_0 \in \Psi_{\mathrm{cl}}^{-s}(M; \mathbf{E}, \mathbf{E}). \tag{15.181}$$

Both have principal symbol $\|\xi\|_{\mathbf{g}}^{\pm s} I_{\mathbf{E}_x}$.

Proof. Theorem 15.7.9 applied to $B_{\mathbf{E}}$ gives the first assertion. Proposition 15.7.11 and the spectral characterization in Theorem 12.4.10 prove (15.178). The mapping properties of $B_{\mathbf{E}}^{\pm\frac{s}{2}}$ and the group law give the Sobolev isomorphism. The spectral identity

$$\|B_{\mathbf{E}}^{\frac{s}{2}}\mathbf{u}\|_{L^2(M,\mathbf{E})}^2 = \sum_{j=1}^{\infty} (1+\lambda_j)^s |u_j|^2$$

is the norm of the spectral scale in the preceding chapter. Equivalence of this scale with the localized scale, applied in both directions, gives exactly (15.179) and the stated dependencies. Theorem 15.7.9 adds the pseudodifferential description of the same scale.

The kernel of $L_{\mathbf{E}}$ is finite-dimensional and consists of smooth sections. Thus Π_0 has smooth kernel and belongs to $\Psi^{-\infty}(M; \mathbf{E}, \mathbf{E})$. The operator $L_{\mathbf{E}} + \Pi_0$ is strictly positive, invertible, and has the same principal symbol as $L_{\mathbf{E}}$. On $\ker L_{\mathbf{E}}$ its eigenvalue is one, while on the complement it agrees with $L_{\mathbf{E}}$. The spectral calculus then gives identities (15.180) and (15.181). Subtracting Π_0 does not change the principal symbol. □

On a complete manifold of bounded geometry, Theorems 13.3.25 and 13.3.28 already identify, under their stated hypotheses, the spectral scale of $I + L_{\mathbf{E}}$ with the scale defined by uniform localization. Both inequalities in (15.179) then retain the same form, with constants depending on s and quantitative bounded-geometry bounds, but not on the chart. Theorem 15.6.14 explains the mapping properties of the resulting uniform operators. We do not, however, assert that every complex power automatically belongs to $\Psi_{\mathrm{u}}^{2z}(M; \mathbf{E}, \mathbf{E})$: that conclusion requires a uniform parameter-dependent calculus and global resolvent estimates at infinity, hypotheses that do not follow from the local construction. On a closed manifold, finiteness of the atlas and compactness of the resolvent remove precisely this difficulty and yield the full result proved above.

For the trivial bundle over $\mathbb{R}^n$ and $s > 0$, the same identities can be read directly in Fourier variables. With the unitary normalization fixed in this chapter, the fractional Laplacian is defined exactly as the multiplier

$$\widehat{(-\Delta)^{\frac{s}{2}} u}(\xi) = \|\xi\|^s \widehat{u}(\xi), \qquad u \in \mathcal{S}(\mathbb{R}^n),$$

with closed domain given by

$$\left\{ u \in L^2(\mathbb{R}^n) \;\middle|\; \|\xi\|^s \widehat{u}(\xi) \in L^2(\mathbb{R}^n) \right\}.$$

In contrast,

$$(I - \Delta)^{\frac{s}{2}} = \mathrm{Op}\big((1 + \|\xi\|^2)^{\frac{s}{2}}\big)$$

belongs directly to the global inhomogeneous calculus. To express the pseudodifferential part of the first operator,

choose $\chi \in C^\infty(\mathbb{R}^n)$ vanishing near zero and equal to one for large $\|\xi\|$, and reserve quantization notation for the smooth symbol

$$\operatorname{Op}\big(\chi(\xi)\|\xi\|^s\big) \in \Psi^s_{\mathrm{cl,loc}}(\mathbb{R}^n;\mathbb{C},\mathbb{C}).$$

The symbol is classical, but the frequency cutoff does not imply proper support of the operator. The subscript loc is therefore retained. If a properly supported representative is required, multiply its kernel by a properly supported cutoff equal to one near the diagonal. The difference has smooth kernel because the original kernel is smooth off the diagonal; the resulting representative is not generally the exact Fourier multiplier. The difference between the exact fractional Laplacian and its high-frequency part is supported in a compact frequency set and maps $L^2(\mathbb{R}^n)$ continuously into $H^N(\mathbb{R}^n)$ for every N, without identifying $\|\xi\|^s$ with a symbol smooth at the origin. On a closed manifold, the frequency-zero difficulty is concentrated in the finite-dimensional space $\ker L_{\mathbf{E}}$, and the formulas with Π_0 isolate it exactly. At high frequencies, however, the principal symbols of $L_{\mathbf{E}}^{\frac{s}{2}}$ and $(I+L_{\mathbf{E}})^{\frac{s}{2}}$ coincide. Except for exponents producing a differential operator, these powers are nonlocal: their Schwartz kernels are not supported on the diagonal. For $0<s<2$, this nonlocality is also visible in the representation, valid for $\mathbf{u}\in\Gamma(\mathbf{E})$,

$$L_{\mathbf{E}}^{\frac{s}{2}}\mathbf{u} = \frac{s}{2\Gamma(1-\frac{s}{2})}\int_0^\infty \frac{\mathbf{u}-e^{-tL_{\mathbf{E}}}\mathbf{u}}{t^{1+\frac{s}{2}}}\,dt.$$

The integral converges as a Bochner integral in $L^2(M,\mathbf{E})$. For $\mathbf{u}\in\mathcal{D}(L_{\mathbf{E}})$, the semigroup equation and the fundamental theorem of calculus in $L^2(M,\mathbf{E})$ give the exact identity

$$\mathbf{u}-e^{-tL_{\mathbf{E}}}\mathbf{u} = \int_0^t L_{\mathbf{E}}e^{-\tau L_{\mathbf{E}}}\mathbf{u}\,d\tau. \tag{15.182}$$

Since the semigroup is contractive and commutes with $L_{\mathbf{E}}$ on $\mathcal{D}(L_{\mathbf{E}})$,

$$\|\mathbf{u}-e^{-tL_{\mathbf{E}}}\mathbf{u}\|_{L^2(M,\mathbf{E})} \le \int_0^t \|e^{-\tau L_{\mathbf{E}}}L_{\mathbf{E}}\mathbf{u}\|_{L^2(M,\mathbf{E})}\,d\tau \le t\|L_{\mathbf{E}}\mathbf{u}\|_{L^2(M,\mathbf{E})}. \tag{15.183}$$

Thus, for $0<t\le 1$, the norm of the integrand is at most $\|L_{\mathbf{E}}\mathbf{u}\|_{L^2(M,\mathbf{E})}t^{-\frac{s}{2}}$, which is integrable because $s<2$. For $t\ge 1$, contractivity gives

$$\left\|\frac{\mathbf{u}-e^{-tL_{\mathbf{E}}}\mathbf{u}}{t^{1+\frac{s}{2}}}\right\|_{L^2(M,\mathbf{E})} \le 2\|\mathbf{u}\|_{L^2(M,\mathbf{E})}t^{-1-\frac{s}{2}},$$

and this majorant is integrable because $s>0$. The $\ker L_{\mathbf{E}}$ component vanishes exactly in the numerator.

Negative powers and heat are two presentations of the same functional calculus. The first integrates the resolvent against λ^{-s}; the second integrates the spectrum against $e^{-t\lambda}$. The Mellin transform in (15.176) identifies them.

Proposition 15.7.13. (Heat smoothing and trace) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold, and let $\mathbf{E}\longrightarrow M$ be a complex vector bundle of finite rank equipped with a Hermitian bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. Let $A\ge 0$ be a classical elliptic self-adjoint pseudodifferential operator of order $m>0$ on $\mathbf{E}$. For each $t>0$,

$$e^{-tA}\in\Psi^{-\infty}(M;\mathbf{E},\mathbf{E}).$$

Its kernel $\mathbf{K}_A(t,x,y)$ is smooth on $(0,\infty)\times M\times M$. Moreover, e^{-tA} is trace class and

$$\operatorname{Tr}(e^{-tA}) = \int_{M_x} \operatorname{tr}_{\mathbf{E}_x} \mathbf{K}_A(t,x,x)\, d\lambda_{\mathbf{g}}(x). \tag{15.184}$$

Proof. The spectral calculus gives, for each $N\in\mathbb{N}$,

$$\|A^N e^{-tA}\|_{\mathcal{L}(L^2(M,\mathbf{E}),L^2(M,\mathbf{E}))} \le \sup_{\lambda\ge 0} \lambda^N e^{-t\lambda} < \infty.$$

Thus e^{-tA} maps $L^2(M,\mathbf{E})$ into $\mathcal{D}(A^N)$. Elliptic regularity identifies this domain, locally and with equivalent norms, with $H^{mN}(M,\mathbf{E})$. Since N is arbitrary, the operator gains arbitrarily many derivatives. The same argument for the adjoint shows that its kernel is smooth; hence it belongs to $\Psi^{-\infty}(M;\mathbf{E},\mathbf{E})$. For t in a compact subset of $(0,\infty)$, the identities $\partial_t^k e^{-tA} = (-A)^k e^{-tA}$ and the same estimates, with arbitrary N, give joint smoothness in (t,x,y). On a compact manifold, a smooth kernel defines a trace-class operator and the diagonal formula (15.184) holds. □

For the McKean–Singer argument, smoothing, smoothness of the kernel, and the diagonal trace formula suffice; the fine heat asymptotics will be needed only later, in studying the local index density. For $B_{\mathbf{E}} = I + L_{\mathbf{E}}$, we obtain

$$e^{-tB_{\mathbf{E}}} = e^{-t} e^{-tL_{\mathbf{E}}}$$

and

$$B_{\mathbf{E}}^{-\frac{s}{2}} = \frac{1}{\Gamma(\frac{s}{2})} \int_0^\infty t^{\frac{s}{2}-1} e^{-t} e^{-tL_{\mathbf{E}}}\, dt,$$

which is exactly the Bochner formula used to define Bessel potentials.

15.7.5 From heat to the index

The chapter's last step shows how the preceding theory enters the index problem. The parametrix gives the Fredholm property, and heat turns the difference between kernel and cokernel into a difference of traces. Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold; let $\mathbf{E}^+,\mathbf{E}^-\longrightarrow M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics and Hermitian connections; and let

$$P\in\Psi^m_{\mathrm{cl}}(M;\mathbf{E}^+,\mathbf{E}^-), \qquad P\colon \Gamma(M,\mathbf{E}^+)\longrightarrow\Gamma(M,\mathbf{E}^-), \qquad m>0,$$

be a classical elliptic operator. Its parametrix implies that its closed realization

$$P\colon H^m(M,\mathbf{E}^+)\subset L^2(M,\mathbf{E}^+)\longrightarrow L^2(M,\mathbf{E}^-)$$

is Fredholm. Its Hilbert space adjoint $P^\dagger$ has domain $H^m(M,\mathbf{E}^-)$ and agrees with the closed realization of the formal adjoint P_h^*. Thus

$$\operatorname{ind} P = \dim\ker P - \dim\ker P^\dagger.$$

This functional-analytic part of the index is a consequence of Atkinson's theorem and compactness of remainders on a closed manifold; see also [21, Chapters 3 and 9].

Proposition 15.7.14. (McKean–Singer formula) Let $(M,\mathbf{g})$ be a smooth closed Riemannian manifold; let $\mathbf{E}^+,\mathbf{E}^- \longrightarrow M$ be complex vector bundles of finite rank equipped with Hermitian bundle metrics; and let $P \in \Psi^m_{\mathrm{cl}}(M;\mathbf{E}^+,\mathbf{E}^-)$ be elliptic, with $m>0$. For every $t>0$,

$$\operatorname{ind} P = \operatorname{Tr}(e^{-tP^\dagger P}) - \operatorname{Tr}(e^{-tPP^\dagger}). \tag{15.185}$$

The spectral proof corresponds to [66, Lemma 1.6.5].

Proof. The operators $P^\dagger P$ and $PP^\dagger$ are nonnegative, self-adjoint, and elliptic. Their semigroups are smoothing and trace class. For $\lambda>0$, the map

$$P : \ker(P^\dagger P - \lambda I) \longrightarrow \ker(PP^\dagger - \lambda I)$$

is an isomorphism with inverse $\lambda^{-1}P^\dagger$. Thus the contributions $e^{-t\lambda}$ from all positive eigenvalues cancel in the difference of traces. At eigenvalue zero, what remains is

$$\ker(P^\dagger P) = \ker P, \qquad \ker(PP^\dagger) = \ker P^\dagger,$$

and the difference of multiplicities is precisely $\operatorname{ind} P$. This proves the spectral formula. □

The right-hand side of (15.185) is independent of t. The diagonal formula (15.184) interprets both traces and the spectral cancellation; its local limit is expressed through the fine asymptotics of the heat kernel.

The analytic conclusion depends only on the class of the principal symbol. To see this, let us specify which datum remains invariant under the preceding operations. If $\pi : T^*M \setminus 0_M \to M$ is the projection and P has order m, ellipticity says that

$$\sigma^\Psi_m(P) : \pi^*\mathbf{E}^+ \longrightarrow \pi^*\mathbf{E}^-$$

is a bundle isomorphism over $T^*M \setminus 0_M$. If $R \in \Psi^{m-1}_{\mathrm{cl}}(M;\mathbf{E}^+,\mathbf{E}^-)$, the family $P_t = P + tR$ preserves this principal symbol and is therefore elliptic for every $t \in [0,1]$. Viewed between the appropriate Sobolev spaces, it is a norm-continuous family of Fredholm operators; local constancy of the index on the Fredholm set gives $\operatorname{ind}(P+R) = \operatorname{ind} P$. If R is smoothing, the same conclusion follows directly from Atkinson's theorem, since R is compact. Finally, fixing bundle metrics h_+ and h_- on $\mathbf{E}^+$ and $\mathbf{E}^-$, compactness of S^*M gives

$$\delta := \inf_{(x,\xi)\in S^*M} \left\| \sigma^\Psi_m(P)(x,\xi)^{-1} \right\|^{-1}_{\mathcal{L}((\mathbf{E}^-_x,h_-(x)),(\mathbf{E}^+_x,h_+(x)))} > 0.$$

If another homogeneous principal symbol b_m satisfies

$$\sup_{(x,\xi)\in S^*M} \| b_m(x,\xi) - \sigma^\Psi_m(P)(x,\xi) \|_{\mathcal{L}((\mathbf{E}^+_x,h_+(x)),(\mathbf{E}^-_x,h_-(x)))} < \delta,$$

the straight-line segment between them remains invertible by the Neumann series. Quantizing it again gives a norm-continuous family of elliptic operators with unchanged index. The analytic problem is thus reduced to the topological class of the principal symbol. The following chapters construct that class and explain how the index is computed from it.

16

Fredholm operators and the analytic index

The pseudodifferential calculus of Chapter 15 assigns to every elliptic operator on a closed manifold a parametrix whose remainders are smoothing. Our task now is to isolate the functional-analytic consequences of this construction and establish the properties of the index that will be used in passing from the principal symbol to K–theory. The first part is formulated for bounded operators between Banach spaces. The second returns to Sobolev spaces of sections and shows that the resulting integer depends on the homotopy class of the elliptic symbol, independently of the chosen completion.

The functional-analytic exposition follows Chapters 1–3 of [21, pp. 3–88]; the application to elliptic operators corresponds to Theorem 9.10 and Corollary 9.18 of [21, pp. 240–242]. We give the proofs that make the passage between the two parts explicit.

Fredholm and the persistence of finite dimension

Ivar Fredholm discovered that certain infinite-dimensional integral equations retain an alternative governed by finite-dimensional kernels and obstructions. Modern theory abstracts this situation in the notion of a Fredholm operator. Its index does not count all solutions; it measures the stable imbalance between solutions and compatibility conditions. This stability explains why an analytic integer can survive deformations of the operator and ultimately depend only on its principal symbol.

16.1 Fredholm operators and parametrices modulo compact operators

Let X and Y be Banach spaces over $\mathbb{K}$, where $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$. Recall Definition B.2.40: an operator $T \in \mathcal{L}(X, Y)$ is Fredholm when $\ker T$ is finite-dimensional, $\operatorname{Ran} T$ is closed, and the cokernel

$$\operatorname{coker} T := Y / \operatorname{Ran} T$$

is finite-dimensional. In this case,

$$\operatorname{ind} T := \dim \ker T - \dim \operatorname{coker} T.$$

We explicitly require the range to be closed because of its analytic role: it gives the cokernel a Banach space structure and ensures that the inverse induced by T on a closed complement of its kernel is continuous. For a

bounded operator between Banach spaces, however, closedness also follows from the finite dimensionality of the algebraic cokernel.

Indeed, suppose that $Y/\operatorname{Ran} T$ is finite-dimensional and set $K := \ker T$. The subspace K is closed by the continuity of T, so X/K is Banach by Proposition B.2.20. Choose representatives of a basis of $Y/\operatorname{Ran} T$ and denote their span by C. Then C is finite-dimensional and $Y = \operatorname{Ran} T \oplus C$ as an algebraic direct sum. Consider

$$S\colon (X/K)\times C \longrightarrow Y, \qquad S([x],c) := Tx + c.$$

This operator is well defined because T vanishes on K, and the algebraic direct sum shows that it is linear and bijective. Moreover, for every $k \in K$, $\|Tx\|_Y = \|T(x-k)\|_Y \le \|T\|\|x-k\|_X$; taking the infimum yields

$$\|S([x],c)\|_Y \le \|T\|\|[x]\|_{X/K} + \|c\|_Y.$$

Thus S is continuous when the product is equipped with the sum norm. Both spaces are Banach, so Corollary B.2.17 implies that S^{-1} is continuous. Consequently,

$$\operatorname{Ran} T = S\big((X/K)\times\{0\}\big)$$

is closed, since a homeomorphism takes closed sets to closed sets. This conclusion does not require $\ker T$ to be finite-dimensional.

Lemma 16.1.1. (Complements associated with a Fredholm operator) Let $T \in \mathcal{L}(X,Y)$ be Fredholm. There exist closed subspaces $X_0 \subseteq X$ and $C \subseteq Y$ such that

$$X = \ker T \oplus X_0, \qquad Y = \operatorname{Ran} T \oplus C,$$

and the restriction

$$T_0 := T\restriction_{X_0}\colon X_0 \longrightarrow \operatorname{Ran} T$$

is an isomorphism of Banach spaces. Moreover, $\dim C = \dim \operatorname{coker} T$.

Proof. Every finite-dimensional subspace of a normed space is complemented. Indeed, if $(e_1,\dots,e_r)$ is a basis of $\ker T$, the coordinate functionals on $\ker T$ are continuous, and Corollary B.2.29 allows us to extend them to $\ell_1,\dots,\ell_r \in X'$. The operator

$$P_N x := \sum_{j=1}^{r} \ell_j(x) e_j$$

is a continuous projection onto $\ker T$; therefore, $X_0 := \ker P_N$ is closed and $X = \ker T \oplus X_0$.

Since $\operatorname{Ran} T$ is closed and has finite codimension, choose $c_1,\dots,c_q \in Y$ whose classes form a basis of $Y/\operatorname{Ran} T$ and set $C := \operatorname{span}\{c_1,\dots,c_q\}$. Every $y \in Y$ has a unique expression $y = r + c$, with $r \in \operatorname{Ran} T$ and $c \in C$. The projection onto C has closed graph: if $y_\nu \to y$ and their components satisfy $c_\nu \to c$, then $y - c \in \operatorname{Ran} T$. Theorem B.2.22 shows that the projection is continuous. Thus $Y = \operatorname{Ran} T \oplus C$ is a topological direct sum and $\dim C = q = \dim \operatorname{coker} T$.

The restriction T_0 is linear, continuous, and injective. It is also surjective: if $Tx \in \operatorname{Ran} T$ and $x = n + x_0$ is the first decomposition, then $Tx = Tx_0$. Theorem B.2.16 shows that T_0^{-1} is continuous. □

The central characterization identifies the Fredholm property with invertibility up to compact errors. This equivalence is Atkinson's theorem.

Theorem 16.1.2. (Atkinson) For $T \in \mathcal{L}(X,Y)$, the following statements are equivalent.

(i) The operator T is Fredholm.

(ii) There exists $S \in \mathcal{L}(Y,X)$ such that

$$ST = I_X - K_X, \qquad TS = I_Y - K_Y, \tag{16.1}$$

with $K_X \in \mathcal{K}(X)$ and $K_Y \in \mathcal{K}(Y)$.

If $X = Y$, the equivalence states that the class of T in the Calkin algebra

$$\mathcal{C}(X) := \mathcal{L}(X)/\mathcal{K}(X)$$

is invertible.

Proof. First suppose that T is Fredholm and use the decompositions in Lemma 16.1.1. Define $S\colon Y \to X$ by

$$S(r+c) := T_0^{-1} r, \qquad r \in \operatorname{Ran} T, \quad c \in C.$$

The projections associated with the two direct sums and T_0^{-1} are continuous, so $S \in \mathcal{L}(Y,X)$. If P_N and P_C are the projections onto $\ker T$ and C, respectively, then

$$ST = I_X - P_N, \qquad TS = I_Y - P_C.$$

Both projections have finite rank and are therefore compact. This proves (ii).

Now assume (ii). For $x \in \ker T$, the first identity in (16.1) gives $x = K_X x$. The unit ball of $\ker T$ is therefore the image under K_X of a bounded set and is relatively compact. The unit ball of an infinite-dimensional normed space cannot be relatively compact; hence $\ker T$ is finite-dimensional.

Choose a closed complement X_0 of $\ker T$ as in the first part of Lemma 16.1.1. We claim that there exists $c > 0$ such that

$$\|Tx\|_Y \geq c\|x\|_X, \qquad x \in X_0. \tag{16.2}$$

If this estimate were false, there would be a sequence $(x_\nu) \subseteq X_0$ with $\|x_\nu\|_X = 1$ and $Tx_\nu \to 0$. By compactness, a subsequence of $(K_X x_\nu)$ would converge. The identity

$$x_\nu = STx_\nu + K_X x_\nu$$

would show that the same subsequence of (x_ν) converges to some $x \in X_0$. Then $\|x\|_X = 1$ and $Tx = 0$, contradicting $X_0 \cap \ker T = \{0\}$. This proves (16.2).

The estimate implies that the range is closed. Indeed, if $Tx_\nu \to y$, write $x_\nu = n_\nu + x_\nu^0$ with $n_\nu \in \ker T$ and $x_\nu^0 \in X_0$. Then $Tx_\nu^0 = Tx_\nu$ and

$$\|x_\nu^0 - x_\mu^0\|_X \leq \frac{1}{c}\|Tx_\nu - Tx_\mu\|_Y.$$

The sequence (x_ν^0) converges to an element $x^0 \in X_0$, and the continuity of T gives $y = Tx^0$.
Let $Q\colon Y \to Y/\operatorname{Ran} T$ be the quotient map. Since the range is closed, the codomain of Q is Banach. Set $K_Y = I_Y - TS$. If $y = Tx$, then

$$K_Y y = Tx - TSTx = T(I_X - ST)x = TK_X x \in \operatorname{Ran} T.$$

Consequently, K_Y induces a compact operator

$$\overline{K}_Y\colon Y/\operatorname{Ran} T \longrightarrow Y/\operatorname{Ran} T, \qquad \overline{K}_Y[y] := [K_Y y].$$

To verify compactness, observe that every class of norm less than one has a representative of norm less than two. The image of these representatives under K_Y is relatively compact in Y, and its projection under Q remains relatively compact in the quotient. The second identity in (16.1) implies

$$\overline{K}_Y[y] = [y - TSy] = [y],$$

so the identity on the cokernel is compact. Its unit ball is relatively compact, and the cokernel is finite-dimensional. Thus T is Fredholm.
When $X = Y$, the two identities in (16.1) are equivalent to $[S][T] = [I_X] = [T][S]$ in $\mathcal{C}(X)$, which is precisely the invertibility of $[T]$. □

The preceding theorem appears in its Calkin algebra formulation in [21, Theorem 3.2, pp. 63–65]. The proof reveals a point that will be decisive in geometry: there is no need to construct an exact inverse; a parametrix with compact remainders contains all the Fredholm information.

Example 16.1.3. (Unilateral shifts) Let $\ell^2(\mathbb{N}_0)$ be the space of square-summable sequences and define

$$S_+(a_0, a_1, a_2, \ldots) := (0, a_0, a_1, \ldots), \qquad S_-(a_0, a_1, a_2, \ldots) := (a_1, a_2, a_3, \ldots).$$

Both operators have norm one and

$$S_- S_+ = I, \qquad S_+ S_- = I - \Pi_0,$$

where $\Pi_0(a_0, a_1, \ldots) = (a_0, 0, 0, \ldots)$ has rank one. Thus each is a parametrix for the other modulo compact operators. Moreover,

$$\ker S_+ = \{0\}, \qquad \operatorname{Ran} S_+ = \{(a_j) \in \ell^2(\mathbb{N}_0) \mid a_0 = 0\},$$

whereas $\ker S_- = \operatorname{span}\{(1, 0, 0, \ldots)\}$ and S_- is surjective. Therefore,

$$\operatorname{ind} S_+ = -1, \qquad \operatorname{ind} S_- = 1.$$

This example shows that the index is not a formal difference between two infinite dimensions: it records the finite defect left after inverting the operator modulo compact operators.

16.2 Stability and index calculus

The definition of the index uses two dimensions that may change separately. Their difference, however, remains fixed under perturbations that preserve the Fredholm property.

Theorem 16.2.1. (Stability of the Fredholm index) Let X and Y be Banach spaces.

(a) The set
$$\operatorname{Fred}(X,Y) := \{T \in \mathcal{L}(X,Y) \mid T \text{ is Fredholm}\}$$
is open in the operator norm, and $T \mapsto \operatorname{ind} T$ is locally constant.

(b) If $T \in \operatorname{Fred}(X,Y)$ and $K \in \mathcal{K}(X,Y)$, then $T+K$ is Fredholm and
$$\operatorname{ind}(T+K) = \operatorname{ind} T.$$

(c) If Z is a connected topological space and $z \mapsto T_z \in \operatorname{Fred}(X,Y)$ is norm-continuous, then $\operatorname{ind} T_z$ is independent of z.

Proof. Fix $T \in \operatorname{Fred}(X,Y)$ and the decompositions
$$X = X_0 \oplus N, \qquad Y = R \oplus C, \qquad N = \ker T, \quad R = \operatorname{Ran} T,$$
of Lemma 16.1.1. With respect to these, T has matrix
$$T = \begin{pmatrix} T_0 & 0 \\ 0 & 0 \end{pmatrix}, \qquad T_0 \colon X_0 \longrightarrow R \text{ invertible.}$$
For A sufficiently close to T, write
$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$
The block $a \colon X_0 \to R$ is invertible because $\|a - T_0\| < \|T_0^{-1}\|^{-1}$ implies that $a = T_0(I_{X_0} + T_0^{-1}(a - T_0))$ can be inverted using the Neumann series. Multiplying A on the left and right by invertible operators yields
$$\begin{pmatrix} I_R & 0 \\ -ca^{-1} & I_C \end{pmatrix} \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} I_{X_0} & -a^{-1}b \\ 0 & I_N \end{pmatrix} = \begin{pmatrix} a & 0 \\ 0 & d - ca^{-1}b \end{pmatrix}.$$
The second block acts between the finite-dimensional spaces N and C. Composition on the left or right with an isomorphism identifies the corresponding kernels and cokernels and does not change the index. If $D := d - ca^{-1}b$, the rank–nullity theorem gives
$$\dim\ker D - \dim(C/\operatorname{Ran} D) = (\dim N - \dim \operatorname{Ran} D) - (\dim C - \dim \operatorname{Ran} D) = \dim N - \dim C.$$
Thus A is Fredholm and
$$\operatorname{ind} A = \dim N - \dim C = \operatorname{ind} T.$$
This proves both openness and local constancy.

If K is compact and S is a parametrix for T, then

$$S(T+K)-I_X=(ST-I_X)+SK,\qquad (T+K)S-I_Y=(TS-I_Y)+KS$$

are compact. Theorem 16.1.2 shows that $T+tK$ is Fredholm for every $t\in[0,1]$. Since $t\mapsto T+tK$ is continuous and $[0,1]$ is connected, the local constancy just proved gives $\operatorname{ind}(T+K)=\operatorname{ind}T$. The same argument, applied to the continuous image of any connected space Z, proves (c). □

For local constancy, see also [21, Theorem 3.11, pp. 68–71]. The block argument explains why the dimensions of the kernel and cokernel need not be constant: all their variation is confined to the finite-dimensional operator $d-ca^{-1}b$, whose index is always $\dim N-\dim C$.

Proposition 16.2.2. (Rules for index calculus) Let $T\colon X\to Y$ and $U\colon Y\to Z$ be Fredholm operators between Banach spaces, and let $V\colon X_1\to Y_1$ be another Fredholm operator. Then

$$\operatorname{ind}(T\oplus V)=\operatorname{ind}T+\operatorname{ind}V, \tag{16.3}$$

$$\operatorname{ind}(UT)=\operatorname{ind}T+\operatorname{ind}U. \tag{16.4}$$

If X and Y are Hilbert spaces and $T^*\colon Y\to X$ is the adjoint, then T^* is Fredholm and

$$\operatorname{ind}T^*=-\operatorname{ind}T. \tag{16.5}$$

Proof. The direct sum satisfies

$$\ker(T\oplus V)=\ker T\oplus\ker V,\qquad \operatorname{coker}(T\oplus V)\cong\operatorname{coker}T\oplus\operatorname{coker}V,$$

which proves (16.3).

Let $S_T\colon Y\to X$ and $S_U\colon Z\to Y$ be parametrices for T and U. Since compact operators form a two-sided ideal, S_TS_U is a parametrix for UT modulo compact operators. By Theorem 16.1.2, UT is Fredholm. Consider the sequence

$$\begin{aligned}0\longrightarrow\ker T\longrightarrow\ker(UT)\xrightarrow{T}\ker U\xrightarrow{q_T}\operatorname{coker}T\\ \xrightarrow{\overline{U}}\operatorname{coker}(UT)\xrightarrow{q_U}\operatorname{coker}U\longrightarrow 0,\end{aligned} \tag{16.6}$$

where $q_T(y)=[y]$, $\overline{U}([y])=[Uy]$, and $q_U([z])=[z]$. These maps are well defined: $U(\operatorname{Ran}T)=\operatorname{Ran}(UT)$, and the quotient by $\operatorname{Ran}(UT)$ projects naturally onto the quotient by $\operatorname{Ran}U$. Let us verify exactness at the points where it is not tautological. If $y\in\ker U$ and $q_T(y)=0$, then $y=Tx$ and $x\in\ker(UT)$, so y lies in the image of the third map. If $[y]\in\operatorname{coker}T$ and $[Uy]=0$ in $\operatorname{coker}(UT)$, there exists $x\in X$ such that $Uy=UTx$; therefore, $y-Tx\in\ker U$ and $[y]=q_T(y-Tx)$. Finally, if $[z]\in\operatorname{coker}(UT)$ vanishes in $\operatorname{coker}U$, then $z=Uy$ and $[z]=\overline{U}([y])$. The sequence is exact.

All its terms are finite-dimensional. The alternating sum of the dimensions in a finite exact sequence is zero; applying this to (16.6) gives

$$\dim\ker T-\dim\ker(UT)+\dim\ker U-\dim\operatorname{coker}T+\dim\operatorname{coker}(UT)-\dim\operatorname{coker}U=0,$$

which is equivalent to (16.4).

Now suppose that X and Y are Hilbert spaces. Their orthogonal decompositions are

$$X = \ker T \oplus (\ker T)^{\perp}, \qquad Y = \operatorname{Ran} T \oplus (\operatorname{Ran} T)^{\perp}.$$

The restriction $T_0 \colon (\ker T)^{\perp} \to \operatorname{Ran} T$ is an isomorphism. Its adjoint $T_0^* \colon \operatorname{Ran} T \to (\ker T)^{\perp}$ is also an isomorphism. Moreover,

$$\ker T^* = (\operatorname{Ran} T)^{\perp}, \qquad \operatorname{Ran} T^* = (\ker T)^{\perp}.$$

The first equality follows directly from the definition of the adjoint; the second follows from the invertibility of T_0^* and the fact that T^* vanishes on $(\operatorname{Ran} T)^{\perp}$. In particular, T^* has closed range,

$$\dim \ker T^* = \dim \operatorname{coker} T, \qquad \dim \operatorname{coker} T^* = \dim \ker T,$$

and we obtain (16.5). □

16.3 Continuous families and finite-dimensional stabilization

For a norm-continuous family of Fredholm operators, the numerical index is constant on each connected component of the parameter space. When the parameter ranges over a compact space, a single finite-dimensional correction can be chosen to make all the operators surjective simultaneously. This will be the appropriate form for constructing a K–theory class in the next chapter.

Proposition 16.3.1. (Stabilization of a Fredholm family) Let B be a compact Hausdorff space and let

$$T \colon B \longrightarrow \operatorname{Fred}(X, Y), \qquad b \longmapsto T_b,$$

be continuous in the operator norm. There exists a finite-dimensional subspace $V \subseteq Y$ such that

$$\operatorname{Ran} T_b + V = Y, \qquad b \in B. \tag{16.7}$$

The surjective operators

$$\widetilde{T}_b \colon X \oplus V \longrightarrow Y, \qquad \widetilde{T}_b(x, v) := T_b x + v,$$

have kernels forming a vector bundle of locally constant rank over B. If $V \subseteq V'$ are two stabilizations satisfying (16.7), then

$$[\ker \widetilde{T}^{V'}] - [B \times V'] = [\ker \widetilde{T}^{V}] - [B \times V] \tag{16.8}$$

as stable differences of vector bundles.

Proof. Fix $b_0 \in B$ and choose a finite-dimensional complement C_{b_0} of $\operatorname{Ran} T_{b_0}$. The operator

$$A_{b_0} \colon X \oplus C_{b_0} \longrightarrow Y, \qquad A_{b_0}(x, c) = T_{b_0} x + c,$$

is surjective. Since $C_{b_0} \cap \operatorname{Ran} T_{b_0} = \{0\}$, its kernel is $\ker T_{b_0} \oplus \{0\}$ and is therefore finite-dimensional. Hence the kernel of A_{b_0} admits a closed complement W_{b_0} and $A_{b_0} \restriction_{W_{b_0}} \colon W_{b_0} \to Y$ is an isomorphism. For b sufficiently close to b_0, the restriction $A_b \restriction_{W_{b_0}}$ remains invertible by the Neumann series; in particular, $\operatorname{Ran} T_b + C_{b_0} = Y$.

These neighborhoods cover B. Choose a finite subcover, associated with $b_1,\dots,b_N$, and set

$$V := C_{b_1} + \cdots + C_{b_N}.$$

The space V is finite-dimensional and satisfies (16.7).
To prove the bundle structure, fix b_0 again and choose a closed complement W of $N_0 := \ker \widetilde{T}_{b_0}$ in $X \oplus V$. The restriction

$$\widetilde{T}_{b_0} \restriction_W : W \longrightarrow Y$$

is an isomorphism and remains so for b near b_0. For $n \in N_0$ define

$$\Phi_b(n) := n - \big(\widetilde{T}_b \restriction_W\big)^{-1} \widetilde{T}_b n.$$

Then $\Phi_b(n) \in \ker \widetilde{T}_b$. If $z = n + w \in N_0 \oplus W$ belongs to $\ker \widetilde{T}_b$, the equation $\widetilde{T}_b z = 0$ forces $w = -(\widetilde{T}_b \restriction_W)^{-1} \widetilde{T}_b n$; therefore, $z = \Phi_b(n)$. Thus $\Phi_b : N_0 \to \ker \widetilde{T}_b$ is an isomorphism depending continuously on b. These maps are local trivializations of the set of kernels.
Finally, suppose that $V \subseteq V'$. The projection $V' \to V'/V$ induces an exact sequence of bundles

$$0 \longrightarrow \ker \widetilde{T}^{\,V} \longrightarrow \ker \widetilde{T}^{\,V'} \longrightarrow B \times (V'/V) \longrightarrow 0.$$

Surjectivity of the last arrow is checked fiber by fiber. Given $w \in V'$, surjectivity of $\widetilde{T}_b^{\,V}$ provides $(x, v) \in X \oplus V$ such that $T_b x + v = -w$; then $(x, v + w)$ belongs to $\ker \widetilde{T}_b^{\,V'}$ and projects to $[w] \in V'/V$. A bundle metric on the middle bundle, Euclidean if $\mathbb{K} = \mathbb{R}$ and Hermitian if $\mathbb{K} = \mathbb{C}$, splits the sequence orthogonally, so

$$\ker \widetilde{T}^{\,V'} \cong \ker \widetilde{T}^{\,V} \oplus B \times (V'/V).$$

Subtracting the trivial bundles $B \times V'$ and $B \times V$ yields (16.8).
It remains to compare two arbitrary stabilizations $V_0, V_1 \subseteq Y$. The subspace $W := V_0 + V_1$ is finite-dimensional and also satisfies (16.7). Applying the equality just proved to the inclusions $V_0 \subseteq W$ and $V_1 \subseteq W$ yields

$$[\ker \widetilde{T}^{\,V_0}] - [B \times V_0] = [\ker \widetilde{T}^{\,W}] - [B \times W] = [\ker \widetilde{T}^{\,V_1}] - [B \times V_1].$$

Thus the stable difference is independent of every choice used in its construction. □

Stabilization replaces a family whose kernels may vary in dimension with a well-defined difference of finite-dimensional bundles. The Grothendieck group in the next chapter will allow us to consider this difference without retaining the auxiliary subspace V. This is the index bundle construction developed in [21, Theorem 3.30, pp. 82–85].

16.4 Elliptic operators on closed manifolds

Let $(M, \mathbf{g})$ be a closed smooth Riemannian manifold and let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be finite-rank complex vector bundles equipped with Hermitian bundle metrics and Hermitian connections. For $m, s \in \mathbb{R}$ and

$$P \in \Psi^m_{\mathrm{cl}}(M; \mathbf{E}, \mathbf{F}),$$

, Corollary 15.6.6 gives a unique continuous extension

$$P_s\colon H^{s+m}(M,\mathbf{E}) \longrightarrow H^s(M,\mathbf{F}).$$

In what follows, P will be elliptic. Chapter 15 constructed a parametrix $Q \in \Psi^{-m}_{\mathrm{cl}}(M;\mathbf{F},\mathbf{E})$ with

$$QP = I_{\mathbf{E}} - R_{\mathbf{E}}, \qquad PQ = I_{\mathbf{F}} - R_{\mathbf{F}}, \qquad R_{\mathbf{E}}, R_{\mathbf{F}} \in \Psi^{-\infty}. \tag{16.9}$$

Theorem 16.4.1. (Elliptic Fredholm operators and the analytic index) Let $(M,\mathbf{g})$ be a closed Riemannian manifold, let $\mathbf{E},\mathbf{F} \to M$ be finite-rank complex vector bundles equipped with Hermitian bundle metrics, and let $P \in \Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$ be elliptic. For every $s \in \mathbb{R}$, the operator

$$P_s\colon H^{s+m}(M,\mathbf{E}) \longrightarrow H^s(M,\mathbf{F})$$

is Fredholm. Its kernel consists of the smooth solutions of $P\mathbf{u} = 0$, and its cokernel is identified, by means of the orthogonal projection extended by duality, with the space of smooth solutions of $P^*\mathbf{v} = 0$, where P^* is the Hermitian formal adjoint. In particular,

$$\operatorname{ind} P_s = \dim\ker\bigl(P\colon \Gamma(M,\mathbf{E}) \to \Gamma(M,\mathbf{F})\bigr) - \dim\ker\bigl(P^*\colon \Gamma(M,\mathbf{F}) \to \Gamma(M,\mathbf{E})\bigr). \tag{16.10}$$

The right-hand side is independent of s.

Proof. The parametrix in (16.9) induces

$$Q_s\colon H^s(M,\mathbf{F}) \longrightarrow H^{s+m}(M,\mathbf{E}).$$

By Proposition 15.6.18, $R_{\mathbf{E}}$ and $R_{\mathbf{F}}$ act compactly on the Sobolev spaces occurring in the two identities. Applying Theorem 16.1.2 to P_s and Q_s proves that P_s is Fredholm.

If $\mathbf{u} \in H^{s+m}(M,\mathbf{E})$ and $P_s\mathbf{u} = 0$, the first parametrix identity gives $\mathbf{u} = R_{\mathbf{E}}\mathbf{u}$. A smoothing operator takes every distribution to a smooth section, so $\mathbf{u} \in \Gamma(M,\mathbf{E})$. Conversely, every smooth solution belongs to $H^{s+m}(M,\mathbf{E})$ because M is compact. Thus

$$\ker P_s = \{\mathbf{u} \in \Gamma(M,\mathbf{E}) \mid P\mathbf{u} = 0\}, \tag{16.11}$$

independently of s.

The formal adjoint $P^* \in \Psi^m_{\mathrm{cl}}(M;\mathbf{F},\mathbf{E})$ is characterized by

$$\int_M \mathbf{h}_{\mathbf{F}}(P\mathbf{u},\mathbf{v})\,d\lambda_{\mathbf{g}} = \int_M \mathbf{h}_{\mathbf{E}}(\mathbf{u},P^*\mathbf{v})\,d\lambda_{\mathbf{g}}, \qquad \mathbf{u} \in \Gamma(M,\mathbf{E}), \quad \mathbf{v} \in \Gamma(M,\mathbf{F}). \tag{16.12}$$

The principal symbol of P^* is the adjoint of the principal symbol of P by Theorem 15.2.8; therefore, P^* is elliptic. Proposition 14.5.5, applied to the closed manifold, identifies the continuous annihilator of $\operatorname{Ran} P_s \subseteq H^s(M,\mathbf{F})$ with

$$\ker\bigl(P^*\colon H^{-s}(M,\mathbf{F}) \longrightarrow H^{-s-m}(M,\mathbf{E})\bigr),$$

by an antilinear identification, since the Hermitian inner product is linear in its first variable. The elliptic regularity of Corollary 15.6.5 shows that this kernel consists of smooth sections. Denote it by K and choose

an orthonormal basis $\mathbf{v}_1,\dots,\mathbf{v}_q$ of K for the $L^2(M,\mathbf{F})$ inner product. For $\mathbf{f}\in H^s(M,\mathbf{F})$ define

$$\Pi_K\mathbf{f} := \sum_{j=1}^{q}\langle \mathbf{f},\mathbf{v}_j\rangle \mathbf{v}_j.$$

Each pairing is continuous on H^s, because $\mathbf{v}_j$ is smooth and belongs to H^{-s}. Thus $\Pi_K : H^s(M,\mathbf{F})\to K$ is linear and continuous, agrees with the orthogonal projection when $\mathbf{f}\in L^2\cap H^s$, and is the identity on K. Its kernel is $\operatorname{Ran} P_s$: inclusion of the range follows from the formal adjoint; conversely, if all the pairings vanish, all continuous functionals annihilating $\operatorname{Ran} P_s$ vanish at $\mathbf{f}$. Hahn–Banach and closedness of the range imply $\mathbf{f}\in\operatorname{Ran} P_s$. Thus Π_K induces a complex-linear isomorphism $\operatorname{coker} P_s\cong K$, independent of the chosen orthonormal basis.

Since $\operatorname{Ran} P_s$ is closed, the dual of the cokernel is this annihilator. Both are finite-dimensional and therefore have the same dimension. Together with (16.11), this gives (16.10) and proves independence of s. □

Definition 16.4.2. (Analytic index) Let $(M,\mathbf{g})$ be a closed Riemannian manifold, let $\mathbf{E},\mathbf{F}\to M$ be finite-rank complex vector bundles equipped with Hermitian bundle metrics, and let $P\in\Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$ be elliptic. The **analytic index** of a classical elliptic operator P is the integer

$$\operatorname{ind}_{\mathrm{a}}(P) := \operatorname{ind}\big(P_s\colon H^{s+m}(M,\mathbf{E})\longrightarrow H^s(M,\mathbf{F})\big),$$

where $s\in\mathbb{R}$ is arbitrary. Theorem 16.4.1 ensures that the definition is independent of s.

Formula (16.10) can be written as

$$\operatorname{ind}_{\mathrm{a}}(P) = \dim\ker P - \dim\ker P^*.$$

Here both kernels are taken among smooth sections. Using the Hilbert space adjoint of P_s for specific Sobolev inner products gives an operator different from P^*; the Riesz isomorphism identifies their kernels and yields the same dimension. The formal adjoint preserves the geometric content and the principal symbol.

Corollary 16.4.3. (Properties of the analytic index) Let M be a closed smooth manifold, let $\mathbf{E},\mathbf{F},\mathbf{E}_0,\mathbf{F}_0,\mathbf{G}\to M$ be finite-rank smooth complex vector bundles, and let $P\in\Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$, $P_0\in\Psi^m_{\mathrm{cl}}(M;\mathbf{E}_0,\mathbf{F}_0)$, and $Q\in\Psi^\ell_{\mathrm{cl}}(M;\mathbf{F},\mathbf{G})$ be elliptic. Then

$$\begin{aligned}\operatorname{ind}_{\mathrm{a}}(P\oplus P_0) &= \operatorname{ind}_{\mathrm{a}}(P)+\operatorname{ind}_{\mathrm{a}}(P_0),\\ \operatorname{ind}_{\mathrm{a}}(QP) &= \operatorname{ind}_{\mathrm{a}}(P)+\operatorname{ind}_{\mathrm{a}}(Q),\\ \operatorname{ind}_{\mathrm{a}}(P^*) &= -\operatorname{ind}_{\mathrm{a}}(P).\end{aligned}$$

If P is invertible, or if $P=P^*$, then $\operatorname{ind}_{\mathrm{a}}(P)=0$.

Proof. Choose Sobolev exponents making all compositions continuous. The first two identities are, respectively, (16.3) and (16.4); independence of the exponent allows us to change scales without changing the integer. An invertible operator has zero kernel and cokernel. For the third identity, apply (16.10) to P and P^*: since $(P^*)^*=P$, the two dimensions exchange places. If $P=P^*$, this identity gives $\operatorname{ind}_{\mathrm{a}}(P)=-\operatorname{ind}_{\mathrm{a}}(P)$, and since the index is an integer, it must be zero. □

16.5 Dependence on the principal symbol

Let $\pi\colon T^*M \to M$ be the projection. The principal symbol of P is a homogeneous homomorphism

$$\sigma_m^{\Psi}(P)\colon \pi^*\mathbf{E} \longrightarrow \pi^*\mathbf{F}$$

that is invertible over $T^*M \setminus 0_M$. Its restriction to the unit cosphere bundle S^*M contains the same information, since homogeneity recovers the symbol on every nonzero ray.

Proposition 16.5.1. (Continuous quantization of a homotopy of symbols) Let M be a closed smooth manifold, let $\mathbf{E},\mathbf{F} \to M$ be finite-rank smooth complex vector bundles, and let $a_t\colon \pi^*\mathbf{E} \to \pi^*\mathbf{F}$, $t \in [0,1]$, be classical principal symbols of order m, depending continuously on t in the C^∞ topology on S^*M. There exists a family

$$P_t \in \Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$$

continuous as a map

$$[0,1] \longrightarrow \mathcal{L}\big(H^{s+m}(M,\mathbf{E}), H^s(M,\mathbf{F})\big)$$

for every $s \in \mathbb{R}$, such that $\sigma_m^{\Psi}(P_t) = a_t$. If each a_t is invertible, each P_t is elliptic.

Proof. Choose a finite atlas, bundle frames, a partition of unity, and cutoffs in the position and frequency variables as in the global construction of Chapter 15. Extend each restriction homogeneously from S^*M for $\|\xi\|_{\mathbf{g}} \geq 1$ and multiply it by a cutoff vanishing near the zero section. The localized sum of the quantizations has principal symbol a_t; terms arising from changes of chart and cutoffs have order at most $m-1$ and do not alter this symbol.

In a finite atlas, every symbol seminorm of the full symbol of $P_t - P_{t_0}$ is bounded by a finite sum of C^N seminorms of $a_t - a_{t_0}$ on S^*M. Theorem 15.6.2, followed by the finite localization used in Corollary 15.6.6, shows that

$$\|P_t - P_{t_0}\|_{\mathcal{L}(H^{s+m}(M,\mathbf{E}),H^s(M,\mathbf{F}))} \longrightarrow 0 \qquad (t \longrightarrow t_0).$$

The last assertion is the definition of ellipticity. □

Corollary 16.5.2. (The index depends only on the symbol) Let M be a closed smooth manifold and let $\mathbf{E},\mathbf{F} \to M$ be finite-rank smooth complex vector bundles. Let $P_0, P_1 \in \Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$ be elliptic.

(a) If $\sigma_m^{\Psi}(P_0) = \sigma_m^{\Psi}(P_1)$, then

$$\mathrm{ind_a}(P_0) = \mathrm{ind_a}(P_1).$$

(b) If the restrictions of $\sigma_m^{\Psi}(P_0)$ and $\sigma_m^{\Psi}(P_1)$ to S^*M are joined by a homotopy of bundle isomorphisms continuous in the C^∞ topology on sections, then the same equality holds.

Proof. In (a), the exact sequence in Theorem 15.3.7 shows that the difference $P_1 - P_0$ has order at most $m-1$. For any $s \in \mathbb{R}$, it factors as

$$H^{s+m}(M,\mathbf{E}) \xrightarrow{P_1-P_0} H^{s+1}(M,\mathbf{F}) \hookrightarrow H^s(M,\mathbf{F}).$$

The first arrow is continuous by the pseudodifferential mapping theorem and the second is compact by

Rellich–Kondrashov. Thus $P_1 - P_0$ is compact between the spaces defining the index, and Theorem 16.2.1 proves the equality.

In (b), Proposition 16.5.1 produces a norm-continuous family $(\widehat{P}_t)_{t\in[0,1]}$ of elliptic operators with the prescribed symbols. It is a Fredholm family by Theorem 16.4.1, so part (c) of Theorem 16.2.1 gives

$$\operatorname{ind}_{\mathrm{a}}(\widehat{P}_0) = \operatorname{ind}_{\mathrm{a}}(\widehat{P}_1).$$

Since $\widehat{P}_j$ and P_j have the same principal symbol for $j = 0, 1$, part (a) completes the proof. □

To see directly that small homotopies remain elliptic, fix metrics $\mathbf{h}_{\mathbf{E}}$ and $\mathbf{h}_{\mathbf{F}}$ on the bundles. Compactness of S^*M gives

$$\delta := \inf_{(x,\xi)\in S^*M} \left\| \boldsymbol{\sigma}_m^{\Psi}(P)(x,\xi)^{-1} \right\|^{-1}_{\mathcal{L}((\mathbf{F}_x,\mathbf{h}_{\mathbf{F}}),(\mathbf{E}_x,\mathbf{h}_{\mathbf{E}}))} > 0.$$

If another symbol b_m satisfies

$$\sup_{(x,\xi)\in S^*M} \| b_m(x,\xi) - \boldsymbol{\sigma}_m^{\Psi}(P)(x,\xi) \|_{\mathcal{L}((\mathbf{E}_x,\mathbf{h}_{\mathbf{E}}),(\mathbf{F}_x,\mathbf{h}_{\mathbf{F}}))} < \delta,$$

then

$$b_m(x,\xi) = \boldsymbol{\sigma}_m^{\Psi}(P)(x,\xi)\left[I + \boldsymbol{\sigma}_m^{\Psi}(P)(x,\xi)^{-1}\left(b_m(x,\xi) - \boldsymbol{\sigma}_m^{\Psi}(P)(x,\xi) \right) \right]$$

is invertible at every point, because the second factor can be inverted using the Neumann series. The same calculation applies to the segment joining the two symbols.

Corollary 16.5.2 thus reduces the analytic problem to a topological one: turning the isomorphism $\boldsymbol{\sigma}_m^{\Psi}(P)$ over $T^*M \setminus 0_M$ into a stable class and proving that the index defines a homomorphism on these classes. This will be the construction in Chapter 17.

17

K-theory of vector bundles and the symbol class

Let X be a compact Hausdorff space. Direct sum of complex vector bundles over X gives a commutative monoid, but does not allow bundles to be subtracted. The Grothendieck construction remedies precisely this deficiency: it adds formal inverses without identifying any more elements than direct sum requires. In this sense the construction is algebraic. The resulting group, however, depends on the base space and on homotopies of maps; it is therefore called *topological K–theory*. It is distinct from the algebraic K–theory of rings.

The usefulness of this construction for an elliptic operator is already apparent in its principal symbol. If M is closed and

$$P \in \Psi^{m}_{\mathrm{cl}}(M; \mathbf{E}, \mathbf{F})$$

is elliptic, then

$$\sigma^{\Psi}_{m}(P)\colon \pi^{*}\mathbf{E} \longrightarrow \pi^{*}\mathbf{F}$$

is an isomorphism away from the zero section of $T^{*}M$. The pair of bundles and this isomorphism determine a compactly supported class on $T^{*}M$. In this chapter we construct this class and prove the properties of the operations used to define the topological and analytic indices. The construction follows [21, Chapter 10, in particular pp. 262–269].

All bundles considered will be complex, finite-rank, and locally trivial. Over a smooth manifold they will also be smooth. Real K–theory requires different groups and will not enter the proof of the complex index theorem.

Grothendieck and Atiyah: subtracting bundles

Grothendieck completion turns a monoid of geometric objects into a group of formal differences. Applied to vector bundles, this idea gives a stable expression for the difference between the domain and codomain of an elliptic symbol. Atiyah developed topological K–theory as the natural language for these classes and, together with Singer, made it the topological side of the index theorem. Stabilization does not erase the geometry: it retains precisely the information that persists when trivial bundles are added.

17.1 Grothendieck completion

Denote by $\mathrm{Vect}_{\mathbb{C}}(X)$ the set of isomorphism classes of complex vector bundles over X. The operation

$$[\mathbf{E}] + [\mathbf{F}] := [\mathbf{E} \oplus \mathbf{F}]$$

makes it a commutative monoid whose identity element is the class of the rank-zero bundle. Cancellation does not hold in general: $\mathbf{E} \oplus \mathbf{G} \cong \mathbf{F} \oplus \mathbf{G}$ does not necessarily imply $\mathbf{E} \cong \mathbf{F}$. This is why differences of bundles must not be defined by first imposing a cancellation property that does not hold.

Theorem 17.1.1. (Grothendieck group) Let $(A, +, 0)$ be a commutative monoid. On $A \times A$ define

$$(a, b) \sim (c, d) \quad \Longleftrightarrow \quad \text{there exists } e \in A \text{ such that } a + d + e = c + b + e. \tag{17.1}$$

Then

$$G(A) := (A \times A)/\!\sim$$

is an abelian group with

$$[(a, b)] + [(c, d)] = [(a + c, b + d)], \qquad -[(a, b)] = [(b, a)].$$

The map

$$\iota_A \colon A \longrightarrow G(A), \qquad \iota_A(a) = [(a, 0)],$$

is a monoid homomorphism and satisfies the following universal property: if H is an abelian group and $h \colon A \to H$ is a monoid homomorphism, there exists a unique group homomorphism $\widetilde{h} \colon G(A) \to H$ such that $\widetilde{h} \circ \iota_A = h$.

Proof. Let us prove that this is an equivalence relation. Reflexivity follows by taking $e = 0$, and symmetry by interchanging the two sides. If

$$a + d + e = c + b + e \quad \text{and} \quad c + f + e' = g + d + e',$$

then adding the equalities and regrouping yields

$$a + f + (c + d + e + e') = g + b + (c + d + e + e'),$$

so $(a, b) \sim (g, f)$. Thus the relation is transitive.
If (a, b) and (c, d) are replaced by equivalent representatives, adding the witnesses for the two equivalences proves that $(a + c, b + d)$ remains in the same class. Thus addition in $G(A)$ is well defined. Moreover,

$$[(a, b)] + [(b, a)] = [(a + b, a + b)] = [(0, 0)],$$

so each element has the stated inverse.
For the universal property, define

$$\widetilde{h}([(a, b)]) := h(a) - h(b).$$

If $(a,b) \sim (c,d)$, there exists $e \in A$ with $a+d+e = c+b+e$; applying h and canceling in the group H gives $h(a)-h(b) = h(c)-h(d)$. Consequently, $\widetilde{h}$ is well defined. It is a homomorphism, factors h, and is unique because every class can be written as

$$[(a,b)] = \iota_A(a) - \iota_A(b).$$

□

Remark 17.1.2. The relation is often defined by

$$(a,b) \sim (c,d) \quad \Longleftrightarrow \quad \text{there exist } u,v \in A \text{ with } (a+u, b+u) = (c+v, d+v).$$

This form and (17.1) are equivalent: in one direction take $e = u+v$, and in the other take $u = d+e$ and $v = b+e$. The second form is the one used in [21, Theorem 10.5, pp. 262–263].

Definition 17.1.3. (K^0 of a compact space) Let X be compact and Hausdorff. Its complex K–theory group is

$$K^0(X) := G\big(\mathrm{Vect}_{\mathbb{C}}(X)\big).$$

The class of the pair $(\mathbf{E},\mathbf{F})$ is denoted by

$$[\mathbf{E}] - [\mathbf{F}] \in K^0(X).$$

If $\underline{\mathbb{C}}^r_X = X \times \mathbb{C}^r$ is the trivial bundle, we abbreviate its class by r when the base space is unambiguous.

Equality between differences has a stable description that we will use repeatedly.

Proposition 17.1.4. (Criterion for stable equality) Let $\mathbf{E},\mathbf{F},\mathbf{E}',\mathbf{F}'$ be complex vector bundles over a compact Hausdorff space X. Then

$$[\mathbf{E}] - [\mathbf{F}] = [\mathbf{E}'] - [\mathbf{F}'] \tag{17.2}$$

if and only if there exists a bundle $\mathbf{G} \to X$ such that

$$\mathbf{E} \oplus \mathbf{F}' \oplus \mathbf{G} \cong \mathbf{E}' \oplus \mathbf{F} \oplus \mathbf{G}. \tag{17.3}$$

This is also equivalent to the existence of $N \in \mathbb{N}_0$ for which

$$\mathbf{E} \oplus \mathbf{F}' \oplus \underline{\mathbb{C}}^N_X \cong \mathbf{E}' \oplus \mathbf{F} \oplus \underline{\mathbb{C}}^N_X. \tag{17.4}$$

Moreover, every class in $K^0(X)$ can be written as

$$[\mathbf{V}] - [\underline{\mathbb{C}}^N_X] \tag{17.5}$$

for some bundle $\mathbf{V} \to X$ and some $N \in \mathbb{N}_0$.

Proof. The equivalence between (17.2) and (17.3) is precisely (17.1) applied to the monoid of bundle classes. By the complement theorem for bundles over compact bases, stated in Appendix A, there exist a bundle $\mathbf{G}^{\perp}$ and an integer N such that

$$\mathbf{G} \oplus \mathbf{G}^{\perp} \cong \underline{\mathbb{C}}^N_X.$$

Adding $\mathbf{G}^{\perp}$ to both sides of (17.3) yields (17.4). The reverse implication follows immediately by taking $\mathbf{G}$ trivial.

Finally, given $[\mathbf{E}]-[\mathbf{F}]$, choose a complement $\mathbf{F}^{\perp}$ with $\mathbf{F}\oplus\mathbf{F}^{\perp}\cong\underline{\mathbb{C}}^{N}_{X}$. Then

$$[\mathbf{E}]-[\mathbf{F}]=[\mathbf{E}\oplus\mathbf{F}^{\perp}]-[\underline{\mathbb{C}}^{N}_{X}],$$

which has the form (17.5). □

The complement theorem is not a formal property of monoids. Its proof uses a finite trivializing cover, a partition of unity, and an inclusion of the bundle into a trivial bundle; the necessary topological statements are collected in Appendix A. The algebraic consequence follows by applying that theorem in the preceding proposition.

17.1.1 Product, pullback, and homotopy

Tensor product distributes over direct sum. By the universal property of the Grothendieck group, it induces a bilinear product

$$\begin{aligned} K^{0}(X)\times K^{0}(X)&\longrightarrow K^{0}(X),\\ \bigl([\mathbf{E}]-[\mathbf{F}],[\mathbf{G}]-[\mathbf{H}]\bigr)&\longmapsto [\mathbf{E}\otimes\mathbf{G}]+[\mathbf{F}\otimes\mathbf{H}]-[\mathbf{E}\otimes\mathbf{H}]-[\mathbf{F}\otimes\mathbf{G}]. \end{aligned} \tag{17.6}$$

Associativity, commutativity, and distributivity follow from the corresponding canonical bundle isomorphisms. The class of the trivial rank-one bundle is the identity. Consequently, $K^{0}(X)$ is a commutative ring.

If $f\colon Y\to X$ is continuous between compact Hausdorff spaces, pullback satisfies

$$f^{*}(\mathbf{E}\oplus\mathbf{F})\cong f^{*}\mathbf{E}\oplus f^{*}\mathbf{F},\qquad f^{*}(\mathbf{E}\otimes\mathbf{F})\cong f^{*}\mathbf{E}\otimes f^{*}\mathbf{F}.$$

It therefore defines a ring homomorphism

$$f^{*}\colon K^{0}(X)\longrightarrow K^{0}(Y),\qquad f^{*}([\mathbf{E}]-[\mathbf{F}])=[f^{*}\mathbf{E}]-[f^{*}\mathbf{F}].$$

The identities

$$(f\circ g)^{*}=g^{*}\circ f^{*},\qquad \mathrm{Id}_{X}^{*}=\mathrm{Id}_{K^{0}(X)}$$

are verified first for bundles and then for differences. Thus K^{0} is a contravariant functor.

Proposition 17.1.5. (Homotopy invariance) If $f_{0},f_{1}\colon Y\to X$ are homotopic maps between compact Hausdorff spaces, then

$$f_{0}^{*}=f_{1}^{*}\colon K^{0}(X)\longrightarrow K^{0}(Y).$$

In particular, a homotopy equivalence induces an isomorphism in K^{0}.

Proof. Let $H\colon Y\times[0,1]\to X$ be a homotopy from f_{0} to f_{1}. The homotopy invariance theorem for vector bundles in Appendix A gives

$$(H^{*}\mathbf{E})|_{Y\times\{0\}}\cong(H^{*}\mathbf{E})|_{Y\times\{1\}}$$

for every bundle $\mathbf{E}\to X$. Consequently, $f_{0}^{*}[\mathbf{E}]=f_{1}^{*}[\mathbf{E}]$. Since bundle classes generate $K^{0}(X)$, the two homomorphisms agree on the whole group. □

17.2 Reduced groups, pairs, and compact support

Let (X, x_0) be a pointed compact Hausdorff space. The inclusion $i\colon \{x_0\} \hookrightarrow X$ induces the rank homomorphism at the base point

$$i^*\colon K^0(X) \longrightarrow K^0(\{x_0\}) \cong \mathbb{Z}.$$

Definition 17.2.1. (Reduced K–theory) Define

$$\widetilde{K}^0(X) := \ker\bigl(i^*\colon K^0(X) \to \mathbb{Z}\bigr).$$

Since the constant map $r\colon X \to \{x_0\}$ satisfies $i^* r^* = I$, we obtain the natural decomposition

$$K^0(X) \cong \widetilde{K}^0(X) \oplus \mathbb{Z}.$$

Now let $A \subseteq X$ be a nonempty closed subspace and let X/A be the pointed space obtained by collapsing A to a point.

Definition 17.2.2. (Relative K–theory) The relative group of the pair (X, A) is

$$K^0(X, A) := \widetilde{K}^0(X/A).$$

If $A = \varnothing$, we adopt the convention $K^0(X, \varnothing) = K^0(X)$.

The description by triples exhibits the symbol of an operator and is valid for a closed subset of a compact Hausdorff space. In particular, it covers pairs consisting of a disk bundle and its sphere bundle, as well as their products with compact Hausdorff parameter spaces.

Definition 17.2.3. (Relative triple) A triple over (X, A) consists of two complex bundles $\mathbf{E}, \mathbf{F} \to X$ and an isomorphism

$$\alpha\colon \mathbf{E}|_A \longrightarrow \mathbf{F}|_A.$$

We write $(\mathbf{E}, \mathbf{F}, \alpha)$. Direct sum is defined by

$$(\mathbf{E}, \mathbf{F}, \alpha) \oplus (\mathbf{E}', \mathbf{F}', \alpha') := (\mathbf{E} \oplus \mathbf{E}', \mathbf{F} \oplus \mathbf{F}', \alpha \oplus \alpha').$$

The group of triples is obtained by imposing the following relations:

(i) isomorphic triples represent the same class;

(ii) a homotopy from α to α' through isomorphisms over A does not change the class;

(iii) if α extends to an isomorphism $\mathbf{E} \to \mathbf{F}$ over X, then $(\mathbf{E}, \mathbf{F}, \alpha)$ represents zero;

(iv) if $\alpha\colon \mathbf{E}|_A \to \mathbf{F}|_A$ and $\beta\colon \mathbf{F}|_A \to \mathbf{G}|_A$, then

$$[(\mathbf{E}, \mathbf{F}, \alpha)] + [(\mathbf{F}, \mathbf{G}, \beta)] = [(\mathbf{E}, \mathbf{G}, \beta \circ \alpha)]. \tag{17.7}$$

The last relation contains both the existence of inverses and the correct cancellation of an intermediate bundle.

Indeed,

$$-[(\mathbf{E},\mathbf{F},\alpha)] = [(\mathbf{F},\mathbf{E},\alpha^{-1})]$$

because the sum of the two classes is $[(\mathbf{E},\mathbf{E},I_{\mathbf{E}|_A})] = 0$. Addition is commutative: the isomorphism interchanging the summands extends over all of X, so the interchange does not alter the class. Thus the preceding relations produce an abelian group.

Theorem 17.2.4. (The model by triples) Let X be a compact Hausdorff space and let $A \subseteq X$ be closed. The group of triples in Definition 17.2.3 is naturally isomorphic to $K^0(X,A)$. If $A \neq \varnothing$, addition of triples corresponds, under this isomorphism, to addition in $\widetilde{K}^0(X/A)$.

Proof. If $A = \varnothing$, a triple contains only the two bundles, and the relations are those of Grothendieck completion. Thus suppose that $A \neq \varnothing$. We will use stable complements, gluing, homotopy invariance, and exactness of K–theory from Appendix A, all in the category of compact Hausdorff spaces.

First recall why gluing along a closed subset is possible without assuming that the pair is a CW pair. An isomorphism $\alpha : \mathbf{E}|_A \to \mathbf{F}|_A$ extends to an isomorphism on some neighborhood of A. Indeed, the bundle $\mathrm{Hom}(\mathbf{E},\mathbf{F})$ is a summand of a finite-rank trivial bundle by Theorem A.3.1. Regard α as a section of this trivial bundle over A, extend its components to X by the Tietze theorem, and project onto the summand $\mathrm{Hom}(\mathbf{E},\mathbf{F})$. This gives a homomorphism agreeing with α on A. Equality of the ranks holds on a neighborhood of A, and invertibility is open among matrices of that rank, so the homomorphism is invertible after shrinking the neighborhood. Applied to a trivialization, this argument also allows a bundle to descend to the quotient; see [76, Proposition 2.9, pp. 51–52].

Form the double

$$D := X_+ \cup_A X_-,$$

where X_+ and X_- are two copies of X and their copies of A are identified pointwise. It is compact and Hausdorff: the equivalence relation is closed in the compact Hausdorff space $X_+ \coprod X_-$. Denote by $r : D \to X$ the map that is the identity on both copies, and by $i_- : X \to D$ the inclusion of the second copy. We have $r \circ i_- = \mathrm{Id}_X$ and a natural homeomorphism $D/X_- \cong X/A$. Let $q : D \to X/A$ be the corresponding quotient map.

The exact sequence in Theorem A.4.2, applied to (D, X_-), contains

$$K^1(D) \xrightarrow{i_-^*} K^1(X) \xrightarrow{\partial} \widetilde{K}^0(X/A) \xrightarrow{q^*} K^0(D) \xrightarrow{i_-^*} K^0(X).$$

The first map is surjective because $i_-^* r^* = I$ also in degree one. By exactness, $\partial = 0$, the map q^* is injective, and

$$q^* : \widetilde{K}^0(X/A) \xrightarrow{\cong} \ker\bigl(i_-^* : K^0(D) \to K^0(X)\bigr).$$

Thus it suffices to identify the group of triples with this last kernel.

Given $(\mathbf{E},\mathbf{F},\alpha)$, glue $\mathbf{E}$ over X_+ to $\mathbf{F}$ over X_- by means of α, and call $\mathbf{H}_\alpha$ the resulting bundle. Local triviality at the gluing points follows by extending α to a neighborhood of A, as just justified. Define

$$d(\mathbf{E},\mathbf{F},\alpha) := [\mathbf{H}_\alpha] - [r^*\mathbf{F}] \in K^0(D).$$

This class lies in the kernel of i_-^*, because both bundles restrict to $\mathbf{F}$ on X_-. The construction respects direct

sums and isomorphisms of triples. If α extends to an isomorphism $\mathbf{E} \to \mathbf{F}$ on X, this isomorphism on X_+ and the identity on X_- give $\mathbf{H}_\alpha \cong r^*\mathbf{F}$; thus an elementary triple has zero image.

A homotopy $(\alpha_t)_{t\in[0,1]}$ of isomorphisms over A allows us to glue the bundles over $D\times[0,1]$. The product is compact Hausdorff, and extension from $A\times[0,1]$ is justified by the same argument. Theorem A.3.2 identifies the restrictions of the glued bundle at the endpoints. Hence d is unchanged under the homotopy relation.

Let us also verify the composition relation. Let $\alpha : \mathbf{E}|_A \to \mathbf{F}|_A$ and $\beta : \mathbf{F}|_A \to \mathbf{G}|_A$. For $0 \le t \le \pi/2$ consider the isomorphisms

$$h_t(u,v) := \big(\cos t\,\alpha(u) + \sin t\,v, -\sin t\,\beta\alpha(u) + \cos t\,\beta(v)\big)$$

from $(\mathbf{E}\oplus\mathbf{F})|_A$ to $(\mathbf{F}\oplus\mathbf{G})|_A$. They are invertible because they are obtained by composing $\alpha\oplus I$, the rotation of $\mathbf{F}|_A\oplus\mathbf{F}|_A$ through angle t, and $I\oplus\beta$. At $t=0$ we have $h_0 = \alpha\oplus\beta$; at $t=\pi/2$, composition with the global isomorphism $(v,w)\mapsto(-w,v)$ from $\mathbf{F}\oplus\mathbf{G}$ to $\mathbf{G}\oplus\mathbf{F}$ turns $h_{\pi/2}$ into $(\beta\alpha)\oplus I_{\mathbf{F}}$. Gluing and homotopy give

$$\mathbf{H}_\alpha \oplus \mathbf{H}_\beta \cong \mathbf{H}_{\beta\alpha} \oplus r^*\mathbf{F}.$$

Subtracting the classes of $r^*\mathbf{F}$ and $r^*\mathbf{G}$ yields

$$d(\mathbf{E},\mathbf{F},\alpha) + d(\mathbf{F},\mathbf{G},\beta) = d(\mathbf{E},\mathbf{G},\beta\alpha).$$

Consequently, d is well defined on the group of triples.

Let us prove its surjectivity onto the kernel of i_-^*. Let $c \in K^0(D)$ with $i_-^*c = 0$. By Proposition 17.1.4, we may write $c = [\mathbf{V}] - [\underline{\mathbb{C}}^N_D]$. The equality $i_-^*c = 0$ allows us, after adding the same trivial bundle to both sides, to choose a trivialization

$$\tau : \mathbf{V}|_{X_-} \xrightarrow{\cong} \underline{\mathbb{C}}^N_{X_-},$$

where we have retained the letters $\mathbf{V}$ and N for the stabilized data. Take $\mathbf{E} := \mathbf{V}|_{X_+}$, $\mathbf{F} := \underline{\mathbb{C}}^N_X$, and $\alpha := \tau|_A$. The bundle $\mathbf{H}_\alpha$ is isomorphic to $\mathbf{V}$: use the identity on X_+ and τ^{-1} on X_-; these agree along the gluing locus. Thus $d(\mathbf{E},\mathbf{F},\alpha) = c$.

Finally, suppose that $d(\mathbf{E},\mathbf{F},\alpha) = 0$. The same proposition provides an integer N and an isomorphism

$$\mathbf{H}_\alpha \oplus \underline{\mathbb{C}}^N_D \cong r^*\mathbf{F} \oplus \underline{\mathbb{C}}^N_D.$$

Its restrictions to X_+ and X_- are isomorphisms

$$a : \mathbf{E}\oplus\underline{\mathbb{C}}^N_X \longrightarrow \mathbf{F}\oplus\underline{\mathbb{C}}^N_X, \qquad b : \mathbf{F}\oplus\underline{\mathbb{C}}^N_X \longrightarrow \mathbf{F}\oplus\underline{\mathbb{C}}^N_X$$

satisfying $a|_A = b|_A \circ (\alpha\oplus I)$. Thus $b^{-1}a$ extends $\alpha\oplus I$ to all of X. The original triple, stabilized by an identity triple, is elementary and represents zero. Every element of the group is represented by a triple, since addition is direct sum and the inverse interchanges the bundles. This proves injectivity of d.

The composition $(q^*)^{-1}d$ is the asserted isomorphism. The preceding verification also shows that the relations can be realized by stabilizations with elementary triples, isomorphisms, and homotopies: the composition relation is precisely the rotation just constructed. To compare two triples, apply the zero-kernel criterion to the sum of the first with the inverse of the second.

All constructions are compatible with pullbacks. Indeed, a map of pairs induces a map of their doubles commuting with the retractions and quotients, and pullback commutes with gluing. Uniqueness of the

preimage under q^* gives naturality. For a compact Hausdorff space Λ, the same argument applies to $(X \times \Lambda, A \times \Lambda)$ and its product with $[0,1]$; no CW structure on Λ is required. □

We turn to the noncompact case. Let Y be a locally compact, Hausdorff, noncompact space. Its one-point compactification is

$$Y^+ := Y \cup \{\infty\},$$

where neighborhoods of ∞ are complements of compact subsets of Y. If Y is already compact, take the disjoint union with a base point.

Definition 17.2.5. (Compactly supported K–theory) Define

$$K_c^0(Y) := \widetilde{K}^0(Y^+).$$

When Y is the interior of a compact CW pair, and in particular when Y is the total space of a vector bundle over a closed manifold, a class can equivalently be represented by a complex $(\mathbf{E}, \mathbf{F}, a)$ in which $\mathbf{E}$ and $\mathbf{F}$ are bundles over Y and

$$a\colon \mathbf{E} \longrightarrow \mathbf{F}$$

is a bundle homomorphism invertible outside some compact set $C \subseteq Y$. The same relations as in Definition 17.2.3 apply, after enlarging the compact set when necessary.

The word support refers to the region where the two-term complex

$$0 \longrightarrow \mathbf{E} \xrightarrow{a} \mathbf{F} \longrightarrow 0$$

fails to be exact. No compactly supported section is chosen. If Y is the interior of a compact space X with boundary $A = X \setminus Y$ and the collapse map $X/A \to Y^+$ is a homeomorphism, then

$$K_c^0(Y) \cong K^0(X, A). \tag{17.8}$$

If $f\colon Y \to Z$ is proper, it extends continuously to $f^+\colon Y^+ \to Z^+$ by sending ∞ to ∞. Pullback defines

$$f^*\colon K_c^0(Z) \longrightarrow K_c^0(Y).$$

Properness is necessary: without it, the preimage of the compact support of a representative need not be compact.

17.2.1 Suspension and the exact sequence

For a pointed space X, its reduced suspension is

$$\Sigma X := S^1 \wedge X,$$

where $\wedge$ denotes the smash product. We will need the odd group only to write the exact sequence of a pair.

Definition 17.2.6. (The group K^1) For a compact pointed space X, define

$$\widetilde{K}^1(X) := \widetilde{K}^0(\Sigma X).$$

For an unpointed compact space, adjoin a disjoint base point and set $K^1(X) := \widetilde{K}^1(X_+)$. For a locally compact space,

$$K^1_c(Y) := \widetilde{K}^1(Y^+).$$

For a compact pair, set

$$K^1(X,A) := \widetilde{K}^1(X/A).$$

The definition by suspension agrees with the description that we will use when applying periodicity. Indeed, Proposition A.4.1 provides a natural isomorphism

$$K^1_c(Y) \cong K^0_c(\mathbb{R} \times Y). \tag{17.9}$$

This is not a second definition: the pointed homeomorphism $(\mathbb{R}\times Y)^+ \cong S^1 \wedge Y^+$ identifies the right-hand side with the suspension appearing in Definition 17.2.6.

Theorem 17.2.7. (Exactness for a pair) Let (X,A) be a compact CW pair. There exist connecting homomorphisms for which the cyclic sequence

$$\begin{array}{ccccc} K^0(X,A) & \longrightarrow & K^0(X) & \longrightarrow & K^0(A) \\ \uparrow{\scriptstyle \partial} & & & & \downarrow{\scriptstyle \partial} \\ K^1(A) & \longleftarrow & K^1(X) & \longleftarrow & K^1(X,A) \end{array}$$

is exact. In particular,

$$\operatorname{im}\bigl(K^0(X,A) \to K^0(X)\bigr) = \ker\bigl(K^0(X) \to K^0(A)\bigr). \tag{17.10}$$

The proof belongs to algebraic topology: it identifies the connecting maps with suspensions of quotient maps and uses Bott periodicity to close the sequence. The statement, cofibration hypotheses, and references for the proof are included in Theorem A.4.2 of Appendix A. For the elementary construction of the segment (17.10), see [21, Exercise 10.12(c), pp. 264–265]; for the compactly supported formulation, see [21, §10.4, pp. 266–269].

17.3 External product

Let X and Y be compact, and let $p_X\colon X\times Y\to X$ and $p_Y\colon X\times Y\to Y$ be the projections. For bundles $\mathbf{E}\to X$ and $\mathbf{G}\to Y$ define

$$\mathbf{E}\boxtimes\mathbf{G} := p_X^*\mathbf{E}\otimes p_Y^*\mathbf{G}.$$

The fiber over (x,y) is $\mathbf{E}_x\otimes\mathbf{G}_y$. Distributivity of tensor product gives a bilinear map on the monoids of bundles and, by the universal property of Grothendieck completion, an external product

$$\boxtimes\colon K^0(X)\otimes_{\mathbb{Z}} K^0(Y)\longrightarrow K^0(X\times Y).$$

On representatives,

$$\begin{aligned}\big([\mathbf{E}]-[\mathbf{F}]\big)\boxtimes\big([\mathbf{G}]-[\mathbf{H}]\big) = {}& [\mathbf{E}\boxtimes\mathbf{G}]+[\mathbf{F}\boxtimes\mathbf{H}]\\ & -[\mathbf{E}\boxtimes\mathbf{H}]-[\mathbf{F}\boxtimes\mathbf{G}].\end{aligned} \tag{17.11}$$

The formula proves directly that replacing either representative by a stably equivalent one does not alter the result: a summand added to both the positive and negative parts appears twice with opposite signs. It also proves associativity. The interchange isomorphism $\mathbf{E}_x\otimes\mathbf{G}_y\to\mathbf{G}_y\otimes\mathbf{E}_x$ gives commutativity after interchanging the factors X and Y.

Proposition 17.3.1. (External product with compact support) Let X and Y be locally compact, Hausdorff, paracompact spaces. There exists a natural bilinear product

$$\boxtimes\colon K_c^0(X)\otimes_{\mathbb{Z}} K_c^0(Y)\longrightarrow K_c^0(X\times Y).$$

If a and b admit representatives whose supports are contained in the compact sets $C\subseteq X$ and $D\subseteq Y$, respectively, then $a\boxtimes b$ admits a representative supported in $C\times D$.

Proof. Existence, bilinearity, and naturality are the topological properties of the compactly supported product stated in Theorem A.4.2. In the compactification model, the reduced product on $X^+\times Y^+$ vanishes on both axes and descends to the smash product $X^+\wedge Y^+\cong (X\times Y)^+$.
In the complex model, each factor is exact outside C or D. The graded product of the two complexes is contractible if at least one of them is exact; hence it can fail to be exact only over $C\times D$. This proves the assertion about support. □

This construction agrees with that in [21, Theorem 10.16, pp. 267–268]. In particular, the Bott class on $\mathbb{R}^2$ can be multiplied externally by a class on any locally compact space.

17.4 The class of an elliptic symbol

Let $(M,\mathbf{g})$ be a closed smooth Riemannian manifold. Denote by $\pi\colon T^*M\to M$ the projection and by

$$B^*M:=\{(x,\xi)\in T^*M\mid \|\xi\|_{\mathbf{g}}\le 1\},\qquad S^*M:=\{(x,\xi)\in T^*M\mid \|\xi\|_{\mathbf{g}}=1\}$$

the cotangent disk and sphere bundles. The radial map

$$\begin{aligned}\rho\colon T^*M &\longrightarrow \operatorname{int}(B^*M),\\ (x,\xi)&\longmapsto\left(x,\frac{\xi}{\sqrt{1+\|\xi\|_{\mathbf{g}}^2}}\right)\end{aligned}$$

is a diffeomorphism. Consequently,

$$K_c^0(T^*M)\cong K^0(B^*M,S^*M). \tag{17.12}$$

Let $\mathbf{E},\mathbf{F}\to M$ be complex bundles and let

$$P\in\Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$$

be a classical elliptic operator. By Definition 15.3.4,

$$\sigma_m^{\Psi}(P)(x,t\xi) = t^m \sigma_m^{\Psi}(P)(x,\xi), \qquad t>0,$$

and ellipticity says that this bundle homomorphism is invertible when $\xi \neq 0$. In particular, its restriction to S^*M is an isomorphism.

Definition 17.4.1. (Symbol class) Let M be a closed smooth manifold, let $\mathbf{E},\mathbf{F}\to M$ be finite-rank smooth complex vector bundles, and let $P\in \Psi_{\mathrm{cl}}^m(M;\mathbf{E},\mathbf{F})$ be elliptic. The **K–theory class of the symbol** of P is

$$[\sigma(P)] := \left[\pi^*\mathbf{E}, \pi^*\mathbf{F}, \sigma_m^{\Psi}(P)|_{S^*M}\right] \in K^0(B^*M,S^*M) \cong K_c^0(T^*M). \tag{17.13}$$

The notation does not retain the order m: the class records only the isomorphism on nonzero cotangent directions. For a differential operator, the identity

$$\sigma_m^{\Psi}(P) = i^m \sigma_m(P)$$

from (15.8) does not change the class. Indeed, $i^m\in\mathbb{C}^\times$ can be joined to 1 by a path in $\mathbb{C}^\times$, and homotopy invariance of triples applies.

Proposition 17.4.2. (Independence of choices) Let M be a closed smooth manifold, let $\mathbf{E},\mathbf{F}\to M$ be finite-rank smooth complex vector bundles, and let $P\in\Psi_{\mathrm{cl}}^m(M;\mathbf{E},\mathbf{F})$ be a classical elliptic operator. The class (17.13) is independent of the metric used to define B^*M and S^*M, after the canonical identification with $K_c^0(T^*M)$. It is also unchanged when the symbol is replaced by another elliptic symbol homotopic to it through elliptic symbols.

Proof. Let $\mathbf{g}_0$ and $\mathbf{g}_1$ be two metrics. For every $(x,\xi)\neq 0$, the positive ray $\{(x,t\xi)\mid t>0\}$ meets each unit sphere exactly once. The radial map

$$(x,\xi)\in S^*_{\mathbf{g}_0}M \longmapsto \left(x, \frac{\xi}{\|\xi\|_{\mathbf{g}_1}}\right)\in S^*_{\mathbf{g}_1}M$$

extends to a homeomorphism of the disk bundles, preserves the zero section, and is isotopic, through positive radial rescalings, to the identification induced by the identity of T^*M. Homogeneity of the symbol makes the two boundary isomorphisms compatible. The resulting triples therefore determine the same class in $K_c^0(T^*M)$.

If a_t is a continuous family of invertible symbols over S^*M, the triple over $(B^*M\times[0,1], S^*M\times[0,1])$ restricts at the endpoints to the triples defined by a_0 and a_1. Homotopy invariance of relative K–theory identifies their classes. □

Compact support can also be described using a symbol on the entire cotangent bundle. The normalized symbol

$$a(x,\xi) := \|\xi\|_{\mathbf{g}}^{-m}\sigma_m^{\Psi}(P)(x,\xi), \qquad \xi\neq 0,$$

is homogeneous of degree zero, but does not yet define a bundle homomorphism on the zero section. Choose

$\chi \in C^\infty([0,\infty))$ with $\chi = 0$ for $r \le \varepsilon$ and $\chi = 1$ for $r \ge 2\varepsilon$, and set

$$\widetilde{a}(x,\xi) = \begin{cases} \chi(\|\xi\|_{\mathbf{g}})\|\xi\|_{\mathbf{g}}^{-m}\sigma_m^{\Psi}(P)(x,\xi), & \xi \neq 0, \\ 0, & \xi = 0. \end{cases}$$

Since $\widetilde{a}$ vanishes on a neighborhood of the zero section, it is smooth on all of T^*M; outside the disk of radius 2ε it agrees with a and is invertible. The complex $(\pi^*\mathbf{E}, \pi^*\mathbf{F}, \widetilde{a})$ represents the symbol class. Two cutoffs or two radii can be joined by a homotopy of cutoffs, retaining invertibility outside a common disk.

Theorem 17.4.3. (Realization by elliptic symbols) Let M be a closed smooth manifold. For every class

$$\kappa \in K_c^0(T^*M)$$

there exist smooth complex bundles $\mathbf{E}, \mathbf{F} \to M$ and an elliptic operator

$$P \in \Psi_{\mathrm{cl}}^0(M; \mathbf{E}, \mathbf{F})$$

such that $[\sigma(P)] = \kappa$.

Proof. Using (17.12), represent κ by a triple $(\mathbf{V}, \mathbf{W}, \alpha)$ over (B^*M, S^*M). The projection $\pi\colon B^*M \to M$ and the zero section $\mathbf{s}\colon M \to B^*M$ are homotopy inverses, since

$$H_t(x,\xi) = (x, t\xi), \qquad 0 \le t \le 1,$$

contracts every disk to its center. Homotopy invariance of bundles gives isomorphisms

$$\mathbf{V} \cong \pi^*\mathbf{E}, \qquad \mathbf{W} \cong \pi^*\mathbf{F}, \qquad \mathbf{E} := \mathbf{s}^*\mathbf{V}, \quad \mathbf{F} := \mathbf{s}^*\mathbf{W}.$$

The smoothing theorem for bundles over manifolds allows us to choose smooth structures on $\mathbf{E}$ and $\mathbf{F}$ and to take the two preceding isomorphisms smooth. This result is stated in Appendix A. Fix Hermitian metrics $\mathbf{h}_{\mathbf{E}}$ and $\mathbf{h}_{\mathbf{F}}$ and equip $\mathrm{Hom}(\pi^*\mathbf{E}, \pi^*\mathbf{F})$ with the induced operator norm. After transporting α, we obtain a continuous isomorphism

$$\alpha\colon \pi^*\mathbf{E}|_{S^*M} \longrightarrow \pi^*\mathbf{F}|_{S^*M}.$$

Since S^*M is compact,

$$\delta := \inf_{(x,\xi)\in S^*M} \|\alpha(x,\xi)^{-1}\|_{\mathrm{Hom}(\mathbf{F}_x,\mathbf{E}_x)}^{-1} > 0.$$

Choose a smooth approximation α_1 such that

$$\sup_{(x,\xi)\in S^*M} \|\alpha_1(x,\xi) - \alpha(x,\xi)\|_{\mathrm{Hom}(\mathbf{E}_x,\mathbf{F}_x)} < \delta.$$

For $\alpha_t := \alpha + t(\alpha_1 - \alpha)$ we have

$$\|\alpha(x,\xi)^{-1}(\alpha_t(x,\xi) - \alpha(x,\xi))\|_{\mathrm{End}(\mathbf{E}_x)} < 1.$$

The Neumann series shows that α_t is invertible. Thus α and α_1 define homotopic triples; replace α by α_1.

Extend α to $T^*M \setminus 0_M$ by homogeneity of degree zero:

$$a_0(x,\xi) := \alpha\left(x, \frac{\xi}{\|\xi\|_{\mathbf{g}}}\right).$$

This section is smooth and invertible. Surjectivity in the exact principal symbol sequence, Theorem 15.3.7, provides a classical operator $P \in \Psi^0_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$ with $\sigma^{\Psi}_0(P) = a_0$. Since a_0 is invertible in every nonzero direction, P is elliptic and its symbol triple is the triple representing κ. □

The smoothing used in the proof is an approximation result for continuous maps between bundles over a compact manifold. Its statement and topological reference are included in Appendix A. The analytic step, quantization of a_0, was already proved in Chapter 15. The topological reduction allowing the two bundles of the triple to be represented as pullbacks, and the subsequent realization, are also stated in [21, Exercise 11.4, pp. 279–280].

17.5 Operations on symbol classes

The rules of symbol calculus translate into exact identities in $K^0_c(T^*M)$. We will prove them in the model by triples, keeping track of the bundles and homomorphisms in each construction.

Proposition 17.5.1. (Sum and stabilization) Let M be a closed smooth manifold and let $\mathbf{E},\mathbf{F},\mathbf{E}',\mathbf{F}',\mathbf{G} \to M$ be finite-rank smooth complex vector bundles. Let

$$P \in \Psi^m_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F}), \qquad Q \in \Psi^m_{\mathrm{cl}}(M;\mathbf{E}',\mathbf{F}')$$

be elliptic operators of the same order. Then

$$[\sigma(P \oplus Q)] = [\sigma(P)] + [\sigma(Q)].$$

For an elliptic operator of arbitrary order and a bundle $\mathbf{G} \to M$, stabilization by the identity triple satisfies

$$[\sigma(P)] + [(\pi^*\mathbf{G}, \pi^*\mathbf{G}, I_{\pi^*\mathbf{G}})] = [\sigma(P)].$$

After reducing P to order zero, this equality is realized by direct sum with the operator $I_{\mathbf{G}}$.

Proof. The first equality is the definition of addition of triples:

$$(\pi^*\mathbf{E}, \pi^*\mathbf{F}, \sigma^{\Psi}_m(P)|_{S^*M}) \oplus (\pi^*\mathbf{E}', \pi^*\mathbf{F}', \sigma^{\Psi}_m(Q)|_{S^*M}) = (\pi^*(\mathbf{E}\oplus\mathbf{E}'), \pi^*(\mathbf{F}\oplus\mathbf{F}'), \sigma^{\Psi}_m(P)|_{S^*M} \oplus \sigma^{\Psi}_m(Q)|_{S^*M}).$$

The triple $(\pi^*\mathbf{G}, \pi^*\mathbf{G}, I)$ extends as an isomorphism over all of B^*M and therefore represents zero. To justify the last assertion at the operator level, fix a nonnegative covariant Laplacian $L_{\mathbf{E}}$. Theorem 15.7.9 shows that

$$\Lambda^{-m}_{\mathbf{E}} := (I + L_{\mathbf{E}})^{-\frac{m}{2}} \in \Psi^{-m}_{\mathrm{cl}}(M;\mathbf{E},\mathbf{E})$$

is elliptic and that its principal symbol on S^*M is the identity. Thus

$$P^{(0)} := P\Lambda^{-m}_{\mathbf{E}} \in \Psi^0_{\mathrm{cl}}(M;\mathbf{E},\mathbf{F})$$

has the same symbol class as P, and $P^{(0)} \oplus I_{\mathbf{G}}$ realizes the stated stabilization. □

Proposition 17.5.2. (Composition) Let M be a closed smooth manifold and let $\mathbf{E}, \mathbf{F}, \mathbf{G} \to M$ be finite-rank smooth complex vector bundles. Let

$$P \in \Psi^m_{\mathrm{cl}}(M; \mathbf{E}, \mathbf{F}), \qquad Q \in \Psi^\ell_{\mathrm{cl}}(M; \mathbf{F}, \mathbf{G})$$

be elliptic operators. Then

$$[\sigma(QP)] = [\sigma(P)] + [\sigma(Q)]. \tag{17.14}$$

Proof. Theorem 15.3.7 gives

$$\sigma^\Psi_{m+\ell}(QP) = \sigma^\Psi_\ell(Q) \circ \sigma^\Psi_m(P).$$

Applying the composition relation (17.7) with

$$\alpha = \sigma^\Psi_m(P)|_{S^*M}, \qquad \beta = \sigma^\Psi_\ell(Q)|_{S^*M},$$

yields precisely (17.14). □

Proposition 17.5.3. (Adjoint) Let M be a closed smooth manifold and let $\mathbf{E}, \mathbf{F} \to M$ be finite-rank smooth complex vector bundles; fix Hermitian metrics on them and a positive density on M. If $P \in \Psi^m_{\mathrm{cl}}(M; \mathbf{E}, \mathbf{F})$ is elliptic, then

$$[\sigma(P^*)] = -[\sigma(P)].$$

Proof. Write

$$a := \sigma^\Psi_m(P)|_{S^*M} \colon \pi^*\mathbf{E} \longrightarrow \pi^*\mathbf{F}.$$

By the symbolic adjoint rule, $\sigma^\Psi_m(P^*)|_{S^*M} = a^*$. The inverse of the class of the triple $(\pi^*\mathbf{E}, \pi^*\mathbf{F}, a)$ is represented by $(\pi^*\mathbf{F}, \pi^*\mathbf{E}, a^{-1})$. It suffices to compare a^* with a^{-1}.

The endomorphism a^*a of $\pi^*\mathbf{E}$ is positive definite. Matrix functional calculus depends smoothly on the point of S^*M, so

$$h_t := (a^*a)^{-t} a^*, \qquad 0 \le t \le 1,$$

is a smooth homotopy through isomorphisms $\pi^*\mathbf{F} \to \pi^*\mathbf{E}$. At the endpoints,

$$h_0 = a^*, \qquad h_1 = (a^*a)^{-1} a^* = a^{-1}.$$

Homotopy invariance of triples completes the proof. □

Proposition 17.5.4. (Homotopy and lower-order terms) Let M be a closed smooth manifold, let $\mathbf{E}, \mathbf{F} \to M$ be finite-rank smooth complex vector bundles, and let $P_t \in \Psi^m_{\mathrm{cl}}(M; \mathbf{E}, \mathbf{F})$, $0 \le t \le 1$, be a continuous family whose principal symbols form a family of isomorphisms over S^*M. Then

$$[\sigma(P_0)] = [\sigma(P_1)].$$

In particular, if $R \in \Psi_{\mathrm{cl}}^{m-1}(M;\mathbf{E},\mathbf{F})$ and P is elliptic, then

$$[\sigma(P+R)] = [\sigma(P)].$$

Proof. The first assertion is homotopy invariance of the symbol triple. For the second,

$$\sigma_m^{\Psi}(P+R) = \sigma_m^{\Psi}(P),$$

by exactness of the principal symbol sequence; in fact, the two triples are identical. □

Combining realization with these identities explains why $K_c^0(T^*M)$ is the natural domain of any additive invariant of elliptic operators that is stable under homotopy.

Lemma 17.5.5. (Relative smoothing of invertible homotopies) Let M be a closed smooth manifold, let $\mathbf{E},\mathbf{F} \longrightarrow M$ be finite-rank smooth bundles, and let

$$a\colon S^*M \times [0,1] \longrightarrow \mathrm{Iso}(\pi^*\mathbf{E},\pi^*\mathbf{F})$$

be a continuous homotopy with smooth endpoints. There exists a smooth homotopy $\widetilde{a}$ with the same endpoints, consisting entirely of isomorphisms. Moreover, a and $\widetilde{a}$ are joined, relative to the endpoints, by a homotopy of isomorphisms.

The relative version of this smoothing result also appears in [21, Exercise 12.13, pp. 291–292].

Proof. First reparametrize the interval by a function that is constant near 0 and 1. The resulting homotopy is smooth on a neighborhood of the endpoints. The relative Whitney approximation theorem, applied to the continuous section of the homomorphism bundle over the compact manifold $S^*M \times [0,1]$, produces a smooth map $\widetilde{a}$, equal to a near the endpoints and uniformly as close to it as desired.
After fixing bundle metrics, compactness gives

$$\mu := \min_{(x,\xi,t)\in S^*M\times[0,1]} \|a(x,\xi,t)^{-1}\|_{\mathrm{op}(\mathbf{F}_x,\mathbf{E}_x)}^{-1} > 0.$$

Choose the approximation with $\|\widetilde{a}-a\|_{C^0(S^*M\times[0,1],\mathrm{Hom}(\pi^*\mathbf{E},\pi^*\mathbf{F}))} < \frac{\mu}{2}$. Then

$$(1-\theta)a + \theta\widetilde{a} = a\left[I + \theta a^{-1}(\widetilde{a}-a)\right], \qquad 0 \le \theta \le 1,$$

is invertible by the Neumann series. This segment is fixed near the endpoints and proves all the assertions. □

Theorem 17.5.6. (The analytic index on the symbol class) Let M be a closed smooth manifold. There exists a unique homomorphism

$$\mathrm{ind_a}\colon K_c^0(T^*M) \longrightarrow \mathbb{Z} \tag{17.15}$$

such that, for every classical elliptic pseudodifferential operator P,

$$\mathrm{ind_a}([\sigma(P)]) = \mathrm{ind}\, P.$$

Proof. By Theorem 17.4.3, every class is the symbol of some elliptic operator. For a smooth triple $(\pi^*\mathbf{E}, \pi^*\mathbf{F}, a)$ over (B^*M, S^*M) define

$$I(\mathbf{E}, \mathbf{F}, a) := \operatorname{ind} \operatorname{Op}(a),$$

where $\operatorname{Op}(a)$ is any elliptic quantization of order zero with principal symbol a. Two quantizations differ by an operator of order -1, compact between the corresponding L^2 spaces by Rellich; Corollary 16.5.2 shows that I is independent of the quantization. We must verify that this integer respects the relations in the model by triples.

First consider two isomorphic triples, after any stabilizations forming part of the isomorphism. Write them as

$$(\pi^*\mathbf{E}, \pi^*\mathbf{F}, a), \qquad (\pi^*\mathbf{E}', \pi^*\mathbf{F}', a')$$

over (B^*M, S^*M). There exist isomorphisms $U\colon \pi^*\mathbf{E} \to \pi^*\mathbf{E}'$ and $V\colon \pi^*\mathbf{F} \to \pi^*\mathbf{F}'$ over B^*M such that $a'U = Va$ on S^*M. Although U and V may depend on the covariable, radial contraction defines

$$U_t(x,\xi) = U(x, t\xi), \qquad V_t(x,\xi) = V(x,t\xi), \qquad 0 \le t \le 1.$$

Therefore,

$$a_t := V_t^{-1} a' U_t$$

is a homotopy of invertible symbols over S^*M joining a to $V_0^{-1}a'U_0$. At the second endpoint, U_0 and V_0 are pullbacks of continuous bundle isomorphisms over M. Theorem A.4.4 allows us to approximate them uniformly by smooth isomorphisms $\widehat{U_0}$ and $\widehat{V_0}$; an approximation smaller than the minimum of their singular values preserves invertibility, and the straight segments give homotopies of isomorphisms. Concatenate these segments with (a_t). Both endpoints of the resulting homotopy are now smooth, so Lemma 17.5.5 allows us to replace it by a smooth homotopy of symbols. A realization of the endpoint $\widehat{V_0}^{-1}a'\widehat{U_0}$ is obtained from a realization of a' by composition on the left and right with the bundle isomorphisms; these compositions are invertible operators of order zero and do not change the index. Thus an isomorphism of triples preserves the associated integer, even when its initial isomorphisms depend on ξ.

A continuous homotopy of the boundary isomorphism can be smoothed relative to its endpoints using Lemma 17.5.5 and quantized, by surjectivity of the principal symbol, as a family of elliptic operators: fix a single cover, a single partition of unity, and the same cutoffs in the construction of Theorem 15.3.7; the quantization formula is linear in the symbol and preserves continuity in the parameter. Corollary 16.5.2 gives constancy of its index. After reducing all operators to order zero as in Proposition 17.5.1, direct sum of triples corresponds to direct sum of operators. Proposition 16.2.2 proves additivity.

Suppose that the boundary isomorphism $\alpha\colon \pi^*\mathbf{E}|_{S^*M} \to \pi^*\mathbf{F}|_{S^*M}$ extends to an isomorphism $A\colon \pi^*\mathbf{E} \to \pi^*\mathbf{F}$ over B^*M. Radial contraction shows that $A|_{S^*M}$ is homotopic, through isomorphisms, to the pullback of $A|_{0_M}\colon \mathbf{E} \to \mathbf{F}$. This isomorphism may only be continuous. Approximate it uniformly by a smooth isomorphism $\widehat{A_0}\colon \mathbf{E} \to \mathbf{F}$; if the error is smaller than the minimum of the singular values of $A|_{0_M}$, the segment between them remains invertible. Concatenate this segment with radial contraction and apply Lemma 17.5.5. The smooth endpoint $\pi^*\widehat{A_0}$ is the constant symbol of multiplication by $\widehat{A_0}$, whose index is zero. By homotopy invariance, any realization of this triple has index zero. Thus the third relation in Definition 17.2.3 is respected.

Finally, the composition relation is respected because, for elliptic $P\colon \mathbf{E} \to \mathbf{F}$ and $Q\colon \mathbf{F} \to \mathbf{G}$,

$$\operatorname{ind}(QP) = \operatorname{ind} Q + \operatorname{ind} P$$

by Proposition 16.2.2, while their symbols satisfy (17.14). Consequently, the index descends to the quotient defined by triples and determines the homomorphism (17.15). Realization of all classes also proves uniqueness. □

Bott periodicity and the Thom isomorphism will allow us to construct the topological homomorphism on the same group.

18

Bott periodicity, the Thom isomorphism, and the Euclidean index

The symbol class constructed in Chapter 17 belongs to a compactly supported group,

$$[\sigma(P)] \in K_c^0(T^*M).$$

Two operations are needed to turn it into an integer. Bott periodicity identifies the K–theory of a space with that of its product with $\mathbb{R}^2$, and the Thom isomorphism allows this identification to be made fiber by fiber in a complex vector bundle. Both operations are topological; the analytic work consists in proving that quantization of a class and the Fredholm index behave in the same way.

We begin with the orientation conventions that determine the signs. We then construct the Thom isomorphisms and the pushforward maps associated with embeddings, calculate the indices of two model operators, and prove the Euclidean formula. The final result will be

$$\operatorname{ind}_{\mathrm{a}}(P) = (-1)^n \alpha_n\big([\sigma(P)]\big), \qquad P \in \operatorname{Ell}_c^0(\mathbb{R}^n),$$

where $\alpha_n : K_c^0(\mathbb{R}^{2n}) \longrightarrow \mathbb{Z}$ is the iterated Bott isomorphism with the normalization specified below. This is the form of [21, Theorem 11.5, pp. 281–282] compatible with the Fourier conventions of Chapter 15.

Bott and Thom: transporting topological information

The periodicity discovered by Raoul Bott revealed a deep repetition in the homotopy groups of the classical groups and gave K–theory an extraordinarily rigid structure. The Thom isomorphism allows this periodicity to be applied fiber by fiber in a vector bundle oriented in the appropriate sense. In the proof of the index theorem, these ideas push a localized class from the cotangent bundle of a manifold into Euclidean space, where its index can be calculated using model operators.

18.1 The Bott class and orientation conventions

Identify $\mathbb{R}^2$ with $\mathbb{C}$ by

$$(x,\xi)\longmapsto x+i\xi$$

and orient $\mathbb{R}^2$ by the ordered basis $(\partial_x,\partial_\xi)$. Its one-point compactification is $(\mathbb{R}^2)^+\cong S^2$. Write

$$S^2=D_0\cup_{S^1}D_\infty$$

as the union of two closed disks. If $m\in\mathbb{Z}$, denote by $\mathbf{E}_m\longrightarrow S^2$ the line bundle obtained by identifying the trivial fibers over the equator through

$$(z,v)_0\sim(z,z^m v)_\infty,\qquad z\in S^1,\quad v\in\mathbb{C}.$$

The fiber of $\mathbf{E}_m$ over the point added at infinity is identified with $\mathbb{C}$. Thus the difference of two rank-one bundles defines a reduced class.

Definition 18.1.1. (Bott class) The **Bott class** used in this book is

$$b:=[\mathbf{E}_{-1}]-[\underline{\mathbb{C}}]\in\widetilde{K}^0(S^2)=K_c^0(\mathbb{R}^2).$$

If X is locally compact, write

$$b\boxtimes a\in K_c^0(\mathbb{R}^2\times X),\qquad a\in K_c^0(X),$$

for the external product of Proposition 17.3.1.

The choice of $\mathbf{E}_{-1}$ rather than $\mathbf{E}_1$ is essential to the sign of the index. Indeed, $\mathbf{E}_1\otimes\mathbf{E}_{-1}$ is trivial and the computation of the ring of the sphere gives $b^2=0$; see [76, Theorem 2.2, pp. 41–50]. Since $[\mathbf{E}_{-1}]=1+b$, we obtain

$$[\mathbf{E}_1]=[\mathbf{E}_{-1}]^{-1}=(1+b)^{-1}=1-b.$$

Thus the opposite class $-b=[\mathbf{E}_1]-[\underline{\mathbb{C}}]$ is also a generator of $K_c^0(\mathbb{R}^2)$, but interchanging these generators changes all the odd-degree signs that will appear later.

It is useful to collect the conventions maintained throughout the argument:

$$(x,\xi)\longmapsto x+i\xi,\qquad J(u,v)=(-v,u),\qquad b=[\mathbf{E}_{-1}]-[\underline{\mathbb{C}}],\qquad \lambda_{\mathbb{C}}=-b. \tag{18.1}$$

With this choice, the localized operator representing b will have index -1, whereas the normal oscillator representing $\lambda_{\mathbb{C}}$ will have index $+1$. This difference is not a subsequent sign correction; it is a consequence of the fact that the two operators represent opposite generators.

The deep topological result that we will use is stated, with its local compactness and naturality hypotheses, in Theorem A.5.1. A complete proof can be found in [21, Theorems 10.20 and 10.22, pp. 270–272].

Theorem 18.1.2. (Complex Bott periodicity) For every locally compact space X there exists a natural isomorphism

$$\alpha_X:K_c^0(\mathbb{R}^2\times X)\longrightarrow K_c^0(X)$$

whose inverse is

$$\beta_X : K_c^0(X) \longrightarrow K_c^0(\mathbb{R}^2 \times X), \qquad \beta_X(a) = b \boxtimes a.$$

In particular,

$$\alpha_{\{*\}}(b) = 1 \in K^0(\{*\}) = \mathbb{Z}.$$

These isomorphisms are compatible with external products: if Y is another locally compact space, $u \in K_c^0(\mathbb{R}^2 \times X)$ and $v \in K_c^0(Y)$, then

$$\alpha_{X\times Y}(u \boxtimes v) = \alpha_X(u) \boxtimes v. \tag{18.2}$$

We do not reproduce the topological proof of periodicity here. The consequences we need follow immediately, and it is useful to record them.

Corollary 18.1.3. (Iterated Bott isomorphism) For $n \in \mathbb{N}$ there exists an isomorphism

$$\alpha_{n,X} : K_c^0(\mathbb{R}^{2n} \times X) \longrightarrow K_c^0(X)$$

obtained by applying α successively to the n factors $\mathbb{R}^2$. Its inverse is

$$a \longmapsto b^{\boxtimes n} \boxtimes a, \qquad b^{\boxtimes n} := \underbrace{b \boxtimes \cdots \boxtimes b}_{n \text{ factors}}.$$

In particular,

$$K_c^0(\mathbb{R}^{2n}) = \mathbb{Z}\, b^{\boxtimes n}, \qquad \alpha_n(b^{\boxtimes n}) = 1,$$

where $\alpha_n := \alpha_{n,\{*\}}$.

Proof. The assertion follows by induction. To pass from n to $n+1$, use

$$\mathbb{R}^{2(n+1)} = \mathbb{R}^2 \times \mathbb{R}^{2n}$$

and apply first $\alpha_{\mathbb{R}^{2n}\times X}$ and then $\alpha_{n,X}$. The formula for the inverse follows from (18.2) and associativity of the external product. □

Periodicity also determines the compactly supported K–theory groups in odd dimensions. Using the natural isomorphism (17.9), the definition by suspension in the preceding chapter can be written as

$$K_c^1(X) \cong K_c^0(\mathbb{R} \times X).$$

Periodicity then states that $K_c^{j+2}(X) \cong K_c^j(X)$. In particular,

$$K_c^0(\mathbb{R}^{2n+1}) = 0, \qquad K_c^1(\mathbb{R}^{2n+1}) \cong \mathbb{Z}.$$

Only even degree will be used explicitly, because $T^*\mathbb{R}^n$ has real dimension $2n$.

18.2 The Thom class

Let $\pi : \mathbf{V} \longrightarrow X$ be a complex vector bundle of rank r over a compact Hausdorff space X, equipped with a Hermitian bundle metric $\mathbf{h}_{\mathbf{V}}$. The following construction is performed fiber by fiber. If the base is merely locally compact, the same construction defines a Thom orientation acting on compactly supported classes; the orientation class itself may have noncompact support because its support is the entire zero section.

For $v \in \mathbf{V}_x$, let

$$\varepsilon_v : \Lambda^k \mathbf{V}_x \longrightarrow \Lambda^{k+1} \mathbf{V}_x, \qquad \varepsilon_v(\omega) = v \wedge \omega,$$

and let $\iota_v := \varepsilon_v^*$ be its adjoint with respect to the Hermitian inner product induced on the exterior algebra. The creation and annihilation identities are

$$\varepsilon_v^2 = 0, \qquad \iota_v^2 = 0, \qquad \varepsilon_v \iota_v + \iota_v \varepsilon_v = \|v\|^2 I. \tag{18.3}$$

Define

$$c_{\mathbf{V}}(v) := \varepsilon_v - \iota_v : \Lambda^{\mathrm{ev}} \mathbf{V}_x \longrightarrow \Lambda^{\mathrm{odd}} \mathbf{V}_x.$$

By (18.3),

$$c_{\mathbf{V}}(v)^* c_{\mathbf{V}}(v) = \|v\|^2 I, \qquad c_{\mathbf{V}}(v) c_{\mathbf{V}}(v)^* = \|v\|^2 I. \tag{18.4}$$

Consequently, $c_{\mathbf{V}}(v)$ is an isomorphism if $v \neq 0$, with inverse $\|v\|^{-2} c_{\mathbf{V}}(v)^*$.

Definition 18.2.1. (Complex Thom class) The **Thom class** of $\mathbf{V}$ is the class supported on the zero section represented by

$$\lambda_{\mathbf{V}} := [\pi^* \Lambda^{\mathrm{ev}} \mathbf{V}, \pi^* \Lambda^{\mathrm{odd}} \mathbf{V}, c_{\mathbf{V}}] \in K_c^0(\mathbf{V}).$$

Equivalently, if $B(\mathbf{V})$ and $S(\mathbf{V})$ are the unit ball and sphere bundles, then

$$\lambda_{\mathbf{V}} = \chi\big(\pi^* \Lambda^{\mathrm{ev}} \mathbf{V}, \pi^* \Lambda^{\mathrm{odd}} \mathbf{V}; c_{\mathbf{V}}|_{S(\mathbf{V})}\big) \in K^0(B(\mathbf{V}), S(\mathbf{V})).$$

Equality (18.4) proves all the analytic and algebraic facts needed for the class to be defined. The assertion that this class generates the K–theory of each fiber in a way compatible with variation of the base is the topological content of the Thom isomorphism. It is stated in Theorem A.5.3; see also [21, Theorem 12.8, pp. 289–290].

Theorem 18.2.2. (Thom isomorphism in K–theory) Let $\pi : \mathbf{V} \longrightarrow X$ be a finite-rank complex vector bundle over a locally compact space. The map

$$\mathrm{Th}_{\mathbf{V}} : K_c^0(X) \longrightarrow K_c^0(\mathbf{V}), \qquad \mathrm{Th}_{\mathbf{V}}(a) = \pi^* a \cdot \lambda_{\mathbf{V}},$$

is an isomorphism. If $f : Y \longrightarrow X$ is continuous and $f^{-1}(\operatorname{supp} a)$ is compact, then

$$(f_{\mathbf{V}})^* \mathrm{Th}_{\mathbf{V}}(a) = \mathrm{Th}_{f^*\mathbf{V}}(f^* a), \tag{18.5}$$

where $f_{\mathbf{V}} : f^*\mathbf{V} \longrightarrow \mathbf{V}$ is the induced map. If $\mathbf{V}$ and $\mathbf{W}$ are complex bundles over X, then, under the natural identification of the total bundle $\mathbf{V} \oplus \mathbf{W}$ with the bundle $\pi_{\mathbf{V}}^* \mathbf{W}$ over $\mathbf{V}$,

$$\lambda_{\mathbf{V}\oplus\mathbf{W}} = \lambda_{\mathbf{V}} \boxtimes_X \lambda_{\mathbf{W}}, \qquad \mathrm{Th}_{\mathbf{V}\oplus\mathbf{W}} = \mathrm{Th}_{\pi_{\mathbf{V}}^*\mathbf{W}} \circ \mathrm{Th}_{\mathbf{V}}. \tag{18.6}$$

For a noncompact base, the notation $\pi^*a \cdot \lambda_{\mathbf{V}}$ means that the Thom complex is restricted to the preimage of a compact set containing $\operatorname{supp} a$. Its support is contained in the zero section over that compact set and therefore defines an element of $K_c^0(\mathbf{V})$.

Multiplicativity of the classes can be seen directly before using the fact that the Thom maps are isomorphisms. Indeed,

$$\Lambda^*(\mathbf{V} \oplus \mathbf{W}) \cong \Lambda^*\mathbf{V} \widehat{\otimes} \Lambda^*\mathbf{W}$$

as $\mathbb{Z}_2$–graded bundles, and the corresponding odd operator is

$$c_{\mathbf{V}\oplus\mathbf{W}}(v,w) = c_{\mathbf{V}}(v)\widehat{\otimes} I + \Gamma_{\mathbf{V}} \widehat{\otimes} c_{\mathbf{W}}(w),$$

where $\Gamma_{\mathbf{V}}$ equals 1 in even degree and -1 in odd degree. The two summands anticommute; hence the product of the adjoint with the operator is

$$\big(\|v\|^2 + \|w\|^2\big) I.$$

This is precisely the product complex representing the right-hand side of (18.6).

Let us check the relationship between the Bott and Thom conventions. On a trivial complex line we use the complex structure

$$J(u_1, u_2) = (-u_2, u_1).$$

The map $c_{\mathbb{C}}(u_1 + iu_2)$ is multiplication by $u_1 + iu_2$ from even to odd degree. With the gluing convention of Definition 18.1.1, this class is

$$\lambda_{\mathbb{C}} = -b. \tag{18.7}$$

Indeed, in trivializations over the interior and exterior disks, the transition map of the preceding difference is z, whereas b was defined by z^{-1}. Consequently,

$$\lambda_{\mathbb{C}^r} = (-1)^r b^{\boxtimes r}. \tag{18.8}$$

This normalization will give the oscillator operator associated with the Thom class index 1 and the operator associated with b index -1.

Not every real vector bundle has a canonical Thom class in complex K–theory. A real bundle of even rank requires a Spin^c orientation; once it has been chosen, the spinor bundles $\mathbf{S}^+$ and $\mathbf{S}^-$ and Clifford multiplication produce a class

$$[\pi^*\mathbf{S}^+, \pi^*\mathbf{S}^-, c(v)] \in K_c^0(\mathbf{V}).$$

A complex bundle has a canonical Spin^c orientation, and the resulting class agrees with the exterior-algebra class above. We will not apply the Thom isomorphism directly to an arbitrary real bundle. The embedding used for the index theorem will instead involve the sum of two copies of a real bundle; this sum has a canonical complex structure and does not require an additional choice of Spin^c structure.

18.3 Embeddings and extension by zero

Let $U \subseteq Z$ be an open subset of a locally compact space. We will use the description by supports

$$K_c^0(U) = \varinjlim_{K \Subset U} \mathcal{K}_K^0(U), \tag{18.9}$$

with the notation by complexes invertible outside K introduced in Appendix A. For every compact set $K \Subset U$, excision states that restriction to U and extension to Z are inverse isomorphisms. We will use the second map, written

$$K^0_K(U) \xrightarrow{\cong} K^0_K(Z). \tag{18.10}$$

These identifications commute with the morphisms induced by inclusions of compact sets. Passing to the direct limit defines extension by zero

$$e_U : K^0_c(U) \longrightarrow K^0_c(Z). \tag{18.11}$$

If a class is represented by a complex elementary outside a compact set $K \Subset U$, its image is the relative class determined by the same support K through (18.10). This description avoids requiring the individual bundles of the representative to extend to all of Z. Compatibility of excision with inclusions gives

$$e_V \circ e_U = e_U$$

for open subsets $U \subseteq V \subseteq Z$, where on the left-hand side the first extension is from U to V and the second from V to Z.

Now consider a proper smooth embedding

$$j : X \hookrightarrow Y$$

between manifolds without boundary. Choose metrics and use their musical isomorphisms to identify cotangent bundles with tangent bundles. The differential induces an embedding

$$Tj : TX \hookrightarrow TY.$$

Let $\nu \longrightarrow X$ be the normal bundle of j, obtained from the chosen metric on Y. Identify X with its image and write $T_xY = T_xX \oplus \nu_x$. Fix a connection ∇^Y on TY. The tangential projection of ∇^Y induces a connection ∇^X on TX, and its normal component defines the tensor

$$B_x(w,v) := \big(\nabla^Y_w V\big)^{\perp}, \qquad w, v \in T_xX,$$

where V is any vector field tangent to X with $V(x) = v$. The expression is independent of V: writing a field vanishing at x in a tangent frame, the terms containing derivatives of its coefficients are tangent and disappear upon projection onto ν_x. If ∇^Y is the Levi–Civita connection, B is the second fundamental form.

Proposition 2.7.26, applied to these two connections, gives decompositions

$$T_v(TY) \cong T_xY \oplus T_xY, \qquad T_v(TX) \cong T_xX \oplus T_xX, \qquad (x,v) \in TX.$$

The tangent inclusion is generally not the direct inclusion of the two summands. To calculate it, represent a vector in $T_v(TX)$ by a curve $v(t) \in T_{x(t)}X$ and set $w = x'(0)$, $z = \nabla^X_{\partial t} v(0)$. Decomposition of the connection along the curve gives $\nabla^Y_{\partial t} v(0) = z + B_x(w,v)$. Thus, in horizontal–vertical coordinates, the differential of Tj is

$$T_v(Tj)(w,z) = \big(w, z + B_x(w,v)\big).$$

Now consider the linear map

$$F_v : T_xY \oplus T_xY \longrightarrow \nu_x \oplus \nu_x, \qquad F_v(a,b) := \big(a^{\perp}, b^{\perp} - B_x(a^{\top}, v)\big).$$

It is surjective, since $F_v(u_1,u_2)=(u_1,u_2)$ for $u_1,u_2\in\nu_x$. If $F_v(a,b)=0$, then $a\in T_xX$ and $b=b^{\top}+B_x(a,v)$, so $(a,b)=T_v(Tj)(a,b^{\top})$. Conversely, the formula for $T_v(Tj)$ shows that its entire image lies in the kernel of F_v. Thus F_v induces an isomorphism from the quotient by the image of $T_v(Tj)$ to $\nu_x\oplus\nu_x$.

These maps depend smoothly on (x,v), and their inverse in the quotient is the class of (u_1,u_2). Identifying the normal bundle with this quotient by means of an orthogonal complement yields

$$N(Tj)\cong\pi_{TX}^{*}(\nu\oplus\nu). \tag{18.12}$$

The identification depends on the connection. If two connections are joined by their affine segment, the induced connections, tensors B, and maps F_v depend smoothly on the parameter, and each F_v induces the preceding isomorphism. This gives a homotopy of identifications. On the right-hand side of (18.12), fix the complex structure

$$J(u_1,u_2)=(-u_2,u_1). \tag{18.13}$$

The first summand corresponds to the horizontal direction and the second to the vertical direction. Fix this structure J and a tubular neighborhood Φ_J of Tj; the complex orientation, Thom isomorphism, and extension by zero are always taken with respect to the same pair (J,Φ_J). Thus, even if ν is a real bundle without a Spin^c orientation, the normal bundle of TX in TY is a complex bundle.

A tubular neighborhood provides a diffeomorphism

$$\Phi_J:\mathcal{U}\subseteq N(Tj)\longrightarrow\mathcal{V}\subseteq TY$$

between neighborhoods of the zero sections. By excision, every compactly supported class in $N(Tj)$ can be represented inside $\mathcal{U}$ after a radial dilation. We then compose the Thom isomorphism with Φ_J and extension by zero from $\mathcal{V}$.

Definition 18.3.1. (Pushforward of an embedding) The **pushforward** associated with j is

$$j_!:K_c^0(T^*X)\longrightarrow K_c^0(T^*Y),\qquad j_!:=e_{\mathcal{V}}\circ(\Phi_J^{-1})^{*}\circ\mathrm{Th}_{N(Tj)}, \tag{18.14}$$

where the metrics have been used to identify tangent and cotangent bundles and $N(Tj)$ carries the complex structure (18.13).

Independence of the metrics, connection, and tubular neighborhood follows from homotopy invariance, naturality of Thom, and isotopy of tubular neighborhoods. Full functoriality is the topological result recorded in Theorem A.6.1; in the preceding notation it states

$$(k\circ j)_!=k_!\circ j_! \tag{18.15}$$

for composable proper embeddings $X\xrightarrow{j}Y\xrightarrow{k}Z$. The construction in the form used here is described in [21, pp. 289–294]; independence of choices and functoriality are proved in [92, Appendix C, Theorem C.8; Chapter III, §§12–13].

For the inclusion $i:\{0\}\hookrightarrow\mathbb{R}^N$, the normal bundle of $T\{0\}$ in $T\mathbb{R}^N$ is

$$\mathbb{R}^N\oplus\mathbb{R}^N\cong\mathbb{C}^N$$

with the complex structure of (18.13). By (18.8),

$$i_!(1) = (-1)^N b^{\boxtimes N}. \tag{18.16}$$

Since $\alpha_N(b^{\boxtimes N}) = 1$, we obtain

$$i_!^{-1} = (-1)^N \alpha_N : K_c^0(T\mathbb{R}^N) = K_c^0(\mathbb{R}^{2N}) \longrightarrow \mathbb{Z}. \tag{18.17}$$

This formula explains in advance the sign that will appear in the Euclidean index.

18.4 Euclidean operators equal to the identity at infinity

The phrase "at infinity" will refer to a strong support condition. After stabilizing the bundles by trivial summands, all operators will act on functions with values in a single space $\mathbb{C}^q$.

Definition 18.4.1. (The class $\mathrm{Ell}_c^0(\mathbb{R}^n)$) An operator P belongs to $\mathrm{Ell}_c^0(\mathbb{R}^n;\mathbb{C}^q)$ if it is a classical, properly supported, elliptic pseudodifferential operator of order zero, and there exists a compact set $K \subset \mathbb{R}^n$ such that

$$P = I + Q, \qquad \operatorname{supp}(\mathbf{K}_Q) \subseteq K \times K,$$

where $\mathbf{K}_Q$ is the Schwartz kernel of Q. Direct sum with identity operators is allowed, and we write simply $\mathrm{Ell}_c^0(\mathbb{R}^n)$ for the stable union of these classes.

The condition on the Schwartz kernel is equivalent to the two statements

$$(P - I)u = 0, \qquad (P^* - I)u = 0$$

for every $u \in C_c^\infty(\mathbb{R}^n;\mathbb{C}^q)$ whose support does not meet K. One implication is immediate. For the converse, the first equality shows, in the distributional sense, that the kernel of $P - I$ vanishes when the second variable lies outside K; the equality for the adjoint shows that it vanishes when the first variable lies outside K. It also follows that the principal symbol is the identity if $x \notin K$.

Equality of the principal symbol with I outside a compact set alone is a weaker condition: it does not assert that the operator is exactly the identity there. To compare realizations of this symbol, first carry out the quantization on $S^n = \mathbb{R}^n \cup \{\infty\}$. A matrix-valued principal symbol a_0 equal to I outside a compact set $K \subset \mathbb{R}^n$ extends by I to the cotangent bundle of S^n. Let $I + A \in \Psi_{\mathrm{cl}}^0(S^n;\mathbb{C}^q)$ be a quantization of this extension. Choose $\chi \in C_c^\infty(\mathbb{R}^n)$ equal to 1 on a neighborhood of K, extend it by zero to S^n, and consider

$$I + \chi A \chi.$$

Its principal symbol is $I + \chi^2(a_0 - I) = a_0$. Consequently, $A - \chi A \chi \in \Psi_{\mathrm{cl}}^{-1}(S^n)$ and it is compact on $L^2(S^n)$: it maps $L^2(S^n)$ continuously into $H^1(S^n)$, whose inclusion in $L^2(S^n)$ is compact. By Theorem 15.6.24, the two operators on S^n have the same index. Moreover, the kernel of $\chi A \chi$ is supported in $\operatorname{supp}\chi \times \operatorname{supp}\chi$, so its Euclidean restriction satisfies the strong condition of Definition 18.4.1. This construction allows realizations with strong support to be used in the stable theory described in [21, p. 275]. The compactness comparison has been made on S^n; equality of principal symbols alone does not allow it to be applied to an arbitrary quantization on $\mathbb{R}^n$.

In this compactification, if $P \in \mathrm{Ell}_c^0(\mathbb{R}^n)$, equality with the identity near infinity allows it to be extended by I to

an elliptic pseudodifferential operator

$$\overline{P} \in \Psi^0_{\mathrm{cl}}(S^n).$$

Equality holds exactly on a neighborhood of ∞, so restriction and extension identify the kernels of P and $\overline{P}$, as well as those of their adjoints. Theorem 15.6.22 then gives

$$\operatorname{ind} P = \operatorname{ind} \overline{P}. \tag{18.18}$$

In particular, P is Fredholm on $L^2(\mathbb{R}^n;\mathbb{C}^q)$.

The principal symbol of P gives, by Definition 17.4.1, a class

$$[\sigma(P)] \in K^0_c(T^*\mathbb{R}^n) = K^0_c(\mathbb{R}^{2n}).$$

Its support is compact because the symbol is the identity outside K in the base variable and is invertible in every nonzero cotangent direction. In the relative model it is represented by

$$[\underline{\mathbb{C}}^q, \underline{\mathbb{C}}^q, \sigma_0^{\Psi}(P)|_{S^*\mathbb{R}^n}].$$

Proposition 18.4.2. (Euclidean realization and descent of the index) Every class $a \in K^0_c(T^*\mathbb{R}^n)$ is the symbol class of some $P \in \mathrm{Ell}^0_c(\mathbb{R}^n)$ after stabilization. Moreover, there exists a unique homomorphism

$$I_n : K^0_c(T^*\mathbb{R}^n) \longrightarrow \mathbb{Z} \tag{18.19}$$

such that

$$I_n([\sigma(P)]) = \operatorname{ind} P.$$

Proof. Represent a by a compactly supported triple

$$(\mathbf{E}, \mathbf{F}, \theta)$$

over $T^*\mathbb{R}^n$. Since $T^*\mathbb{R}^n \cong \mathbb{R}^{2n}$ is contractible, after adding an elementary triple we may assume that $\mathbf{E}$ and $\mathbf{F}$ are trivial bundles of the same rank.

Extend a by zero to the cotangent bundle of $S^n = \mathbb{R}^n \cup \{\infty\}$. In the relative model, choose a representative over (B^*S^n, S^*S^n) elementary over T^*U for a neighborhood U of ∞. The relative proof of Theorem 17.4.3 allows us to smooth it without changing that neighborhood. After stabilizing and fixing the elementary trivialization there, we obtain an elliptic symbol of order zero that is exactly the identity over T^*U.

Let us construct the operator representing this class. Let $a_0(x,\xi)$ be the resulting homogeneous symbol, equal to I when x is near ∞. Theorem 15.3.7 gives a quantization A with principal symbol a_0. Choose $\chi \in C^\infty_c(\mathbb{R}^n)$ equal to 1 on the projection to the base of $\operatorname{supp}(a_0 - I)$ and define

$$P := I + \chi(A - I)\chi.$$

Its principal symbol is

$$I + \chi(x)^2(a_0(x,\xi) - I) = a_0(x,\xi),$$

because $a_0 - I$ vanishes where $\chi \neq 1$. Without imposing an additional condition on quantization, the two

multiplications by χ show directly that the Schwartz kernel of $P - I$ is contained in $K \times K$, with $K = \operatorname{supp} \chi$. Therefore, $P \in \mathrm{Ell}_c^0(\mathbb{R}^n)$ and $[\sigma(P)] = a$.

To prove that the index descends to K–theory, all the relative information of the triple must be retained; an isomorphism of triples may depend on ξ and does not automatically become a conjugation of operators. Let a_0 and a_1 be two representatives of the same class. After adding elementary triples, the relations of the relative model provide a parametrized triple over

$$B^*S^n \times [0,1]$$

whose endpoint restrictions are the given representatives and which is elementary over $B^*U \times [0,1]$ for a common neighborhood U of ∞. Relative smoothing keeps this neighborhood fixed. Radial contraction in the fibers of B^*S^n turns the stabilized isomorphisms into bundle isomorphisms over the base, exactly as in the proof of Theorem 17.5.6. Homogeneous extension in the covariable produces a family of elliptic symbols of order zero equal to the identity over T^*U.

Using a single cover, a single partition of unity, and a single cutoff χ, quantization is continuous in the topology of symbols of order zero and, by Calderón–Vaillancourt, continuous in the norm of

$$\mathcal{L}\big(L^2(\mathbb{R}^n;\mathbb{C}^q)\big).$$

Each operator extends to an elliptic operator on S^n. Stability of the Fredholm index gives

$$\operatorname{ind} P_0 = \operatorname{ind} P_1.$$

If the triple is elementary, radial contraction takes it to a bundle isomorphism over the base; its quantization is an isomorphism of order zero plus an operator of order -1 and has index zero. Finally, direct sum of triples is quantized by direct sum of operators, and

$$\operatorname{ind}(P \oplus Q) = \operatorname{ind} P + \operatorname{ind} Q.$$

Thus the index respects the stabilization, homotopy, isomorphism, and addition relations defining $K_c^0(T^*\mathbb{R}^n)$. This determines I_n, and realization of all classes proves its uniqueness. □

The same construction works for families. If Λ is compact Hausdorff and P_λ is a family continuous in the topology of classical symbols of order zero, with a common compact support, then the family is norm-continuous and its principal symbols depend jointly on (x, ξ, λ). Under these hypotheses, the symbols define

$$[\sigma(P_\Lambda)] \in K_c^0(T^*\mathbb{R}^n \times \Lambda). \tag{18.20}$$

Realization of every class and descent of the index bundle will be proved in Proposition 18.7.2. The variable λ is not incorporated into the cotangent variables: it continuously parametrizes the bundles and the symbol isomorphism.

18.5 Two model operators

Periodicity determines the group $K_c^0(T^*\mathbb{R}^n)$, but does not determine the analytic homomorphism I_n until its value on a generator is fixed. We first calculate that value for the class b using a localized Toeplitz operator. We then calculate the oscillator operator representing the opposite class $-b$, which will be the analytic model for the Thom isomorphism.

18.5.1 The localized operator representing b

Let $S^1 \subset \mathbb{C}$ and let

$$e_k(z) = z^k, \qquad k \in \mathbb{Z},$$

be the orthonormal Fourier basis of $L^2(S^1)$. Define

$$H_+ := \overline{\operatorname{span}}\{e_k \mid k \geq 0\}, \qquad H_- := \overline{\operatorname{span}}\{e_k \mid k < 0\},$$

and denote by Π_+ and Π_- the corresponding orthogonal projections. The projection Π_+ is pseudodifferential of order zero: modulo the finite-dimensional projection onto the constants,

$$\Pi_+ = \frac{1}{2}\big(I + \operatorname{sgn} D\big), \qquad D = -i\frac{d}{d\theta},$$

and its principal symbol equals 1 on $\xi > 0$ and 0 on $\xi < 0$.

Let $g : S^1 \longrightarrow S^1$ be a smooth function of degree one equal to 1 on a neighborhood of a point $p \in S^1$. It can be obtained by deforming $z \mapsto z$ through functions of degree one and concentrating all angular variation in an arc disjoint from p. Let M_g be multiplication by g and consider

$$A_g := \Pi_+ M_g \Pi_+ + \Pi_- : L^2(S^1) = H_+ \oplus H_- \longrightarrow L^2(S^1). \tag{18.21}$$

Its principal symbol is

$$\sigma_0^{\Psi}(A_g)(z,\xi) = \begin{cases} g(z), & \xi > 0, \\ 1, & \xi < 0. \end{cases} \tag{18.22}$$

It is invertible and equals 1 over $T^*U \setminus 0$ for some neighborhood U of p. Thus A_g is elliptic.

Lemma 18.5.1. (Index and class of the Bott model) There exists $T_b \in \operatorname{Ell}_c^0(\mathbb{R})$ such that

$$[\sigma(T_b)] = b, \qquad \operatorname{ind} T_b = -1.$$

Proof. We begin with the index of (18.21). A smooth homotopy g_t between $g_0(z) = z$ and $g_1 = g$ gives, through (18.21), a norm-continuous family of elliptic operators. Its index is constant. For $g_0(z) = z$ we have

$$A_{g_0} e_k = \begin{cases} e_{k+1}, & k \geq 0, \\ e_k, & k < 0. \end{cases}$$

Thus

$$\ker A_{g_0} = \{0\}, \qquad \operatorname{Ran} A_{g_0} = \{e_0\}^{\perp},$$

and consequently

$$\operatorname{ind} A_g = \operatorname{ind} A_{g_0} = -1. \tag{18.23}$$

Choose $\chi \in C^\infty(S^1)$ with support disjoint from p, equal to 1 on the support of $g-1$, and define

$$\widetilde{T}_b := I + \chi(A_g - I)\chi.$$

By (18.22), $\widetilde{T}_b$ and A_g have the same principal symbol. Their difference has order -1 on the closed manifold S^1 and is therefore compact on $L^2(S^1)$. By Theorem 15.6.24,

$$\operatorname{ind} \widetilde{T}_b = -1.$$

Moreover, the kernel of $\widetilde{T}_b - I$ is contained in $\operatorname{supp}\chi \times \operatorname{supp}\chi$. Removing the point p and identifying $S^1 \setminus \{p\}$ with $\mathbb{R}$ gives an operator $T_b \in \mathrm{Ell}^0_c(\mathbb{R})$ with the same index.
It remains to identify its class. Compactify the phase plane $T^*\mathbb{R} \cong \mathbb{R}_x \times \mathbb{R}_\xi$ using a large rectangle. On the lower side, on the two vertical sides, and outside the support of $g-1$, the symbol is 1. On the upper side it is $g(x)$. The positive orientation of the boundary traverses the upper side from $x = +R$ to $x = -R$. Since g has degree one when x is traversed from $-R$ to $+R$, the gluing along the boundary has degree -1. By Definition 18.1.1, the glued bundle is $\mathbf{E}_{-1}$ and

$$[\sigma(T_b)] = [\mathbf{E}_{-1}] - [\underline{\mathbb{C}}] = b.$$

□

The preceding proof does not invoke a general Toeplitz index formula: the only index calculated reduces to that of the unilateral shift. With the conventions already specified, the argument agrees with the normalization of [21, proof of Theorem 11.5, pp. 281–282].

18.5.2 The oscillator and the Thom class

On $L^2(\mathbb{R})$ consider the closed operators

$$B^+ u = \frac{du}{dx} + xu, \qquad B^- v = -\frac{dv}{dx} + xv, \tag{18.24}$$

with common domain

$$\mathcal{D} := \{u \in H^1(\mathbb{R}) \mid xu \in L^2(\mathbb{R})\}.$$

The space $C_c^\infty(\mathbb{R})$ is dense in $\mathcal{D}$ for the norm

$$\|u\|_{\mathcal{D}} := \|u\|_{L^2(\mathbb{R})} + \left\|\frac{du}{dx}\right\|_{L^2(\mathbb{R})} + \|xu\|_{L^2(\mathbb{R})}.$$

To justify density, fix $\chi \in C_c^\infty(\mathbb{R})$, $0 \le \chi \le 1$, equal to one on $[-1,1]$, and set $\chi_R(x) = \chi(x/R)$. For $v \in \mathcal{D}$, $\chi_R v \to v$ in $L^2(\mathbb{R})$ and $x\chi_R v \to xv$ in $L^2(\mathbb{R})$ by dominated convergence. Moreover,

$$(\chi_R v)' - v' = (\chi_R - 1)v' + \chi_R' v, \qquad \|\chi_R' v\|_{L^2(\mathbb{R})} \le R^{-1}\|\chi'\|_{L^\infty(\mathbb{R})}\|v\|_{L^2(\mathbb{R})},$$

so $\chi_R v \to v$ in $\mathcal{D}$. For fixed R, convolution regularizations of $\chi_R v$ converge in $H^1(\mathbb{R})$, and their supports remain in a fixed compact interval. On that interval, multiplication by x is bounded on $L^2(\mathbb{R})$, so they also converge in $\mathcal{D}$. Choosing successively $R \to \infty$ and convolution radii producing errors smaller than $1/R$ gives a sequence in $C_c^\infty(\mathbb{R})$ converging in $\mathcal{D}$.

Proposition 18.5.2. (Index of the Thom oscillator) The operator $B^+ : \mathcal{D} \longrightarrow L^2(\mathbb{R})$ is Fredholm and

$$\ker B^+ = \operatorname{span}\{e^{-\frac{x^2}{2}}\}, \qquad \ker B^- = \{0\}, \qquad \operatorname{ind} B^+ = 1.$$

Its elliptic total symbol in the phase plane is $x + i\xi$ and represents

$$[\sigma(B^+)] = -b = \lambda_{\mathbb{C}}.$$

Proof. First we prove that

$$\operatorname{Dom}\big((B^+)^*\big) = \mathcal{D}, \qquad (B^+)^* = B^-. \tag{18.25}$$

Let $v \in \operatorname{Dom}((B^+)^*)$. There then exists $f \in L^2(\mathbb{R})$ such that

$$\int_{\mathbb{R}} \left(\frac{du}{dx} + xu\right) \overline{v}\, dx = \int_{\mathbb{R}} u\overline{f}\, dx, \qquad u \in C_c^\infty(\mathbb{R}).$$

In the distributional sense,

$$-\frac{dv}{dx} + xv = f. \tag{18.26}$$

Since $xv \in L^2_{\mathrm{loc}}(\mathbb{R})$, this identity implies $v \in H^1_{\mathrm{loc}}(\mathbb{R})$.
Fix $\chi \in C_c^\infty(\mathbb{R})$ with $0 \le \chi \le 1$, $\chi = 1$ on $[-1,1]$, and $\operatorname{supp}\chi \subset [-2,2]$, and set $\chi_R(x) = \chi\left(\frac{x}{R}\right)$ for $R \ge 1$. The function $w_R := \chi_R v$ belongs to $\mathcal{D}$ and

$$B^- w_R = \chi_R f - \chi_R' v. \tag{18.27}$$

For every compactly supported $w \in \mathcal{D}$, integration by parts gives

$$\|B^- w\|^2_{L^2(\mathbb{R})} = \left\|\frac{dw}{dx}\right\|^2_{L^2(\mathbb{R})} + \|xw\|^2_{L^2(\mathbb{R})} + \|w\|^2_{L^2(\mathbb{R})}. \tag{18.28}$$

Applied to w_R and combined with (18.27), this equality yields the uniform bound

$$\|x\chi_R v\|^2_{L^2(\mathbb{R})} \le 2\|f\|^2_{L^2(\mathbb{R})} + \frac{2\|\chi'\|^2_{L^\infty(\mathbb{R})}}{R^2}\|v\|^2_{L^2(\mathbb{R})}. \tag{18.29}$$

Fatou's lemma, applied as $R \to \infty$, shows that $xv \in L^2(\mathbb{R})$. The equation (18.26) then gives

$$\frac{dv}{dx} = xv - f \in L^2(\mathbb{R}),$$

so $v \in \mathcal{D}$. The reverse inclusion follows by integrating by parts, now with both sides in $L^2(\mathbb{R})$, and proves (18.25).

The same argument shows that $(B^-)^* = B^+$ with domain $\mathcal{D}$. Indeed, if $B^+u = g$ distributionally, then

$$\left\|\frac{dw}{dx}\right\|^2_{L^2(\mathbb{R})} + \|xw\|^2_{L^2(\mathbb{R})} = \|B^+w\|^2_{L^2(\mathbb{R})} + \|w\|^2_{L^2(\mathbb{R})}$$

for $w = \chi_R u$; the same passage to the limit gives $xu \in L^2(\mathbb{R})$ and $\frac{du}{dx} = g - xu \in L^2(\mathbb{R})$. In particular, B^+ and B^- are closed operators and are adjoints of one another.
The homogeneous equations can be integrated directly:

$$B^+u = 0 \quad \Longleftrightarrow \quad u(x) = Ce^{-\frac{x^2}{2}},$$

whereas

$$B^-v = 0 \quad \Longleftrightarrow \quad v(x) = Ce^{\frac{x^2}{2}}.$$

Only the first solution belongs to $L^2(\mathbb{R})$.
For $v \in C^\infty_c(\mathbb{R})$, identity (18.28) reads

$$\|B^-v\|^2_{L^2(\mathbb{R})} = \int_{\mathbb{R}} \left|-\frac{dv}{dx} + xv\right|^2 dx \tag{18.30}$$

$$= \left\|\frac{dv}{dx}\right\|^2_{L^2(\mathbb{R})} + \|xv\|^2_{L^2(\mathbb{R})} + \|v\|^2_{L^2(\mathbb{R})}. \tag{18.31}$$

The approximation in the norm of $\mathcal{D}$ constructed before the proposition preserves convergence of v, v', and xv simultaneously in $L^2(\mathbb{R})$. Since $B^-v = -v' + xv$, all terms in (18.31) converge and the identity holds on $\mathcal{D}$. In particular, B^- is bounded below by 1 and has closed range. The closed range theorem applied to the adjoint pair B^+, B^- implies that $\operatorname{Ran} B^+$ is closed. Moreover,

$$(\operatorname{Ran} B^+)^\perp = \ker B^- = \{0\},$$

so B^+ is surjective. Its kernel has dimension one and its cokernel is zero; this proves that its index is 1.
With the Fourier normalization $\widehat{\frac{du}{dx}}(\xi) = i\xi\,\widehat{u}(\xi)$, the total symbol is $x + i\xi$. Its restriction to a large circle has degree one. By the same gluing calculation as in the preceding proof, now with the usual orientation of the circle, it represents $[E_1] - [\underline{\mathbb{C}}] = -b$. Equality with $\lambda_{\mathbb{C}}$ is (18.7). □

The oscillator does not belong to $\mathrm{Ell}^0_c(\mathbb{R})$: it is an unbounded operator. It does not have compact resolvent; in fact, $e^{\lambda x - \frac{x^2}{2}} \in \mathcal{D}$ and, for every $\lambda \in \mathbb{C}$,

$$B^+ e^{\lambda x - \frac{x^2}{2}} = \lambda e^{\lambda x - \frac{x^2}{2}}.$$

The self-adjoint supersymmetric operator

$$\mathscr{B} = \begin{pmatrix} 0 & B^- \\ B^+ & 0 \end{pmatrix}$$

does have compact resolvent, since $\mathscr{B}^2$ is the sum of the two scalar harmonic oscillators. The role of B^+ is to realize the Thom class analytically, not to replace the model T_b. The comparison

$$\operatorname{ind} T_b = -1, \qquad \operatorname{ind} B^+ = 1$$

confirms that T_b represents b and B^+ represents $-b$.

18.6 Products of operators and multiplicativity of the index

Reducing dimension n to the one-dimensional case requires checking that external product of classes corresponds to a product of operators and that their indices multiply. A subtlety cannot be omitted: although operators acting separately in each variable are well defined on the Hilbert tensor product, in general they are not classical pseudodifferential operators on the product manifold. This phenomenon is explained in [21, Exercise 9.20, pp. 243–244]. First we calculate the index of the matrix on Hilbert spaces and then regularize it using angular cutoffs.

Let

$$P : H_E^+ \longrightarrow H_E^-, \qquad Q : H_F^+ \longrightarrow H_F^-$$

be bounded Fredholm operators between complex Hilbert spaces. On the Hilbert tensor products define

$$P\#Q := \begin{pmatrix} P\otimes I & -I\otimes Q^* \\ I\otimes Q & P^*\otimes I \end{pmatrix}, \tag{18.32}$$

with domain and codomain

$$H^{\mathrm{ev}} := (H_E^+ \widehat{\otimes} H_F^+) \oplus (H_E^- \widehat{\otimes} H_F^-),$$
$$H^{\mathrm{odd}} := (H_E^- \widehat{\otimes} H_F^+) \oplus (H_E^+ \widehat{\otimes} H_F^-).$$

Proposition 18.6.1. (Product of Fredholm operators) The operator $P\#Q : H^{\mathrm{ev}} \longrightarrow H^{\mathrm{odd}}$ is Fredholm and

$$\operatorname{ind}(P\#Q) = \operatorname{ind} P \operatorname{ind} Q. \tag{18.33}$$

Proof. Multiplying the matrices in (18.32) and using the fact that operators acting on different factors commute yields

$$(P\#Q)^*(P\#Q) = \begin{pmatrix} P^*P\otimes I + I\otimes Q^*Q & 0 \\ 0 & PP^*\otimes I + I\otimes QQ^* \end{pmatrix}, \tag{18.34}$$

$$(P\#Q)(P\#Q)^* = \begin{pmatrix} PP^*\otimes I + I\otimes Q^*Q & 0 \\ 0 & P^*P\otimes I + I\otimes QQ^* \end{pmatrix}. \tag{18.35}$$

Each summand is nonnegative. If $\mathcal{H}_A, \mathcal{H}_B$ are Hilbert spaces and $A \in \mathcal{L}(\mathcal{H}_A)$, $B \in \mathcal{L}(\mathcal{H}_B)$ are nonnegative, then, on $\mathcal{H}_A \widehat{\otimes} \mathcal{H}_B$,

$$\ker(A\otimes I + I\otimes B) = \ker A \widehat{\otimes} \ker B;$$

indeed, for $u \in \mathcal{H}_A \widehat{\otimes} \mathcal{H}_B$,

$$\langle (A\otimes I + I\otimes B)u, u\rangle_{\mathcal{H}_A\widehat{\otimes}\mathcal{H}_B} = \|(A^{\frac{1}{2}}\otimes I)u\|^2_{\mathcal{H}_A\widehat{\otimes}\mathcal{H}_B} + \|(I\otimes B^{\frac{1}{2}})u\|^2_{\mathcal{H}_A\widehat{\otimes}\mathcal{H}_B}.$$

Since P and Q are Fredholm, their restrictions to the orthogonal complements of their kernels are bounded below. The sums in (18.34) and (18.35) are therefore bounded below on the complements of their finite-dimensional kernels. This proves that $P\#Q$ has closed range and finite-dimensional kernels.

The kernel formulas are

$$\ker(P\#Q) \cong (\ker P \widehat{\otimes} \ker Q) \oplus (\ker P^* \widehat{\otimes} \ker Q^*),$$
$$\ker(P\#Q)^* \cong (\ker P^* \widehat{\otimes} \ker Q) \oplus (\ker P \widehat{\otimes} \ker Q^*).$$

If

$$a = \dim\ker P, \quad b_0 = \dim\ker P^*, \quad c = \dim\ker Q, \quad d = \dim\ker Q^*,$$

then

$$\operatorname{ind}(P\#Q) = (ac + b_0 d) - (b_0 c + ad) = (a - b_0)(c - d),$$

which proves (18.33). □

The preceding matrix cannot simply be declared classical pseudodifferential on a product. To obtain a classical matrix while preserving its index, we first raise the order. Let (X, g_X) and (Y, g_Y) be closed Riemannian manifolds and let

$$P \in \Psi^0_{\mathrm{cl}}(X; \mathbb{C}^q), \qquad Q \in \Psi^0_{\mathrm{cl}}(Y; \mathbb{C}^r)$$

be elliptic. Choose nonnegative scalar Laplacians Δ_X and Δ_Y and set

$$\Lambda_{X,q} = (I + \Delta_X)^{\frac{1}{2}} \otimes I_{\mathbb{C}^q}, \qquad \Lambda_{Y,r} = (I + \Delta_Y)^{\frac{1}{2}} \otimes I_{\mathbb{C}^r}.$$

By Theorem 15.7.9, these are positive classical operators of order one and define isomorphisms

$$\Lambda_{X,q} : H^1(X; \mathbb{C}^q) \longrightarrow L^2(X; \mathbb{C}^q), \qquad \Lambda_{Y,r} : H^1(Y; \mathbb{C}^r) \longrightarrow L^2(Y; \mathbb{C}^r).$$

The operators

$$A := P\Lambda_{X,q} \in \Psi^1_{\mathrm{cl}}(X; \mathbb{C}^q), \qquad B := Q\Lambda_{Y,r} \in \Psi^1_{\mathrm{cl}}(Y; \mathbb{C}^r) \tag{18.36}$$

are elliptic of order one and

$$\operatorname{ind} A = \operatorname{ind} P, \qquad \operatorname{ind} B = \operatorname{ind} Q. \tag{18.37}$$

Define

$$\mathcal{D} \colon C^\infty(X \times Y; \mathbb{C}^{qr})^{\oplus 2} \longrightarrow C^\infty(X \times Y; \mathbb{C}^{qr})^{\oplus 2}, \qquad \mathcal{D} := A\#B = \begin{pmatrix} A \otimes I_{\mathbb{C}^r} & -I_{\mathbb{C}^q} \otimes B^* \\ I_{\mathbb{C}^q} \otimes B & A^* \otimes I_{\mathbb{C}^r} \end{pmatrix}. \tag{18.38}$$

Its closure, as an operator on $L^2(X \times Y; \mathbb{C}^{qr})^{\oplus 2}$, has domain $H^1(X \times Y; \mathbb{C}^{qr})^{\oplus 2}$. Indeed, if $\mathcal{L}_X := \Lambda_{X,q} \otimes I_{\mathbb{C}^r}$ and $\mathcal{L}_Y := I_{\mathbb{C}^q} \otimes \Lambda_{Y,r}$, then

$$\mathcal{L} := (\mathcal{L}_X^2 + \mathcal{L}_Y^2)^{\frac{1}{2}} : H^1(X \times Y; \mathbb{C}^{qr}) \longrightarrow L^2(X \times Y; \mathbb{C}^{qr}) \tag{18.39}$$

is an isomorphism, and the same holds for $\mathcal{L}^{\oplus 2}$. The elliptic estimates for A and B show that the graph norm of $\mathcal{D}$ is equivalent to that of $H^1(X \times Y; \mathbb{C}^{qr})^{\oplus 2}$.

The calculation in Proposition 18.6.1 remains valid for these closed operators. The squares A^*A, AA^*, B^*B, and BB^* now have compact resolvent. The spectral theorem applied to

$$\mathcal{D}^*\mathcal{D} = \begin{pmatrix} A^*A \otimes I + I \otimes B^*B & 0 \\ 0 & AA^* \otimes I + I \otimes BB^* \end{pmatrix}, \tag{18.40}$$

$$\mathcal{D}\mathcal{D}^* = \begin{pmatrix} AA^* \otimes I + I \otimes B^*B & 0 \\ 0 & A^*A \otimes I + I \otimes BB^* \end{pmatrix} \tag{18.41}$$

gives the same four kernel formulas as in the preceding proof. In particular,

$$\operatorname{ind} \mathcal{D} = \operatorname{ind} A \operatorname{ind} B = \operatorname{ind} P \operatorname{ind} Q. \tag{18.42}$$

The approximation we need is constructed within the ordinary pseudodifferential calculus on the product. In this way we do not assume that an operator defined by spectral calculus in the two variables is automatically an isotropic pseudodifferential operator.

Lemma 18.6.2. (Angular microlocal cutoffs) Fix finite atlases $\{U_i\}_{i\in I}$ of X and $\{V_j\}_{j\in J}$ of Y, together with real functions

$$\alpha_i \in C_c^\infty(U_i), \qquad \beta_j \in C_c^\infty(V_j), \qquad \sum_{i\in I} \alpha_i^2 = 1, \qquad \sum_{j\in J} \beta_j^2 = 1.$$

There is a choice, depending only on these data, of scalar operators

$$Q_R^X, Q_R^Y \in \Psi^0_{\mathrm{cl}}(X \times Y), \qquad R > 2,$$

with the following property. If $T \in \Psi^1_{\mathrm{cl}}(X; \mathbb{C}^d)$ and $S \in \Psi^1_{\mathrm{cl}}(Y; \mathbb{C}^e)$, extend Q_R^X, Q_R^Y diagonally to $\mathbb{C}^{de}$ and set

$$\mathfrak{K}_R^X(T) := (T \otimes I_{\mathbb{C}^e}) Q_R^X, \qquad \mathfrak{K}_R^Y(S) := (I_{\mathbb{C}^d} \otimes S) Q_R^Y \tag{18.43}$$

These operators belong to $\Psi^1_{\mathrm{cl}}(X \times Y; \mathbb{C}^{de})$ and satisfy

$$\left\| \mathfrak{K}_R^X(T) - T \otimes I_{\mathbb{C}^e} \right\|_{\mathcal{L}(H^1(X\times Y;\mathbb{C}^{de}), L^2(X\times Y;\mathbb{C}^{de}))} \leq \frac{C_T}{R}, \tag{18.44}$$

$$\left\| \mathfrak{K}_R^Y(S) - I_{\mathbb{C}^d} \otimes S \right\|_{\mathcal{L}(H^1(X\times Y;\mathbb{C}^{de}), L^2(X\times Y;\mathbb{C}^{de}))} \leq \frac{C_S}{R}. \tag{18.45}$$

Let $|\xi|_i$ be the Euclidean norm of the components of $\xi \in T_x^*X$ in the chart U_i, and define $|\eta|_j$ similarly. In each summand of the following formulas, these norms are used only on $\operatorname{supp} \alpha_i \times \operatorname{supp} \beta_j$. The principal symbols of T and S are denoted, respectively, by

$$t_1(x,\xi) := \sigma_1^\Psi(T)(x,\xi), \qquad s_1(y,\eta) := \sigma_1^\Psi(S)(y,\eta),$$

and are understood to be lifted to $T^*(X \times Y)$ in the region where their own covariable does not vanish. The principal symbols of the two cutoff operators are

$$\Phi_R(x,y,\xi,\eta) := \sum_{(i,j)\in I\times J} \alpha_i(x)^2 \beta_j(y)^2 \chi\left(\frac{|\eta|_j}{R|\xi|_i} \right), \tag{18.46}$$

$$\Psi_R(x,y,\xi,\eta) := \sum_{(i,j)\in I\times J} \alpha_i(x)^2 \beta_j(y)^2 \chi\left(\frac{|\xi|_i}{R|\eta|_j} \right). \tag{18.47}$$

Here $\chi \in C^\infty([0,\infty),[0,1])$ equals 1 on $[0,1]$, is positive on $[0,2)$, and equals 0 on $[2,\infty)$. On the axis $\xi = 0$, the summand of (18.46) is defined to be 0, and on the axis $\eta = 0$ to be 1; for (18.47) the opposite convention

is used. In particular,

$$\sigma_1^{\Psi}\big(\mathfrak{R}_R^X(T)\big) = \Phi_R t_1, \qquad \sigma_1^{\Psi}\big(\mathfrak{R}_R^Y(S)\big) = \Psi_R s_1. \tag{18.48}$$

The products in (18.48) extend smoothly by zero to the axis of the corresponding covariable: the factor Φ_R is identically zero on a conic neighborhood of $\xi = 0$ when $\eta \neq 0$, and Ψ_R has the symmetric property.

Proof. Set $\lambda_{ij}(x,y) := \alpha_i(x)\beta_j(y)$. Identify $U_i \times V_j$ with an open subset of $\mathbb{R}^{m+k}$ and write

$$\langle \xi \rangle_i = (1 + |\xi|_i^2)^{\frac{1}{2}}, \qquad \langle \eta \rangle_j = (1 + |\eta|_j^2)^{\frac{1}{2}}.$$

Let $M_{ij,R}^X$ and $M_{ij,R}^Y$ be the Fourier multipliers in this product chart with full symbols

$$\vartheta_{ij,R}^X(\xi,\eta) := \chi\left(\frac{\langle \eta \rangle_j}{R\langle \xi \rangle_i}\right), \tag{18.49}$$

$$\vartheta_{ij,R}^Y(\xi,\eta) := \chi\left(\frac{\langle \xi \rangle_i}{R\langle \eta \rangle_j}\right). \tag{18.50}$$

Multiplication by λ_{ij} before and after the multiplier makes its extension by zero outside the chart well defined. Take

$$Q_R^X := \sum_{(i,j)\in I\times J} \lambda_{ij} M_{ij,R}^X \lambda_{ij}, \qquad Q_R^Y := \sum_{(i,j)\in I\times J} \lambda_{ij} M_{ij,R}^Y \lambda_{ij}. \tag{18.51}$$

If all multipliers in (18.51) are replaced by the identity, the result is exactly the identity, since

$$\sum_{(i,j)\in I\times J} \lambda_{ij}^2 = \left(\sum_{i\in I} \alpha_i^2\right)\left(\sum_{j\in J} \beta_j^2\right) = 1. \tag{18.52}$$

For fixed R, the symbols of (18.49) and (18.50) are classical of order zero. We verify this for the first. If $\xi \neq 0$ and $\eta \neq 0$, then

$$\frac{\langle t\eta \rangle_j}{R\langle t\xi \rangle_i} \sim \frac{|\eta|_j}{R|\xi|_i}\left(1 + \sum_{\ell=1}^{\infty} c_{\ell,ij}(\xi,\eta) t^{-2\ell}\right), \qquad t \longrightarrow \infty. \tag{18.53}$$

Taylor's formula for χ gives a homogeneous expansion of degrees $0, -2, -4, \ldots$. Its coefficients extend smoothly to the axes: near $\{\xi = 0,\ \eta \neq 0\}$ the cutoff is identically zero, and near $\{\eta = 0,\ \xi \neq 0\}$ it is identically one. The homogeneous term of degree zero is

$$\chi\left(\frac{|\eta|_j}{R|\xi|_i}\right).$$

The same proof, with variables interchanged, applies to the second symbol. Thus Q_R^X and Q_R^Y are classical operators of order zero, with principal symbols Φ_R and Ψ_R, respectively.

We must check that the compositions in (18.43) belong to the isotropic calculus; this does not follow merely from Q_R^X and Q_R^Y being pseudodifferential operators. Consider Q_R^X. In a chart, the symbol of every summand of (18.51), modulo $S^{-\infty}$, has an expansion whose terms contain a derivative of $\vartheta_{ij,R}^X$. All these terms are supported in

$$\langle \eta \rangle_j \leq 2R\langle \xi \rangle_i, \qquad \langle (\xi,\eta) \rangle \leq C_R \langle \xi \rangle_i. \tag{18.54}$$

Asymptotic summation can be performed after multiplication by a cutoff equal to 1 on this cone; it therefore retains support in a slightly larger cone, up to a remainder in $S^{-\infty}$.

Use a finite partition to decompose the kernel of T into a part near the diagonal and a smooth part. For the first part, the composition formula contains terms

$$\frac{1}{\gamma!}\partial_\xi^\gamma t(x,\xi)D_x^\gamma q_{ij,R}(x,y,\xi,\eta), \tag{18.55}$$

where $q_{ij,R}$ is a full symbol of the corresponding summand of Q_R^X. On the cone (18.54), the estimates for t with respect to ξ become isotropic estimates of order one with respect to (ξ,η). The remainder formula, integrated by parts in the chart variables, gives the same estimates. The smooth part of the kernel of T has rapidly decreasing transform in ξ; since $|\eta|_j \le C_R\langle\xi\rangle_i$ on the support of the cutoff, its composition is rapidly decreasing in (ξ,η). This proves that $(T\otimes I_{\mathbb{C}^e})Q_R^X$ is classical of order one. Moreover, the first term in (18.55) proves the first equality in (18.48). The proof for $(I_{\mathbb{C}^d}\otimes S)Q_R^Y$ is symmetric.

The norm estimate remains. From (18.52) we obtain the exact identity

$$Q_R^X - I = \sum_{(i,j)\in I\times J} \lambda_{ij}(M_{ij,R}^X - I)\lambda_{ij}. \tag{18.56}$$

Let $u \in H^1(X\times Y;\mathbb{C}^{de})$ and let v be the coordinate expression, with values in $\mathbb{C}^{de}$, of $\lambda_{ij}u$. The factor $1-\vartheta_{ij,R}^X$ can be nonzero only when $\langle\eta\rangle_j > R\langle\xi\rangle_i$. By Plancherel,

$$\begin{aligned}
&\left\|(M_{ij,R}^X - I)v\right\|^2_{H^1(\mathbb{R}_x^m;L^2(\mathbb{R}_y^k;\mathbb{C}^{de}))}\\
&\quad= \int_{\mathbb{R}^k}\int_{\mathbb{R}^m} \langle\xi\rangle_i^2 |1-\vartheta_{ij,R}^X(\xi,\eta)|^2 |\widehat{v}(\xi,\eta)|^2_{\mathbb{C}^{de}}\,d\xi\,d\eta\\
&\quad\le \frac{1}{R^2}\int_{\mathbb{R}^k}\int_{\mathbb{R}^m} \langle\eta\rangle_j^2 |\widehat{v}(\xi,\eta)|^2_{\mathbb{C}^{de}}\,d\xi\,d\eta = \frac{1}{R^2}\|v\|^2_{L^2(\mathbb{R}_x^m;H^1(\mathbb{R}_y^k;\mathbb{C}^{de}))}.
\end{aligned} \tag{18.57}$$

Suppressing the chart identifications from the notation, we have

$$(T\otimes I_{\mathbb{C}^e})(Q_R^X - I)u = \sum_{(i,j)\in I\times J} (T\alpha_i\otimes\beta_j I_{\mathbb{C}^e})(M_{ij,R}^X - I)(\lambda_{ij}u). \tag{18.58}$$

The operator $T\alpha_i : H^1(X;\mathbb{C}^d)\to L^2(X;\mathbb{C}^d)$ is bounded. Multiplications by α_i and β_j, changes of coordinates, and their inverses are bounded on the Sobolev spaces appearing in (18.57). Applying $T\alpha_i$ for every value of y and using Fubini yields

$$\|(T\alpha_i\otimes\beta_j I_{\mathbb{C}^e})w\|_{L^2(X\times Y;\mathbb{C}^{de})} \le C_{ij}\|w\|_{H^1(\mathbb{R}_x^m;L^2(\mathbb{R}_y^k;\mathbb{C}^{de}))}.$$

Since the covers are finite, (18.56) and (18.57) give (18.44), with a constant independent of R. Interchanging X and Y gives (18.45). □

The two principal symbols constructed with the same atlas do not vanish simultaneously. Indeed, every summand of Φ_R and Ψ_R is nonnegative, and the weights $\alpha_i^2\beta_j^2$ sum to 1. First suppose that $\xi\neq 0$ and $\eta\neq 0$. If $\Phi_R = 0$, then for every active pair we have

$$\frac{|\eta|_j}{R|\xi|_i} \ge 2.$$

Therefore,

$$\frac{|\xi|_i}{R|\eta|_j} \le \frac{1}{2R^2} < 1$$

for every active pair. All cutoffs occurring in Ψ_R equal 1, whence $\Psi_R = 1$. The same reasoning with the variables interchanged shows that $\Psi_R = 0$ implies $\Phi_R = 1$. On the axes, the conclusion follows directly from the conventions in (18.46) and (18.47).

Apply the lemma to A, A^*, B, and B^* and define

$$\mathcal{D}_R := \begin{pmatrix} \mathfrak{K}_R^X(A) & -\mathfrak{K}_R^Y(B^*) \\ \mathfrak{K}_R^Y(B) & \mathfrak{K}_R^X(A^*) \end{pmatrix}. \tag{18.59}$$

This is an operator

$$\mathcal{D}_R \in \Psi^1_{\mathrm{cl}}(X \times Y; \mathbb{C}^{2qr}).$$

The four estimates in the lemma give

$$\|\mathcal{D}_R - \mathcal{D}\|_{\mathcal{L}(H^1(X\times Y;\mathbb{C}^{qr})^{\oplus 2}, L^2(X\times Y;\mathbb{C}^{qr})^{\oplus 2})} \le \frac{C}{R}. \tag{18.60}$$

Since $\mathcal{D}$ is Fredholm, openness of the set of Fredholm operators implies that, for R sufficiently large,

$$\operatorname{ind} \mathcal{D}_R = \operatorname{ind} \mathcal{D} = \operatorname{ind} P \operatorname{ind} Q. \tag{18.61}$$

It remains to check that the symbol of $\mathcal{D}_R$ is the product complex. Let $a_1(x,\xi)$ and $b_1(y,\eta)$ be the principal symbols of A and B. The full principal symbol is

$$c_R(x,y,\xi,\eta) = \begin{pmatrix} \Phi_R a_1 \otimes I & -\Psi_R I \otimes b_1^* \\ \Psi_R I \otimes b_1 & \Phi_R a_1^* \otimes I \end{pmatrix}. \tag{18.62}$$

Matrix multiplication gives

$$c_R^* c_R = \begin{pmatrix} \Phi_R^2 a_1^* a_1 \otimes I + \Psi_R^2 I \otimes b_1^* b_1 & 0 \\ 0 & \Psi_R^2 I \otimes b_1 b_1^* + \Phi_R^2 a_1 a_1^* \otimes I \end{pmatrix}. \tag{18.63}$$

Let $(\xi,\eta) \neq (0,0)$. If $\xi \neq 0$ and $\Phi_R > 0$, ellipticity of a_1 makes the contribution containing $a_1^* a_1$ in the first diagonal entry and that containing $a_1 a_1^*$ in the second positive definite. If $\xi = 0$ or $\Phi_R = 0$, then $\eta \neq 0$ and $\Psi_R = 1$ by the preceding property; ellipticity of b_1 makes the remaining contributions positive definite. Thus both diagonal entries of (18.63) are positive definite on the entire punctured cotangent bundle. Compactness of the cosphere bundle of $X \times Y$ gives a uniform lower bound, so c_R is elliptic.

To identify the class, a continuous homotopy of exact complexes over the cosphere bundle suffices, as this is one of the relations defining K_c^0; we do not assert that its intermediate terms are classical symbols. Extend a_1 and b_1 continuously by zero on the axes of their covariables. For $t < 1$ these extensions may be merely continuous on the axes, which suffices for this topological homotopy. Set

$$\Phi_{R,t} := (1-t) + t\Phi_R, \qquad \Psi_{R,t} := (1-t) + t\Psi_R, \qquad 0 \le t \le 1,$$

and replace Φ_R, Ψ_R by $\Phi_{R,t}, \Psi_{R,t}$ in (18.62). For $t < 1$ both coefficients are positive. For $t = 1$ they do not vanish

simultaneously. The calculation in (18.63) proves that the entire continuous family of complexes is invertible away from the zero section. At $t = 0$ we obtain

$$a_1 \# b_1 = \begin{pmatrix} a_1 \otimes I & -I \otimes b_1^* \\ I \otimes b_1 & a_1^* \otimes I \end{pmatrix}, \tag{18.64}$$

which is the tensor product complex of the two complexes of length one. This matrix expresses the sign rule for the product of complexes described in [21, Remark 11.3, pp. 278–279]. Proposition 17.3.1 and homotopy invariance therefore give

$$[c_R] = [\sigma(P)] \boxtimes [\sigma(Q)]. \tag{18.65}$$

Multiplication by the positive symbols of Λ_X and Λ_Y does not change the classes of P and Q. This argument is the Euclidean version of the cutoffs c_{r_0} used in the proof of the multiplicative property in [21, pp. 294–301]; raising the order to one beforehand also makes possible the norm comparison (18.60).

Finally,

$$C_R := \mathcal{D}_R(\mathcal{L}^{-1})^{\oplus 2} \in \Psi^0_{\mathrm{cl}}(X \times Y; \mathbb{C}^{2qr}) \tag{18.66}$$

has the same index as $\mathcal{D}_R$. Its symbol is obtained by dividing c_R by the positive function $\sqrt{|\xi|^2_{\mathbf{g}_X} + |\eta|^2_{\mathbf{g}_Y}}$; this division also leaves the class (18.65) unchanged.

Apply the construction to $P \in \mathrm{Ell}^0_c(\mathbb{R}^m)$ and $Q \in \mathrm{Ell}^0_c(\mathbb{R}^k)$. Extend them by the identity to $X = S^m$ and $Y = S^k$. The class on the right-hand side of (18.65) is compactly supported inside

$$T^*(\mathbb{R}^m \times \mathbb{R}^k) = T^*\mathbb{R}^{m+k}.$$

The relative realization of Proposition 18.4.2 allows us to stabilize the complex, deform it while keeping it fixed on a compact set to the identity near the divisor

$$(\{\infty\} \times S^k) \cup (S^m \times \{\infty\})$$

and quantize the homotopy. If ρ equals 1 on the projection of the symbol support, the final replacement

$$\widetilde{C} \longmapsto I + \rho(\widetilde{C} - I)\rho$$

produces an operator in $\mathrm{Ell}^0_c(\mathbb{R}^{m+k})$ with the same symbol class. The intermediate operators are elliptic on the closed manifold $S^m \times S^k$; by Theorem 17.5.6, their index depends only on this class. Combined with (18.61), this proves

$$I_{m+k}(a \boxtimes c) = I_m(a) I_k(c), \qquad a \in K^0_c(T^*\mathbb{R}^m), \quad c \in K^0_c(T^*\mathbb{R}^k). \tag{18.67}$$

18.7 The index theorem in Euclidean space

Define the Euclidean topological index by

$$\mathrm{ind}_{\mathrm{t}}^{\mathbb{R}^n} := (-1)^n \alpha_n : K^0_c(T^*\mathbb{R}^n) = K^0_c(\mathbb{R}^{2n}) \longrightarrow \mathbb{Z}. \tag{18.68}$$

Equality (18.17) shows that it can also be written as

$$\operatorname{ind}_{\mathrm{t}}^{\mathbb{R}^n} = i_!^{-1}, \qquad i : \{0\} \hookrightarrow \mathbb{R}^n.$$

Theorem 18.7.1. (Euclidean index) Let $P \in \mathrm{Ell}_c^0(\mathbb{R}^n)$. Then

$$\operatorname{ind}_{\mathrm{a}}(P) = \operatorname{ind}_{\mathrm{t}}^{\mathbb{R}^n}[\sigma(P)] = (-1)^n \alpha_n([\sigma(P)]). \tag{18.69}$$

Proof. By Corollary 18.1.3, every class in $K_c^0(T^*\mathbb{R}^n)$ has a unique expression

$$[\sigma(P)] = \ell\, b^{\boxtimes n}, \qquad \ell \in \mathbb{Z},$$

and

$$\ell = \alpha_n([\sigma(P)]).$$

Lemma 18.5.1 and multiplicativity (18.67) imply

$$I_n(b^{\boxtimes n}) = I_1(b)^n = (-1)^n.$$

Since I_n is a homomorphism,

$$\operatorname{ind}_{\mathrm{a}}(P) = I_n([\sigma(P)]) = \ell I_n(b^{\boxtimes n}) = (-1)^n \alpha_n([\sigma(P)]).$$

By (18.68), the last expression is the topological index. □

The proof uses Bott periodicity to identify the generator and calculates its index using the unilateral shift and angular regularization; it therefore does not presuppose the index theorem on closed manifolds.

18.7.1 An extension: the families index

Let Λ be a compact Hausdorff space and let $P = (P_\lambda)_{\lambda\in\Lambda}$ be a family of Euclidean elliptic operators of order zero, continuous in the topology of classical symbols and with a common compact support. In particular, both the operators and their principal symbols form continuous families. Their analytic index is a class in $K^0(\Lambda)$. Recall its construction. Choose a finite-dimensional subspace $V \subset L^2(\mathbb{R}^n;\mathbb{C}^q)$ such that

$$\operatorname{Ran} P_\lambda + V = L^2(\mathbb{R}^n;\mathbb{C}^q) \qquad \text{for every } \lambda \in \Lambda.$$

Existence of a single V for all parameters is obtained first locally from openness of surjectivity and then by taking the sum of the spaces corresponding to a finite subcover of Λ. The kernels of the surjective maps

$$\mathcal{P}_\lambda : L^2(\mathbb{R}^n;\mathbb{C}^q) \oplus V \longrightarrow L^2(\mathbb{R}^n;\mathbb{C}^q), \qquad \mathcal{P}_\lambda(u,v) = P_\lambda u + v,$$

form a finite-dimensional vector bundle $\mathbf{K} := \ker \mathcal{P} \longrightarrow \Lambda$. Indeed, fix λ_0 and let R_0 be a right inverse of $\mathcal{P}_{\lambda_0}$. For λ near λ_0, the operator $\mathcal{P}_\lambda R_0$ is invertible by the Neumann series, and

$$R_\lambda := R_0(\mathcal{P}_\lambda R_0)^{-1}$$

is a right inverse depending continuously on λ. The projections

$$\Pi_\lambda := I - R_\lambda \mathcal{P}_\lambda$$

have image $\ker \mathcal{P}_\lambda$, depend continuously on the parameter, and provide local trivializations of these kernels. Define

$$\mathrm{Ind}_{\mathrm{a}}(P) := [\mathbf{K}] - [\underline{V}] \in K^0(\Lambda). \tag{18.70}$$

The class is independent of V. Indeed, if $V \subseteq W$ and both spaces make the stabilized maps surjective, set $\mathbf{K}_V := \ker \mathcal{P}_V$ and $\mathbf{K}_W := \ker \mathcal{P}_W$. There is an exact sequence of bundles

$$0 \longrightarrow \mathbf{K}_V \longrightarrow \mathbf{K}_W \longrightarrow \underline{W/V} \longrightarrow 0.$$

The last arrow sends (u, w) to the class of w modulo V. It is surjective because $\operatorname{Ran} P_\lambda + V = L^2(\mathbb{R}^n; \mathbb{C}^q)$, and its kernel is $\mathbf{K}_V$. Thus

$$[\mathbf{K}_W] - [\underline{W}] = [\mathbf{K}_V] + [\underline{W/V}] - [\underline{V}] - [\underline{W/V}] = [\mathbf{K}_V] - [\underline{V}].$$

Two arbitrary choices are compared by passing to their sum.

Proposition 18.7.2. (Realization and descent for families) Let Λ be a compact Hausdorff space. Every class

$$\kappa \in K_c^0(T^*\mathbb{R}^n \times \Lambda)$$

is the symbol class of a family of operators in $\mathrm{Ell}_c^0(\mathbb{R}^n)$ continuous in the symbol topology, after a fixed stabilization. The index bundle of a family depends only on its symbol class. Consequently, there exists a well-defined homomorphism

$$I_{n,\Lambda} : K_c^0(\mathbb{R}^{2n} \times \Lambda) \longrightarrow K^0(\Lambda) \tag{18.71}$$

sending a class realized by P to $\mathrm{Ind}_{\mathrm{a}}(P)$.

Proof. Extend κ by zero to $T^*S^n \times \Lambda$. The projection of its compact support onto $T^*\mathbb{R}^n$ is compact. We may choose a common neighborhood U of ∞ whose closure does not meet the projection of this support onto S^n. Under the radial identification of T^*S^n with the interior of B^*S^n, the support lies in the complement of the closed set

$$\big(S^*S^n \times \Lambda\big) \cup \big(B^*\overline{U} \times \Lambda\big). \tag{18.72}$$

The description by supports and excision in Theorem A.4.2 allow the class to be represented in the relative group of this pair. Since the total space and the closed subspace are compact Hausdorff, Theorem 17.2.4 provides bundles and an isomorphism over this closed subset, elementary on the second set. No CW structure on Λ is needed. The relative isomorphism extends to a neighborhood of the closed subset by the extension argument in the proof of that theorem. In particular, the relative trivialization is available near $B^*\overline{U} \times \Lambda$. Radial contraction of B^*S^n reduces the bundles, after stabilization, to pullbacks of bundles over $S^n \times \Lambda$. On restriction to $\mathbb{R}^n \times \Lambda$, these bundles are pullbacks of bundles G and H over Λ. The elementary trivialization near ∞ identifies G with H. Choose a complement G' such that $G \oplus G' \cong \underline{\mathbb{C}}^N$ and add the elementary triple defined by G'. Thus, over $\mathbb{R}^n \times \Lambda$ the operators act on a trivial bundle of fixed rank and are the identity on the added summands.

Smoothing must be performed uniformly. Take a finite atlas of S^n and a partition of unity independent of λ, and regularize by convolution only in the variables of S^n and their covariables. Shrink U once and use a cutoff function vanishing near its closure to keep the relative trivialization intact; continue to denote the smaller neighborhood by U. The original isomorphism on the compact set $S^*S^n \times \Lambda$ satisfies

$$\delta := \inf_{(x,\xi,\lambda)\in S^*S^n\times\Lambda} \left\| \theta(x,\xi,\lambda)^{-1} \right\|^{-1}_{\mathrm{op}(\mathbb{C}^N)} > 0.$$

Denote the approximation by $\widetilde{\theta}$ and choose it so that

$$\|\widetilde{\theta} - \theta\|_{C^0(S^*S^n\times\Lambda,\mathrm{End}(\mathbb{C}^N))} < \frac{\delta}{2}.$$

The segment between the two maps remains invertible, so the relative class is unchanged. The smoothed symbol is C^∞ in (x,ξ), continuous in λ in every symbol seminorm, and exactly equal to the identity over $T^*U \times \Lambda$.

Homogeneous extension and quantization are performed with a single cover, a single partition, and the same cutoffs for all parameters. In each chart, Calderón–Vaillancourt estimates the difference of two quantized operators by finitely many seminorms of the difference of their symbols. Therefore,

$$\lambda \longmapsto P_\lambda \quad \text{is continuous in} \quad \mathcal{L}\big(L^2(\mathbb{R}^n;\mathbb{C}^N)\big). \tag{18.73}$$

Choose a single $\chi \in C_c^\infty(\mathbb{R}^n)$ equal to 1 on the projection of the common support, and replace the quantized family A_λ by

$$P_\lambda := I + \chi(A_\lambda - I)\chi. \tag{18.74}$$

The Schwartz kernel of $P_\lambda - I$ is contained in $\operatorname{supp}\chi \times \operatorname{supp}\chi$, uniformly in λ. This proves realization.

We now prove descent. The same model by triples applies to the product of the preceding compact Hausdorff pair with $[0,1]$. Thus a relative homotopy of classes is represented, after stabilization, over

$$B^*S^n \times \Lambda \times [0,1]$$

and is elementary over $B^*U \times \Lambda \times [0,1]$. Repeat the preceding smoothing on the compact space $\Lambda \times [0,1]$ and quantize with the same cutoff χ. This gives a norm-continuous family of Fredholm operators. There exists a common finite-dimensional subspace V making all stabilizations surjective, since $\Lambda \times [0,1]$ is compact. Their kernels form a bundle $\mathcal{K} \to \Lambda \times [0,1]$, and the index of the family is

$$[\mathcal{K}] - [\underline{V}] \in K^0(\Lambda \times [0,1]).$$

The inclusions $i_0, i_1 : \Lambda \longrightarrow \Lambda \times [0,1]$ are homotopic; consequently,

$$i_0^*\big([\mathcal{K}] - [\underline{V}]\big) = i_1^*\big([\mathcal{K}] - [\underline{V}]\big).$$

Thus the index bundle is invariant under relative homotopies.

An isomorphism of triples depending on the covariable reduces, through $(x,\xi,\lambda,t) \mapsto (x,t\xi,\lambda)$, to bundle isomorphisms over the base; the procedure is uniform because Λ is compact. An elementary triple contracts in the same way to a family of isomorphisms and has zero index bundle. Direct sum of triples corresponds

to direct sum of stabilized families. Thus the index respects equivalences, homotopies, elementary triples, and sums, which are all the relations in the relative model. This proves that (18.71) is well defined. □

The Bott isomorphism with parameters is

$$\alpha_{n,\Lambda} : K_c^0(\mathbb{R}^{2n} \times \Lambda) \longrightarrow K^0(\Lambda).$$

Theorem 18.7.3. (Euclidean index for families) Under the preceding hypotheses,

$$\operatorname{Ind}_{\mathrm{a}}(P) = (-1)^n \alpha_{n,\Lambda}\big([\sigma(P_\Lambda)]\big) \in K^0(\Lambda). \tag{18.75}$$

Proof. Proposition 18.7.2 constructs the homomorphism $I_{n,\Lambda}$ and proves its independence of the relative representative and quantization. This homomorphism is $K^0(\Lambda)$–linear. Indeed, if $\mathbf{G} \longrightarrow \Lambda$ is a vector bundle, the stabilization defining the index of $P \otimes \mathbf{G}$ is the preceding stabilization tensored with $\mathbf{G}$; consequently,

$$\operatorname{Ind}_{\mathrm{a}}(P \otimes \mathbf{G}) = \operatorname{Ind}_{\mathrm{a}}(P)\,[\mathbf{G}].$$

By Theorem 18.1.2, every class in the domain has a unique expression

$$b^{\boxtimes n} \boxtimes a, \qquad a \in K^0(\Lambda).$$

Iterating the angular regularization of (18.59) and relative realization, we obtain an operator

$$R_n \in \mathrm{Ell}_c^0(\mathbb{R}^n)$$

such that

$$[\sigma(R_n)] = b^{\boxtimes n}, \qquad \operatorname{ind} R_n = (-1)^n.$$

Write $a = [G] - [H]$ and represent G and H, after adding trivial bundles if necessary, by continuous projections

$$p_G : \Lambda \longrightarrow M_N(\mathbb{C}), \qquad p_H : \Lambda \longrightarrow M_N(\mathbb{C}).$$

The family

$$\mathcal{R}_G(\lambda) := R_n \otimes p_G(\lambda) + I \otimes \big(I - p_G(\lambda)\big) \tag{18.76}$$

is the identity on the complement of G_λ. Its symbol class and index are

$$[\sigma(\mathcal{R}_G)] = b^{\boxtimes n} \boxtimes [G], \qquad \operatorname{Ind}_{\mathrm{a}}(\mathcal{R}_G) = (-1)^n [G].$$

For the negative term, use

$$\mathcal{R}_H^-(\lambda) := R_n^* \otimes p_H(\lambda) + I \otimes \big(I - p_H(\lambda)\big). \tag{18.77}$$

Proposition 17.5.3 and the equality $\operatorname{ind} R_n^* = -\operatorname{ind} R_n$ give

$$[\sigma(\mathcal{R}_H^-)] = -b^{\boxtimes n} \boxtimes [H], \qquad \operatorname{Ind}_{\mathrm{a}}(\mathcal{R}_H^-) = -(-1)^n [H].$$

The direct sum of (18.76) and (18.77) realizes $b^{\boxtimes n} \boxtimes a$ and has index $(-1)^n a$. Therefore,

$$I_{n,\Lambda}(b^{\boxtimes n} \boxtimes a) = (-1)^n a.$$

Since

$$\alpha_{n,\Lambda}(b^{\boxtimes n} \boxtimes a) = a,$$

we obtain (18.75). □

18.8 Compatibility with embeddings of closed manifolds

The preceding constructions supply the three maps in the embedding argument. If $j : X \hookrightarrow \mathbb{R}^N$ is an embedding of a closed manifold and $a \in K_c^0(T^*X)$, we have

$$K_c^0(T^*X) \xrightarrow{\mathrm{Th}_{N(Tj)}} K_c^0(N(Tj)) \xrightarrow{e} K_c^0(T^*\mathbb{R}^N) \xrightarrow{(-1)^N \alpha_N} \mathbb{Z}.$$

The composition of the first two arrows is $j_!$, and the last is the Euclidean index. Thus the topological expression associated with a is

$$\mathrm{ind}_{\mathrm{t}}(a) := (-1)^N \alpha_N(j_! a). \tag{18.78}$$

Naturality of Thom, functoriality (18.15), and (18.17) show that (18.78) is independent of the Euclidean space in which the embedding is stabilized. Full independence of the embedding and equality with the analytic index will be proved in Chapter 19. Analytically, the remaining step is to realize the Thom class using the normal oscillator and to prove that extension from a tubular neighborhood changes neither kernel nor cokernel. Topologically, all the ingredients are already contained in Theorems 18.1.2 and 18.2.2 and in functoriality of the pushforward.

19

The index theorem on closed manifolds

Let M be a closed smooth manifold of real dimension n, and let $\mathbf{E}^{+}, \mathbf{E}^{-} \longrightarrow M$ be complex vector bundles. If

$$P \colon \Gamma(M, \mathbf{E}^{+}) \longrightarrow \Gamma(M, \mathbf{E}^{-})$$

is a classical elliptic pseudodifferential operator, Theorem 15.6.22 and Corollary 15.6.23 show that

$$\operatorname{ind}_{\mathrm{a}}(P) = \dim_{\mathbb{C}} \ker P - \dim_{\mathbb{C}} \ker P^{*}$$

is well defined and independent of the Sobolev exponent used to realize P as a bounded operator. Definition 17.4.1 associates a class to its principal symbol,

$$[\sigma(P)] \in K_{c}^{0}(T^{*}M).$$

Theorem 17.5.6, using the stability of Theorem 15.6.24, proves that the index depends only on this class. It remains to identify the resulting homomorphism $K_{c}^{0}(T^{*}M) \longrightarrow \mathbb{Z}$.

The identification will be made using an embedding of M into a Euclidean space. The proof keeps two arguments separate. The first is topological: the Thom isomorphism and extension by zero produce an integer from a compactly supported class in $T^{*}M$. The second is analytic: a Bott operator in the normal directions allows an elliptic operator on M to be transferred to a tubular neighborhood without changing its index. The Euclidean formula of Chapter 18 then completes the comparison. This is the embedding argument of Atiyah and Singer; our reference exposition is [21, Chapter 12, pp. 284–301].

Atiyah and Singer: two ways to count

The theorem announced by Michael Atiyah and Isadore Singer in the 1960s states that two constructions of very different natures produce the same integer. The analytic index counts solutions and obstructions of an elliptic equation; the topological index combines the symbol class with operations in K–theory. The equality is more than a computational formula: it explains why global data of an equation remain invariant under deformation and why geometric operators recover invariants such as the Euler characteristic or characteristic genera [11].

19.1 The topological index

Fix a Riemannian metric on M. The musical isomorphism

$$\sharp_g \colon T^*M \longrightarrow TM, \qquad \xi \longmapsto \xi^{\sharp_g},$$

induces an isomorphism $K_c^0(T^*M) \cong K_c^0(TM)$. Although it will be used to write the construction, the final result is independent of the metric: two metrics are joined by the convex segment $g_t = (1-t)g_0 + tg_1$, and the corresponding musical isomorphisms form a proper homotopy of bundles.

By the Whitney embedding theorem in the form [21, Theorem 6.7(c), pp. 162–163], there exists a smooth embedding

$$j \colon M \hookrightarrow \mathbb{R}^N$$

for some N. Let $\nu \longrightarrow M$ be its normal bundle, of rank $r = N - n$. Theorem 2.12.3 provides open subsets $V \subseteq \nu$ and $U \subseteq \mathbb{R}^N$ containing, respectively, the zero section and $j(M)$, and a diffeomorphism

$$\Theta \colon V \longrightarrow U, \qquad \Theta(x, 0) = j(x).$$

The differential $Tj \colon TM \hookrightarrow T\mathbb{R}^N$ is also an embedding. The differential of the projection of ν defines a real vector bundle

$$T\pi_\nu \colon T\nu \longrightarrow TM$$

of rank $2r$: the fiber over $X \in T_xM$ consists of the vectors tangent to ν that project to X. A normal connection separates the horizontal and vertical directions and gives an identification

$$T\nu \cong \pi_{TM}^*(\nu \oplus \nu)$$

as bundles over TM. This is the normal bundle of $Tj(TM)$ in $T\mathbb{R}^N$ under the differential of a tubular identification; in the notation of Definition 18.3.1, $N(Tj) \cong (T\nu, T\pi_\nu)$. The identification is not canonical, but two connections give homotopic identifications. The complex structure

$$J(u, v) = (-v, u), \qquad (u, v) \in \nu_x \oplus \nu_x, \tag{19.1}$$

, however, determines a canonical complex orientation up to homotopy. By Theorem 18.2.2, we obtain the Thom isomorphism

$$\mathrm{Th}_{T\nu} \colon K_c^0(TM) \longrightarrow K_c^0(T\nu).$$

The tubular neighborhood identifies a neighborhood of TM in $T\mathbb{R}^N$ with a neighborhood of the zero section of $T\nu$. Extension by zero then defines

$$\mathrm{ext} \colon K_c^0(T\nu) \longrightarrow K_c^0(T\mathbb{R}^N).$$

For the structure (19.1), the complex coordinate is $u + iv$ and the Thom class of a line is $\lambda_{\mathbb{C}} = -b$ with the normalization of Definition 18.1.1. Thus, in rank s, we have simultaneously

$$\lambda_{\mathbb{C}^s} = (-1)^s b^{\boxtimes s}, \qquad \mathrm{ch}_c(\lambda_{\mathbf{W}}) = (-1)^s \Phi_{\mathbf{W}}\left(\mathrm{Td}(\overline{\mathbf{W}})^{-1}\right). \tag{19.2}$$

The complex orientation and Thom class are fixed by (19.2).

In accordance with Definition 18.3.1, and using the Euclidean metric to identify the last tangent bundle with the cotangent bundle, the *pushforward* of the embedding is

$$j_! := \mathrm{ext} \circ \mathrm{Th}_{T\nu} \circ (\sharp_g)_* \colon K_c^0(T^*M) \longrightarrow K_c^0(T^*\mathbb{R}^N). \tag{19.3}$$

Let $i_N \colon \{0\} \hookrightarrow \mathbb{R}^N$ be the inclusion. With the conventions of Chapter 18, if $b \in K_c^0(\mathbb{R}^2)$ is the Bott class and $\alpha_N \colon K_c^0(\mathbb{R}^{2N}) \longrightarrow \mathbb{Z}$ is the periodicity isomorphism, then

$$(i_N)_!(1) = (-1)^N b^{\boxtimes N}, \qquad (i_N)_!^{-1} = (-1)^N \alpha_N. \tag{19.4}$$

These are precisely identities (18.16) and (18.17). The sign comes from the complex structure (19.1): in rank one, the Thom bundle homomorphism is $z = v + i\eta$, whereas b was normalized using the gluing function z^{-1}.

Definition 19.1.1. (Topological index) Let M be a closed smooth manifold and fix a smooth embedding $j \colon M \hookrightarrow \mathbb{R}^N$. For $a \in K_c^0(T^*M)$ define

$$\mathrm{ind}_{\mathrm{t}}(a) := (i_N)_!^{-1}(j_! a) \in \mathbb{Z}. \tag{19.5}$$

The definition appears to depend on the metric, embedding, and tubular neighborhood. This dependence is only apparent.

Proposition 19.1.2. (Independence of choices) Let M be a closed smooth manifold. The integer in (19.5) is independent of the metric, normal connection, tubular neighborhood, and embedding $j \colon M \hookrightarrow \mathbb{R}^N$. Moreover,

$$\mathrm{ind}_{\mathrm{t}} \colon K_c^0(T^*M) \longrightarrow \mathbb{Z}$$

is a homomorphism.

Independence under stabilization is stated in [21, Definition 12.11 and Exercise 12.10, p. 290]; a detailed proof appears in [92, Chapter III, §13, Definition 13.1].

Proof. Independence of the metric was already obtained using the homotopy g_t. The space of connections on a fixed bundle is affine; thus two normal connections are joined by a segment and give homotopic Thom classes. Two tubular neighborhoods admit, after restricting their domains, an isotopy fixing the zero section. Homotopy invariance and excision in compactly supported K–theory show that the extensions by zero agree. These topological results are stated in Theorem A.6.1 of Appendix A.

It remains to compare two embeddings $j_0 \colon M \hookrightarrow \mathbb{R}^{N_0}$ and $j_1 \colon M \hookrightarrow \mathbb{R}^{N_1}$. Their stabilizations in $\mathbb{R}^{N_0+N_1}$ are joined by the family

$$j_\theta(x) = \big((\cos\theta) j_0(x), (\sin\theta) j_1(x)\big), \qquad 0 \le \theta \le \frac{\pi}{2}.$$

Each j_θ is an embedding. At the endpoints this is immediate; if both components are nonzero, injectivity of either component proves injectivity, and the same observation applied to the differentials proves that it is an immersion. Since M is compact, an injective immersion into a Hausdorff space is an embedding. Isotopy invariance gives equality of the stabilized pushforwards. By functoriality of the Thom isomorphism,

$$(\iota \circ j)_! = \iota_! \circ j_!$$

for a linear inclusion ι between Euclidean spaces. The same identity holds for inclusions of points; hence the Bott factors introduced by stabilization cancel when $(i_N)_!^{-1}$ is applied. This proves independence of the embedding. Additivity follows from additivity of the Thom isomorphism, extension by zero, and $(i_N)_!^{-1}$. □

19.2 Excision and products for the analytic index

Passing from M to a tubular neighborhood requires two analytic properties. The first allows a symbol supported in an open subset to be transferred without changing the index; the second calculates the index of an external product.

Proposition 19.2.1. (Analytic excision) Let X_0 and X_1 be manifolds without boundary and let U be an open set identified with open subsets of both. For $i = 0, 1$, let $\mathbf{E}_i, \mathbf{F}_i \to X_i$ be complex vector bundles equipped with Hermitian bundle metrics and identified over U, and let $R_i \colon \mathbf{E}_i \to \mathbf{F}_i$ be a bundle homomorphism inducing a bounded multiplication operator and corresponding, over U, to a common homomorphism R. Suppose that there exist $L \Subset U$ such that R_i is invertible outside L and a bounded operator

$$B \colon L^2(U, \mathbf{E}|_U) \longrightarrow L^2(U, \mathbf{F}|_U)$$

whose Schwartz kernel is supported in $L \times L$ and agrees under the identifications. If

$$P_i := R_i + \operatorname{ext}_i B \colon L^2(X_i, \mathbf{E}_i) \longrightarrow L^2(X_i, \mathbf{F}_i)$$

is Fredholm for $i = 0, 1$, then

$$\operatorname{ind} P_0 = \operatorname{ind} P_1. \tag{19.6}$$

In particular, the analytic index of a class in $K_c^0(T^*U)$ extended by zero depends only on a neighborhood of the projection of its support.

Proof. Choose on U a Riemannian metric, its associated measure, and Hermitian metrics on the bundles, and extend the metrics to X_0 and X_1. Thus the identifications over U preserve the L^2 inner products and adjoints. If $P_i u = 0$, then $R_i u = 0$ outside L; invertibility of R_i there implies $\operatorname{supp} u \subseteq L$. The same argument for P_i^* shows $\operatorname{supp} v \subseteq L$ for every $v \in \ker P_i^*$.
Over U, the operators P_0 and P_1 agree with $R + B$, and the same holds for their adjoints. Restriction therefore identifies $\ker P_0$ with $\ker P_1$ and $\ker P_0^*$ with $\ker P_1^*$. Subtracting their dimensions proves (19.6).
For a class $a \in K_c^0(T^*U)$, the extension-by-zero construction allows us, after stabilization, to choose a localized representative of this form: if A is a quantization and R its invertible part outside a compact set, take $Q := R + \chi(A - R)\chi$ with $\chi \in C_c^\infty(U)$ equal to one near the support. The operator $B := Q - R$ has kernel supported in a compact subset of $U \times U$, and the preceding argument applies to its two extensions. □

To state the second property, it is convenient to use graded operators. If $P \colon H_P^+ \longrightarrow H_P^-$ and $Q \colon H_Q^+ \longrightarrow H_Q^-$ are closed densely defined operators, write

$$D_P = \begin{pmatrix} 0 & P^* \\ P & 0 \end{pmatrix}, \qquad D_Q = \begin{pmatrix} 0 & Q^* \\ Q & 0 \end{pmatrix}, \qquad \Gamma_P = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}.$$

The odd operator

$$D_P \widehat{\otimes} I + \Gamma_P \widehat{\otimes} D_Q \tag{19.7}$$

acts on the graded tensor product. Its component from even to odd degree is

$$P\#Q = \begin{pmatrix} P \otimes I & -I \otimes Q^* \\ I \otimes Q & P^* \otimes I \end{pmatrix}. \tag{19.8}$$

Theorem 19.2.2. (Analytic multiplicativity) Let $P \in \Psi^1_{\mathrm{cl}}(M;\mathbf{E}^+,\mathbf{E}^-)$ and $Q \in \Psi^1_{\mathrm{cl}}(N;\mathbf{F}^+,\mathbf{F}^-)$ be elliptic operators on closed smooth manifolds M and N, respectively. The closure of the operator $P\#Q$ in (19.8) is Fredholm and

$$\operatorname{ind_a}(P\#Q) = \operatorname{ind_a}(P)\operatorname{ind_a}(Q). \tag{19.9}$$

Proof. Set

$$\mathcal{H}_P := L^2(M,\mathbf{E}^+) \oplus L^2(M,\mathbf{E}^-), \qquad \mathcal{H}_Q := L^2(N,\mathbf{F}^+) \oplus L^2(N,\mathbf{F}^-), \qquad \mathcal{H} := \mathcal{H}_P \widehat{\otimes} \mathcal{H}_Q,$$

with their natural orthogonal sums and gradings. The anticommutation relation $D_P\Gamma_P + \Gamma_P D_P = 0$ implies

$$\left(D_P \widehat{\otimes} I + \Gamma_P \widehat{\otimes} D_Q\right)^2 = D_P^2 \widehat{\otimes} I + I \widehat{\otimes} D_Q^2. \tag{19.10}$$

For every vector u in the algebraic tensor product of smooth sections,

$$\begin{aligned} &\left\langle \left(D_P^2 \widehat{\otimes} I + I \widehat{\otimes} D_Q^2\right) u, u \right\rangle_{\mathcal{H}} \\ &\qquad = \left\| (D_P \widehat{\otimes} I) u \right\|_{\mathcal{H}}^2 + \left\| (I \widehat{\otimes} D_Q) u \right\|_{\mathcal{H}}^2. \end{aligned}$$

Let us specify the closure used in these identities. Elliptic regularity and Rellich imply that D_P and D_Q, with domain H^1 on their respective bases, are self-adjoint with compact resolvent. Let $(\lambda_j)_{j\in I}$ and $(\mu_k)_{k\in J}$ be the distinct eigenvalues of D_P^2 and D_Q^2, respectively, and let V_j and W_k be their eigenspaces. The index sets I, J are finite or countable. Every eigenspace is finite-dimensional and invariant under the corresponding operator and its grading. On $V_j \widehat{\otimes} W_k$, the operator in (19.7) is a self-adjoint matrix whose square is $(\lambda_j + \mu_k)I$. The orthogonal sum of these matrices is self-adjoint on the domain

$$\left\{ \mathbf{u} = \sum_{(j,k)\in I\times J} \mathbf{u}_{jk} \;\middle|\; \sum_{(j,k)\in I\times J} (\lambda_j + \mu_k)\|\mathbf{u}_{jk}\|^2 < \infty \right\},$$

where the first sum converges in $\mathcal{H}$. Vectors with finitely many components form a core in the graph norm, by truncation of the second sum. This proves that the orthogonal sum is the closure of the product initially defined on the algebraic tensor product of smooth sections. For every $R > 0$, there are only finitely many pairs (j,k) with $\lambda_j + \mu_k \le R$, since both spectral sequences have this property. Zero therefore has finite multiplicity and is separated from the rest of the spectrum. The product is Fredholm. The only blocks contributing to its kernel are those satisfying $\lambda_j = \mu_k = 0$. Hence

$$\ker\left(D_P \widehat{\otimes} I + \Gamma_P \widehat{\otimes} D_Q\right) = \ker D_P \widehat{\otimes} \ker D_Q \subset \mathcal{H}.$$

Separating even and odd components gives

$$\ker(P\#Q) \cong (\ker P \otimes \ker Q) \oplus (\ker P^* \otimes \ker Q^*),$$
$$\ker(P\#Q)^* \cong (\ker P^* \otimes \ker Q) \oplus (\ker P \otimes \ker Q^*).$$

Subtracting dimensions yields

$$\big(\dim\ker P - \dim\ker P^*\big)\big(\dim\ker Q - \dim\ker Q^*\big),$$

which is (19.9). □

19.3 The normal Bott operator

The preceding multiplicativity must be applied uniformly in the fibers of the normal bundle. We begin with the model on $\mathbb{R}^r$. On $\Lambda^*\mathbb{C}^r$ let ε_j be exterior multiplication by the jth basis vector and $\iota_j = \varepsilon_j^*$ contraction. On the Schwartz class define

$$\mathcal{B}_r = \sum_{j=1}^{r} \left(\varepsilon_j \left(\frac{\partial}{\partial v_j} + v_j \right) + \iota_j \left(-\frac{\partial}{\partial v_j} + v_j \right) \right). \tag{19.11}$$

This is an odd symmetric operator. Denote by $\mathcal{B}_r^+$ its component from even to odd forms.

Lemma 19.3.1. (Kernel and index of the Bott operator) The closure of $\mathcal{B}_r$ is self-adjoint, has compact resolvent, and

$$\ker \mathcal{B}_r = \mathbb{C} e^{-\frac{|v|^2}{2}} \otimes \Lambda^0 \mathbb{C}^r.$$

In particular,

$$\operatorname{ind}_a(\mathcal{B}_r^+) = 1.$$

Its total symbol in the variables $(v,\eta) \in \mathbb{R}^r \oplus \mathbb{R}^r$ is

$$\beta_r(v,\eta) = \varepsilon(v+i\eta) + \varepsilon(v+i\eta)^*, \tag{19.12}$$

where $\varepsilon(z) = \sum_{j=1}^{r} z_j \varepsilon_j$ and $\varepsilon(z)^* = \sum_{j=1}^{r} \overline{z_j} \iota_j$. Its component from even to odd degree represents the Thom class of $\mathbb{R}^r \oplus \mathbb{R}^r$ with the complex structure $J(v,\eta) = (-\eta, v)$.

Proof. The relations

$$\varepsilon_i\varepsilon_j + \varepsilon_j\varepsilon_i = 0, \qquad \iota_i\iota_j + \iota_j\iota_i = 0, \qquad \varepsilon_i\iota_j + \iota_j\varepsilon_i = \delta_{ij} I$$

give, on $\mathcal{S}(\mathbb{R}^r, \Lambda^*\mathbb{C}^r)$,

$$\mathcal{B}_r^2 = -\Delta_v + |v|^2 - r + 2\mathcal{N}, \qquad \mathcal{N} = \sum_{j=1}^{r} \varepsilon_j \iota_j. \tag{19.13}$$

The operator $\mathcal{N}$ acts by multiplication by q on $\Lambda^q\mathbb{C}^r$. The scalar oscillator $-\Delta_v + |v|^2$ has eigenvalues $r + 2|\alpha|$, $\alpha \in \mathbb{N}_0^r$, and its ground state is $e^{-\frac{|v|^2}{2}}$. Thus the eigenvalues of (19.13) are $2|\alpha| + 2q$. Zero occurs exactly once, for $\alpha = 0$ and $q = 0$. The Hermite function basis proves both essential self-adjointness and compactness of

the resolvent.

The first-order part together with the linear potential gives (19.12). Since

$$\beta_r(v,\eta)^2 = (|v|^2 + |\eta|^2)I,$$

its restriction to the sphere is an isomorphism between the even and odd parts. To compare it with the sign in Definition 18.2.1, set $z = v + i\eta$ and consider $c_t(z) = \varepsilon(z) + e^{i\pi t}\varepsilon(z)^*$, $0 \le t \le 1$. The creation and annihilation relations give $c_t(z)^2 = e^{i\pi t}|z|^2 I$. Thus the even-to-odd components are invertible when $z \neq 0$ and join the preceding symbol to $\varepsilon(z) - \varepsilon(z)^*$, which defines the Thom class. The normalization agrees with (19.4): for $r = 1$, the bundle homomorphism is $v + i\eta$ and represents $-b$. □

Formula (19.11) is invariant under the natural action of $O(r)$. Indeed, differentiation, multiplication by v, and the exterior and interior operations transform simultaneously. This equivariance allows us to pass from the vector-space model to the normal bundle without choosing global frames.

Existence of a global representative on the fiber compactification uses the equivariant Bott normalization for the standard representation of $O(r)$, stated in Theorem A.5.2. The result provides the class and its index in $R(O(r))$; the next lemma develops the analytic normalization we need and adapts it to the normal bundle. Before stating it, let us specify the compactification used in this step.

Let $G = O(r)$ and let $S^r = \mathbb{R}^r \cup \{\infty\}$, with the action of G fixing ∞. Denote the orthonormal frame bundle of ν by $\mathcal{P}_\nu \longrightarrow M$. The fiberwise spherical compactification is the closed manifold

$$\widehat{\nu} := \mathcal{P}_\nu \times_G S^r, \qquad \widehat{\pi} : \widehat{\nu} \longrightarrow M. \tag{19.14}$$

The section $\mathbf{s}_\infty = \mathcal{P}_\nu \times_G \{\infty\}$ is the complement of the open copy of ν in $\widehat{\nu}$.

Lemma 19.3.2. (Equivariant normal representative) Let S^r be the closed smooth sphere and let $G = O(r)$ with the action described above. There exist complex bundles $\mathbf{W}^+, \mathbf{W}^- \longrightarrow S^r$ with an action of G and a classical elliptic G–equivariant pseudodifferential operator of order one

$$B \colon \Gamma(S^r, \mathbf{W}^+) \longrightarrow \Gamma(S^r, \mathbf{W}^-)$$

such that its symbol class is the extension by zero from $T^*\mathbb{R}^r$ of the class of (19.12). The equality holds in equivariant K–theory. Moreover, after modifying B by an G–equivariant smoothing operator, we may assume that

$$\ker B = \mathbb{C}, \qquad \ker B^* = 0, \tag{19.15}$$

where G acts trivially on $\mathbb{C}$.

Proof. The bounded transform

$$F_r^+ = \mathcal{B}_r^+ \left(I + \mathcal{B}_r^- \mathcal{B}_r^+\right)^{-\frac{1}{2}}$$

is Fredholm and G–equivariant. The calculation in Lemma 19.3.1 shows, as representations of G and not merely after taking dimensions, that

$$[\ker F_r^+] - [\ker (F_r^+)^*] = [\mathbb{C}] \quad \text{in } R(G). \tag{19.16}$$

To pass to the compactification, apply Theorem A.5.2 of Appendix A. If $i : \{0\} \hookrightarrow \mathbb{R}^r$, this result provides an elliptic G–equivariant representative of $\beta_r = i_!(1)$ on S^r, elementary near ∞, and establishes

$$\operatorname{Ind}_G(\beta_r) = [\mathbb{C}] \quad \text{in } R(G), \tag{19.17}$$

with the trivial representation on the right-hand side.

The normalization in (19.17) agrees with the one adopted here. Indeed, the local representative is (19.12), and (19.16) calculates its index as a representation, not just its dimension: the Gaussian is fixed by $O(r)$ and the cokernel is zero. This rules out the determinant representation and fixes the right-hand side of (19.17).

Let B_0 be an order-zero quantization of the symbol provided by that theorem. We can make it G–equivariant by averaging its conjugates with respect to normalized Haar measure on G: the principal symbol remains unchanged because it is equivariant. Then

$$[\ker B_0] - [\ker B_0^*] = [\mathbb{C}] \quad \text{in } R(G).$$

Since G is compact, its finite-dimensional representations are semisimple. The preceding equality provides a G–equivariant decomposition

$$\ker B_0 \cong \mathbb{C} \oplus \ker B_0^*.$$

Let K be the operator identifying the second summand with $\ker B_0^*$ and vanishing on its orthogonal complement. It has finite rank and is G–equivariant. Elliptic regularity of both kernels shows that its integral kernel is smooth. The operator $B_1 := B_0 + K$ is surjective: B_0 identifies $(\ker B_0)^\perp$ with its closed image, and K covers the orthogonal complement of that image. Its kernel is the first copy of $\mathbb{C}$. Finally, compose on the right with the positive, invertible, G–equivariant operator

$$\Lambda := \left(I + (\nabla^{\mathbf{W}^+})^* \nabla^{\mathbf{W}^+}\right)^{1/2},$$

of order one, using the round metric and a G–invariant Hermitian metric and connection on $\mathbf{W}^+$. The map $\Lambda : H^1(S^r, \mathbf{W}^+) \to L^2(S^r, \mathbf{W}^+)$ is an isomorphism by the calculus of powers in Chapter 15. Thus $B := B_1 \Lambda$ has the same image as B_1 and $\ker B = \Lambda^{-1}(\ker B_1)$. This identification is G–equivariant and preserves the one-dimensional trivial kernel. The positive principal symbol of Λ does not change the symbol class after normalizing the order. This gives the operator B in the statement. □

Fix a metric h_ν on ν. A metric connection on ν splits the cotangent bundle of $\widehat{\nu}$ into horizontal and vertical parts,

$$T^*\widehat{\nu} = \mathbf{H}^* \oplus \mathbf{V}^*, \qquad \mathbf{H}^* \cong \widehat{\pi}^* T^* M, \qquad \mathbf{V}^* \cong \boldsymbol{\mathcal{P}}_\nu \times_G T^* S^r. \tag{19.18}$$

Denote by $|\cdot|_{\mathbf{H}}$ and $|\cdot|_{\mathbf{V}}$ the norms induced on $\mathbf{H}^*$ and $\mathbf{V}^*$, and by $|\cdot|_{\widehat{g}}$ the norm of the orthogonal sum. The operator B induces a vertical operator B_ν on $\widehat{\nu}$, between the associated bundles

$$\mathbf{W}_\nu^\pm := \boldsymbol{\mathcal{P}}_\nu \times_G \mathbf{W}^\pm \longrightarrow \widehat{\nu}.$$

Its kernel is the trivial line over M and its cokernel is zero, by (19.15).

The product construction will use cutoffs depending on the vertical operator. These cutoffs have two properties that we will need simultaneously: they preserve its spectral subspaces and turn local products into classical operators on the total manifold. We begin by specifying the domain corresponding to the latter.

Lemma 19.3.3. (Domain of a classical elliptic operator) Let X be a closed smooth manifold and let $\mathbf{E},\mathbf{F}\to X$ be complex vector bundles equipped with Hermitian bundle metrics. If $A\in\Psi^{1}_{\mathrm{cl}}(X;\mathbf{E},\mathbf{F})$ is elliptic, its closure in L^2 has domain $H^1(X,\mathbf{E})$, and the domain of its Hilbert space adjoint is $H^1(X,\mathbf{F})$. There exist constants $C_0,C_1>0$ such that, for every $\mathbf{u}\in H^1(X,\mathbf{E})$,

$$\|A\mathbf{u}\|_{L^2(X,\mathbf{F})}\le C_0\|\mathbf{u}\|_{H^1(X,\mathbf{E})}, \tag{19.19}$$

$$\|\mathbf{u}\|_{H^1(X,\mathbf{E})}\le C_1\left(\|A\mathbf{u}\|_{L^2(X,\mathbf{F})}+\|\mathbf{u}\|_{L^2(X,\mathbf{E})}\right). \tag{19.20}$$

The corresponding assertions hold for the formal adjoint. In particular, a formally self-adjoint classical elliptic operator of order one is self-adjoint with domain H^1.

Proof. The first inequality is Corollary 15.6.6. A parametrix $Q\in\Psi^{-1}_{\mathrm{cl}}(X;\mathbf{F},\mathbf{E})$ satisfies $QA=I-K$, where K is smoothing. Applying the identity $\mathbf{u}=QA\mathbf{u}+K\mathbf{u}$ and the same corollary yields (19.20). If $\mathbf{u}_j\in\Gamma(\mathbf{E})$ converges to $\mathbf{u}$ in $H^1(X,\mathbf{E})$, the first bound gives $A\mathbf{u}_j\to A\mathbf{u}$ in $L^2(X,\mathbf{F})$; thus $\mathbf{u}$ belongs to the domain of the closure. Conversely, if $(\mathbf{u}_j,A\mathbf{u}_j)$ converges in $L^2(X,\mathbf{E})\times L^2(X,\mathbf{F})$ to $(\mathbf{u},\mathbf{f})$, the second bound applied to $\mathbf{u}_j-\mathbf{u}_k$ proves that $(\mathbf{u}_j)$ is Cauchy in $H^1(X,\mathbf{E})$. Its limit in that space agrees with $\mathbf{u}$ by the continuous inclusion into $L^2(X,\mathbf{E})$; the first bound identifies $A\mathbf{u}=\mathbf{f}$. This proves both inclusions for the domain.

If $\mathbf{v}$ belongs to the domain of the Hilbert space adjoint, the identity defining that adjoint says that $A_h^{*}\mathbf{v}$ belongs to L^2 in the distributional sense. The parametrix of the classical elliptic operator A_h^{*} then gives $\mathbf{v}\in H^1(X,\mathbf{F})$. Conversely, let $\mathbf{v}\in H^1(X,\mathbf{F})$ and take $\mathbf{v}_j\in\Gamma(\mathbf{F})$ with $\mathbf{v}_j\to\mathbf{v}$ in $H^1(X,\mathbf{F})$. The mapping bound for A_h^{*} gives $A_h^{*}\mathbf{v}_j\to A_h^{*}\mathbf{v}$ in $L^2(X,\mathbf{E})$. For each $\mathbf{u}\in\Gamma(\mathbf{E})$, Cauchy–Schwarz allows us to pass to the limit in

$$\langle A\mathbf{u},\mathbf{v}_j\rangle_{L^2(X,\mathbf{F})}=\langle\mathbf{u},A_h^{*}\mathbf{v}_j\rangle_{L^2(X,\mathbf{E})}.$$

The resulting identity and $|\langle\mathbf{u},A_h^{*}\mathbf{v}\rangle_{L^2(X,\mathbf{E})}|\le\|\mathbf{u}\|_{L^2(X,\mathbf{E})}\|A_h^{*}\mathbf{v}\|_{L^2(X,\mathbf{E})}$ are precisely the definition of the domain of the Hilbert space adjoint. The two operators agree there. If $A_h^{*}=A$, their domains and actions agree, which is the asserted self-adjointness. □

Lemma 19.3.4. (Compactness from the first-order domain) Let X be a closed smooth manifold and let $\mathbf{E},\mathbf{F}\to X$ be complex vector bundles equipped with Hermitian bundle metrics. If $T:L^2(X,\mathbf{E})\to L^2(X,\mathbf{F})$ is bounded, its restriction is compact as a map

$$T:H^1(X,\mathbf{E})\longrightarrow L^2(X,\mathbf{F}).$$

This applies, in particular, to classical operators of order zero.

Proof. The restriction is the composition of the compact inclusion $H^1(X,\mathbf{E})\hookrightarrow L^2(X,\mathbf{E})$, given by Theorem 9.2.2, with the bounded operator T. For classical operators of order zero, boundedness on L^2 is Corollary 15.6.6. □

Lemma 19.3.5. (Spectral cutoffs on a local product) Let $n\in\mathbb{N}$, let Z be a closed smooth manifold, and let $\mathbf{W}\to Z$ be a complex vector bundle equipped with a Hermitian bundle metric. Suppose that $D\in\Psi^{1}_{\mathrm{cl}}(Z;\mathbf{W},\mathbf{W})$ is elliptic and self-adjoint with domain $H^1(Z,\mathbf{W})$. Set $L=I+D^2$ and denote the principal

symbol of D by $b_1(z,\eta)$. Fix $h \in C_c^\infty(\mathbb{R})$ such that

$$0 \le h \le 1, \qquad h(t) = 1 \quad (-1 \le t \le 1), \qquad h(t) = 0 \quad (t \ge 4).$$

For $R \ge 1$ define Φ_R using the partial Fourier transform in $x \in \mathbb{R}^n$:

$$\widehat{\Phi_R \mathbf{u}}(\xi) = h\left(\frac{R^2 L}{1+|\xi|^2}\right)\widehat{\mathbf{u}}(\xi), \qquad \xi \in \mathbb{R}^n. \tag{19.21}$$

It is self-adjoint and $0 \le \Phi_R \le I$ on $L^2(\mathbb{R}^n \times Z, \mathbf{W})$. After multiplication on the left and right by smooth compactly supported functions in x, the operators

$$\Phi_R, \qquad (P \otimes I)\Phi_R, \qquad \Phi_R(P \otimes I), \qquad (I \otimes D)(I - \Phi_R)$$

are classical in the joint variables (x,z), of orders $0,1,1,1$, respectively, for every classical operator P of order one in $\mathbb{R}^n$ between trivial bundles of finite rank. Identities on the additional factors are understood in the formulas.

The principal symbol of the cutoff is

$$f_R(z;\xi,\eta) = h\left(\frac{R^2 b_1(z,\eta)^2}{|\xi|^2}\right) \quad (\xi \ne 0), \tag{19.22}$$

extended by zero when $\xi = 0$ and $\eta \ne 0$. Near the axis $\eta = 0$, with $\xi \ne 0$, it is the identity. The other three principal symbols are $p_1 f_R$, $f_R p_1$, and $b_1(I - f_R)$.

Every bounded operator in the vertical variable commuting with the resolvent of D commutes with Φ_R. Every grading anticommuting with D also commutes with Φ_R. If a compact group acts unitarily on $\mathbf{W}$ and D is equivariant, the cutoffs are equivariant.

Proof. By the spectral theorem, for every $\xi \in \mathbb{R}^n$ the operator $h(R^2 L/(1+|\xi|^2))$ is a positive self-adjoint contraction. Plancherel in the variable x proves the same properties for Φ_R. The commutation relations follow from functional calculus; if $\Gamma D = -D\Gamma$, then Γ commutes with L and all its spectral functions.

Let us prove the assertion about joint symbols. We use the construction of the resolvent parametrix in Proposition 15.7.6, retaining the dependence of the bounds on distance to the real axis. Write

$$\tau = R^{-1}(1+|\xi|^2)^{1/2}, \qquad h\left(\frac{R^2 L}{1+|\xi|^2}\right) = h(\tau^{-2} L).$$

In a chart of Z, the symbol of L has an expansion $\ell \sim \sum_{j=0}^{\infty} \ell_{2-j}$, whose first term is $\ell_2 = b_1^2$. It is a positive Hermitian matrix for $\eta \ne 0$. Compactness and ellipticity give constants $c_Z, C_Z > 0$ such that

$$c_Z |\eta|^2 I \le \ell_2(z,\eta) \le C_Z |\eta|^2 I. \tag{19.23}$$

To integrate the resolvent against a smooth function, fix $N \in \mathbb{N}$ and a cutoff $\vartheta \in C_c^\infty(\mathbb{R})$ equal to one near

zero. With $w = a + it$ set

$$\widetilde{h}_N(a+it) = \vartheta(t) \sum_{j=0}^{N} \frac{(it)^j}{j!} h^{(j)}(a).$$

The operator $\partial_{\overline{w}} = \frac{1}{2}(\partial_a + i\partial_t)$ satisfies $|\partial_{\overline{w}} \widetilde{h}_N(a+it)| \le C_N |t|^N$ for $|t|$ sufficiently small. The Cauchy–Green formula, first for a real number and then integrated against the spectral resolution of L, gives

$$h(\tau^{-2}L) = \frac{1}{\pi} \int_{\mathbb{R}^2} \partial_{\overline{w}} \widetilde{h}_N(w)\, \tau^2 (L - \tau^2 w)^{-1}\, da\, dt. \tag{19.24}$$

The integrand is considered for $t \neq 0$; the set $t = 0$ has measure zero. The spectral bound

$$\|\tau^2 (L - \tau^2 w)^{-1}\|_{\mathcal{L}(L^2(Z,\mathbf{W}))} \le |t|^{-1}$$

justifies the integral in operator norm when $N \ge 1$.

The symbol recurrence of Chapter 15 now applies to $L - \tau^2 w$. In the region $\eta \neq 0$ it starts with

$$r_{-2} = (\ell_2 - \tau^2 w)^{-1}$$

and, for $j \in \mathbb{N}$, continues by

$$r_{-2-j} = -r_{-2} \sum_{\substack{a,b \in \mathbb{N}_0,\ \gamma \in \mathbb{N}_0^{\dim Z} \\ a+b+|\gamma| = j,\ b<j}} \frac{i^{-|\gamma|}}{\gamma!} (\partial_\eta^\gamma \ell_{2-a})(\partial_z^\gamma r_{-2-b}). \tag{19.25}$$

On an annulus where $|\eta|$ and τ are comparable, all derivatives of r_{-2-j} satisfy the parameter-dependent estimates of order $-2-j$. Their constants are bounded by a power of $|t|^{-1}$: this is seen first for r_{-2} from (19.23), and when the inverse is differentiated, each new derivative adds finitely many factors r_{-2}. The finite sum in (19.25) retains this property. Specifically, for every finite set of derivatives, there exists an integer m_N bounding the power of $|t|^{-1}$ needed both in the finite parametrix and in its remainder.

In (19.24) choose an extension of order greater than $m_N + 2$. We can then integrate each term and its remainder. The left and right parametrix identities, followed by the bound for the exact resolvent, control the difference between the two resolvents: if $(L - \tau^2 w) Q_N = I - S_N$, then

$$(L - \tau^2 w)^{-1} - Q_N = (L - \tau^2 w)^{-1} S_N.$$

Choose the expansion length so that S_N has the required negative order before integration. This produces, on the annulus $|\eta| \asymp \tau$, a classical expansion whose first term is $h(\ell_2/\tau^2)$.

Let us also examine what happens outside this annulus. Every term in the recurrence is a rational function of w; its poles lie in the spectrum of ℓ_2/τ^2. If $|\eta|/\tau$ is sufficiently small, this spectrum lies in an interval where $h = 1$. The integral of the first term is then I. Those of the subsequent terms vanish: they are integrals of products of resolvents whose expansion in w starts with w^{-2}, and integrating a constant function around all its poles gives zero. This argument remains valid for noncommuting matrices, since it applies entry by entry to the complete rational function. If $|\eta|/\tau$ is sufficiently large, h vanishes near all the poles and all the integrals vanish. Introducing cutoffs in these three regions leaves the terms differentiating the cutoffs in the transition annuli.

To control the remainders near the axis $\eta = 0$ as well, separate the frequencies $|\eta| \le 2\tau^{1/2}$, assuming first that $\tau \ge 1$. Let Q_τ be a vertical localization whose symbol is one for $|\eta| \le \tau^{1/2}$ and zero for $|\eta| \ge 2\tau^{1/2}$, with the spatial cutoffs of the chart. For $N \in \mathbb{N}$ define

$$g_N(t) = \frac{h(t) - 1}{t^N} \quad (t > 0), \qquad g_N(0) = 0.$$

This function is smooth and bounded on $[0, +\infty)$, since its numerator vanishes near zero. Spectral calculus gives the exact identity

$$\big(h(\tau^{-2}L) - I\big)Q_\tau = \tau^{-2N} g_N(\tau^{-2}L) L^N Q_\tau.$$

Vertical Sobolev norms can be expressed using powers of L, by Proposition 15.7.10. Thus $g_N(\tau^{-2}L)$ is uniformly bounded on each of these spaces. For $s \in \mathbb{N}_0$, symbol calculus and the bound $\langle \eta \rangle \le C\tau^{1/2}$ on the cutoff support give

$$\|L^N Q_\tau\|_{\mathcal{L}(H^{-s}(Z,\mathbf{W}),H^s(Z,\mathbf{W}))} \le C_{N,s}\tau^{N+s}.$$

Indeed, conjugating by the powers of L defining the two norms produces a symbol of order $2N + 2s$ with this support; dividing it by τ^{N+s} leaves bounded the order-zero seminorms needed for the estimate on L^2. We thus obtain

$$\|\big(h(\tau^{-2}L) - I\big)Q_\tau\|_{\mathcal{L}(H^{-s}(Z,\mathbf{W}),H^s(Z,\mathbf{W}))} \le C_{N,s}\tau^{-N+s}.$$

The integer N is arbitrary. Differentiating in τ produces derivatives of the cutoff and functions obtained from g_N by applying $t\partial_t$; these functions remain bounded. The same choice of N therefore controls any prescribed number of parameter derivatives.

In the complementary region $|\eta| \ge \tau^{1/2}$, use the weak resolvent estimates from the chapter on pseudodifferential operators. For every prescribed set of derivatives, the remainders are bounded by a fixed power of $1 + \tau$ multiplied by a negative power of $\langle \eta \rangle$ whose exponent can be made as large in magnitude as desired by increasing the length of the parametrix. Conversion to a joint bound is seen in the inequality

$$(1+\tau)^a \langle \eta \rangle^{-J} \le C_{a,K} \langle (\tau, \eta) \rangle^{-K}, \qquad |\eta| \ge \tau^{1/2}, \quad \tau \ge 1, \quad J \ge 2(a+K),$$

where $a, K \ge 0$. If $|\eta| \le \tau$, use $\langle \eta \rangle^{-J} \le \tau^{-J/2}$; if $|\eta| \ge \tau$, absorb $(1+\tau)^a$ into $\langle \eta \rangle^a$. The order of the almost analytic extension is increased after fixing J, so that the powers of $|t|^{-1}$ that have appeared can be integrated. The derivatives of Q_τ lie in this same region, so the two localizations can be recombined with the stated bounds. Finally, for $R^{-1} \le \tau \le 1$ the horizontal parameter stays bounded; smoothing spectral calculus in the vertical variable and horizontal localization give jointly smooth remainders. This justifies, for the remainders as well, that in the extreme cones the symbol is respectively I and 0 modulo arbitrarily negative order.

More precisely, after localization in x and in a chart of Z, we obtain a symbol f with homogeneous components f_{-j}, extended using a common cutoff near the origin. For $J \in \mathbb{N}$ and multiindices $\alpha, \beta \in \mathbb{N}_0^{\dim Z}$ and $\delta \in \mathbb{N}_0^n$ we have

$$\left\| \partial_z^\alpha \partial_\eta^\beta \partial_\xi^\delta \left(f - \sum_{j=0}^{J-1} f_{-j} \right) \right\|_{\mathrm{op}} \le C_{J,\alpha,\beta,\delta,R} \langle (\xi, \eta) \rangle^{-J-|\beta|-|\delta|}. \tag{19.26}$$

The same estimate allows derivatives in x after inserting the cutoffs. The smooth-kernel remainders satisfy these bounds for every J: use the identity with S_N between vertical Sobolev spaces of arbitrary orders and apply the kernel regularity established in Chapter 15. Derivatives in ξ are obtained by differentiating the

resolvent and τ before integration. The principal term, upon replacing $1+|\xi|^2$ by its homogeneous part, is (19.22). Its extensions to the axes are smooth because h is constant on the specified intervals.

In Kohn–Nirenberg quantization, P acts only in x and the symbol of the cutoff is independent of x before localization. The symbol of $(P\otimes I)\Phi_R$ is therefore the product $p(x,\xi)f(z,\eta,\xi)$. In the cone where $|\eta|$ dominates $|\xi|$, the second factor has arbitrarily negative order; in its complement, $|\xi|$ controls the joint frequency. The symbol estimates for p and (19.26) prove that the product has joint order one and is classical. The assertion for $\Phi_R(P\otimes I)$ follows by taking adjoints.

For $D(I-\Phi_R)$ use vertical composition with a parameter. In the cone where $|\xi|$ dominates $|\eta|$, the symbol of $I-\Phi_R$ has arbitrarily negative order. In the remaining cone, $|\eta|$ controls the joint frequency, and the symbol estimates for D apply. This yields a classical joint symbol of order one with principal part $b_1(I-f_R)$. The localizations and changes of coordinates are those of the classical calculus already constructed, completing the proof. □

Lemma 19.3.6. (Product symbol and normal Thom class) Let M be a closed smooth manifold and let $a=[\mathbf{E}^+,\mathbf{E}^-,p]\in K_c^0(T^*M)$, where $\mathbf{E}^+,\mathbf{E}^-\to M$ are smooth complex vector bundles. Use the normal connection, metrics, and compactification $\nu\subset\widehat{\nu}$ fixed above. Denote by $q:T^*\nu\to M$ the projection and set

$$\mathbf{\Lambda}_\nu^+=q^*\left(\bigoplus_{\substack{j\in\{0,\dots,r\}\\ j\text{ even}}}\Lambda^j(\nu\otimes_{\mathbb{R}}\mathbb{C})\right),\qquad \mathbf{\Lambda}_\nu^-=q^*\left(\bigoplus_{\substack{j\in\{0,\dots,r\}\\ j\text{ odd}}}\Lambda^j(\nu\otimes_{\mathbb{R}}\mathbb{C})\right).$$

The component from even to odd degree of the normal Koszul homomorphism is

$$\beta^+(v,\eta)=\big(\varepsilon(v+i\eta^\sharp)+\iota(v-i\eta^\sharp)\big)\Big|_{\mathbf{\Lambda}_\nu^+}.$$

On $T^*\nu$, the graded matrix

$$\mathbf{c}(x,v;\xi,\eta)=\begin{pmatrix}p(x,\xi)\otimes I & -I\otimes\beta^+(v,\eta)^*\\ I\otimes\beta^+(v,\eta) & p(x,\xi)^*\otimes I\end{pmatrix},\tag{19.27}$$

is invertible outside a compact set. Its class, extended from this open subset, satisfies

$$\operatorname{ext}_{T^*\nu}^{T^*\widehat{\nu}}[\mathbf{c}]=\operatorname{ext}_{T^*\nu}^{T^*\widehat{\nu}}\operatorname{Th}_{T\nu}\big((\sharp_g)_*a\big)\quad\text{in } K_c^0(T^*\widehat{\nu}).\tag{19.28}$$

Proof. The connection identifies the normal bundle $T\nu$ over TM with $\pi_{TM}^*(\nu\oplus\nu)$. The metric identifies the second copy of ν with the vertical covariables, and the complex structure of (19.1) expresses its coordinate as

$$z=v+i\eta^\sharp,\qquad J(v,\eta^\sharp)=(-\eta^\sharp,v).$$

The normal Koszul homomorphism on the full exterior bundle is $\beta(v,\eta)=\varepsilon(z)+\iota(\overline{z})$. It is self-adjoint and odd and satisfies

$$\beta^2=(|v|^2+|\eta|^2)I,\qquad (\beta^+)^*\beta^+=(|v|^2+|\eta|^2)I\quad\text{on }\mathbf{\Lambda}_\nu^+.$$

The corresponding identity holds in odd degree. Thus β^+ is invertible away from the zero section. These formulas are preserved under changes of frame of $O(r)$ and define global homomorphisms of the stated bundles. The graded product of the horizontal complex $(\mathbf{E}^+,\mathbf{E}^-,p)$ with this normal complex has even and

odd parts, respectively,

$$(q^*\mathbf{E}^+ \otimes \mathbf{\Lambda}_\nu^+) \oplus (q^*\mathbf{E}^- \otimes \mathbf{\Lambda}_\nu^-), \qquad (q^*\mathbf{E}^- \otimes \mathbf{\Lambda}_\nu^+) \oplus (q^*\mathbf{E}^+ \otimes \mathbf{\Lambda}_\nu^-),$$

and its odd differential from even to odd degree is exactly the matrix (19.27). By the definition of the product of complexes and the Thom isomorphism, its class is $\mathrm{Th}_{T\nu}((\sharp_g)_* a)$, identifying $T\nu$ with $T^*\nu$ by the fixed metrics. To check the support, the product of the matrix with its adjoint has diagonal blocks

$$p^*p \otimes I + (|v|^2 + |\eta|^2)I, \qquad pp^* \otimes I + (|v|^2 + |\eta|^2)I.$$

Thus the matrix can fail to be invertible only when $v = \eta = 0$ and $p(x, \xi)$ is not invertible. The latter set is compact because a is a compactly supported class.

The factors are ordered with the horizontal factor first and the normal factor second; the sign of the upper-right block is the corresponding Koszul sign and does not introduce an additional sign into the class. In complex rank one, the preceding coordinate gives the convention $\lambda_{\mathbb{C}} = -b$ of (18.7); by multiplicativity, it fixes both the orientation and the sign in every rank. Finally, the matrix class has compact support in $T^*\nu$. The extension-by-zero map for the open subset $T^*\nu \subset T^*\widehat{\nu}$ gives, by definition, precisely the right-hand side of (19.28). □

Spectral cutoffs allow the product to be formed within the classical calculus on $\widehat{\nu}$. The vertical kernel provides a copy of the sections over M. On its complement, a symmetry interchanging the degrees will make the contributions to the index cancel.

Lemma 19.3.7. (Horizontal and vertical product) Let M be a closed smooth manifold and let $\mathbf{E}^+, \mathbf{E}^- \to M$ be smooth complex vector bundles. Let $P \in \Psi^1_{\mathrm{cl}}(M; \mathbf{E}^+, \mathbf{E}^-)$ be elliptic and let B be the operator of Lemma 19.3.2. There exist a classical elliptic operator of order one

$$C : \Gamma(\widehat{\nu}, \boldsymbol{\mathcal{E}}^+) \longrightarrow \Gamma(\widehat{\nu}, \boldsymbol{\mathcal{E}}^-)$$

and bundles

$$\boldsymbol{\mathcal{E}}^+ = (\widehat{\pi}^*\mathbf{E}^+ \otimes \mathbf{W}_\nu^+) \oplus (\widehat{\pi}^*\mathbf{E}^- \otimes \mathbf{W}_\nu^-),$$
$$\boldsymbol{\mathcal{E}}^- = (\widehat{\pi}^*\mathbf{E}^- \otimes \mathbf{W}_\nu^+) \oplus (\widehat{\pi}^*\mathbf{E}^+ \otimes \mathbf{W}_\nu^-)$$

such that, if $a = [\sigma(P)]$, then

$$[\sigma(C)] = \mathrm{ext}^{T^*\widehat{\nu}}_{T^*\nu} \mathrm{Th}_{T\nu}\left((\sharp_{\mathbf{g}})_* a\right) \quad \text{in } K^0_c(T^*\widehat{\nu}) \tag{19.29}$$

and

$$\mathrm{ind_a}(C) = \mathrm{ind_a}(P). \tag{19.30}$$

The domain of the closure of C is $H^1(\widehat{\nu}, \boldsymbol{\mathcal{E}}^+)$, and that of its Hilbert space adjoint is $H^1(\widehat{\nu}, \boldsymbol{\mathcal{E}}^-)$.

Proof. Set $\mathbf{W} = \mathbf{W}^+ \oplus \mathbf{W}^-$ and consider on the fiber the operator and grading

$$D_B = \begin{pmatrix} 0 & B^* \\ B & 0 \end{pmatrix}, \qquad \Gamma_B = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}.$$

By Lemma 19.3.3, D_B is self-adjoint with domain $H^1(S^r,\mathbf{W})$. Denote by Π_0 the orthogonal projection onto its kernel. Elliptic regularity shows that Π_0 is smoothing. By (19.15), its image is a line in even degree, and the action of G on it is trivial. Choose a generator $\mathbf{e}_0$ with L^2 norm equal to one. Both D_B and Π_0 are G–equivariant and therefore induce vertical operators on $\widehat{\nu}$; we retain the same letters for them.

Equip $\widehat{\nu}$ with the connection metric making horizontal and vertical directions orthogonal, using the round metric on the fibers. In an associated trivialization, its measure is $d\lambda_{\mathbf{g}}(x)\,d\lambda_{S^r}(z)$. Changes of trivialization are fiber isometries. Thus

$$(\mathcal{I}\mathbf{u})(x,z)=\mathbf{u}(x)\otimes\mathbf{e}_0(z) \tag{19.31}$$

defines a global isometry from $L^2(M,\mathbf{E}^+\oplus\mathbf{E}^-)$ onto $\Pi_0L^2(\widehat{\nu},\boldsymbol{\mathcal{E}})$, where $\boldsymbol{\mathcal{E}}=\boldsymbol{\mathcal{E}}^+\oplus\boldsymbol{\mathcal{E}}^-$. It also identifies the corresponding H^1 spaces: in a product chart, derivatives in x act on $\mathbf{u}$ and vertical derivatives on the fixed smooth section $\mathbf{e}_0$; the norm identity in L^2 gives the reverse bound. Finitely many charts give the global equivalence.

First suppose that $n=\dim M\geq 1$. Choose a finite cover $(U_\ell)_{\ell=1}^J$ trivializing ν and $\mathbf{E}^\pm$, and real functions $\chi_\ell\in C_c^\infty(U_\ell)$ such that

$$\sum_{\ell=1}^J\chi_\ell^2=1\quad\text{on } M.$$

Use orthonormal frames for ν and unitary frames for the complex bundles. When passing to Euclidean coordinates in U_ℓ, incorporate the square root of the measure Jacobian into the isomorphism between the L^2 spaces. Thus the adjoints in coordinates are the Hilbert space adjoints of the transported operators.

Let P_ℓ be the local expression of $\zeta_\ell P\zeta_\ell$, extended to $\mathbb{R}^n$, where $\zeta_\ell\in C_c^\infty(U_\ell)$ equals one near $\operatorname{supp}\chi_\ell$. Set

$$A_\ell=\begin{pmatrix}0 & P_\ell^*\\ P_\ell & 0\end{pmatrix},\qquad \Gamma_P=\begin{pmatrix}I & 0\\ 0 & -I\end{pmatrix}$$

on the factor $\mathbf{E}^+\oplus\mathbf{E}^-$. In the product chart $U_\ell\times S^r$ apply Lemma 19.3.5 to D_B and write $\Phi_{\ell,R}$ for the cutoff constructed there. Before multiplying by χ_ℓ, perform horizontal quantization on all of $\mathbb{R}^n$. Define the odd operator

$$\mathscr{C}_R=\sum_{\ell=1}^J\chi_\ell\left[\frac{1}{2}\left(A_\ell\Phi_{\ell,R}+\Phi_{\ell,R}A_\ell\right)+R\Gamma_PD_B(I-\Phi_{\ell,R})\right]\chi_\ell. \tag{19.32}$$

Transport each summand to $\widehat{\pi}^{-1}(U_\ell)$ and extend it by zero in the base variable. The outer functions make this extension globally defined. The cutoff lemma proves that $\mathscr{C}_R\in\Psi^1_{\mathrm{cl}}(\widehat{\nu};\boldsymbol{\mathcal{E}},\boldsymbol{\mathcal{E}})$. Symmetrization of the horizontal term and commutation of D_B with the cutoffs show that it is formally self-adjoint.

Let us verify its ellipticity and fix the size of R. Denote by $a_1(x,\xi)$ the odd principal matrix of P and by $b_1(y,\eta)$ that of D_B, where $y\in\widehat{\nu}$, $x=\widehat{\pi}(y)$, and $(\xi,\eta)\in\mathbf{H}^*_y\oplus\mathbf{V}^*_y$. Extend both symbols by zero at their respective origins. They are continuous and homogeneous of degree one. There exist constants $c_P,c_B,C_B>0$ such that

$$a_1(x,\xi)^2\geq c_P^2|\xi|^2I,\qquad c_B^2|\eta|^2I\leq b_1(y,\eta)^2\leq C_B^2|\eta|^2I. \tag{19.33}$$

Homogeneity also gives a constant $L_P>0$ for which

$$\|a_1(x,\xi')-a_1(x,\xi)\|_{\mathrm{op}}\leq L_P|\xi'-\xi|.$$

Indeed, first derivatives in the covariable are homogeneous of degree zero and bounded in a finite atlas.

Integrate this bound along the segment between ξ and ξ'; if it passes through the origin, apply it on the two subsegments and use continuity there.

The product coordinates of the trivialization and the fixed horizontal splitting need not give the same decomposition. In the trivialization ℓ, the coordinate horizontal covariable corresponds to

$$\xi_\ell = \xi + T_\ell(y)\eta \in T_x^*M, \qquad \|T_\ell(y)\|_{\mathrm{op}} \le A_0.$$

The constant A_0 exists because we use only finitely many trivializations over compact sets. If $|\cdot|_\ell$ is the Euclidean norm of the components in that chart, fix $c_x, C_x > 0$ such that

$$c_x|\omega| \le |\omega|_\ell \le C_x|\omega|, \qquad \omega \in T_x^*M, \quad x \in \operatorname{supp}\chi_\ell, \quad \ell \in \{1,\dots,J\}.$$

The symbol of the cutoff, transported to the corresponding fiber, is

$$f_{\ell,R}(y;\xi,\eta) = h\!\left(\frac{R^2 b_1(y,\eta)^2}{|\xi_\ell|_\ell^2}\right).$$

On the axes, use the extensions of the lemma. These endomorphisms are positive, bounded by I, and commute with one another and with b_1, since they are functions of the same matrix b_1^2. Set

$$F_R = \sum_{\ell=1}^{J} \chi_\ell(x)^2 f_{\ell,R},$$

extending each term by zero outside its trivialization. The principal symbol of (19.32) is

$$c_R = \sum_{\ell=1}^{J} \chi_\ell^2 a_1(x,\xi_\ell) f_{\ell,R} + R\Gamma_P b_1(y,\eta)(I - F_R). \tag{19.34}$$

The identity factors on $\mathbf{E}$ and $\mathbf{W}$ remain implicit in this formula; the two operators act on distinct tensor factors.

Compare c_R with

$$m_R = a_1(x,\xi)F_R + R\Gamma_P b_1(y,\eta)(I - F_R).$$

The preceding bounds imply

$$\|c_R - m_R\|_{\mathrm{op}} \le L_P A_0 |\eta|. \tag{19.35}$$

Since $a_1\Gamma_P = -\Gamma_P a_1$, and F_R commutes with the vertical factors, the cross terms in the square cancel exactly:

$$m_R^2 = a_1(x,\xi)^2 F_R^2 + R^2 b_1(y,\eta)^2 (I - F_R)^2. \tag{19.36}$$

Choose

$$\delta = \min\left\{\frac{1}{4}, \frac{c_x}{4C_B}, \frac{c_B}{8C_x}\right\}, \qquad R \ge \max\{1, A_0/\delta\}.$$

If $R|\eta| \le \delta|\xi|$, then $|\xi_\ell| \ge (1-\delta^2)|\xi| \ge \tfrac{3}{4}|\xi|$. All matrices $R^2 b_1^2/|\xi_\ell|_\ell^2$ have spectrum in $[0,1]$ for the indices $\ell \in \{1,\dots,J\}$ with $\chi_\ell(x) \neq 0$. Thus $f_{\ell,R} = I$ in the terms occurring in the sum, and $F_R = I$. If $|\xi| \le \delta R|\eta|$, then $|\xi_\ell|_\ell \le 2C_x\delta R|\eta|$. The corresponding spectra then lie in $[4,+\infty)$; hence $F_R = 0$. In the remaining region, we

have simultaneously

$$|\xi| > \delta R|\eta|, \qquad R|\eta| > \delta|\xi|.$$

Thus each of $|\xi|^2$ and $R^2|\eta|^2$ is at least $\frac{\delta^2}{2}(|\xi|^2 + R^2|\eta|^2)$. Moreover,

$$F_R^2 + (I - F_R)^2 = 2(F_R - \tfrac{1}{2}I)^2 + \tfrac{1}{2}I \geq \tfrac{1}{2}I.$$

Applying (19.36) in the three regions gives, with $c_* = \min\{c_P, c_B\}$,

$$\|m_R \mathbf{v}\| \geq \frac{\delta c_*}{2}(|\xi|^2 + R^2|\eta|^2)^{1/2}\|\mathbf{v}\|$$

for every fiber vector $\mathbf{v}$. Finally, fix

$$R \geq \max\left\{1, \frac{A_0}{\delta}, \frac{4L_P A_0}{\delta c_*}\right\}.$$

Inequality (19.35) implies

$$\|c_R \mathbf{v}\| \geq \frac{\delta c_*}{4}(|\xi|^2 + R^2|\eta|^2)^{1/2}\|\mathbf{v}\|. \tag{19.37}$$

This proves ellipticity of $\mathscr{C}_R$. Lemma 19.3.3 and Theorem 15.6.22 give

$$\mathcal{D}(\mathscr{C}_R) = H^1(\widehat{\nu}, \boldsymbol{\mathcal{E}}), \qquad \mathcal{D}(\mathscr{C}_R^{\pm}) = H^1(\widehat{\nu}, \boldsymbol{\mathcal{E}}^{\pm}). \tag{19.38}$$

The operator $\mathscr{C}_R$ is self-adjoint, and its component $C := \mathscr{C}_R^+$ is Fredholm, with adjoint $\mathscr{C}_R^-$ on the stated domain.

Let us calculate its index. The operator $D_B^2 + \Pi_0$ is positive, invertible, and classical elliptic of order two on the fiber. The complex powers of Theorem 15.7.9 allow us to define

$$J_B = D_B(D_B^2 + \Pi_0)^{-1/2} \in \Psi^0_{\mathrm{cl}}(S^r; \mathbf{W}, \mathbf{W}).$$

It is equivariant and satisfies

$$J_B^* = J_B, \qquad J_B^2 = I - \Pi_0, \qquad J_B\Gamma_B = -\Gamma_B J_B.$$

The vertical operators Π_0 and J_B are bounded on the spaces L^2 and H^1 of the total manifold. To check the second assertion, in a product chart they commute with derivatives in x and are bounded on vertical H^1 by the order-zero calculus; a finite partition of unity gives the global bound.

Every summand of (19.32) commutes with Π_0. On the complement of its image define

$$\mathcal{T} = \Gamma_P \Gamma_B J_B.$$

This operator is unitary, interchanges degrees, and satisfies $\mathcal{T}^2 = -I$. The cutoffs commute with J_B and Γ_B; the operators A_ℓ commute with them and anticommute with Γ_P. Thus

$$\mathcal{T}\mathscr{C}_R = -\mathscr{C}_R\mathcal{T} \quad \text{on } (I - \Pi_0)H^1(\widehat{\nu}, \boldsymbol{\mathcal{E}}). \tag{19.39}$$

First verify the identity on smooth sections. Boundedness of $\mathcal{T}$ on H^1 and (19.38) allows it to extend to the domain. Consequently, $\mathcal{T}$ identifies the even and odd parts of the kernel of $\mathscr{C}_R$ lying in $(I - \Pi_0)L^2$. Their

dimensions are finite and their contributions to the index cancel.

On $\Pi_0 L^2$, the vertical operator vanishes and the cutoff is the scalar horizontal multiplier

$$a_{0,R}(\xi) = h\left(\frac{R^2}{1+|\xi|^2}\right).$$

This function equals one outside a ball. Through (19.31), the even-to-odd component of the restriction of $\mathscr{C}_R$ is identified with the operator

$$P_R = \frac{1}{2}\sum_{\ell=1}^{J} \chi_\ell \big(P_\ell a_{0,R}(D_x) + a_{0,R}(D_x) P_\ell\big)\chi_\ell$$

on M, transporting each summand from its chart. Since $a_{0,R} - 1$ has compact support in the horizontal frequency,

$$P_R - P = \sum_{\ell=1}^{J} \chi_\ell [P, \chi_\ell] + S_R, \qquad S_R \in \Psi^{-\infty}(M; \mathbf{E}^+, \mathbf{E}^-). \tag{19.40}$$

The commutators are classical of order zero. By Lemma 19.3.4, $P_R - P$ is compact from H^1 to L^2, so $\operatorname{ind} P_R = \operatorname{ind} P$ by Theorem 16.2.1.

If $K^\pm$ denotes the part of the kernel of $\mathscr{C}_R$ lying in $(I - \Pi_0)L^2$ and of degree $\pm$, we have proved the decompositions

$$\begin{aligned} \ker C &= \mathcal{I}(\ker P_R) \oplus K^+, \\ \ker C^* &= \mathcal{I}(\ker P_R^*) \oplus K^-, \qquad \mathcal{T} : K^+ \xrightarrow{\cong} K^-. \end{aligned} \tag{19.41}$$

Subtracting dimensions yields

$$\operatorname{ind} C = \operatorname{ind} P_R = \operatorname{ind} P. \tag{19.42}$$

It remains to identify the symbol class. In (19.34) replace T_ℓ simultaneously by tT_ℓ, with $t \in [0,1]$, both in $a_1(x, \xi_\ell)$ and in $f_{\ell,R}$. The estimates leading to (19.37) remain valid, since $\|tT_\ell\|_{\mathrm{op}} \le A_0$. This gives a homotopy of invertible symbols on the cotangent bundle with its zero section removed. At $t = 0$ it takes the form

$$a_1(x,\xi)F + R\Gamma_P b_1(y,\eta)(I - F),$$

where F is a convex sum of functions of b_1^2 and $0 \le F \le I$. For $s \in [0,1]$ replace the two coefficients by

$$F_s = (1-s)F + sI, \qquad G_s = (1-s)(I-F) + sI.$$

The square of $a_1 F_s + R\Gamma_P b_1 G_s$ is $a_1^2 F_s^2 + R^2 b_1^2 G_s^2$. Since $F_s \ge F$ and $G_s \ge I - F$, the lower bound at the start of the homotopy is preserved. At the end we obtain $a_1 + R\Gamma_P b_1$. Deforming the positive factor R to one yields $a_1 + \Gamma_P b_1$.

These last homotopies are continuous homotopies of bundle homomorphisms on the cosphere bundle. They are not used to define operators at intermediate values. Continuity suffices for homotopy invariance of the K–theory class. The even-to-odd component of the final symbol is

$$\begin{pmatrix} p_1(x,\xi)\otimes I & -I \otimes b_1^+(y,\eta)^* \\ I \otimes b_1^+(y,\eta) & p_1(x,\xi)^* \otimes I \end{pmatrix},$$

where b_1^+ is the symbol of B. This is the graded product of the horizontal class with the vertical class. Lemma 19.3.2 identifies the latter with the extension of the normal Bott class. Lemma 19.3.6 identifies its product with the Thom class, with the order of factors and orientation already fixed. This gives (19.29).
If $\dim M = 0$, M is a finite set. Over each point, use the vertical operator $\Gamma_P D_B$ directly in the graded product with $\mathbf{E}^+ \oplus \mathbf{E}^-$. Its index is $\dim \mathbf{E}^+ - \dim \mathbf{E}^-$, which agrees with the index of any linear map from $\mathbf{E}^+$ to $\mathbf{E}^-$ over that point. Its symbol is the product of this virtual class with the Bott class. Summing over the points of M gives both identities in the statement and completes the proof. □

Theorem 19.3.8. (Analytic compatibility with the pushforward) Let M be a closed smooth manifold, let $j\colon M \hookrightarrow \mathbb{R}^N$ be a smooth embedding, and let $a \in K_c^0(T^*M)$. Then

$$\operatorname{ind}_{\mathrm{a}}^{\mathbb{R}^N}(j_! a) = \operatorname{ind}_{\mathrm{a}}^{M}(a). \tag{19.43}$$

Proof. Represent a by the symbol of an elliptic operator P on M. Theorem 17.4.3 allows this after stabilization, which adds an identity of index zero. If the resulting representative has order zero, fix a positive invertible operator

$$\Lambda_+ \in \Psi_{\mathrm{cl}}^1(M;\mathbf{E}^+), \qquad \Lambda_+^{-1} \in \Psi_{\mathrm{cl}}^{-1}(M;\mathbf{E}^+),$$

and replace P by $P\Lambda_+$. Composition with Λ_+ does not change the index. Its positive scalar symbol contracts to the identity symbol after normalizing the order, so it also leaves the class a unchanged. We may therefore apply Lemma 19.3.7. This gives an operator C on $\widehat{\nu}$ with

$$\operatorname{ind}_{\mathrm{a}}(C) = \operatorname{ind}_{\mathrm{a}}(P) \tag{19.44}$$

and symbol class

$$[\sigma(C)] = \operatorname{ext}_{T^*\nu}^{T^*\widehat{\nu}} \operatorname{Th}_{T\nu}\big((\sharp_g)_* a\big) \in K_c^0(T^*\widehat{\nu}), \tag{19.45}$$

where the metric and connection identify the Thom representative on $T\nu$ with the corresponding complex on $T^*\nu$, followed by extension from the open subset $T^*\nu \subset T^*\widehat{\nu}$. This equality is precisely (19.29).
To pass from $\widehat{\nu}$ to the tubular neighborhood, we reduce the order of the operator and localize its symbol. Let

$$\Lambda_{-1} \in \Psi_{\mathrm{cl}}^{-1}(\widehat{\nu};\boldsymbol{\mathcal{E}}^+)$$

be positive and elliptic, chosen so that $\Lambda_{-1} : L^2(\widehat{\nu},\boldsymbol{\mathcal{E}}^+) \longrightarrow H^1(\widehat{\nu},\boldsymbol{\mathcal{E}}^+)$ is an isomorphism; its inverse has order one. The operator

$$C\Lambda_{-1}\colon L^2(\widehat{\nu},\boldsymbol{\mathcal{E}}^+) \longrightarrow L^2(\widehat{\nu},\boldsymbol{\mathcal{E}}^-)$$

has order zero. Since Λ_{-1} is invertible, it preserves the kernel, cokernel, and index of C; its normalized positive symbol is homotopic to the identity and also leaves the symbol class unchanged. Denote by A an order-zero quantization obtained in this way. By (19.45), its symbol triple is elementary on a neighborhood of $\mathbf{s}_\infty$. After adding an elementary triple, the input and output bundles are identified on that neighborhood. The polar retraction

$$s \longmapsto s(s^*s)^{-\frac{1}{2}}$$

is applied only to the symbol isomorphism in that region and makes it unitary. The triple being elementary means precisely that, after the chosen stabilization, this unitary admits a homotopy there to the identity

through isomorphisms. With a single cutoff supported in the same region, quantization of this homotopy is continuous in

$$\mathcal{L}\big(L^2(\widehat{\nu},\boldsymbol{\mathcal{E}}^+),L^2(\widehat{\nu},\boldsymbol{\mathcal{E}}^-)\big);$$

and all its members are elliptic and Fredholm, so the index remains constant.

At the end of the homotopy, replacing A by the final quantization, the principal symbol is the identity on a neighborhood $\mathcal{U}_0$ of $\mathbf{s}_\infty$. Fix a smaller neighborhood $\mathcal{U}_\infty$ whose closure is contained in $\mathcal{U}_0$. The identification already chosen between $\boldsymbol{\mathcal{E}}^+$ and $\boldsymbol{\mathcal{E}}^-$ over $\mathcal{U}_0$ determines an identity morphism I_∞ there. Choose $\zeta\in C_c^\infty(\mathcal{U}_0)$ equal to one on a neighborhood of $\overline{\mathcal{U}_\infty}$ and extend the morphism ζI_∞ by zero. This gives a global smooth morphism

$$R:\boldsymbol{\mathcal{E}}^+\longrightarrow\boldsymbol{\mathcal{E}}^-$$

agreeing with I_∞ near $\overline{\mathcal{U}_\infty}$; we do not assert that R is invertible outside this region. If $r=\sigma_0^\Psi(R)$, let

$$K_A:=\operatorname{supp}\big(\sigma_0^\Psi(A)-r\big)\subset S^*\widehat{\nu}.$$

This actual support is compact, and its projection to $\widehat{\nu}$ does not meet $\mathcal{U}_\infty$. Choose $\chi\in C^\infty(\widehat{\nu})$ equal to one on a neighborhood of $\pi(K_A)$ and zero on $\mathcal{U}_\infty$, and define

$$A_0:=R+\chi(A-R)\chi. \tag{19.46}$$

The operators A and R act between the same pair $\boldsymbol{\mathcal{E}}^+,\boldsymbol{\mathcal{E}}^-$, and χ acts by scalar multiplication; therefore, A_0 is a global operator on this bundle. Moreover,

$$\sigma_0^\Psi(A_0)=r+\chi^2\big(\sigma_0^\Psi(A)-r\big)=\sigma_0^\Psi(A),$$

because $\chi=1$ on the support of the difference. By composition calculus, A_0-A has order -1 on the closed manifold $\widehat{\nu}$ and is compact as an operator

$$L^2(\widehat{\nu},\boldsymbol{\mathcal{E}}^+)\longrightarrow L^2(\widehat{\nu},\boldsymbol{\mathcal{E}}^-).$$

On $\mathcal{U}_\infty$ we have $\chi=0$ and $R=I_\infty$. Thus

$$\operatorname{ind_a}(A_0)=\operatorname{ind_a}(A)=\operatorname{ind_a}(P),\qquad A_0=I_\infty\text{ on }\mathcal{U}_\infty. \tag{19.47}$$

This formula supplies the exact equality near the boundary needed to extend the operator; it is not the unbounded oscillator that is being extended.

After shrinking the tubular domain, we may assume that $V\subset\nu$ is the open disk $|v|_{h_\nu}<\rho(x)$ for a positive smooth function ρ. The proper radial contraction

$$\kappa\colon\nu\longrightarrow V,\qquad \kappa(x,v)=\left(x,\frac{\rho(x)v}{\sqrt{1+|v|_{h_\nu}^2}}\right),$$

with a positive function ρ chosen within the tubular radius sends the regions $|v|_{h_\nu}\geq R$ to progressively thinner collars of the boundary of V. Conjugate A_0 by the unitary isomorphism incorporating the Jacobian

of κ and then by the tubular diffeomorphism $\Theta\colon V \longrightarrow U$. Since A_0 is exactly the identity near $\mathbf{s}_\infty$, the transported operator is the identity on a collar of the boundary of U, under the identification already chosen between the input and output bundles. Denote by $d \in K_c^0(T^*U)$ the class of this localized symbol.
Extension must be performed after stabilizing the bundles; identification on the collar alone does not suffice. Consider

$$e := \operatorname{ext}(d) \in K_c^0(T^*\mathbb{R}^N).$$

In the difference model, choose finite-rank Hermitian complements of the two bundles of the triple representing e over a pair (B^{2N}, S^{2N-1}) whose interior contains the support. The space B^{2N} is contractible, so these complements and both bundles are trivial. The isomorphism over S^{2N-1} forces the input and output bundles to have equal ranks. After adding the same trivial elementary triple of sufficiently large rank, both are identified with $\underline{\mathbb{C}}^q$. Stabilization adds the symbol of an identity, so it changes neither the K–theory class nor the index.
On the collar, the identification coming from $A_0 = I$ and the preceding trivializations make the input and output bundle the same. The polar retraction, followed by the elementary homotopy of the stabilized triple, allows us to choose a representative

$$s_e : T^*\mathbb{R}^N \longrightarrow \operatorname{End}(\mathbb{C}^q)$$

invertible outside a compact set in phase space, equal to I when the base variable lies outside a compact set, and whose restriction to T^*U represents d. Quantize this homotopy with a single cutoff and localize as in (19.46); this gives

$$\widetilde{A} \in \operatorname{Ell}_c^0(\mathbb{R}^N; \mathbb{C}^q), \qquad [\sigma(\widetilde{A})] = e.$$

All homotopies are norm-continuous on L^2, and stabilization only adds identities, so they do not alter the index. Now A_0, viewed on $\widehat{\nu}$, and $\widetilde{A}$, viewed on $\mathbb{R}^N$, are the two extensions of the same localized class d. Proposition 19.2.1 and (19.47) give

$$\operatorname{ind}_{\mathrm{a}}^{\mathbb{R}^N}(\widetilde{A}) = \operatorname{ind}_{\mathrm{a}}^{M}(P). \tag{19.48}$$

e is the extension by zero of (19.45); by (19.3), it is precisely $j_! a$. Since the analytic index depends only on the symbol class, (19.48) proves (19.43). □

The preceding compatibility is the property of the analytic index that allows passage from a closed manifold to its tubular neighborhood. The embedding construction and its relation to the product of symbols are also developed in [21, equations (12.8)–(12.16), pp. 293–301].

19.4 The Atiyah–Singer theorem

Before the main theorem, let us clarify why the analytic index can be evaluated directly on a K–theory class. Theorem 17.4.3 realizes every $a \in K_c^0(T^*M)$ as the symbol of an elliptic operator, and Theorem 17.5.6 proves that two realizations of the same class have the same index. Indeed, after adding identities, they are joined by a homotopy of elliptic symbols; this is quantized as a continuous family of Fredholm operators, and Theorem 15.6.24 keeps the index constant. This gives the homomorphism

$$\operatorname{ind}_{\mathrm{a}}^{M}\colon K_c^0(T^*M) \longrightarrow \mathbb{Z}.$$

Theorem 19.4.1. (Atiyah–Singer, K–theoretic version) Let M be a closed smooth manifold and let $P\colon \Gamma(M,\mathbf{E}^+) \longrightarrow \Gamma(M,\mathbf{E}^-)$ be a classical elliptic pseudodifferential operator between complex vector bundles. Then

$$\operatorname{ind}_{\mathrm{a}}(P) = \operatorname{ind}_{\mathrm{t}}([\sigma(P)]) \tag{19.49}$$

with the topological index of Definition 19.1.1.

Proof. Write $a = [\sigma(P)]$. By Theorem 19.3.8,

$$\operatorname{ind}_{\mathrm{a}}^{M}(a) = \operatorname{ind}_{\mathrm{a}}^{\mathbb{R}^N}(j_! a). \tag{19.50}$$

Theorem 18.7.1 and (19.4) state that, for every $c \in K_c^0(T^*\mathbb{R}^N)$,

$$\operatorname{ind}_{\mathrm{a}}^{\mathbb{R}^N}(c) = (i_N)_!^{-1}(c).$$

Applying this to $c = j_! a$ turns equality (19.50) into precisely

$$\operatorname{ind}_{\mathrm{a}}^{M}(a) = (i_N)_!^{-1}(j_! a) = \operatorname{ind}_{\mathrm{t}}(a).$$

□

The argument also proves two properties often included in the statement of the theorem. If P_0 and P_1 have symbols homotopic through elliptic symbols, their indices agree. If a symbol class is supported in T^*U for an open subset $U \subseteq M$, its index can be calculated in any manifold containing U. Neither assertion requires a local formula for the heat kernel.

19.5 Cohomological form

The K–theoretic version is integral and does not require an orientation of M. To obtain an integral formula, apply the compactly supported Chern character

$$\operatorname{ch}_c\colon K_c^0(TM) \longrightarrow H_c^{\mathrm{even}}(TM;\mathbb{Q}).$$

The total space TM has a canonical orientation, even if M is nonorientable: a connection identifies

$$T(TM) \cong \pi_{TM}^* TM \oplus \pi_{TM}^* TM,$$

and $J(X,Y) = (-Y,X)$ defines an almost complex structure. Denote by $[TM]_{\mathrm{BM}} \in H_{2n}^{\mathrm{BM}}(TM;\mathbb{Z})$ its Borel–Moore fundamental class.

For a complex bundle $\mathbf{W}$ with formal Chern roots $x_1,\dots,x_s$, fix the normalizations

$$\operatorname{ch}(\mathbf{W}) = \sum_{j=1}^{s} e^{x_j}, \qquad \operatorname{Td}(\mathbf{W}) = \prod_{j=1}^{s} \frac{x_j}{1-e^{-x_j}}. \tag{19.51}$$

In particular,

$$\operatorname{Td}(\mathbf{W}) = 1 + \frac{1}{2}c_1(\mathbf{W}) + \frac{1}{12}\bigl(c_1(\mathbf{W})^2 + c_2(\mathbf{W})\bigr) + \cdots.$$

Theorem 19.5.1. (Cohomological index formula) Let M be a closed smooth manifold of real dimension n, let $\mathbf{E}^+, \mathbf{E}^- \to M$ be smooth complex vector bundles, and let $P\colon \Gamma(M,\mathbf{E}^+) \to \Gamma(M,\mathbf{E}^-)$ be a classical elliptic pseudodifferential operator. Identify T^*M with TM using a metric and write $a = (\sharp_g)_*[\sigma(P)]$. Then

$$\operatorname{ind}_{\mathrm{a}}(P) = (-1)^n \left\langle \operatorname{ch}_c(a) \smile \pi_{TM}^* \operatorname{Td}(TM \otimes_{\mathbb{R}} \mathbb{C}), [TM]_{\mathrm{BM}} \right\rangle. \tag{19.52}$$

If M is oriented and

$$\Phi_{TM}\colon H^*(M;\mathbb{Q}) \longrightarrow H_c^{*+n}(TM;\mathbb{Q})$$

is the cohomological Thom isomorphism for this orientation, then

$$\operatorname{ind}_{\mathrm{a}}(P) = (-1)^{\frac{n(n+1)}{2}} \int_M \left[\Phi_{TM}^{-1}(\operatorname{ch}_c(a)) \smile \operatorname{Td}(TM \otimes_{\mathbb{R}} \mathbb{C}) \right]_n. \tag{19.53}$$

Here $[\cdot]_n$ denotes the component of degree n.

Compatibility between Thom and the Chern character is also proved in [21, Theorem 13.1, pp. 313–315].

Proof. Comparison of the Thom isomorphisms in K–theory and cohomology is a purely topological result. With the normalizations (19.51), if $\mathbf{W} \longrightarrow X$ is a complex bundle of rank s, $\lambda_{\mathbf{W}} \in K_c^0(\mathbf{W})$ is its Thom class, and $\Phi_{\mathbf{W}}$ is the cohomological Thom isomorphism, then

$$\Phi_{\mathbf{W}}^{-1}(\operatorname{ch}_c(\lambda_{\mathbf{W}})) = \prod_{j=1}^{s} \frac{1 - e^{x_j}}{x_j} = (-1)^s \operatorname{Td}(\overline{\mathbf{W}})^{-1}. \tag{19.54}$$

The proof using the splitting principle and naturality of the Chern character is given in Appendix A.
For the embedding $j\colon M \hookrightarrow \mathbb{R}^N$, the stable complex sum

$$\pi_{TM}^*(TM \otimes_{\mathbb{R}} \mathbb{C}) \oplus T\nu \cong TM \times \mathbb{C}^N$$

is trivial. By multiplicativity of the Todd class,

$$\operatorname{Td}(T\nu) = \pi_{TM}^* \operatorname{Td}(TM \otimes_{\mathbb{R}} \mathbb{C})^{-1}. \tag{19.55}$$

Here both $T\nu$, with the structure of (19.1), and $TM \otimes_{\mathbb{R}} \mathbb{C}$ are isomorphic to their conjugates; hence (19.54) produces the Todd class appearing in (19.55). Since $T\nu$ has complex rank $r = N - n$, the Thom formula gives explicitly

$$\operatorname{ch}_c(j_! a) = (-1)^r \operatorname{ext} \Phi_{T\nu}\left(\operatorname{ch}_c(a) \smile \pi_{TM}^* \operatorname{Td}(TM \otimes_{\mathbb{R}} \mathbb{C}) \right). \tag{19.56}$$

On the other hand, $\alpha_N(b^{\boxtimes N}) = 1$ and the normalization $b = [\mathbf{E}_{-1}] - [1]$ satisfies

$$\left\langle \operatorname{ch}_c(b^{\boxtimes N}), [\mathbb{C}^N]_{\mathrm{BM}} \right\rangle = 1.$$

Thus (19.4) becomes

$$(i_N)_!^{-1}(c) = (-1)^N \left\langle \operatorname{ch}_c(c), [\mathbb{C}^N]_{\mathrm{BM}} \right\rangle. \tag{19.57}$$

Naturality of cohomological Thom and extension by zero identifies the pairing in (19.56) with the pairing

over TM. The two sign factors are

$$(-1)^r(-1)^N = (-1)^{N-n+N} = (-1)^n.$$

Consequently,

$$(i_N)_!^{-1}(j_!a) = (-1)^n \left\langle \mathrm{ch}_c(a) \smile \pi_{TM}^* \,\mathrm{Td}(TM \otimes_{\mathbb{R}} \mathbb{C}), [TM]_{\mathrm{BM}} \right\rangle.$$

Theorem 19.4.1 proves (19.52).

If M is oriented, the complex orientation of TM orders each horizontal direction first and its vertical direction next. The tangent bundle orientation orders the n horizontal directions first, followed by the n vertical directions. Passing from one ordering to the other requires

$$(n-1) + (n-2) + \cdots + 1 = \frac{n(n-1)}{2}$$

transpositions. Thus, for $u \in H_c^{2n}(TM;\mathbb{Q})$,

$$\langle u, [TM]_{\mathrm{BM}} \rangle = (-1)^{\frac{n(n-1)}{2}} \int_M \Phi_{TM}^{-1}(u).$$

Multiplying this sign by $(-1)^n$ gives $(-1)^{\frac{n(n+1)}{2}}$ and proves (19.53). □

19.6 Three geometric operators

The following examples verify the analytic hypotheses and show how the symbol class recovers familiar invariants.

19.6.1 The Euler–de Rham operator

First suppose that $(M, \mathbf{g})$ is a closed Riemannian manifold. Define the total odd operator

$$D_{\mathrm{dR}} := d + d^* \quad \text{on } \Omega^\bullet(M;\mathbb{C}).$$

With the even and odd grading of complex forms, its restriction is

$$D_{\mathrm{dR}}^+ \colon \Omega^{\mathrm{even}}(M;\mathbb{C}) \longrightarrow \Omega^{\mathrm{odd}}(M;\mathbb{C}).$$

For $\xi \in T_x^*M \setminus \{0\}$, its two symbols are

$$\sigma_1(D_{\mathrm{dR}}^+)(x,\xi) = c(\xi), \qquad \sigma_1^\Psi(D_{\mathrm{dR}}^+)(x,\xi) = i\,c(\xi), \qquad c(\xi) := \varepsilon(\xi) - \iota(\xi^\sharp), \qquad c(\xi)^2 = -|\xi|_{\mathbf{g}}^2 I.$$

Consequently, D_{dR}^+ is elliptic.

Proposition 19.6.1. (Euler–de Rham index) Let $(M, \mathbf{g})$ be a closed Riemannian manifold of dimension n,

and let D^{+}_{dR} be the Euler–de Rham operator defined above. Then

$$\operatorname{ind}_{\mathrm{a}}(D^{+}_{\mathrm{dR}}) = \sum_{q=0}^{n} (-1)^{q} \dim_{\mathbb{C}} H^{q}_{\mathrm{dR}}(M;\mathbb{C}) = \chi(M). \tag{19.58}$$

If M is oriented, the cohomological formula reduces to

$$\operatorname{ind}_{\mathrm{a}}(D^{+}_{\mathrm{dR}}) = \int_{M} e(TM), \tag{19.59}$$

where $e(TM)$ is the Euler class represented in de Rham cohomology.

The identity of classes used in the proof can be found in [21, equation (17.148) and Theorem 17.68, pp. 611–612]; its integral is identified with $\chi(M)$ in [21, Theorem 13.6(d), pp. 320–321].

Proof. The square of $D_{\mathrm{dR}} = d + d^{*}$ is the Hodge Laplacian $\Delta = dd^{*} + d^{*}d$. The elliptic theory already developed gives

$$L^{2}\Omega^{q}(M;\mathbb{C}) = \ker \Delta_{q} \oplus \operatorname{Ran} \Delta_{q}$$

and a Green operator G_{q}, defined as Δ_{q}^{-1} on $(\ker \Delta_{q})^{\perp}$ and zero on $\ker \Delta_{q}$, which gains two derivatives. If $\omega \in \Omega^{q}(M;\mathbb{C})$ and $d\omega = 0$, write

$$\omega = h + \Delta G_{q}\omega, \qquad h \in \ker \Delta_{q}.$$

The identities $d\Delta = \Delta d$ and uniqueness of the inverse on $(\ker \Delta)^{\perp}$ imply that $dG_{q}\omega$ is harmonic. Since it is also exact,

$$\| dG_{q}\omega \|^{2}_{L^{2}\Omega^{q+1}(M;\mathbb{C})} = \langle G_{q}\omega, d^{*}dG_{q}\omega \rangle_{L^{2}\Omega^{q}(M;\mathbb{C})} = 0.$$

Therefore, $dG_{q}\omega = 0$ and

$$\omega = h + d(d^{*}G_{q}\omega).$$

Every de Rham cohomology class thus has a harmonic representative. If a harmonic form is exact, the same calculation shows that it is zero; the representative is unique. Consequently,

$$\ker \Delta_{q} \cong H^{q}_{\mathrm{dR}}(M;\mathbb{C}).$$

The kernels of D^{+}_{dR} and its adjoint are the even and odd harmonic forms, respectively, proving the first equality in (19.58). Theorem A.8.1 identifies the alternating sum of these dimensions with $\chi(M)$.
Finally, the preceding Clifford symbol defines the *Euler symbol class* in $K^{0}_{c}(T^{*}M)$; it is not identified here with a Thom class of a real bundle. Denote by $\sharp_{g}\colon T^{*}M \to TM$ the metric isomorphism and by $(\sharp_{g})_{*}$ the induced isomorphism in compactly supported K–theory. Its characteristic identity is

$$(-1)^{\frac{n(n+1)}{2}} \Phi^{-1}_{TM}\left(\operatorname{ch}_{c}\left((\sharp_{g})_{*}[\sigma(D^{+}_{\mathrm{dR}})]\right)\right) \operatorname{Td}(TM \otimes_{\mathbb{R}} \mathbb{C}) = e(TM).$$

This is an identity for the full symbol class, including the Thom isomorphism and its orientations; it does not follow by identifying the exterior difference with a single difference of half-spinor bundles. Indeed, for a pair of roots $\pm x$ we have

$$\operatorname{ch}(\Lambda^{\mathrm{even}} - \Lambda^{\mathrm{odd}}) = 2 - e^{x} - e^{-x} = -\left(e^{x/2} - e^{-x/2}\right)^{2},$$

and the remaining factors come precisely from Thom. Substituting this identity into (19.53) yields (19.59). □

19.6.2 The Dolbeault operator

Now let M be a closed complex manifold of complex dimension m and let $\mathbf{E} \longrightarrow M$ be a holomorphic vector bundle equipped with a Hermitian metric. Also fix a Hermitian metric on M. The complex structure splits the complexified bundles as

$$TM \otimes_{\mathbb{R}} \mathbb{C} = T^{1,0}M \oplus T^{0,1}M, \qquad T^*M \otimes_{\mathbb{R}} \mathbb{C} = T^{*1,0}M \oplus T^{*0,1}M,$$

and we write

$$\Omega^{p,q}(M,\mathbf{E}) = \Gamma\left(M, \Lambda^p T^{*1,0}M \otimes \Lambda^q T^{*0,1}M \otimes \mathbf{E}\right).$$

In a holomorphic trivialization of $\mathbf{E}$ and holomorphic coordinates $z^1,\dots,z^m$, the twisted Dolbeault operator is

$$\bar\partial_{\mathbf{E}} = \sum_{j=1}^{m} d\bar z^j \wedge \frac{\partial}{\partial \bar z^j} \colon \Omega^{p,q}(M,\mathbf{E}) \longrightarrow \Omega^{p,q+1}(M,\mathbf{E}). \tag{19.60}$$

The transition functions of $\mathbf{E}$ are holomorphic, so (19.60) is independent of the trivialization. Commutation of the derivatives $\partial/\partial\bar z^j$ and anticommutation of exterior products prove $\bar\partial_{\mathbf{E}}^2 = 0$.

The Hermitian metrics on M and $\mathbf{E}$ define the formal adjoint $\bar\partial_{\mathbf{E}}^*$. The total odd operator

$$D_{\bar\partial,\mathbf{E}} := \sqrt{2}\,(\bar\partial_{\mathbf{E}} + \bar\partial_{\mathbf{E}}^*) \quad \text{on } \Omega^{0,\bullet}(M,\mathbf{E})$$

has as its component from even to odd degree the restriction

$$D^+_{\bar\partial,\mathbf{E}} := D_{\bar\partial,\mathbf{E}}\big|_{\Omega^{0,\mathrm{even}}} \colon \Omega^{0,\mathrm{even}}(M,\mathbf{E}) \longrightarrow \Omega^{0,\mathrm{odd}}(M,\mathbf{E})$$

This operator is elliptic. Indeed, if ξ is a real covariable, the preceding local formula and the adjoint symbol formula give, respectively,

$$\sigma_1(D^+_{\bar\partial,\mathbf{E}})(x,\xi) = \sqrt{2}\left(\varepsilon(\xi^{0,1}) - \varepsilon(\xi^{0,1})^*\right) \otimes I_{\mathbf{E}_x}, \qquad \sigma_1^{\Psi}(D^+_{\bar\partial,\mathbf{E}})(x,\xi) = i\sqrt{2}\left(\varepsilon(\xi^{0,1}) - \varepsilon(\xi^{0,1})^*\right) \otimes I_{\mathbf{E}_x}. \tag{19.61}$$

Since $2|\xi^{0,1}|_{\mathbf{g}}^2 = |\xi|_{\mathbf{g}}^2$ for a real covariable and $\varepsilon\varepsilon^* + \varepsilon^*\varepsilon = |\xi^{0,1}|_{\mathbf{g}}^2 I$, we obtain

$$\sigma_1^{\Psi}(D^+_{\bar\partial,\mathbf{E}})(x,\xi)^*\sigma_1^{\Psi}(D^+_{\bar\partial,\mathbf{E}})(x,\xi) = |\xi|_{\mathbf{g}}^2 I.$$

The factor $\sqrt{2}$ does not affect the symbol class. Write

$$H^{0,q}_{\bar\partial}(M,\mathbf{E}) := \frac{\ker(\bar\partial_{\mathbf{E}} \colon \Omega^{0,q}(M,\mathbf{E}) \longrightarrow \Omega^{0,q+1}(M,\mathbf{E}))}{\mathrm{Ran}(\bar\partial_{\mathbf{E}} \colon \Omega^{0,q-1}(M,\mathbf{E}) \longrightarrow \Omega^{0,q}(M,\mathbf{E}))}.$$

Proposition 19.6.2. (Analytic Hirzebruch–Riemann–Roch) Let M be a closed complex manifold of complex dimension m equipped with a Hermitian metric; let $\mathbf{E} \to M$ be a holomorphic vector bundle equipped

with a Hermitian bundle metric, and let $D^+_{\bar\partial,\mathbf{E}}$ be the twisted Dolbeault operator defined above. Then

$$\operatorname{ind}_a(D^+_{\bar\partial,\mathbf{E}}) = \sum_{q=0}^{m}(-1)^q \dim_{\mathbb{C}} H^{0,q}_{\bar\partial}(M,\mathbf{E}) = \int_M \left[\operatorname{ch}(\mathbf{E}) \smile \operatorname{Td}(T^{1,0}M)\right]_{2m}. \tag{19.62}$$

Proof. The square of $D_{\bar\partial,\mathbf{E}}$ is twice the Dolbeault Laplacian,

$$\Delta_{\bar\partial,\mathbf{E}} = \bar\partial_{\mathbf{E}}\bar\partial^*_{\mathbf{E}} + \bar\partial^*_{\mathbf{E}}\bar\partial_{\mathbf{E}}.$$

It is elliptic and self-adjoint, so its range is closed and it has a Green operator $G_{\bar\partial,\mathbf{E}}$ equal to the inverse on the orthogonal complement of its kernel and zero on the kernel. If $\boldsymbol{\alpha} \in \Omega^{0,q}(M,\mathbf{E})$ satisfies $\bar\partial_{\mathbf{E}}\boldsymbol{\alpha} = 0$, write

$$\boldsymbol{\alpha} = h + \Delta_{\bar\partial,\mathbf{E}} G_{\bar\partial,\mathbf{E}}\boldsymbol{\alpha}, \qquad h \in \ker \Delta_{\bar\partial,\mathbf{E}}.$$

The identity $\bar\partial_{\mathbf{E}}\Delta_{\bar\partial,\mathbf{E}} = \Delta_{\bar\partial,\mathbf{E}}\bar\partial_{\mathbf{E}}$ shows that $\bar\partial_E G_{\bar\partial,\mathbf{E}}\boldsymbol{\alpha}$ is harmonic. Since it is exact, its squared norm is

$$\left\|\bar\partial_E G_{\bar\partial,\mathbf{E}}\boldsymbol{\alpha}\right\|^2_{L^2\Omega^{0,q+1}(M,\mathbf{E})} = \left\langle G_{\bar\partial,\mathbf{E}}\boldsymbol{\alpha}, \bar\partial^*_{\mathbf{E}}\bar\partial_E G_{\bar\partial,\mathbf{E}}\boldsymbol{\alpha}\right\rangle_{L^2\Omega^{0,q}(M,\mathbf{E})} = 0.$$

Therefore,

$$\boldsymbol{\alpha} = h + \bar\partial_{\mathbf{E}}\left(\bar\partial^*_{\mathbf{E}} G_{\bar\partial,\mathbf{E}}\boldsymbol{\alpha}\right).$$

The same identity proves that an exact harmonic form is zero. We thus obtain, without losing or adding any classes,

$$\ker \Delta^{0,q}_{\bar\partial,\mathbf{E}} \cong H^{0,q}_{\bar\partial}(M,\mathbf{E}).$$

This gives the first equality in (19.62).
The Clifford module

$$\mathbf{S}_{\mathbb{C}} = \Lambda^{0,*}T^*M = \Lambda^{0,\mathrm{even}}T^*M \oplus \Lambda^{0,\mathrm{odd}}T^*M$$

defines the canonical Spin^c structure of a complex manifold and its corresponding orientation. Formula (19.61) shows that the symbol class is the Spin^c Thom class of this module multiplied by $\pi^*[\mathbf{E}]$; it does not depend on choosing the summand $T^{0,1}M$ in isolation. If $x_1,\dots,x_m$ are the formal Chern roots of $T^{1,0}M$, the identity (19.54) cancels, root by root, the factor coming from $TM\otimes_{\mathbb{R}}\mathbb{C}$ and leaves

$$\prod_{j=1}^{m}\frac{x_j}{1-e^{-x_j}} = \operatorname{Td}(T^{1,0}M).$$

The complex manifold carries its canonical orientation. Formula (19.53) gives the second equality in (19.62). □

19.6.3 The twisted Dirac operator

Let $(M^{2m},\mathbf{g})$ be a closed oriented Riemannian spin manifold, and let $\mathbf{E}\to M$ be a complex vector bundle equipped with a Hermitian bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. Clifford geometry, the spin structure, the spinor bundle, and its connection were constructed in Section 2.17. The twisted differential operator was defined

later, once the general theory of operators on bundles was available, in Definition 8.3.7. In particular,

$$\mathbf{S} := \Sigma M = \mathbf{S}^+ \oplus \mathbf{S}^-, \qquad D_{\mathbf{E}} = \begin{pmatrix} 0 & D_{\mathbf{E}}^- \\ D_{\mathbf{E}}^+ & 0 \end{pmatrix}, \qquad (D_{\mathbf{E}}^+)^* = D_{\mathbf{E}}^-.$$

$$D_{\mathbf{E}}^2 = \begin{pmatrix} D_{\mathbf{E}}^- D_{\mathbf{E}}^+ & 0 \\ 0 & D_{\mathbf{E}}^+ D_{\mathbf{E}}^- \end{pmatrix} \quad \text{with respect to } \mathbf{S}^+ \oplus \mathbf{S}^-.$$

The corresponding Weitzenböck formula is (8.35). To calculate the index, we also use the two symbol conventions introduced at different stages: by Proposition 11.2.4 and Example 15.3.5, the differential and Fourier symbols are, respectively,

$$\sigma_1(D_{\mathbf{E}}^+)(x,\xi) = c(\xi) \otimes I_{\mathbf{E}_x}, \qquad \sigma_1^{\Psi}(D_{\mathbf{E}}^+)(x,\xi) = i\, c(\xi) \otimes I_{\mathbf{E}_x}. \tag{19.63}$$

The Clifford relation proves their invertibility for $\xi \neq 0$.

The McKean–Singer identity expresses the Dirac index as the supertrace of the heat semigroup associated with the square of the operator.

Corollary 19.6.3. (McKean–Singer for the Dirac operator) Let $(M^{2m}, \mathbf{g})$ be a closed oriented Riemannian spin manifold, let $\mathbf{E} \to M$ be a complex vector bundle equipped with a Hermitian bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$, and let $D_{\mathbf{E}}^+$ be the twisted Dirac operator. For every $t > 0$,

$$\begin{aligned} \operatorname{ind}_{\mathrm{a}}(D_{\mathbf{E}}^+) &= \operatorname{Tr}\big(e^{-tD_{\mathbf{E}}^- D_{\mathbf{E}}^+}\big) - \operatorname{Tr}\big(e^{-tD_{\mathbf{E}}^+ D_{\mathbf{E}}^-}\big) \\ &= \operatorname{Str}\big(e^{-tD_{\mathbf{E}}^2}\big) = \int_M \operatorname{str}_{\mathbf{S}_x \otimes \mathbf{E}_x} \mathbf{K}_{D_{\mathbf{E}}^2}(t,x,x)\, d\lambda_{\mathbf{g}}(x), \end{aligned} \tag{19.64}$$

where $\mathbf{K}_{D_{\mathbf{E}}^2}$ is the heat kernel of $D_{\mathbf{E}}^2$ and $\operatorname{str}(A) = \operatorname{tr}(A|_{\mathbf{S}^+ \otimes \mathbf{E}}) - \operatorname{tr}(A|_{\mathbf{S}^- \otimes \mathbf{E}})$.

Proof. Apply Proposition 15.7.14 to $P = D_{\mathbf{E}}^+$. Formula (8.35) shows that $D_{\mathbf{E}}^2$ is a Laplace-type operator with a zeroth-order potential, but its heat kernel is not the kernel of the connection Laplacian constructed in Chapter 12. Regularity, the trace-class property, and the diagonal formula come from Proposition 15.7.13. No asymptotic expansion as $t \to 0^+$ is used. □

If the formal Chern roots of $TM \otimes_{\mathbb{R}} \mathbb{C}$ are ordered as $x_1, -x_1, \dots, x_m, -x_m$, define

$$\widehat{A}(TM) = \prod_{j=1}^{m} \frac{\frac{x_j}{2}}{\sinh\left(\frac{x_j}{2}\right)}. \tag{19.65}$$

Proposition 19.6.4. (Index of the Dirac operator) Let $(M^{2m}, \mathbf{g})$ be a closed oriented Riemannian spin manifold, let $\mathbf{E} \to M$ be a complex vector bundle equipped with a Hermitian bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$, and let $D_{\mathbf{E}}^+$ be the twisted Dirac operator. Then

$$\operatorname{ind}_{\mathrm{a}}(D_{\mathbf{E}}^+) = \int_M \big[\widehat{A}(TM) \smile \operatorname{ch}(\mathbf{E})\big]_{2m}. \tag{19.66}$$

In particular, for $\mathbf{E} = M \times \mathbb{C}$ we obtain the $\widehat{A}(M)$ genus.

The analytic construction and spinor Thom orientation are described in [21, Definitions 17.22–17.23, pp. 531–532] and [92, Appendix C, Theorem C.12; Chapter III, §12, Proposition 12.5].

Proof. The second formula in (19.63) shows that the symbol class is the complex

$$\pi^*(\mathbf{S}^+ \otimes \mathbf{E}) \xrightarrow{ic(\xi)\otimes I_{\mathbf{E}}} \pi^*(\mathbf{S}^- \otimes \mathbf{E}), \qquad \xi \in T^*M,$$

exact away from the zero section. The complex without $\mathbf{E}$ is the spinor Thom class, and the twisting factor is $\pi^*[\mathbf{E}]$; multiplying the morphism by i does not change its class. The Chern defect of the spinor Thom class, stated in Theorem A.8.5, is

$$\Phi_{TM}^{-1}\,\mathrm{ch}_c(s(TM)) = (-1)^m \widehat{A}(TM)^{-1}.$$

Moreover, the splitting principle applied to the pairs of roots $x_j, -x_j$ gives

$$\mathrm{Td}(TM \otimes_{\mathbb{R}} \mathbb{C}) = \widehat{A}(TM)^2.$$

The factor $\pi^*[\mathbf{E}]$ contributes $\mathrm{ch}(\mathbf{E})$. Since the overall sign in (19.53) in dimension $2m$ is $(-1)^m$, the two signs cancel, leaving $\widehat{A}(TM)\,\mathrm{ch}(\mathbf{E})$. This proves (19.66). □

Proposition 19.6.5. (Index of the Spin^c Dirac operator) Let M^{2m} be a closed oriented smooth manifold equipped with a Spin^c structure with determinant line $\mathbf{L}$. Let A be a unitary connection on $\mathbf{L}$ and let $\mathbf{E}$ be a complex vector bundle equipped with a Hermitian bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. The operator $D_{A,\mathbf{E}}$ is obtained by twisting the operator of Proposition 8.3.9 by $\nabla^{\mathbf{E}}$, using the same product connection construction as in Definition 8.3.7. The geometric data of the Spin^c structure are those of Section 2.17. Its chiral restriction satisfies

$$D^+_{A,\mathbf{E}} \colon \Gamma(\Sigma^{c,+}M \otimes \mathbf{E}) \longrightarrow \Gamma(\Sigma^{c,-}M \otimes \mathbf{E}).$$

Then

$$\mathrm{ind}_{\mathrm{a}}(D^+_{A,\mathbf{E}}) = \int_M \left[\widehat{A}(TM) \smile e^{c_1(\mathbf{L})/2} \smile \mathrm{ch}(\mathbf{E})\right]_{2m}. \tag{19.67}$$

If the structure comes from an almost complex structure, then $\mathbf{L} = \det_{\mathbb{C}}(T^{1,0}M)$ and

$$\widehat{A}(TM)e^{c_1(\mathbf{L})/2} = \mathrm{Td}(T^{1,0}M).$$

If the almost complex structure is Kähler, the connection on $\mathbf{L} = K_M^{-1}$ is the one induced by Levi–Civita, and $\mathbf{E}$ is holomorphic with its Chern connection, the canonical operator is exactly $\sqrt{2}(\bar\partial_{\mathbf{E}} + \bar\partial^*_{\mathbf{E}})$. In the general almost complex case, the Spin^c Dirac operator and the associated Dolbeault-type operator have the same symbol and index, although they may differ by a zeroth-order term.

The canonical topological identifications are collected in [92, Appendix D, Theorem D.2 and Examples D.5–D.6; Appendix C, Theorem C.12; Appendix D, Theorem D.15].

Proof. The Spin^c Thom class is obtained from the spinor class formally twisted by the square root of $\mathbf{L}$; in the Chern character this introduces the well-defined factor $e^{c_1(\mathbf{L})/2}$. The same Thom calculation and (19.53) used in the preceding proposition give (19.67). For the almost complex structure, the determinant line and characteristic identity follow, under the splitting principle, from

$$\frac{x/2}{\sinh(x/2)}e^{x/2} = \frac{x}{1-e^{-x}}.$$

The Kähler identification follows from the Chern–Levi–Civita connection on $\Lambda^{0,\bullet}T^*M$. □

These cases illustrate different roles of the same theorem. For de Rham, the index is the Euler characteristic; for Dolbeault, the holomorphic Euler characteristic; in the spinor case, a characteristic number built from $\widehat{A}(TM)$. The equality is independent of the auxiliary metrics and connections: smooth variation preserves the symbol class and gives a continuous family of Fredholm operators.

Part V

Geometric evolution equations

Introduction to Part V

Until now, the Riemannian metric has been a fixed part of the geometry. In this part we allow it to change with time. The idea is simple to state: instead of seeking a metric with special properties directly, we start with an initial metric and let it evolve according to an equation determined by its curvature. The geometric problem thereby becomes a nonlinear partial differential equation.

Before studying Ricci flow, we need a parabolic theory that establishes existence, uniqueness, and regularity for systems on manifolds. The flow also presents a difficulty specific to geometry: the equation is invariant under diffeomorphisms, and this symmetry appears analytically as a degeneracy of the symbol. DeTurck's procedure removes this degeneracy through a choice of gauge and reduces the problem, for a short time, to a strictly parabolic system.

Once the solution has been constructed, the evolution equations for curvature and the maximum principles yield a priori estimates. When curvature grows and a singularity appears, rescaling allows the geometry to be observed at its natural scale. Compactness extracts limits of these magnified regions, while Perelman's monotone quantities and noncollapsing restrict the possible models. In dimension three, this analysis leads to surgery and shows particularly clearly how an evolution equation can reveal the topological structure of a manifold.

Hamilton, DeTurck, and Perelman

Hamilton introduced Ricci flow in 1982 with the idea of deforming a metric using its own curvature. It soon became clear that diffeomorphism invariance required careful treatment; DeTurck's procedure supplied the adjustment needed to apply parabolic theory. Two decades later, Perelman introduced new monotone quantities, the noncollapsing theorem, and a decisive analysis of singularities and surgery. This history illustrates a characteristic feature of geometric analysis: an intuition about the shape of space leads to an equation, the equation demands precise analytic tools, and those tools ultimately return to a geometric or topological problem.

20

Geometric parabolic equations on closed manifolds

A geometric evolution equation resembles the heat equation only after several difficulties have been resolved. The unknown is usually a section of a bundle, the coefficients of the principal part depend on that same section, and geometric symmetries may conceal the parabolicity of the system. Before studying Ricci flow, it is useful to separate these problems and develop a theory that identifies precisely which part of the argument comes from diffusion and which depends on the nonlinear structure.

We work on a closed Riemannian manifold $(M, \mathbf{g}_0)$ of dimension m. Let $\mathbf{E} \to M$ be a real vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$, abbreviated to ∇ together with its induced connections. These structures are used to measure sections and write the equations; any other smooth choice gives equivalent norms. Denote by $H^r(M, \mathbf{E})$ the Sobolev space of integer order r constructed in Chapter 9. The operator $\Delta_\nabla = \nabla^*\nabla$ defining the spectral scale is nonnegative, whereas the covariant trace $\operatorname{tr}_{\mathbf{g}_0}(\nabla^2)$ used in the maximum principles has the opposite sign.

Throughout this chapter, fix an integer

$$s > \frac{m}{2} + 2. \tag{20.1}$$

Set $\Lambda = (I + \Delta_\nabla)^{1/2}$. By Theorem 12.4.10, the norm

$$\|\mathbf{u}\|_{H^r(M,\mathbf{E})} := \|\Lambda^r \mathbf{u}\|_{L^2(M,\mathbf{E})} \tag{20.2}$$

is equivalent to the covariant norm when $r \geq 0$ is an integer; for $r < 0$ it is interpreted by completion. We use this choice because it makes energy identities in the Sobolev scale exact. Estimates obtained with it remain valid for the covariant norms by equivalence. In particular, $H^{s-2}(M)$, $H^{s-1}(M)$, and $H^s(M)$ are algebras and the inclusion $H^{s-1}(M, \mathbf{E}) \hookrightarrow C^0(M, \mathbf{E})$ is continuous.

The linear estimate must control both the solution and its time derivative and retain its constants as the coefficients vary within fixed bounds. This uniformity allows us to solve the quasilinear equation: each approximation determines the coefficients of the next, while a common energy controls the entire sequence. Maximum principles will then provide pointwise information that integral norms alone do not supply.

From the heat equation to geometric flows

Parabolic theory grew out of the study of diffusion: heat dampens irregularities and produces smoothness at positive times. In a geometric flow the unknown may be a metric, a connection, or a section, and the coefficients of the equation change with it. Energy estimates, maximum principles, and product inequalities preserve the smoothing mechanism of heat in this nonlinear regime. The results of this chapter prepare this transition before applying it to Ricci flow.

20.1 Product estimates and energy spaces

The nonlinear estimates we need are precise consequences of the Leibniz rule and the Gagliardo–Nirenberg inequality in Theorem 9.3.1. We first collect them to make explicit where condition (20.1) is used.

Lemma 20.1.1. (Sobolev product with distributed orders) Let $\mathbf{V}_1, \mathbf{V}_2, \mathbf{V}_3 \to M$ be vector bundles with fixed metrics and connections, and let $\beta\colon \mathbf{V}_1 \otimes \mathbf{V}_2 \to \mathbf{V}_3$ be a smooth homomorphism. If $a, b \in \mathbb{N}_0$ and $a + b > m/2$, there exists a constant C such that

$$\|\beta(\mathbf{u}, \mathbf{v})\|_{L^2(M,\mathbf{V}_3)} \leq C\|\mathbf{u}\|_{H^a(M,\mathbf{V}_1)}\|\mathbf{v}\|_{H^b(M,\mathbf{V}_2)}. \tag{20.3}$$

The same estimate holds if one factor is a covariant derivative of a section and the orders a, b describe the regularity remaining after taking that derivative.

Proof. By a finite partition of unity and local equivalence of Sobolev norms, it suffices to prove the assertion for vector-valued functions supported in a relatively compact Euclidean open subset. Since $a + b > m/2$, we can choose $p, q \in [2, \infty]$ so that

$$\frac{1}{p} + \frac{1}{q} = \frac{1}{2}, \qquad H^a \hookrightarrow L^p, \qquad H^b \hookrightarrow L^q.$$

Let us specify the choice in the critical cases. If $a > m/2$, take $p = \infty$ and $q = 2$; if $b > m/2$, proceed symmetrically. Thus suppose that $a, b \leq m/2$. When both are less than $m/2$, the inequality $a + b > m/2$ allows us to choose a number θ such that

$$\frac{1}{2} - \frac{a}{m} < \theta < \frac{b}{m}, \qquad \frac{1}{p} = \theta, \qquad \frac{1}{q} = \frac{1}{2} - \theta.$$

The corresponding Sobolev inclusions are continuous. If $a = m/2$, choose $0 < \theta < b/m$; the inclusion $H^{m/2} \hookrightarrow L^p$ holds for every $p < \infty$. The case $b = m/2$ is analogous, taking $1/2 - a/m < \theta < 1/2$. This also covers the critical orders using finite exponents. The inclusion $H^{m/2} \hookrightarrow L^\infty$ does not hold in general. Hölder and the two inclusions give

$$\|\beta(\mathbf{u}, \mathbf{v})\|_{L^2(M,\mathbf{V}_3)} \leq C\|\mathbf{u}\|_{L^p(M,\mathbf{V}_1)}\|\mathbf{v}\|_{L^q(M,\mathbf{V}_2)} \leq C\|\mathbf{u}\|_{H^a(M,\mathbf{V}_1)}\|\mathbf{v}\|_{H^b(M,\mathbf{V}_2)}.$$

The coefficients of β, the connections, and the local frames are smooth on finitely many compact sets and can therefore be absorbed into the constant. □

Lemma 20.1.2. (Moser estimates) Let $(M,\mathbf{g}_0)$ be a closed Riemannian manifold of dimension m. In the following estimates, $\|\cdot\|_\infty$ denotes the L^∞ norm on the corresponding bundle, with the fixed metrics. Let $\mathbf{V}_1,\mathbf{V}_2,\mathbf{V}_3 \longrightarrow M$ be vector bundles with fixed metrics and connections, and let $\beta\colon \mathbf{V}_1\otimes\mathbf{V}_2 \longrightarrow \mathbf{V}_3$ be a smooth homomorphism. For every integer $r\geq 0$ there exists a constant C, depending on the fixed structures and r, such that, for $\mathbf{u}\in H^r(M,\mathbf{V}_1)\cap L^\infty(M,\mathbf{V}_1)$ and $\mathbf{v}\in H^r(M,\mathbf{V}_2)\cap L^\infty(M,\mathbf{V}_2)$,

$$\|\beta(\mathbf{u},\mathbf{v})\|_{H^r(M,\mathbf{V}_3)} \leq C\big(\|\mathbf{u}\|_\infty\|\mathbf{v}\|_{H^r(M,\mathbf{V}_2)} + \|\mathbf{u}\|_{H^r(M,\mathbf{V}_1)}\|\mathbf{v}\|_\infty\big), \tag{20.4}$$

$$\|[\nabla^r,\mathbf{a}]\mathbf{v}\|_{L^2(M,T^{(0,r)}(TM)\otimes\mathbf{V}_3)} \leq C\big(\|\nabla\mathbf{a}\|_\infty\|\mathbf{v}\|_{H^{r-1}(M,\mathbf{V}_2)} + \|\mathbf{a}\|_{H^r(M,\mathrm{Hom}(\mathbf{V}_2,\mathbf{V}_3))}\|\mathbf{v}\|_\infty\big) \tag{20.5}$$

In the commutator estimate, assume $r\geq 1$, $\mathbf{v}\in H^{r-1}(M,\mathbf{V}_2)\cap L^\infty(M,\mathbf{V}_2)$, and $\mathbf{a}\in H^r(M,\mathrm{Hom}(\mathbf{V}_2,\mathbf{V}_3))$ with $\nabla\mathbf{a}\in L^\infty(M,T^*M\otimes\mathrm{Hom}(\mathbf{V}_2,\mathbf{V}_3))$. The action of $\mathbf{a}$ on the tensor factors is the identity on $T^{(0,r)}(TM)$, and

$$[\nabla^r,\mathbf{a}]\mathbf{v} := \nabla^r(\mathbf{a}\mathbf{v}) - (I_{T^{(0,r)}(TM)}\otimes\mathbf{a})(\nabla^r\mathbf{v}) \in L^2\big(M,T^{(0,r)}(TM)\otimes\mathbf{V}_3\big).$$

For nonsmooth sections, the difference defining the commutator is taken first in distributions; the estimate states that this distribution is represented by an L^2 section. If $\mathbf{a}\in H^s(M,\mathrm{Hom}(T^*M\otimes\mathbf{V}_1,\mathbf{V}_3))$ and $\mathbf{u}\in H^r(M,\mathbf{V}_1)$, the same commutator applied to $\nabla\mathbf{u}$ satisfies

$$\|[\nabla^r,\mathbf{a}](\nabla\mathbf{u})\|_{L^2(M,T^{(0,r)}(TM)\otimes\mathbf{V}_3)} \leq C\|\mathbf{a}\|_{H^s(M,\mathrm{Hom}(T^*M\otimes\mathbf{V}_1,\mathbf{V}_3))}\|\mathbf{u}\|_{H^r(M,\mathbf{V}_1)}, \qquad 1\leq r\leq s. \tag{20.6}$$

Now let $\mathcal{U}\subseteq\mathbf{V}_1$ be an open subset of a bundle and let $G\colon\mathcal{U}\longrightarrow\mathbf{V}_2$ be a smooth bundle map. If $K\subseteq\mathcal{U}$ is compact, there exists a neighborhood $\mathcal{V}$ of K and, for each $R>0$, a constant $C_{K,R}$ with the following properties. If $\mathbf{u},\mathbf{v}\in H^r(M,\mathbf{V}_1)$, the images of $\mathbf{u}$ and $\mathbf{v}$ lie in $\mathcal{V}$, and $\|\mathbf{u}\|_{H^r(M,\mathbf{V}_1)}+\|\mathbf{v}\|_{H^r(M,\mathbf{V}_1)}\leq R$, then

$$\|G(\mathbf{u})\|_{H^r(M,\mathbf{V}_2)} \leq C_{K,R}, \tag{20.7}$$

$$\|G(\mathbf{u})-G(\mathbf{v})\|_{H^r(M,\mathbf{V}_2)} \leq C_{K,R}\|\mathbf{u}-\mathbf{v}\|_{H^r(M,\mathbf{V}_1)}. \tag{20.8}$$

These last two estimates hold whenever $r>\frac{m}{2}$. Moreover, for every integer $r\geq 0$ and every section $\mathbf{u}$ with image in $\mathcal{V}$, we have the higher-order estimate

$$\|G(\mathbf{u})\|_{H^r(M,\mathbf{V}_2)} \leq C_{K,r}\big(1+\|\mathbf{u}\|_{H^r(M,\mathbf{V}_1)}\big). \tag{20.9}$$

Here the constant depends on a uniform bound for the values of $\mathbf{u}$ and derivatives of G up to order r on a fixed neighborhood of those values; it does not depend on the order-r norm of $\mathbf{u}$. These estimates also hold for maps depending smoothly on several arguments, with the norm of the difference of all of them on the right-hand side.

Proof. Localize using a finite partition of unity and work in a chart and local frame. The covariant norms and Euclidean norms of the components are equivalent by Lemma 9.1.28. Its triangular formula shows which connection coefficients enter at each order; on the compact sets of this localization, all their required derivatives are bounded. It therefore suffices to justify the estimates for partial derivatives of vector-valued functions. Fix a regular coordinate ball (U,φ) and set $\Omega := \varphi(U)\subset\mathbb{R}^m$. In the following local calculations, u,v,a denote the scalar components of the sections or coefficients in the fixed frames; their Euclidean norms are taken over Ω.

Let $1 \le k \le r$ and $|\gamma| = k$. The Leibniz rule gives

$$\partial^\gamma (uv) = \sum_{\substack{\mu \in \mathbb{N}_0^m \\ \mu \le \gamma}} \binom{\gamma}{\mu} (\partial^\mu u)(\partial^{\gamma-\mu} v).$$

The terms $\mu = 0$ and $\mu = \gamma$ are bounded, respectively, by $\|u\|_{L^\infty(\Omega)} \|v\|_{H^k(\Omega)}$ and $\|u\|_{H^k(\Omega)} \|v\|_{L^\infty(\Omega)}$. If $0 < |\mu| < k$, set $\theta = |\mu|/k$ and choose $p = 2/\theta$, $q = 2/(1-\theta)$. The Gagliardo–Nirenberg inequality gives

$$\|\partial^\mu u\|_{L^p(\Omega)} \le C \|u\|_{L^\infty(\Omega)}^{1-\theta} \|u\|_{H^k(\Omega)}^{\theta},$$
$$\|\partial^{\gamma-\mu} v\|_{L^q(\Omega)} \le C \|v\|_{L^\infty(\Omega)}^{\theta} \|v\|_{H^k(\Omega)}^{1-\theta}.$$

Since $1/p + 1/q = 1/2$, Hölder and the weighted Young inequality give

$$\begin{aligned} \|(\partial^\mu u)(\partial^{\gamma-\mu} v)\|_{L^2(\Omega)} &\le C \left(\|u\|_{H^k(\Omega)} \|v\|_{L^\infty(\Omega)} \right)^{\theta} \left(\|u\|_{L^\infty(\Omega)} \|v\|_{H^k(\Omega)} \right)^{1-\theta} \\ &\le C \left(\|u\|_{H^k(\Omega)} \|v\|_{L^\infty(\Omega)} + \|u\|_{L^\infty(\Omega)} \|v\|_{H^k(\Omega)} \right). \end{aligned}$$

Summing over $|\gamma| \le r$ proves (20.4).
For the commutator, observe that

$$[\partial^\gamma, a] v = \sum_{\substack{\mu \in \mathbb{N}_0^m \\ 0 < \mu \le \gamma}} \binom{\gamma}{\mu} (\partial^\mu a)(\partial^{\gamma-\mu} v).$$

Each summand distributes at most $k-1$ derivatives between ∂a and v. The product estimate just proved, applied at order $k-1$, gives

$$\|[\partial^\gamma, a] v\|_{L^2(\Omega)} \le C \left(\|\partial a\|_{L^\infty(\Omega)} \|v\|_{H^{k-1}(\Omega)} + \|\partial a\|_{H^{k-1}(\Omega)} \|v\|_{L^\infty(\Omega)} \right),$$

and summing over $k \le r$ yields (20.5).
Now consider the asymmetric commutator. For $|\gamma| = k \le r$, its components are sums of terms

$$(\partial^\mu a) \partial^{\gamma-\mu+1} u, \qquad 1 \le |\mu| \le k.$$

After taking the indicated derivatives, the first factor retains $s - |\mu|$ derivatives in L^2 and the second retains $|\mu| - 1$. The sum of these orders is $s - 1 > m/2$. Lemma 20.1.1 implies

$$\|(\partial^\mu a) \partial^{\gamma-\mu+1} u\|_{L^2(\Omega)} \le C \|a\|_{H^s(\Omega)} \|u\|_{H^k(\Omega)}.$$

Summing over all multiindices yields (20.6).
For the composition estimates, choose an open subset $\mathcal{V}$ whose closure is compact, contains K, and is contained in $\mathcal{U}$. A cutoff function on the total space, equal to one on $\mathcal{V}$ and supported in $\mathcal{U}$, allows us to extend G to a smooth bundle map $\widetilde{G}$ defined on all fibers. The Faà di Bruno formula of Theorem 1.1.19, including

derivatives in the base variable, expresses every derivative of order $k \le r$ of $\widetilde{G}(x,u(x))$ as terms of the form

$$(\partial_x^\alpha D_z^j \widetilde{G})(x,u(x))[\partial^{\mu_1}u,\dots,\partial^{\mu_j}u], \qquad \begin{aligned} &1 \le j \le k, \quad \alpha,\mu_1,\dots,\mu_j \in \mathbb{N}_0^m,\\ &|\mu_i| \ge 1 \ (1 \le i \le j), \qquad |\alpha| + \sum_{i=1}^{j} |\mu_i| = k, \end{aligned}$$

and uniformly bounded terms with no derivatives of u. For $r \ge 1$, choose $p_i = 2r/|\mu_i|$. The Gagliardo–Nirenberg inequality gives

$$\|\partial^{\mu_i} u\|_{L^{p_i}(\Omega)} \le C \|u\|_{L^\infty(\Omega)}^{1-|\mu_i|/r} \|u\|_{H^r(\Omega)}^{|\mu_i|/r}.$$

If $\theta := \sum_{i=1}^{j} |\mu_i|/r$, then $0 < \theta \le 1$ and $\sum_{i=1}^{j} 1/p_i = \theta/2 \le 1/2$. Hölder, followed by the inclusion $L^{2/\theta} \hookrightarrow L^2$ on the compact subset of the chart, bounds the product by $C_K \|u\|_{H^r(\Omega)}^{\theta}$. The inequality $x^\theta \le 1 + x$ for $x \ge 0$ proves (20.9). The case $r = 0$ follows by integrating the uniform bound for G on the image of u. The finite sum over charts preserves these estimates. In particular, a bound $\|u\|_{H^r(M,\mathbf{V}_1)} \le R$ gives (20.7). Finally,

$$\widetilde{G}(u) - \widetilde{G}(v) = \int_0^1 D\widetilde{G}\big(v + \theta(u-v)\big)[u-v]\,d\theta.$$

The global extension ensures that the segment always lies within the domain. Applying the preceding estimate to the integrand, with constants uniform in θ, yields (20.8). The same argument handles several arguments and completes the proof. □

For $T > 0$ and $r \ge 0$ define

$$\begin{aligned} \mathcal{X}_T^r(\mathbf{E}) &:= \big\{ \mathbf{u} \in L^2(0,T;H^{r+1}(M,\mathbf{E})) \;\big|\; \partial_t \mathbf{u} \in L^2(0,T;H^{r-1}(M,\mathbf{E})) \big\},\\ \mathcal{Y}_T^r(\mathbf{E}) &:= L^2(0,T;H^{r-1}(M,\mathbf{E})), \end{aligned}$$

where the time derivative is understood in the sense of distributions with values in $H^{r-1}(M,\mathbf{E})$. Initially equip $\mathcal{X}_T^r(\mathbf{E})$ with the graph norm

$$\|\mathbf{u}\|_{\mathcal{X}_T^r(\mathbf{E}),0}^2 := \int_0^T \|\mathbf{u}(t)\|_{H^{r+1}(M,\mathbf{E})}^2\,dt + \int_0^T \|\partial_t \mathbf{u}(t)\|_{H^{r-1}(M,\mathbf{E})}^2\,dt. \tag{20.10}$$

This norm is complete. Indeed, if $(\mathbf{u}_j)$ is Cauchy, there exist $\mathbf{u} \in L^2(0,T;H^{r+1})$ and $\mathbf{v} \in L^2(0,T;H^{r-1})$ such that $\mathbf{u}_j \to \mathbf{u}$ and $\partial_t \mathbf{u}_j \to \mathbf{v}$ in the corresponding spaces. Passing to the limit in the identity defining the distributional derivative gives $\partial_t \mathbf{u} = \mathbf{v}$. The next lemma allows the supremum in time to be incorporated into the norm.

We use the pairing of the Hilbert triple $H^{r+1}(M,\mathbf{E}) \subseteq H^r(M,\mathbf{E}) \subseteq H^{r-1}(M,\mathbf{E})$ given, on smooth sections, by

$$\langle \mathbf{f}, \mathbf{v} \rangle_{H^{r-1},H^{r+1}} := (\Lambda^{r-1}\mathbf{f}, \Lambda^{r+1}\mathbf{v})_{L^2(M,\mathbf{E})}. \tag{20.11}$$

Thus H^{r-1} plays the role of the dual of H^{r+1} when H^r is the pivot space.

Lemma 20.1.3. (Time trace) Let $(M,\mathbf{g}_0)$ be a closed Riemannian manifold and let $\mathbf{E} \to M$ be a vector bundle with a bundle metric and compatible connection. Every element of $\mathcal{X}_T^r(\mathbf{E})$ has a unique representative in

$C([0,T];H^r(M,\mathbf{E}))$. For this representative,

$$\|\mathbf{u}(t)\|^2_{H^r(M,\mathbf{E})} - \|\mathbf{u}(\tau)\|^2_{H^r(M,\mathbf{E})} = 2\int_\tau^t \langle \partial_\rho \mathbf{u}(\rho), \mathbf{u}(\rho)\rangle_{H^{r-1},H^{r+1}}\, d\rho \tag{20.12}$$

for $0 \le \tau \le t \le T$. In particular, evaluation $\mathbf{u} \mapsto \mathbf{u}(0)$ is continuous from $\mathcal{X}^r_T(\mathbf{E})$ to $H^r(M,\mathbf{E})$.

Proof. Let $\Delta_\nabla = \nabla^*\nabla$ be the connection Laplacian and set $\Lambda = (I+\Delta_\nabla)^{1/2}$. By Theorem 12.4.10, there exists an orthonormal basis $(\mathbf{e}_j)_{j\ge1}$ of $L^2(M,\mathbf{E})$ consisting of smooth eigensections of Δ_∇. Denote by P_N the orthogonal projection onto the subspace spanned by $\mathbf{e}_1,\dots,\mathbf{e}_N$. The projections P_N commute with all powers of Λ, are contractions on each $H^\sigma(M,\mathbf{E})$, and converge strongly to the identity on these spaces.

Let $\mathbf{u} \in \mathcal{X}^r_T(\mathbf{E})$ and set $\mathbf{u}_N = P_N\mathbf{u}$. Since $\partial_t \mathbf{u}_N = P_N \partial_t \mathbf{u}$ in the distributional sense, each scalar coefficient of $\mathbf{u}_N$ belongs to $H^1(0,T)$. Thus $\mathbf{u}_N \in C([0,T];H^r(M,\mathbf{E}))$, and the differentiation rule on the finite-dimensional subspace gives

$$\|\mathbf{u}_N(t)\|^2_{H^r(M,\mathbf{E})} - \|\mathbf{u}_N(\tau)\|^2_{H^r(M,\mathbf{E})} = 2\int_\tau^t \langle \partial_\rho \mathbf{u}_N(\rho), \mathbf{u}_N(\rho)\rangle_{H^{r-1},H^{r+1}}\, d\rho. \tag{20.13}$$

Let us prove that $(\mathbf{u}_N)$ converges in $C([0,T];H^r(M,\mathbf{E}))$. If $\mathbf{w} = \mathbf{u}_N - \mathbf{u}_M$, there exists $\tau \in [0,T]$ such that

$$\|\mathbf{w}(\tau)\|^2_{H^r(M,\mathbf{E})} \le \frac{1}{T}\int_0^T \|\mathbf{w}(\rho)\|^2_{H^r(M,\mathbf{E})}\, d\rho \le \frac{1}{T}\|\mathbf{w}\|^2_{L^2(0,T;H^{r+1}(M,\mathbf{E}))}.$$

Applying (20.13) to $\mathbf{w}$ and using Cauchy–Schwarz in the pairing of (20.11) yields, for every $t \in [0,T]$,

$$\begin{aligned}\|\mathbf{w}(t)\|^2_{H^r(M,\mathbf{E})} &\le \frac{1}{T}\|\mathbf{w}\|^2_{L^2(0,T;H^{r+1}(M,\mathbf{E}))} + 2\|\partial_t\mathbf{w}\|_{L^2(0,T;H^{r-1}(M,\mathbf{E}))}\|\mathbf{w}\|_{L^2(0,T;H^{r+1}(M,\mathbf{E}))}\\ &\le \left(1+\frac{1}{T}\right)\|\mathbf{w}\|^2_{L^2(0,T;H^{r+1}(M,\mathbf{E}))} + \|\partial_t\mathbf{w}\|^2_{L^2(0,T;H^{r-1}(M,\mathbf{E}))}.\end{aligned}$$

Since $P_N \to I$ strongly in both Bochner spaces occurring here, the right-hand side tends to zero as $M,N \to \infty$. Consequently, there exists a section $\widetilde{\mathbf{u}} \in C([0,T];H^r(M,\mathbf{E}))$ such that $\mathbf{u}_N \to \widetilde{\mathbf{u}}$ uniformly on H^r. On the other hand, $\mathbf{u}_N \to \mathbf{u}$ in $L^2(0,T;H^{r+1})$; hence $\widetilde{\mathbf{u}} = \mathbf{u}$ for almost every time. Thus $\widetilde{\mathbf{u}}$ is a representative of $\mathbf{u}$. Two continuous representatives agreeing almost everywhere agree on all of $[0,T]$, proving uniqueness.

In (20.13), the endpoint terms converge uniformly. Moreover,

$$\begin{aligned}&\left|\int_\tau^t \left(\langle \partial_\rho \mathbf{u}_N, \mathbf{u}_N\rangle_{H^{r-1},H^{r+1}} - \langle \partial_\rho \mathbf{u}, \mathbf{u}\rangle_{H^{r-1},H^{r+1}}\right) d\rho\right|\\ &\quad\le \|\partial_t\mathbf{u}_N - \partial_t\mathbf{u}\|_{L^2(0,T;H^{r-1}(M,\mathbf{E}))}\|\mathbf{u}_N\|_{L^2(0,T;H^{r+1}(M,\mathbf{E}))}\\ &\qquad + \|\partial_t\mathbf{u}\|_{L^2(0,T;H^{r-1}(M,\mathbf{E}))}\|\mathbf{u}_N - \mathbf{u}\|_{L^2(0,T;H^{r+1}(M,\mathbf{E}))},\end{aligned}$$

where the norms are taken over $(0,T)$. The right-hand side tends to zero. Letting $N \to \infty$ gives (20.12) for all $0 \le \tau \le t \le T$.

Finally, choose $\tau \in [0,T]$ such that

$$\|\mathbf{u}(\tau)\|^2_{H^r(M,\mathbf{E})} \le \frac{1}{T}\|\mathbf{u}\|^2_{L^2(0,T;H^r)} \le \frac{1}{T}\|\mathbf{u}\|^2_{L^2(0,T;H^{r+1}(M,\mathbf{E}))}.$$

The energy identity and the same preceding argument give

$$\|\mathbf{u}\|^2_{L^\infty(0,T;H^r(M,\mathbf{E}))} \le \left(1+\frac{1}{T}\right)\|\mathbf{u}\|^2_{L^2(0,T;H^{r+1}(M,\mathbf{E}))} + \|\partial_t \mathbf{u}\|^2_{L^2(0,T;H^{r-1}(M,\mathbf{E}))}.$$

This proves continuity of all time evaluations with respect to the graph norm, in particular of the trace at $t=0$. □

From now on, equip $\mathcal{X}^r_T(\mathbf{E})$ with the norm

$$\|\mathbf{u}\|^2_{\mathcal{X}^r_T(\mathbf{E})} := \|\mathbf{u}\|^2_{L^\infty(0,T;H^r(M,\mathbf{E}))} + \int_0^T \|\mathbf{u}(t)\|^2_{H^{r+1}(M,\mathbf{E})}\,dt + \int_0^T \|\partial_t\mathbf{u}(t)\|^2_{H^{r-1}(M,\mathbf{E})}\,dt. \tag{20.14}$$

The preceding estimate shows that this norm is equivalent to (20.10).

20.2 Strongly parabolic linear systems

The preceding estimates control the products arising when an equation is differentiated. We now turn to the linear problem used at each step of the quasilinear iteration. Set $\mathcal{H} := T^*M \otimes \mathbf{E}$, with its induced metric and connection. Let

$$\mathbf{A}(t) \in \Gamma(\operatorname{End}\mathcal{H}), \qquad \mathbf{B}(t) \in \Gamma(\operatorname{Hom}(\mathcal{H},\mathbf{E})), \qquad \mathbf{C}(t) \in \Gamma(\operatorname{End}\mathbf{E})$$

be time-dependent sections. Consider the intrinsic operator

$$P_t\mathbf{u} := \nabla^*\big(\mathbf{A}(t)\nabla\mathbf{u}\big) + \mathbf{B}(t)(\nabla\mathbf{u}) + \mathbf{C}(t)\mathbf{u} \tag{20.15}$$

and the equation

$$\partial_t\mathbf{u} + P_t\mathbf{u} = \mathbf{f}, \qquad \mathbf{u}(0) = \mathbf{u}_0. \tag{20.16}$$

After fixing a chart and a local frame of $\mathbf{E}$, the indices i,j,k range over $\{1,\dots,m\}$, and we write $(\mathbf{A}\nabla\mathbf{u})_i = \sum_{j=1}^m A_i{}^j \nabla_j u$ and $\mathbf{B}(\nabla\mathbf{u}) = \sum_{j=1}^m B^j \nabla_j u$. With $A^{ij} := \sum_{k=1}^m g_0^{ik} A_k{}^j$, the local formula for (20.15) is

$$P_t u = -\sum_{i,j=1}^m \nabla_i\big(A^{ij}(t)\nabla_j u\big) + \sum_{j=1}^m B^j(t)\nabla_j u + C(t)u.$$

Definition 20.2.1. (Strong parabolicity) Let $(M,\mathbf{g}_0)$ be a closed Riemannian manifold and let $\mathbf{E}\to M$ be a vector bundle with a bundle metric and compatible connection. We say that the family of operators (20.15) is **strongly parabolic** with constant $\lambda>0$ if $\mathbf{A}(t)$ is self-adjoint on $\mathcal{H}$ and

$$\langle \mathbf{A}(x,t)\zeta,\zeta\rangle_{\mathbf{g}_0,\mathbf{h}_\mathbf{E}} \ge \lambda|\zeta|^2_{\mathbf{g}_0,\mathbf{h}_\mathbf{E}} \tag{20.17}$$

for every $(x,t)\in M\times[0,T]$ and $\zeta\in T^*_xM\otimes\mathbf{E}_x$. Taking $\zeta=\xi\otimes v$ shows that this condition implies uniform positivity of the symbol. For operators with scalar symbol $a^{ij}\operatorname{Id}_\mathbf{E}$, the two conditions are equivalent.

The systems we use admit a divergence-form formulation. In a fixed chart and frame, an operator with prin-

cipal part $-\sum_{i,j=1}^{m} A^{ij}(\nabla^2\cdot)_{ij}$ can be written as $-\sum_{i,j=1}^{m}\nabla_i(A^{ij}\nabla_j)+\sum_{j=1}^{m}\widetilde{B}^j\nabla_j$, with $\widetilde{B}^j = B^j + \sum_{i=1}^{m}\nabla_i A^{ij}$ after incorporating the original term $\sum_{j=1}^{m} B^j\nabla_j$.

For integrations by parts, use the covariant energy

$$\mathscr{E}_r(\mathbf{u}) := \sum_{q=0}^{r} \|\nabla^q \mathbf{u}\|^2_{L^2(M,T^{(0,q)}(TM)\otimes\mathbf{E})}. \tag{20.18}$$

There exist constants $c_r, C_r > 0$ such that

$$c_r\|\mathbf{u}\|^2_{H^r(M,\mathbf{E})} \le \mathscr{E}_r(\mathbf{u}) \le C_r\|\mathbf{u}\|^2_{H^r(M,\mathbf{E})}.$$

The trace identity refers to the spectral norm, whereas the following differential identities are written for $\mathscr{E}_r$; integrated estimates transfer between them through this equivalence.

Lemma 20.2.2. (Higher-order energy estimate) Let $(M,\mathbf{g}_0)$ be a closed Riemannian manifold and let $\mathbf{E}\to M$ be a vector bundle with a bundle metric and compatible connection. Suppose that (20.17) holds and that

$$\sup_{t\in[0,T]}\Big(\|\mathbf{A}(t)\|_{H^s(M,\operatorname{End}\mathcal{H})} + \|\mathbf{B}(t)\|_{H^s(M,\operatorname{Hom}(\mathcal{H},\mathbf{E}))} + \|\mathbf{C}(t)\|_{H^s(M,\operatorname{End}\mathbf{E})}\Big) \le K. \tag{20.19}$$

For $r\in\{0,1,\dots,s\}$ there exist constants $c>0$ and $C>0$, depending only on r,s,λ,K and the fixed metrics and connections, such that every smooth solution of (20.16) satisfies

$$\frac{d}{dt}\mathscr{E}_r(\mathbf{u}(t)) + c\|\mathbf{u}(t)\|^2_{H^{r+1}(M,\mathbf{E})} \le C\mathscr{E}_r(\mathbf{u}(t)) + C\|\mathbf{f}(t)\|^2_{H^{r-1}(M,\mathbf{E})}. \tag{20.20}$$

Consequently,

$$\|\mathbf{u}\|^2_{L^\infty(0,T;H^r(M,\mathbf{E}))} + c\int_0^T \|\mathbf{u}(t)\|^2_{H^{r+1}(M,\mathbf{E})}\,dt \le Ce^{CT}\left(\|\mathbf{u}_0\|^2_{H^r(M,\mathbf{E})} + \int_0^T \|\mathbf{f}(t)\|^2_{H^{r-1}(M,\mathbf{E})}\,dt\right). \tag{20.21}$$

Proof. For $q\in\{0,1,\dots,r\}$, apply ∇^q to the equation and pair with $\nabla^q\mathbf{u}$. The new derivative occupies the first slot, according to Definition 9.1.1. Let $\mathbf{V}_q$ be the tensor obtained from $\nabla(\nabla^q\mathbf{u})$ by moving this first slot to the last covariant slot:

$$\mathbf{V}_q(X_1,\dots,X_q,Y) := (\nabla(\nabla^q\mathbf{u}))(Y,X_1,\dots,X_q).$$

Thus $\mathbf{A}$ acts on the pair consisting of Y and the value in $\mathbf{E}$, and $|\mathbf{V}_q| = |\nabla^{q+1}\mathbf{u}|$. Green's formula in Theorem 9.1.29 gives the principal contribution

$$\int_M \langle (I_{T^{(0,q)}(TM)}\otimes\mathbf{A})\mathbf{V}_q,\mathbf{V}_q\rangle\,d\lambda_{\mathbf{g}_0} + \mathcal{R}_q.$$

The integral is at least $\lambda\|\nabla^{q+1}\mathbf{u}\|^2_{L^2(M,T^{(0,q+1)}(TM)\otimes\mathbf{E})}$.

Let us describe the contributions of $\mathcal{R}_q$. When the q derivatives are distributed between $\mathbf{A}$ and $\nabla\mathbf{u}$, the terms with one derivative on $\mathbf{A}$ form $[\nabla^q,\mathbf{A}](\nabla\mathbf{u})$. Reordering the remaining covariant slots introduces commutators of two derivatives. For $q=1$ use the curvature identity of the induced connection. If the

interchanges have been carried out up to order q, applying one more derivative produces two types of terms: a derivative of a curvature coefficient already present and a derivative of the section to which that coefficient is applied. The new interchange contributes another curvature multiplied by a lower-order derivative of the section. The Leibniz rule in Proposition 9.1.40 controls the first two types. This is the same commutation step developed in Lemma 9.1.41; here it also applies to $T^{(0,q)}(TM)\otimes\mathbf{E}$. At order q, only curvatures of the fixed structures and their derivatives up to order $q-1$ occur. These terms therefore have bounded coefficients and contain at most q derivatives of $\mathbf{u}$ after integration by parts.
For $q=0$ there is no commutator. For $1\le q\le r$, estimate (20.6) gives, for each $\varepsilon>0$,

$$|\mathcal{R}_q|\le CK\|\mathbf{u}\|_{H^r(M,\mathbf{E})}\|\mathbf{u}\|_{H^{r+1}(M,\mathbf{E})}\le \varepsilon\|\mathbf{u}\|^2_{H^{r+1}(M,\mathbf{E})}+C_\varepsilon\|\mathbf{u}\|^2_{H^r(M,\mathbf{E})}.$$

The lower-order terms obey

$$\|\mathbf{B}(\nabla\mathbf{u})+\mathbf{C}\mathbf{u}\|_{H^q(M,\mathbf{E})}\le CK\|\mathbf{u}\|_{H^{q+1}(M,\mathbf{E})},\qquad q\in\{0,\dots,r\}.$$

Indeed, in every Leibniz product containing $|\mu|$ derivatives of a coefficient, the available orders for applying Lemma 20.1.1 are $s-|\mu|$ and $|\mu|$; their sum is $s>m/2$. This observation includes $q=0$ and avoids requiring an L^∞ norm of the solution. After pairing with $\nabla^q\mathbf{u}$, Young gives the same bound with ε for each of these terms.
If $r=0$, interpret the source term directly by duality:

$$|\langle\mathbf{f},\mathbf{u}\rangle_{H^{-1}(M,\mathbf{E}),H^1(M,\mathbf{E})}|\le\|\mathbf{f}\|_{H^{-1}(M,\mathbf{E})}\|\mathbf{u}\|_{H^1(M,\mathbf{E})},$$

and Young gives the required bound. Now suppose that $r\ge1$. For smooth $\mathbf{f}$, the contribution obtained by summing the covariant energies is

$$\mathcal{B}_r(\mathbf{f},\mathbf{u}):=\sum_{q=0}^{r}\int_M\langle\nabla^q\mathbf{f},\nabla^q\mathbf{u}\rangle\,d\lambda_{\mathbf{g}_0}.$$

For $0\le q\le r-1$, Cauchy–Schwarz gives directly

$$\left|\int_M\langle\nabla^q\mathbf{f},\nabla^q\mathbf{u}\rangle\,d\lambda_{\mathbf{g}_0}\right|\le C\|\mathbf{f}\|_{H^{r-1}(M,\mathbf{E})}\|\mathbf{u}\|_{H^{r-1}(M,\mathbf{E})}.$$

In the highest-order term, write $\nabla^r\mathbf{f}=\nabla(\nabla^{r-1}\mathbf{f})$ and apply the definition of the covariant adjoint:

$$\int_M\langle\nabla^r\mathbf{f},\nabla^r\mathbf{u}\rangle\,d\lambda_{\mathbf{g}_0}=\int_M\langle\nabla^{r-1}\mathbf{f},\nabla^*(\nabla^r\mathbf{u})\rangle\,d\lambda_{\mathbf{g}_0}.$$

The operator $\mathbf{u}\mapsto\nabla^*(\nabla^r\mathbf{u})$ has order $r+1$, so its L^2 norm is bounded by $C\|\mathbf{u}\|_{H^{r+1}(M,\mathbf{E})}$. Summing the preceding terms yields

$$|\mathcal{B}_r(\mathbf{f},\mathbf{u})|\le C\|\mathbf{f}\|_{H^{r-1}(M,\mathbf{E})}\|\mathbf{u}\|_{H^{r+1}(M,\mathbf{E})}.$$

For $\mathbf{f}\in H^{r-1}(M,\mathbf{E})$ and $\mathbf{u}\in H^{r+1}(M,\mathbf{E})$, the expression defining the extension is

$$\mathcal{B}_r(\mathbf{f},\mathbf{u})=\sum_{q=0}^{r-1}\int_M\langle\nabla_w^q\mathbf{f},\nabla_w^q\mathbf{u}\rangle\,d\lambda_{\mathbf{g}_0}+\int_M\langle\nabla_w^{r-1}\mathbf{f},\nabla^*(\nabla_w^r\mathbf{u})\rangle\,d\lambda_{\mathbf{g}_0}.$$

Each pairing is between two L^2 sections of the same bundle $T^{(0,q)}(TM)\otimes\mathbf{E}$; in the last term, take $q=r-1$. Thus the integrals are defined. If $\mathbf{f}_j\to\mathbf{f}$ in $H^{r-1}(M,\mathbf{E})$ and $\mathbf{u}_j\to\mathbf{u}$ in $H^{r+1}(M,\mathbf{E})$ are smooth Meyers–Serrin approximations, bilinearity and the preceding bound give

$$\begin{aligned}|\mathcal{B}_r(\mathbf{f}_j,\mathbf{u}_j)-\mathcal{B}_r(\mathbf{f},\mathbf{u})| &\le C\|\mathbf{f}_j-\mathbf{f}\|_{H^{r-1}(M,\mathbf{E})}\|\mathbf{u}_j\|_{H^{r+1}(M,\mathbf{E})}\\ &\quad + C\|\mathbf{f}\|_{H^{r-1}(M,\mathbf{E})}\|\mathbf{u}_j-\mathbf{u}\|_{H^{r+1}(M,\mathbf{E})}\longrightarrow 0.\end{aligned}$$

Thus the extension agrees with the smooth expression, is independent of both approximations, and satisfies the same bound. Young then gives

$$|\mathcal{B}_r(\mathbf{f},\mathbf{u})|\le \varepsilon\|\mathbf{u}\|^2_{H^{r+1}(M,\mathbf{E})}+C\|\mathbf{f}\|^2_{H^{r-1}(M,\mathbf{E})}.$$

Now sum all contributions. The sum of the coercive terms controls $\|\mathbf{u}\|^2_{H^{r+1}(M,\mathbf{E})}$ up to a multiple of $\|\mathbf{u}\|^2_{L^2(M,\mathbf{E})}$, which is incorporated into the right-hand side. Choose ε after this summation, smaller than the coercivity constant divided by twice the number of terms to be absorbed. A positive constant c remains, and we obtain (20.20). Integration over $[0,t]$ and Grönwall's inequality in Lemma 1.8.19 prove (20.21). □

Theorem 20.2.3. (Linear existence and parabolic regularity) Let $(M,\mathbf{g}_0)$ be a closed Riemannian manifold and let $\mathbf{E}\to M$ be a vector bundle with a bundle metric and compatible connection. Let $r\in\{0,1,\dots,s\}$. Suppose that

$$\begin{aligned}&\mathbf{A}\in C([0,T];H^s(M,\operatorname{End}\mathcal{H})),\\ &\mathbf{B}\in C([0,T];H^s(M,\operatorname{Hom}(\mathcal{H},\mathbf{E}))),\\ &\mathbf{C}\in C([0,T];H^s(M,\operatorname{End}\mathbf{E})),\end{aligned}$$

satisfy (20.17) with a constant independent of t and obey (20.19). For every

$$\mathbf{u}_0\in H^r(M,\mathbf{E}),\qquad \mathbf{f}\in\mathcal{Y}^r_T(\mathbf{E}),$$

there exists a unique solution $\mathbf{u}\in\mathcal{X}^r_T(\mathbf{E})$ of (20.16). Moreover,

$$\|\mathbf{u}\|_{\mathcal{X}^r_T(\mathbf{E})}\le C_T\big(\|\mathbf{u}_0\|_{H^r(M,\mathbf{E})}+\|\mathbf{f}\|_{\mathcal{Y}^r_T(\mathbf{E})}\big),\tag{20.22}$$

where C_T can be chosen uniformly when T, K, and λ^{-1} remain bounded. If the coefficients, $\mathbf{f}$, and $\mathbf{u}_0$ are smooth, then $\mathbf{u}$ is smooth on $M\times[0,T]$.

Proof. Let $(\mathbf{e}_k)_{k\ge1}$ be an orthonormal basis of $L^2(M,\mathbf{E})$ consisting of eigensections of the connection Laplacian, ordered by eigenvalues $0\le\mu_1\le\mu_2\le\cdots$ counted with multiplicity. Let V_N be the span of $\mathbf{e}_1,\dots,\mathbf{e}_N$. Seek $\mathbf{u}_N(t)=\sum_{k=1}^{N}d_k(t)\mathbf{e}_k$ and require that, for every $\mathbf{v}\in V_N$,

$$(\partial_t\mathbf{u}_N,\mathbf{v})_{L^2(M,\mathbf{E})}+\int_M\langle\mathbf{A}\nabla\mathbf{u}_N,\nabla\mathbf{v}\rangle_{\mathbf{g}_0,\mathbf{h}_\mathbf{E}}\,d\lambda_{\mathbf{g}_0}+\int_M\langle\mathbf{B}(\nabla\mathbf{u}_N)+\mathbf{C}\mathbf{u}_N,\mathbf{v}\rangle_{\mathbf{h}_\mathbf{E}}\,d\lambda_{\mathbf{g}_0}=\langle\mathbf{f},\mathbf{v}\rangle_{H^{-1}(M,\mathbf{E}),H^1(M,\mathbf{E})}.\tag{20.23}$$

For smooth data, this is a finite-dimensional linear differential equation with continuous coefficients and

therefore has a solution on all of $[0,T]$, with $\mathbf{u}_N(0)$ equal to the orthogonal projection of $\mathbf{u}_0$ onto V_N. Taking $\mathbf{v} = \mathbf{u}_N$ and using (20.17) gives, with constants independent of N,

$$\|\mathbf{u}_N\|^2_{L^\infty(0,T;L^2(M,\mathbf{E}))} + \int_0^T \|\mathbf{u}_N(t)\|^2_{H^1(M,\mathbf{E})}\,dt \le C_T\left(\|\mathbf{u}_0\|^2_{L^2(M,\mathbf{E})} + \int_0^T \|\mathbf{f}(t)\|^2_{H^{-1}(M,\mathbf{E})}\,dt\right). \tag{20.24}$$

Let Π_N be the spectral projection onto V_N. It is a contraction on H^1 and H^{-1}, because it retains the first coefficients in the spectral norms. The projected equation reads $\partial_t \mathbf{u}_N = \Pi_N(\mathbf{f} - P_t\mathbf{u}_N)$. The operator $P_t\colon H^1 \to H^{-1}$ is uniformly bounded by the coefficient bounds and the weak formula. The order-zero energy then gives a uniform bound for $\partial_t\mathbf{u}_N$ in $L^2(0,T;H^{-1}(M,\mathbf{E}))$. Reflexivity allows us to extract a subsequence converging weakly in $L^2(0,T;H^1(M,\mathbf{E}))$ whose time derivatives converge weakly in $L^2(0,T;H^{-1}(M,\mathbf{E}))$. Strong convergence in $L^2(0,T;L^2(M,\mathbf{E}))$ can be seen directly. If Q_J is the projection onto the first J eigensections, the bound H^1 gives

$$\int_0^T \|(I-Q_J)\mathbf{u}_N(t)\|^2_{L^2(M,\mathbf{E})}\,dt \le \frac{C}{1+\mu_{J+1}},$$

where $\mu_{J+1} \to \infty$ is the next eigenvalue. For fixed J, the coordinates of $Q_J\mathbf{u}_N$ are uniformly bounded in $H^1(0,T)$ by the bound for $\partial_t\mathbf{u}_N$ in $H^{-1}(M,\mathbf{E})$; a subsequence converges uniformly in the finite-dimensional space $Q_JL^2(M,\mathbf{E})$. First choose J large and then a diagonal subsequence. Passing to the limit in (20.23) gives a weak solution $\mathbf{u}$. Moreover, the two preceding weak convergences show that $\mathbf{u}_N \rightharpoonup \mathbf{u}$ in the energy space $\mathcal{X}^0_T(\mathbf{E})$. The trace $\mathcal{X}^0_T(\mathbf{E}) \to L^2(M,\mathbf{E})$ is linear and continuous by Lemma 20.1.3 and is therefore weakly continuous. Since $\mathbf{u}_N(0) = \Pi_N\mathbf{u}_0 \to \mathbf{u}_0$ strongly in L^2, we conclude that $\mathbf{u}(0) = \mathbf{u}_0$.

We now show that data of order r give exactly the asserted regularity. For $r = 0$, the preceding construction and the equation already give $\mathbf{u} \in \mathcal{X}^0_T(\mathbf{E})$. Thus suppose that $r \ge 1$. We obtain each spatial derivative using difference quotients. Begin with the first derivative.

Let us justify the test sections depending on the solution. First fix the spatial step $h \ne 0$ and a time $T' < T$. For $0 < \varepsilon < T - T'$ use the Steklov averages

$$\mathbf{u}^\varepsilon(t) = \frac{1}{\varepsilon}\int_t^{t+\varepsilon} \mathbf{u}(\rho)\,d\rho, \qquad t \in [0,T'].$$

Spatial difference quotients of $\mathbf{u}^\varepsilon$, localized in a chart, belong to $L^2(0,T';H^1)$ and are admissible in the averaged weak equation. Integrate between 0 and a time in $[0,T']$, using time cutoffs approximating its indicator function and including the initial term. For fixed h, first let $\varepsilon \to 0^+$. For example, $(\mathbf{A}\nabla\mathbf{u})^\varepsilon$ and $\mathbf{A}\nabla\mathbf{u}^\varepsilon$ both converge to $\mathbf{A}\nabla\mathbf{u}$ in L^2; continuity in time and the uniform bound for $\mathbf{A}$ justify this assertion. Quotients with a fixed step are bounded operators on L^2 and therefore preserve this convergence. Moreover, $\mathbf{u}^\varepsilon(0) \to \mathbf{u}_0$ in L^2 by the order-zero trace already obtained. This recovers the initial term for the difference quotients. Only afterward do we let $h \to 0$, using the uniform estimates below. At the end we may take $T' \to T^-$.

In a chart and a trivialization of rank $d := \operatorname{rank}\mathbf{E}$, let δ^ℓ_h be the difference quotient in the coordinate direction ℓ, and let η be a smooth function compactly supported in the chart. Choose an open subset U' relatively compact in the same chart and containing a neighborhood of $\operatorname{supp}\eta$; the steps h are chosen so that all translations used remain in U'. If $d\lambda_{\mathbf{g}_0} = a(x)\,dx$ and $H(x)$ is the matrix of the bundle metric, set $\mathsf{G}(x) := a(x)H(x)$. In the weak formulation, use as test section the weighted discrete adjoint

$$-\mathsf{G}^{-1}\delta^\ell_{-h}\big(\mathsf{G}\eta^2\delta^\ell_h\mathbf{u}\big).$$

The exact discrete identity in the chart is

$$\int \langle \mathsf{G}\delta_h^\ell v, w\rangle_{\mathbb{R}^d}\, dx = -\int \langle \mathsf{G}v, \mathsf{G}^{-1}\delta_{-h}^\ell(\mathsf{G}w)\rangle_{\mathbb{R}^d}\, dx. \tag{20.25}$$

The weighted operator differs from δ_{-h}^ℓ by an operator uniformly bounded on L^2. Indeed, if $\tau_h^\ell w(x) = w(x + he_\ell)$, the discrete product rule is

$$\delta_h^\ell(fw) = (\tau_h^\ell f)\delta_h^\ell w + (\delta_h^\ell f)w.$$

In these estimates, compactly supported functions are understood to be extended by zero to $\mathbb{R}^m$. Applying it to $\mathsf{G}w$, the first additional coefficient is $O(|h|)$; its product with $\delta_{-h}^\ell w$ is bounded because $\|h\delta_{-h}^\ell w\|_{L^2(\mathbb{R}^m,\mathbb{R}^d)} \le 2\|w\|_{L^2(\mathbb{R}^m,\mathbb{R}^d)}$. The second coefficient is bounded by the first derivatives of G.

The principal part contains the translated matrix $A(x + he_\ell, t)$, together with the translated metric weights. Comparison with the weights at x introduces an error $O(|h|)$, uniform by the C^1 bounds for the fixed coefficients. Thus, for $|h|$ sufficiently small, the principal integral controls

$$\frac{\lambda}{2}\int_M \eta^2 |\nabla \delta_h^\ell \mathbf{u}|^2_{\mathbf{g}_0,\mathbf{h}_\mathbf{E}}\, d\lambda_{\mathbf{g}_0}.$$

The time term is

$$\frac{1}{2}\frac{d}{dt}\int_M \eta^2 |\delta_h^\ell \mathbf{u}|^2_{\mathbf{h}_\mathbf{E}}\, d\lambda_{\mathbf{g}_0}.$$

Terms in which the difference quotient falls on the local representation of $\mathbf{A}$, on η, or on the connection coefficients are bounded by

$$\frac{\lambda}{4}\int_M \eta^2 |\nabla \delta_h^\ell \mathbf{u}|^2_{\mathbf{g}_0,\mathbf{h}_\mathbf{E}}\, d\lambda_{\mathbf{g}_0} + C\int_{U'} \left(|\nabla \mathbf{u}|^2_{\mathbf{g}_0,\mathbf{h}_\mathbf{E}} + |\mathbf{u}|^2_{\mathbf{h}_\mathbf{E}} + |\mathbf{f}|^2_{\mathbf{h}_\mathbf{E}}\right) d\lambda_{\mathbf{g}_0}.$$

The bound is uniform for $|h|$ smaller than the distance between $\operatorname{supp}\eta$ and the edge of the chart. Integrating over $[0,T]$ and letting $h \to 0$ gives one additional spatial derivative in a smaller chart.

To iterate, we do not assume in advance that $\nabla\mathbf{u}$ is bounded. Apply difference quotients of order q, $1 \le q \le r$, and use as test sections the backward quotients of order q of the same localized expression. The commutator with the principal part follows from the discrete product rule. For $\gamma \in \mathbb{N}_0^m$ and a common step in each direction, writing τ_h^γ for translation by $h\gamma$, we have

$$\delta_h^\gamma(fw) = \sum_{\substack{\mu\in\mathbb{N}_0^m \\ \mu\le\gamma}} \binom{\gamma}{\mu} (\tau_h^{\gamma-\mu}\delta_h^\mu f)(\delta_h^{\gamma-\mu} w).$$

This identity follows by applying the first-order rule once for each direction in the multiindex. Translations are bounded in the localized norms, and quotients of order $|\mu|$ are controlled by derivatives of that order in U'. Thus the commutator terms satisfy the same bounds as the differential expressions to which they converge:

$$(\partial^\mu A)\,\partial^{\gamma-\mu+1}\mathbf{u}, \qquad \mu,\gamma \in \mathbb{N}_0^m, \quad 0 < \mu \le \gamma, \quad |\gamma| = q, \tag{20.26}$$

and the connection terms have strictly lower order. The asymmetric estimate (20.6) shows that the sum of

all terms (20.26) is bounded by $C\|\mathbf{A}\|_{H^s(M,\operatorname{End}\mathcal{H})}\|\mathbf{u}\|_{H^{|\gamma|}(M,\mathbf{E})}$. The first-order and zeroth-order terms obey

$$\|\mathbf{B}(\nabla\mathbf{u})+\mathbf{C}\mathbf{u}\|_{H^{q-1}(M,\mathbf{E})}\le CK\|\mathbf{u}\|_{H^q(M,\mathbf{E})},$$

while the sum of the source terms is the preceding covariant form $\mathcal{B}_q(\mathbf{f},\mathbf{u})$. Moving one derivative in the highest-order term and then using spectral duality (20.11) gives

$$|\mathcal{B}_q(\mathbf{f},\mathbf{u})|\le\frac{c}{4}\|\mathbf{u}\|^2_{H^{q+1}(M,\mathbf{E})}+C\|\mathbf{f}\|^2_{H^{q-1}(M,\mathbf{E})}.$$

Let us specify the induction that passes from these local estimates to global regularity. For $0\le q\le r$, let $\mathcal{P}_q$ be the assertion

$$\mathbf{u}\in C([0,T];H^q(M,\mathbf{E}))\cap L^2(0,T;H^{q+1}(M,\mathbf{E}))$$

together with the energy estimate of order q written below. The assertion $\mathcal{P}_0$ is (20.24) after passage to the limit. The difference-quotient calculation just carried out proves $\mathcal{P}_1$: the uniform bound for $\delta_h^\ell\mathbf{u}$ allows a weak limit to be extracted, and the difference-quotient characterization identifies that limit with $\partial_\ell\mathbf{u}$.

Now suppose that $\mathcal{P}_0,\dots,\mathcal{P}_{q-1}$ have been proved, where $2\le q\le r$. Apply a difference quotient of order q to the equation and test against its localized backward quotient. When all quotients fall on $\mathbf{u}$, parabolicity gives the coercive term of order $q+1$. If at least one falls on $\mathbf{A}$, we obtain a difference-quotient and translation version of one of the terms in (20.26); the preceding Moser estimate and Young allow the part containing $\|\mathbf{u}\|^2_{H^{q+1}(M,\mathbf{E})}$ to be absorbed. Quotients falling on $\mathbf{B},\mathbf{C}$, connection coefficients, or cutoffs contain at most q derivatives of $\mathbf{u}$ and are controlled by $\mathcal{P}_{q-1}$ and the uniform coefficient bound. The source term is controlled by $\mathcal{B}_q$, as shown above. Finally, quotients of the initial data are uniformly bounded by $\|\mathbf{u}_0\|_{H^q(M,\mathbf{E})}$.

Choose a finite cover by charts and a subordinate partition of unity. Summing the local estimates, terms in which derivatives reach the cutoffs have lower order and are already covered by $\mathcal{P}_{q-1}$. The resulting bounds are uniform in the quotient step; letting $h\to0$, weak lower semicontinuity of the norm gives $\mathbf{u}\in L^2(0,T;H^{q+1}(M,\mathbf{E}))$. The equation itself, viewed as an identity in $H^{q-1}(M,\mathbf{E})$, then gives $\partial_t\mathbf{u}\in L^2(0,T;H^{q-1}(M,\mathbf{E}))$. Applying Lemma 20.1.3 to the Hilbert triple

$$H^{q+1}(M,\mathbf{E})\hookrightarrow H^q(M,\mathbf{E})\hookrightarrow H^{q-1}(M,\mathbf{E})$$

yields $\mathbf{u}\in C([0,T];H^q(M,\mathbf{E}))$. This proves $\mathcal{P}_q$. The inductive step is complete, and for each $1\le q\le r$ we obtain

$$\frac{d}{dt}\mathscr{E}_q(\mathbf{u}(t))+c\|\mathbf{u}(t)\|^2_{H^{q+1}(M,\mathbf{E})}\le C\mathscr{E}_q(\mathbf{u}(t))+C\|\mathbf{f}(t)\|^2_{H^{q-1}(M,\mathbf{E})}. \tag{20.27}$$

Each step uses only the coefficient bound and regularity from the preceding step. Integrating the last inequality gives

$$\|\mathbf{u}\|^2_{L^\infty(0,T;H^r(M,\mathbf{E}))}+\int_0^T\|\mathbf{u}(t)\|^2_{H^{r+1}(M,\mathbf{E})}\,dt\le C_T\left(\|\mathbf{u}_0\|^2_{H^r(M,\mathbf{E})}+\int_0^T\|\mathbf{f}(t)\|^2_{H^{r-1}(M,\mathbf{E})}\,dt\right). \tag{20.28}$$

Control up to $t=0$ follows by applying the same calculation to approximations with smooth initial data and using the term $\|\mathbf{u}_0\|_{H^r(M,\mathbf{E})}$ when integrating the energy identity. No additional compatibility condition arises, since M is closed.

The equation and continuity of multiplication imply

$$\|\partial_t \mathbf{u}\|_{L^2(0,T;H^{r-1}(M,\mathbf{E}))} \le C\big(\|\mathbf{u}\|_{L^2(0,T;H^{r+1}(M,\mathbf{E}))} + \|\mathbf{u}\|_{L^2(0,T;H^{r}(M,\mathbf{E}))} + \|\mathbf{f}\|_{L^2(0,T;H^{r-1}(M,\mathbf{E}))}\big).$$

This proves (20.22) for smooth data and coefficients.

We turn to coefficients and data with the regularity in the statement. Choose smooth approximations $\mathbf{A}_j, \mathbf{B}_j, \mathbf{C}_j, \mathbf{f}_j$ and $\mathbf{u}_{0,j}$ converging in the stated spaces. Replace $\mathbf{A}_j$ by its self-adjoint part. Since $H^s(M) \hookrightarrow C^1(M)$, convergence of $\mathbf{A}_j$ is uniform; thus, from some index onward,

$$\langle \mathbf{A}_j(x,t)\zeta, \zeta\rangle \ge \frac{\lambda}{2}|\zeta|^2$$

for every (x,t) and every $\zeta \in T^*_xM \otimes \mathbf{E}_x$. The smooth solutions $\mathbf{u}_j$ satisfy a uniform bound in $\mathcal{X}^r_T(\mathbf{E})$ by (20.21) and the equation itself.

Reflexivity of the Bochner spaces allows us to extract a subsequence such that

$$\begin{aligned} \mathbf{u}_j &\rightharpoonup \mathbf{u} && \text{in } L^2(0,T;H^{r+1}(M,\mathbf{E})),\\ \partial_t \mathbf{u}_j &\rightharpoonup \partial_t \mathbf{u} && \text{in } L^2(0,T;H^{r-1}(M,\mathbf{E})). \end{aligned}$$

To pass to the limit in the principal term, write

$$\mathbf{A}_j \nabla \mathbf{u}_j - \mathbf{A}\nabla \mathbf{u} = (\mathbf{A}_j - \mathbf{A})\nabla \mathbf{u}_j + \mathbf{A}\nabla(\mathbf{u}_j - \mathbf{u}).$$

The first part converges strongly to zero in $L^2(0,T;H^{r-1})$ by the product estimates, and the second converges weakly. The terms containing $\mathbf{B}_j$ and $\mathbf{C}_j$ are handled in the same way. Testing the equation against time-dependent smooth sections therefore gives the limiting problem.

The trace map $\mathcal{X}^r_T(\mathbf{E}) \to H^r(M,\mathbf{E})$ is linear and continuous by Lemma 20.1.3 and is therefore weakly continuous. Since $\mathbf{u}_j(0) = \mathbf{u}_{0,j} \to \mathbf{u}_0$, we conclude that $\mathbf{u}(0) = \mathbf{u}_0$. Weak lower semicontinuity preserves estimate (20.22). If two solutions have the same data, the order-zero energy estimate applied to their difference gives uniqueness. Finally, when all data are smooth, repeat the estimate at every spatial order; the equation expresses time derivatives in terms of the spatial derivatives already controlled and gives joint smoothness. □

Proposition 20.2.4. (Stability with respect to coefficients) Let $(M,\mathbf{g}_0)$ be a closed Riemannian manifold and let $\mathbf{E} \to M$ be a vector bundle with a bundle metric and compatible connection. Let P_t and $\widetilde{P}_t$ be two families satisfying the hypotheses of Theorem 20.2.3 with the same bounds K and λ. Let $\mathbf{u}, \widetilde{\mathbf{u}} \in \mathcal{X}^s_T(\mathbf{E})$ be the solutions corresponding to $(\mathbf{u}_0, \mathbf{f})$ and $(\widetilde{\mathbf{u}}_0, \widetilde{\mathbf{f}})$. Then

$$\begin{aligned} &\|\mathbf{u} - \widetilde{\mathbf{u}}\|_{\mathcal{X}^{s-1}_T(\mathbf{E})}\\ &\quad\le C_T\Big(\|\mathbf{u}_0 - \widetilde{\mathbf{u}}_0\|_{H^{s-1}(M,\mathbf{E})} + \|\mathbf{f} - \widetilde{\mathbf{f}}\|_{\mathcal{Y}^{s-1}_T(\mathbf{E})}\\ &\qquad + \|\mathbf{A} - \widetilde{\mathbf{A}}\|_{C([0,T];H^{s-1}(M,\operatorname{End}\mathcal{H}))}\|\widetilde{\mathbf{u}}\|_{L^2(0,T;H^{s+1}(M,\mathbf{E}))}\\ &\qquad + \|\mathbf{B} - \widetilde{\mathbf{B}}\|_{C([0,T];H^{s-1}(M,\operatorname{Hom}(\mathcal{H},\mathbf{E})))}\|\widetilde{\mathbf{u}}\|_{L^2(0,T;H^{s}(M,\mathbf{E}))}\\ &\qquad + \|\mathbf{C} - \widetilde{\mathbf{C}}\|_{C([0,T];H^{s-1}(M,\operatorname{End}\mathbf{E}))}\|\widetilde{\mathbf{u}}\|_{L^2(0,T;H^{s}(M,\mathbf{E}))}\Big). \end{aligned} \tag{20.29}$$

Proof. Set $\mathbf{w} = \mathbf{u} - \widetilde{\mathbf{u}}$. Subtracting the equations and retaining P_t on the left-hand side gives

$$\partial_t \mathbf{w} + P_t \mathbf{w} = \mathbf{f} - \widetilde{\mathbf{f}} - \nabla^*\big((\mathbf{A} - \widetilde{\mathbf{A}})\nabla\widetilde{\mathbf{u}}\big) - (\mathbf{B} - \widetilde{\mathbf{B}})(\nabla\widetilde{\mathbf{u}}) - (\mathbf{C} - \widetilde{\mathbf{C}})\widetilde{\mathbf{u}}.$$

Since $s - 1 > \frac{m}{2}$, product estimate (20.4) shows that the right-hand side belongs to $L^2(0,T;H^{s-2}(M,\mathbf{E}))$ and is bounded by the terms appearing in (20.29). Apply Theorem 20.2.3 with $r = s - 1$. □

20.3 Quasilinear equations

The linear theory can be applied with coefficients frozen at a given section. The nonlinear solution will be constructed by repeating this procedure and showing that, on a sufficiently short interval, the iteration stays in a uniformly parabolic region and becomes contractive in a weaker norm. Let $\mathcal{U} \subseteq \mathbf{E}$ be an open subset of a bundle and consider two smooth bundle maps

$$A\colon \mathcal{U} \longrightarrow \operatorname{End}(T^*M \otimes \mathbf{E}),$$
$$F\colon J^1(\mathcal{U}) \longrightarrow \mathbf{E}.$$

Here $J^1(\mathcal{U})$ denotes the open subset of the bundle $\mathbf{E} \oplus (T^*M \otimes \mathbf{E})$ consisting of pairs (z,p) with $z \in \mathcal{U}$. We study

$$\partial_t \mathbf{u} + \nabla^*\big(A(\mathbf{u})\nabla\mathbf{u}\big) = F(j^1\mathbf{u}), \qquad \mathbf{u}(0) = \mathbf{u}_0. \tag{20.30}$$

For $\xi \in T^*_xM$, let $\iota_\xi\colon \mathbf{E}_x \to T^*_xM \otimes \mathbf{E}_x$ be the map $v \mapsto \xi \otimes v$. The principal symbol is $\iota_\xi^* A(\mathbf{u}(x))\iota_\xi$. In a chart and local frame, the equation takes the form

$$\partial_t u - \sum_{i,j=1}^{m} \nabla_i\big(A^{ij}(x,u)\nabla_j u\big) = F(x,u,\nabla u).$$

Expanding the divergence, the horizontal derivative $\nabla_x A$ and vertical derivative $D_z A(u)[\nabla u]$ contribute only lower-order terms.

Theorem 20.3.1. (Short-time quasilinear existence) Let $(M,\mathbf{g}_0)$ be a closed Riemannian manifold, let $\mathbf{E} \to M$ be a vector bundle with a bundle metric and compatible connection, and let $\mathcal{U} \subseteq \mathbf{E}$ be an open subset of the bundle. Let $\mathbf{u}_0 \in H^s(M,\mathbf{E})$ be a section whose image is contained in $\mathcal{U}$. Suppose that there exists $\lambda_0 > 0$ such that

$$\langle A(\mathbf{u}_0(x))\zeta,\zeta\rangle_{\mathbf{g}_0,\mathbf{h}_\mathbf{E}} \geq \lambda_0 |\zeta|^2_{\mathbf{g}_0,\mathbf{h}_\mathbf{E}} \tag{20.31}$$

for every $x \in M$ and $\zeta \in T^*_xM \otimes \mathbf{E}_x$, and that $A(z)$ is self-adjoint for every $z \in \mathcal{U}$. Then there exists $T > 0$ for which (20.30) has a unique solution

$$\mathbf{u} \in \mathcal{X}^s_T(\mathbf{E}) \quad \text{con} \quad \mathbf{u}(x,t) \in \mathcal{U}.$$

The time T can be chosen uniformly as $\mathbf{u}_0$ ranges over a bounded subset of $H^s(M,\mathbf{E})$ whose image stays a positive distance from the complement of $\mathcal{U}$ and for which the constant in (20.31) has a positive lower bound.

Proof. The image of $\mathbf{u}_0$ is compact because $s > \frac{m}{2}$ and M is compact. By continuity of A, choose an open subset $\mathcal{V} \subseteq \mathbf{E}$ such that

$$\mathbf{u}_0(M) \subseteq \mathcal{V}, \qquad \overline{\mathcal{V}} \text{ is compact and contained in } \mathcal{U},$$

and on whose closure we have

$$\langle A(z)\zeta, \zeta\rangle_{\mathbf{g}_0, \mathbf{h}_\mathbf{E}} \geq \frac{\lambda_0}{2} |\zeta|^2_{\mathbf{g}_0, \mathbf{h}_\mathbf{E}}. \tag{20.32}$$

Define $\mathbf{u}^{(0)}(t) = \mathbf{u}_0$ and, once $\mathbf{u}^{(k)}$ is constructed, solve the linear problem

$$\partial_t \mathbf{u}^{(k+1)} + \nabla^*\big(A(\mathbf{u}^{(k)})\nabla \mathbf{u}^{(k+1)}\big) = F(j^1\mathbf{u}^{(k)}), \qquad \mathbf{u}^{(k+1)}(0) = \mathbf{u}_0. \tag{20.33}$$

We show simultaneously that the iteration is well defined and contractive.
Let $D_s = c_s^{-1}$, with c_s as in the equivalence following (20.18). Fix R large enough that $R^2 > 2D_s\mathscr{E}_s(\mathbf{u}_0) + 1$. Suppose inductively that

$$\|\mathbf{u}^{(k)}\|_{L^\infty(0,T;H^s(M,\mathbf{E}))} \leq R, \qquad \mathbf{u}^{(k)}(M \times [0,T]) \subseteq \mathcal{V}. \tag{20.34}$$

Lemma 20.1.2 gives bounds independent of k for $A(\mathbf{u}^{(k)})$ in $C([0,T]; H^s(M, \operatorname{End}\mathcal{H}))$ and for $F(j^1\mathbf{u}^{(k)})$ in $C([0,T]; H^{s-1}(M,\mathbf{E}))$. Together with (20.32), Theorem 20.2.3 gives $\mathbf{u}^{(k+1)} \in \mathcal{X}^s_T(\mathbf{E})$. Differential inequality (20.20), before replacement by the coarser bound (20.22), gives a constant C_R independent of k and $T \leq 1$ such that

$$\|\mathbf{u}^{(k+1)}\|^2_{L^\infty(0,T;H^s(M,\mathbf{E}))} \leq D_s e^{C_R T}\big(\mathscr{E}_s(\mathbf{u}_0) + C_R T\big), \tag{20.35}$$

$$\|\mathbf{u}^{(k+1)}\|_{\mathcal{X}^s_T(\mathbf{E})} \leq C_R. \tag{20.36}$$

The first bound tends to $D_s\mathscr{E}_s(\mathbf{u}_0)$ as $T \to 0$. Thus, after reducing T, its right-hand side is less than R^2. Moreover, by Lemma 20.1.3,

$$\begin{aligned}\|\mathbf{u}^{(k+1)}(t) - \mathbf{u}_0\|_{H^{s-1}(M,\mathbf{E})} &\leq \int_0^t \|\partial_\rho \mathbf{u}^{(k+1)}(\rho)\|_{H^{s-1}(M,\mathbf{E})}\, d\rho \\ &\leq T^{\frac{1}{2}} \|\partial_t \mathbf{u}^{(k+1)}\|_{L^2(0,T;H^{s-1}(M,\mathbf{E}))}.\end{aligned} \tag{20.37}$$

The embedding $H^{s-1}(M,\mathbf{E}) \hookrightarrow C^0(M,\mathbf{E})$ and (20.36) show that, for T still smaller, the image of $\mathbf{u}^{(k+1)}$ stays in $\mathcal{V}$. This closes the induction.
Set $\mathbf{w}^{(k+1)} = \mathbf{u}^{(k+1)} - \mathbf{u}^{(k)}$ and $\mathbf{A}_k = A(\mathbf{u}^{(k)})$, $\mathbf{F}_k = F(j^1\mathbf{u}^{(k)})$. The difference of two consecutive equations is

$$\begin{aligned}\partial_t \mathbf{w}^{(k+1)} + \nabla^*(\mathbf{A}_k \nabla \mathbf{w}^{(k+1)}) = &-\nabla^*\big((\mathbf{A}_k - \mathbf{A}_{k-1})\nabla \mathbf{u}^{(k)}\big) \\ &+ \mathbf{F}_k - \mathbf{F}_{k-1}, \qquad \mathbf{w}^{(k+1)}(0) = 0.\end{aligned} \tag{20.38}$$

Contraction is obtained in the lower-order energy space

$$\mathcal{Z}_T(\mathbf{E}) := C([0,T]; L^2(M,\mathbf{E})) \cap L^2(0,T; H^1(M,\mathbf{E})),$$

with

$$\|\mathbf{w}\|^2_{\mathcal{Z}_T(\mathbf{E})} := \|\mathbf{w}\|^2_{L^\infty(0,T;L^2(M,\mathbf{E}))} + \int_0^T \|\mathbf{w}(t)\|^2_{H^1(M,\mathbf{E})}\, dt. \tag{20.39}$$

The preceding bounds and the embedding $H^s(M,\mathbf{E}) \hookrightarrow C^1(M,\mathbf{E})$ confine the first jets of the iteration to a compact subset of $J^1(\mathcal{U})$. Using cutoff functions as in the proof of Lemma 20.1.2, extend A and F to smooth maps defined on the full vector fibers of a neighborhood of this compact set. The mean value theorem applied to these extensions allows us to write

$$\mathbf{A}_k - \mathbf{A}_{k-1} = \boldsymbol{\mathcal{A}}_k[\mathbf{w}^{(k)}], \tag{20.40}$$

$$\mathbf{F}_k - \mathbf{F}_{k-1} = \boldsymbol{\mathcal{B}}_k[\mathbf{w}^{(k)}] + \boldsymbol{\mathcal{C}}_k[\nabla \mathbf{w}^{(k)}]. \tag{20.41}$$

For every $t \in [0,T]$, these coefficients belong to

$$\begin{aligned}
\boldsymbol{\mathcal{A}}_k(t) &\in H^s\big(M, \operatorname{Hom}(\mathbf{E}, \operatorname{End}\boldsymbol{\mathcal{H}})\big),\\
\boldsymbol{\mathcal{B}}_k(t) &\in H^{s-1}(M, \operatorname{End}\mathbf{E}),\\
\boldsymbol{\mathcal{C}}_k(t) &\in H^{s-1}(M, \operatorname{Hom}(\boldsymbol{\mathcal{H}}, \mathbf{E})),
\end{aligned}$$

and depend continuously on t in these spaces. The bounds (20.34) and the embedding $H^s(M,\mathbf{E}) \hookrightarrow C^2(M,\mathbf{E})$ uniformly bound, in the corresponding L^∞ spaces, $\boldsymbol{\mathcal{A}}_k, \boldsymbol{\mathcal{B}}_k, \boldsymbol{\mathcal{C}}_k$, $\nabla\boldsymbol{\mathcal{C}}_k$, and $\nabla \mathbf{u}^{(k)}$. Here $\nabla\boldsymbol{\mathcal{C}}_k$ is a section of $T^*M \otimes \operatorname{Hom}(\boldsymbol{\mathcal{H}}, \mathbf{E})$ with the induced connection.

Take the $L^2(M,\mathbf{E})$ inner product of (20.38) with $\mathbf{w}^{(k+1)}$. Integrate by parts the term containing $\mathbf{A}_k - \mathbf{A}_{k-1}$ and also the term with $\nabla \mathbf{w}^{(k)}$. Since $\boldsymbol{\mathcal{C}}_k$ and $\nabla\boldsymbol{\mathcal{C}}_k$ are uniformly bounded, the latter satisfies

$$\left| \int_M \left\langle \boldsymbol{\mathcal{C}}_k[\nabla \mathbf{w}^{(k)}], \mathbf{w}^{(k+1)} \right\rangle_{\mathbf{h}_\mathbf{E}} d\lambda_{\mathbf{g}_0} \right| \le C_R \|\mathbf{w}^{(k)}\|_{L^2(M,\mathbf{E})} \big(\|\nabla \mathbf{w}^{(k+1)}\|_{L^2(M,\boldsymbol{\mathcal{H}})} + \|\mathbf{w}^{(k+1)}\|_{L^2(M,\mathbf{E})} \big).$$

Parabolicity and Young's inequality give

$$\frac{d}{dt}\|\mathbf{w}^{(k+1)}(t)\|^2_{L^2(M,\mathbf{E})} + \frac{\lambda_0}{2}\|\nabla \mathbf{w}^{(k+1)}(t)\|^2_{L^2(M,\boldsymbol{\mathcal{H}})} \le C_R \|\mathbf{w}^{(k+1)}(t)\|^2_{L^2(M,\mathbf{E})} + C_R \|\mathbf{w}^{(k)}(t)\|^2_{L^2(M,\mathbf{E})}. \tag{20.42}$$

Since $\mathbf{w}^{(k+1)}(0) = 0$, Grönwall's lemma 1.8.19 implies

$$\|\mathbf{w}^{(k+1)}\|^2_{\mathcal{Z}_T(\mathbf{E})} \le C_R T e^{C_R T} \|\mathbf{w}^{(k)}\|^2_{C([0,T];L^2(M,\mathbf{E}))} \le C_R T e^{C_R T} \|\mathbf{w}^{(k)}\|^2_{\mathcal{Z}_T(\mathbf{E})}. \tag{20.43}$$

Reduce T until $q := C_R T e^{C_R T} < 1$. Then

$$\|\mathbf{w}^{(k+1)}\|_{\mathcal{Z}_T(\mathbf{E})} \le q^{\frac{1}{2}} \|\mathbf{w}^{(k)}\|_{\mathcal{Z}_T(\mathbf{E})},$$

For $k = 1$ the bound $\|\mathbf{w}^{(k)}\|_{\mathcal{Z}_T} \le q^{(k-1)/2}\|\mathbf{w}^{(1)}\|_{\mathcal{Z}_T}$ is an equality. If it holds for k, the preceding inequality gives it for $k+1$ after multiplication by $q^{1/2}$. Thus, summing the geometric series,

$$\sum_{k=1}^{\infty} \|\mathbf{w}^{(k)}\|_{\mathcal{Z}_T(\mathbf{E})} \le \frac{\|\mathbf{w}^{(1)}\|_{\mathcal{Z}_T(\mathbf{E})}}{1 - q^{\frac{1}{2}}} < \infty.$$

The space $\mathcal{Z}_T(\mathbf{E})$ is complete as the intersection of the two Banach spaces defining it, with the sum norm. Therefore, $(\mathbf{u}^{(k)})$ is Cauchy in $\mathcal{Z}_T(\mathbf{E})$.

The uniform bounds for $(\mathbf{u}^{(k)})_{k\ge1}$ in $\mathcal{X}^s_T(\mathbf{E})$ improve this convergence. The section $\mathbf{u}^{(0)}(t) = \mathbf{u}_0$ is used only to start the iteration and need not belong to $L^2(0,T;H^{s+1}(M,\mathbf{E}))$. At each time, interpolation of the Sobolev

scale gives

$$\|\mathbf{w}\|_{H^{s-1}(M,\mathbf{E})} \le C\|\mathbf{w}\|^{\frac{1}{s}}_{L^2(M,\mathbf{E})}\|\mathbf{w}\|^{\frac{s-1}{s}}_{H^s(M,\mathbf{E})}, \tag{20.44}$$

and, after integration in time,

$$\|\mathbf{w}\|_{L^2(0,T;H^s(M,\mathbf{E}))} \le C\|\mathbf{w}\|^{\frac{1}{s}}_{L^2(0,T;H^1(M,\mathbf{E}))}\|\mathbf{w}\|^{\frac{s-1}{s}}_{L^2(0,T;H^{s+1}(M,\mathbf{E}))}. \tag{20.45}$$

Thus $(\mathbf{u}^{(k)})$ converges strongly in $C([0,T];H^{s-1}(M,\mathbf{E}))\cap L^2(0,T;H^s(M,\mathbf{E}))$. Weak compactness in the L^2 factors, weak-* compactness in $L^\infty(0,T;H^s(M,\mathbf{E}))$, and the uniform bounds produce a limit $\mathbf{u}\in\mathcal{X}^s_T(\mathbf{E})$. The composition estimates allow passage to the limit in $A(\mathbf{u}^{(k)})$ and $F(j^1\mathbf{u}^{(k)})$, so $\mathbf{u}$ satisfies (20.30). Continuity in H^{s-1} and the embedding into C^0 ensure that its image stays in $\mathcal{U}$.

If $\mathbf{u}$ and $\mathbf{v}$ are two solutions, repeat the calculation (20.40)– (20.42) for $\mathbf{w}=\mathbf{u}-\mathbf{v}$. Now $\mathbf{w}(0)=0$, and the right-hand side contains $C_R\|\mathbf{w}(t)\|^2_{L^2(M,\mathbf{E})}$ in place of the difference from the preceding step. Grönwall's lemma 1.8.19 gives $\mathbf{w}=0$ on all of $[0,T]$. Uniformity of the existence time follows because all constants used depend only on the bound H^s, distance from the complement of $\mathcal{U}$, and the lower parabolicity bound. □

The autonomous form of the equation suffices for most of the chapter. Geometric applications will also involve coefficients with explicit time dependence; the same argument gives the following version.

Corollary 20.3.2. (Explicit time dependence) Let $T_*>0$ and let

$$A\colon [0,T_*]\times\mathcal{U}\longrightarrow \operatorname{End}(T^*M\otimes\mathbf{E}),$$
$$F\colon [0,T_*]\times J^1(\mathcal{U})\longrightarrow \mathbf{E}$$

be smooth bundle maps. Suppose that $A(t,z)$ is self-adjoint and the strong parabolicity condition holds on $(0,\mathbf{u}_0)$ with a positive constant. Then there exist $T\in(0,T_*]$ and a unique solution $\mathbf{u}\in\mathcal{X}^s_T(\mathbf{E})$ of

$$\partial_t\mathbf{u}+\nabla^*\big(A(t,\mathbf{u})\nabla\mathbf{u}\big)=F(t,j^1\mathbf{u}),\qquad \mathbf{u}(0)=\mathbf{u}_0.$$

The assertions on regularity, dependence on data, and uniformity of the time remain valid when the bounds for derivatives of A and F are uniform for $t\in[0,T_*]$ on the compact sets considered.

Proof. In the iteration of (20.33), replace the coefficients by $A(t,\mathbf{u}^{(k)})$ and $F(t,j^1\mathbf{u}^{(k)})$. The composition estimates of Lemma 20.1.2 are uniform in t because the time interval is compact. The energy estimate, remaining inside $\mathcal{V}$, and contraction in $\mathcal{Z}_T(\mathbf{E})$ are unchanged. The proofs of regularity and parameter dependence add only derivatives of the coefficients with respect to t, which are uniformly bounded lower-order terms. □

Corollary 20.3.3. (Regularity and dependence on data) Let $(M,\mathbf{g}_0)$ be a closed Riemannian manifold, let $\mathbf{E}\to M$ be a vector bundle with a bundle metric and compatible connection, and consider the quasilinear equation (20.30). Under the hypotheses of Theorem 20.3.1, the following assertions hold.

(a) On bounded subsets of initial data sharing bounds for parabolicity and distance from $\mathbf{E}\setminus\mathcal{U}$, the solutions satisfy

$$\|\mathbf{u}-\mathbf{v}\|_{\mathcal{X}^{s-1}_T(\mathbf{E})}\le C\|\mathbf{u}_0-\mathbf{v}_0\|_{H^{s-1}(M,\mathbf{E})}. \tag{20.46}$$

(b) If $\mathbf{u}_0 \in H^{s+q}(M,\mathbf{E})$ for some integer $q \geq 0$, then, after reducing T using only a bound for $\|\mathbf{u}_0\|_{H^s(M,\mathbf{E})}$, we have $\mathbf{u} \in \mathcal{X}_T^{s+q}(\mathbf{E})$.

(c) If $\mathbf{u}_0$ is smooth, the solution is smooth on $M \times [0,T]$. For merely H^s initial data, the solution is smooth on $M \times (0,T]$.

(d) A smooth family of smooth initial data gives a smooth family of solutions, as long as they all remain in a set on which the preceding bounds are uniform.

Proof. The equation for $\mathbf{u}-\mathbf{v}$ is

$$\begin{aligned}\partial_t(\mathbf{u}-\mathbf{v}) + \nabla^*(A(\mathbf{u})\nabla(\mathbf{u}-\mathbf{v})) = &-\nabla^*\big((A(\mathbf{u})-A(\mathbf{v}))\nabla\mathbf{v}\big)\\ &+F(j^1\mathbf{u})-F(j^1\mathbf{v}).\end{aligned}$$

Apply ∇^q, $0 \leq q \leq s-1$, and repeat the integration by parts in Lemma 20.2.2. For the term containing the coefficient difference, use

$$\|(A(\mathbf{u})-A(\mathbf{v}))\nabla\mathbf{v}\|_{H^{s-1}(M,\boldsymbol{\mathcal{H}})} \leq C_R\|\mathbf{u}-\mathbf{v}\|_{H^{s-1}(M,\mathbf{E})}\|\mathbf{v}\|_{H^s(M,\mathbf{E})}. \tag{20.47}$$

This estimate is valid because $H^{s-1}(M)$ is an algebra. The difference of the F terms is bounded in $H^{s-2}(M,\mathbf{E})$ by $C_R\|\mathbf{u}-\mathbf{v}\|_{H^{s-1}(M,\mathbf{E})}$. After absorbing the derivative of order s of $\mathbf{u}-\mathbf{v}$, we obtain

$$\frac{d}{dt}\mathscr{E}_{s-1}(\mathbf{u}-\mathbf{v}) + c\|\mathbf{u}-\mathbf{v}\|^2_{H^s(M,\mathbf{E})} \leq C_R\mathscr{E}_{s-1}(\mathbf{u}-\mathbf{v}). \tag{20.48}$$

Grönwall's lemma 1.8.19 controls the $C([0,T];H^{s-1}(M,\mathbf{E}))\cap L^2(0,T;H^s(M,\mathbf{E}))$ part. The difference equation also controls $\partial_t(\mathbf{u}-\mathbf{v})$ in $L^2(0,T;H^{s-2}(M,\mathbf{E}))$, giving (20.46).

We now prove persistence of regularity using an energy of arbitrary order. Let $N \geq s$ and first suppose that $\mathbf{u}$ is smooth. On an interval $[0,T]$ where $\|\mathbf{u}\|_{L^\infty(0,T;H^s(M,\mathbf{E}))} \leq R$, the Moser estimates with higher-order control give

$$\|[\nabla^N, A(\mathbf{u})](\nabla\mathbf{u})\|_{L^2(M,T^{(0,N)}(TM)\otimes\boldsymbol{\mathcal{H}})} + \|F(j^1\mathbf{u})\|_{H^{N-1}(M,\mathbf{E})} \leq C_{N,R}\big(1+\|\mathbf{u}\|_{H^N(M,\mathbf{E})}\big). \tag{20.49}$$

Indeed, (20.5) gives

$$\begin{aligned}&\|[\nabla^N, A(\mathbf{u})]\nabla\mathbf{u}\|_{L^2(M,T^{(0,N)}(TM)\otimes\boldsymbol{\mathcal{H}})}\\ &\quad\leq C_N\|\nabla A(\mathbf{u})\|_{L^\infty(M,T^*M\otimes\mathrm{End}(\boldsymbol{\mathcal{H}}))}\|\nabla\mathbf{u}\|_{H^{N-1}(M,\boldsymbol{\mathcal{H}})}\\ &\qquad+C_N\|A(\mathbf{u})\|_{H^N(M,\mathrm{End}(\boldsymbol{\mathcal{H}}))}\|\nabla\mathbf{u}\|_{L^\infty(M,\boldsymbol{\mathcal{H}})}.\end{aligned}$$

The bound $H^s \hookrightarrow C^2$ controls both factors with infinity norms. Estimate (20.9) controls $A(\mathbf{u})$ in H^N by $C_{N,R}(1+\|\mathbf{u}\|_{H^N(M,\mathbf{E})})$. Applied to $(\mathbf{u},\nabla\mathbf{u}) \mapsto F(\mathbf{u},\nabla\mathbf{u})$ at order $N-1$, the same estimate controls the remaining term in (20.49). All constants use the bounds for the first jets and the fixed structures. Applying ∇^N to the equation, integrating by parts, and using (20.49) yields

$$\frac{d}{dt}\mathscr{E}_N(\mathbf{u}(t)) + c\|\mathbf{u}(t)\|^2_{H^{N+1}(M,\mathbf{E})} \leq C_{N,R}\big(1+\mathscr{E}_N(\mathbf{u}(t))\big). \tag{20.50}$$

For a solution $\mathbf{u} \in \mathcal{X}_T^N(\mathbf{E})$, the identity allowing this energy to be used is

$$\frac{d}{dt}\mathscr{E}_N(\mathbf{u}(t)) = 2\mathcal{B}_N(\partial_t \mathbf{u}(t), \mathbf{u}(t)) \quad \text{for almost every } t \in (0,T), \tag{20.51}$$

where $\mathcal{B}_N$ is the form extended in the proof of Lemma 20.2.2. To verify it, fix a compact interval $J \subset (0,T)$ and regularize only in time: $\mathbf{u}_\varepsilon = \rho_\varepsilon *_t \mathbf{u}$, with ε smaller than the distance from J to the endpoints. Continuity of translations in Bochner spaces gives

$$\mathbf{u}_\varepsilon \to \mathbf{u} \quad \text{in } L^2(J; H^{N+1}(M,\mathbf{E})), \qquad \partial_t \mathbf{u}_\varepsilon \to \partial_t \mathbf{u} \quad \text{in } L^2(J; H^{N-1}(M,\mathbf{E})).$$

The first convergence implies $\mathscr{E}_N(\mathbf{u}_\varepsilon) \to \mathscr{E}_N(\mathbf{u})$ in $L^1(J)$. By the bound for $\mathcal{B}_N$, the error on the right-hand side, integrated over J, is at most

$$\begin{aligned} &C\|\partial_t \mathbf{u}_\varepsilon - \partial_t \mathbf{u}\|_{L^2(J;H^{N-1}(M,\mathbf{E}))}\|\mathbf{u}_\varepsilon\|_{L^2(J;H^{N+1}(M,\mathbf{E}))} \\ &\quad + C\|\partial_t \mathbf{u}\|_{L^2(J;H^{N-1}(M,\mathbf{E}))}\|\mathbf{u}_\varepsilon - \mathbf{u}\|_{L^2(J;H^{N+1}(M,\mathbf{E}))}, \end{aligned}$$

which tends to zero. For $\mathbf{u}_\varepsilon$, differentiation of the covariant norm and the formula for $\mathcal{B}_N$ give the classical identity; testing against a function in $C_c^\infty(J)$ and taking limits gives (20.51) in distributions. Its right-hand side belongs to $L^1(0,T)$. Lemma 20.1.3 provides the continuous representative in $H^N(M,\mathbf{E})$, so the energy has the absolutely continuous representative determined by this identity.

Finally, for almost every t, substitute the equation into $\mathcal{B}_N(\partial_t \mathbf{u}, \mathbf{u})$. Spatial integrations by parts are valid for $\mathbf{u}(t) \in H^{N+1}(M,\mathbf{E})$ by the explicit definition of that form. The product and Moser estimates in (20.49) control the resulting terms in the same spaces; they are also obtained as limits of smooth approximations in $H^{N+1}(M,\mathbf{E})$. Thus the energy estimate holds for almost every time and can be integrated on any subinterval of $[0,T]$.

Let us justify application of this estimate on the existence interval determined by the norm of order s. If $\mathbf{u}_0 \in H^N$, the quasilinear theorem applied initially at order N gives a solution on a possibly smaller interval. By uniqueness, it agrees there with the solution of order s. While both are defined, Grönwall applied to (20.50) bounds its H^N norm in terms of N, R, T and $\|\mathbf{u}_0\|_{H^N(M,\mathbf{E})}$. Distance to the boundary of $\mathcal{U}$ and parabolicity retain the bounds from the order-s construction. Restarting the existence theorem at any time in this interval, these bounds and the bound H^N give a positive additional time independent of the restart time. If the interval of H^N regularity ended before T, restarting sufficiently near its endpoint would extend beyond it. By uniqueness, the extension would remain the same solution. This gives H^N regularity up to T.

To justify the identities for H^N data, approximate the data in that norm by smooth sections. The order-s estimate gives a common interval, and the preceding argument and (20.50) give uniform bounds in $\mathcal{X}_T^N$. Weak passage to the limit and identification of the trace are as in the linear theorem; uniqueness identifies the limit with $\mathbf{u}$. We conclude that $\mathbf{u} \in \mathcal{X}_T^N$. The interval T is fixed using the order-s bounds, although the order-N norm of the solution also depends on that of the initial data.

The same energy proves smoothing without attributing to the data derivatives it does not have. Fix $0 < \tau < T$ and an integer $q \geq 1$. Choose numbers

$$0 = \tau_0 < \tau_1 < \cdots < \tau_q = \tau$$

and smooth functions χ_j vanishing on a neighborhood of $[0,\tau_{j-1}]$ and equal to one on $[\tau_j,T]$. Suppose inductively that, after shifting the time origin to τ_{j-1}, the restriction of the solution to $[\tau_{j-1},T]$ belongs to $\mathcal{X}^{s+j-1}_{T-\tau_{j-1}}(\mathbf{E})$; for $j=1$ this is precisely the existence regularity. Apply the calculation in (20.50) with $N=s+j$ and weight χ_j^2 to smooth approximations of $\mathbf{u}$. The only new term is

$$2\chi_j\chi_j'\mathscr{E}_{s+j}(\mathbf{u}),$$

whose integral is finite because the induction hypothesis includes $\mathbf{u}\in L^2(\tau_{j-1},T;H^{s+j}(M,\mathbf{E}))$. Passing to the limit gives

$$\begin{aligned}\|\mathbf{u}\|^2_{L^\infty(\tau_j,T;H^{s+j}(M,\mathbf{E}))}+\int_{\tau_j}^{T}\|\mathbf{u}(t)\|^2_{H^{s+j+1}(M,\mathbf{E})}\,dt\\ \le C_{j,R,\tau}\left(1+\int_{\tau_{j-1}}^{\tau_j}\|\mathbf{u}(t)\|^2_{H^{s+j}(M,\mathbf{E})}\,dt\right).\end{aligned}\tag{20.52}$$

The induction reaches every q. Sobolev embedding gives spatial smoothness on $M\times(0,T]$, and the equation expresses every time derivative in terms of spatial derivatives already controlled; this gives joint smoothness. If $\mathbf{u}_0$ is smooth, estimate (20.50) starts at $t=0$ for every N, and the solution is smooth up to the initial time.

Finally, we justify smooth dependence without assuming in advance that differentiation with respect to the parameter is possible. Let $a\mapsto\mathbf{u}_{0,a}$ be a smooth family of smooth data and let $\mathbf{u}_a$ be the family of solutions obtained on a common interval. For a fixed parameter direction define the quotient

$$\mathbf{h}_\varepsilon:=\frac{\mathbf{u}_{a+\varepsilon}-\mathbf{u}_a}{\varepsilon}.$$

The integral mean value formula applied to the extensions of A and F constructed in the proof of the theorem shows that $\mathbf{h}_\varepsilon$ satisfies a linear system whose principal term is $\nabla^*(A(\mathbf{u}_a)\nabla\mathbf{h}_\varepsilon)$ and whose other coefficients are averages of D_zA, D_zF, and D_pF along the segment between the two solutions. The energies (20.48) and (20.50) uniformly bound $\mathbf{h}_\varepsilon$ at every order, because the initial-data quotients are uniformly bounded. Subtracting the equations for $\mathbf{h}_\varepsilon$ and $\mathbf{h}_\delta$, the averaged coefficients converge by the Moser composition estimates. The energy of the difference shows that $(\mathbf{h}_\varepsilon)$ is Cauchy in every space of one lower order. Its limit $\mathbf{h}=\partial_a\mathbf{u}_a$ satisfies

$$\begin{aligned}\partial_t\mathbf{h}+\nabla^*\big(A(\mathbf{u}_a)\nabla\mathbf{h}+D_zA(\mathbf{u}_a)[\mathbf{h}]\nabla\mathbf{u}_a\big)\\ =D_zF(\mathbf{u}_a,\nabla\mathbf{u}_a)[\mathbf{h}]+D_pF(\mathbf{u}_a,\nabla\mathbf{u}_a)[\nabla\mathbf{h}].\end{aligned}\tag{20.53}$$

Let us make the passage to higher parameter derivatives explicit. For a real variable a write $\mathbf{u}^{[k]}=\partial_a^k\mathbf{u}_a$ and define the nonlinear differential operator

$$\mathcal{H}(\mathbf{v}):=-\nabla^*(A(\mathbf{v})\nabla\mathbf{v})+F(\mathbf{v},\nabla\mathbf{v}).$$

Suppose that the derivatives $\mathbf{u}^{[1]},\dots,\mathbf{u}^{[q-1]}$ have been constructed and are continuous at all spatial orders,

with $q \geq 2$. The Faà di Bruno formula gives the candidate equation

$$(\partial_t - D\mathcal{H}(\mathbf{u}_a))\mathbf{u}^{[q]} = \sum_{j=2}^{q} \sum_{\substack{k_1,\dots,k_j \in \mathbb{N} \\ k_1+\cdots+k_j=q}} \frac{q!}{j!\,k_1!\cdots k_j!} D^j\mathcal{H}(\mathbf{u}_a)[\mathbf{u}^{[k_1]},\dots,\mathbf{u}^{[k_j]}].$$

In this sum, every k_i is less than q; by the induction hypothesis, the right-hand side is known. The operator on the left is precisely that of (20.53) and retains the principal part $\nabla^*(A(\mathbf{u}_a)\nabla\cdot)$. The initial data are $\partial_a^q \mathbf{u}_{0,a}$. Linear theory gives a unique solution at every spatial order.

To identify it as a derivative, take the incremental quotient of the equation for $\mathbf{u}^{[q-1]}$. The integral product and composition rules express its coefficients as averages of derivatives of A and F. The induction hypothesis makes the sources converge to the preceding right-hand side. Subtracting two quotient equations, the linear estimate controls their difference by differences of the data, coefficients, and sources, which tend to zero. The quotients are therefore Cauchy, and their limit is the linear solution just constructed. The same estimate, applied to two nearby values of a, proves continuity. This closes the step from $q-1$ to q, with the case $q = 1$ already proved. For parameters in an open subset of $\mathbb{R}^d$, apply this argument to successive directional derivatives; the multilinear Faà di Bruno formulas give the mixed derivatives with the same control. The bounds are taken locally in the parameter, on compact sets where the interval and existence hypotheses are uniform. This proves the last assertion. □

Theorem 20.3.4. (Continuation criterion) Let $(M, \mathbf{g}_0)$ be a closed Riemannian manifold, let $\mathbf{E} \to M$ be a vector bundle with a bundle metric and compatible connection, and let $\mathbf{u}$ be a maximal solution of (20.30) defined on $[0, T_{\max})$, with $T_{\max} < \infty$, and suppose that $\mathbf{u} \in \mathcal{X}_T^s(\mathbf{E})$ for every $T < T_{\max}$. If there exist $R, \delta > 0$ such that, for every $0 \leq t < T_{\max}$,

$$\|\mathbf{u}(t)\|_{H^s(M,\mathbf{E})} \leq R, \tag{20.54}$$

$$\inf_{x \in M} \operatorname{dist}_{\mathbf{E}_x}\big(\mathbf{u}(x,t), \mathbf{E}_x \setminus \mathcal{U}_x\big) \geq \delta, \tag{20.55}$$

$$\langle A(\mathbf{u}(x,t))\zeta, \zeta\rangle_{\mathbf{g}_0,\mathbf{h}_\mathbf{E}} \geq \delta |\zeta|^2_{\mathbf{g}_0,\mathbf{h}_\mathbf{E}}. \tag{20.56}$$

The last inequality is required for every $x \in M$ and $\zeta \in T_x^*M \otimes \mathbf{E}_x$. Then $\mathbf{u}$ extends to an interval $[0, T_{\max} + \varepsilon)$, contradicting maximality. Thus, if the maximal time is finite, at least one quantity controlled in (20.54)–(20.56) must degenerate.

Proof. The last assertion of Theorem 20.3.1 gives a time $\varepsilon > 0$ depending only on R, δ, and bounds for A, F on the compact set traversed by the first jets of $\mathbf{u}$. These latter bounds follow from $H^s(M,\mathbf{E}) \hookrightarrow C^1(M,\mathbf{E})$. For any $t_0 \in (T_{\max} - \frac{\varepsilon}{2}, T_{\max})$, apply the existence theorem with initial data $\mathbf{u}(t_0)$. This gives a solution on $[t_0, t_0 + \varepsilon]$. Uniqueness makes it agree with $\mathbf{u}$ on $[t_0, T_{\max})$, thus extending it beyond $T_{\max}$. □

20.4 Maximum principles

Energy estimates control the solution in global norms, but do not by themselves record the sign of a function or whether a tensor belongs to a convex cone. Maximum principles provide this pointwise information and will be the basic tool for studying curvature under Ricci flow.

Theorem 20.4.1. (Scalar maximum principle) Let $(M, \mathbf{g}_0)$ be a closed Riemannian manifold. Let

$$L_t\varphi = \sum_{i,j=1}^m a^{ij}(x,t)(\nabla^2\varphi)_{ij} + \sum_{i=1}^m b^i(x,t)\nabla_i\varphi + c(x,t)\varphi,$$

where a^{ij}, b^i, and c are continuous on $M\times[0,T]$, (a^{ij}) is symmetric, and there exists $\lambda > 0$ such that $\sum_{i,j=1}^m a^{ij}(x,t)\xi_i\xi_j \geq \lambda|\xi|^2_{\mathbf{g}_0}$ for every $(x,t)\in M\times[0,T]$ and every $\xi\in T^*_xM$. Suppose that $f\in C^0(M\times[0,T])$ and that $u\in C^0(M\times[0,T])\cap C^{2,1}(M\times(0,T])$ satisfies

$$\partial_t u - L_t u \leq f \tag{20.57}$$

and let $\gamma\in\mathbb{R}$ be an upper bound for c on $M\times[0,T]$. Then, for $0\leq t\leq T$,

$$\sup_{x\in M} u(x,t) \leq e^{\gamma t}\left(\max\left\{0, \sup_{x\in M} u(x,0)\right\} + \int_0^t e^{-\gamma\rho}\max\left\{0, \sup_{x\in M} f(x,\rho)\right\} d\rho\right). \tag{20.58}$$

In particular, if $c\leq 0$, $f\leq 0$, and $u(0)\leq 0$, then $u\leq 0$ on $M\times[0,T]$.

Proof. Set $v(x,t) = e^{-\gamma t}u(x,t)$ and

$$F_+(t) := \max\left\{0, \sup_{x\in M} e^{-\gamma t}f(x,t)\right\}, \qquad z(t) := \max\left\{0, \sup_{x\in M} u(x,0)\right\} + \int_0^t F_+(\rho)\,d\rho.$$

The function $w = v - z$ satisfies

$$\partial_t w - \sum_{i,j=1}^m a^{ij}(\nabla^2 w)_{ij} - \sum_{i=1}^m b^i\nabla_i w - (c-\gamma)w \leq 0, \qquad w(0)\leq 0, \tag{20.59}$$

because $c-\gamma\leq 0$ and $z\geq 0$.

If w attained a positive value, then for small $\varepsilon > 0$ the function $w_\varepsilon = w - \varepsilon t - \varepsilon$ would have a first nonnegative maximum at some (x_0,t_0) with $t_0 > 0$. There,

$$\partial_t w_\varepsilon \geq 0, \qquad \nabla w_\varepsilon = 0, \qquad \sum_{i,j=1}^m a^{ij}(\nabla^2 w_\varepsilon)_{ij} \leq 0.$$

If $D = \partial_t - \sum_{i,j=1}^m a^{ij}(\nabla^2\cdot)_{ij} - \sum_{i=1}^m b^i\nabla_i - (c-\gamma)$, the three preceding relations and $c-\gamma\leq 0$ imply $Dw_\varepsilon(x_0,t_0)\geq 0$. On the other hand,

$$Dw_\varepsilon = Dw - \varepsilon + (c-\gamma)\varepsilon(t+1) \leq -\varepsilon,$$

a contradiction. Therefore, $w\leq 0$. Multiplying by $e^{\gamma t}$ gives (20.58). □

Corollary 20.4.2. (Scalar comparison) Let $(M,\mathbf{g}_0)$ be a closed Riemannian manifold and let L_t be the

operator of Theorem 20.4.1. Let $u, v \in C^0(M\times[0,T]) \cap C^{2,1}(M\times(0,T])$. If

$$\partial_t u - L_t u \le \partial_t v - L_t v \quad \text{y} \quad u(0) \le v(0),$$

then $u \le v$ on $M\times[0,T]$ when $c \le 0$. For bounded c, the same conclusion follows after multiplying both functions by $e^{-\gamma t}$ with $\gamma \ge \sup_{(x,t)\in M\times[0,T]} c(x,t)$.

Proof. Apply Theorem 20.4.1 to $u - v$. □

To formulate the tensor version, a family $\mathcal{K} = (K_x)_{x\in M}$ of subsets of $\mathbf{E}_x$ is called *invariant under parallel transport* if transport along any curve takes K_x into the set corresponding to its endpoint. In particular, this condition identifies all the K_x locally using the connection. If $q \in \partial K_x$, a vector $\nu \in \mathbf{E}_x$ is an outward supporting normal if

$$\langle \nu, z - q\rangle_{\mathbf{E}_x} \le 0 \qquad \text{for every } z \in K_x.$$

Theorem 20.4.3. (Tensor maximum principle) Let $(M, \mathbf{g}_0)$ be a closed Riemannian manifold and let $\mathbf{E} \to M$ be a real vector bundle with a bundle metric and compatible connection. Let $\mathcal{K} = (K_x)_{x\in M}$ be a family of nonempty closed convex sets invariant under parallel transport. Let $\mathbf{S} \in C^0(M\times[0,T],\mathbf{E}) \cap C^{2,1}(M\times(0,T],\mathbf{E})$ be a solution of

$$\partial_t \mathbf{S} = \sum_{i,j=1}^{m} a^{ij}(x,t)(\nabla^2 \mathbf{S})_{ij} + \sum_{i=1}^{m} b^i(x,t)\nabla_i \mathbf{S} + \Phi(x,t,\mathbf{S}), \tag{20.60}$$

where $\mathbf{a} \in C^0(M\times[0,T], S^2TM)$ and $\mathbf{b} \in C^0(M\times[0,T], TM)$ are fields whose components a^{ij} and b^i multiply the identity of $\mathbf{E}$, and (a^{ij}) is symmetric and uniformly positive. Suppose that Φ is continuous and locally Lipschitz in its last variable, uniformly in (x,t) on compact sets, and that for every $q \in \partial K_x$ and every outward supporting normal ν at q we have

$$\langle \nu, \Phi(x,t,q)\rangle_{\mathbf{h}_\mathbf{E}} \le 0. \tag{20.61}$$

If $\mathbf{S}(x,0) \in K_x$ for every $x \in M$, then $\mathbf{S}(x,t) \in K_x$ for every $(x,t) \in M\times[0,T]$.

Proof. Let $\Pi_x \colon \mathbf{E}_x \longrightarrow K_x$ be the metric projection, unique by convexity. Define

$$\rho(x,t) := \frac{1}{2}\,|\mathbf{S}(x,t) - \Pi_x(\mathbf{S}(x,t))|^2_{\mathbf{E}_x}.$$

The squared-distance function to a closed convex set in a Euclidean space is of class C^1 and has gradient $z \mapsto z - \Pi_x z$. It is also convex and of class $C^{1,1}$. Invariance of $\mathcal{K}$ under parallel transport identifies the distance functions on neighboring fibers. In particular, ρ is continuous, is of class C^1 in positive time, and

$$\partial_t \rho(x,t) = \langle \mathbf{S}(x,t) - \Pi_x \mathbf{S}(x,t), \partial_t \mathbf{S}(x,t)\rangle_{\mathbf{h}_\mathbf{E}}. \tag{20.62}$$

Fix $t > 0$ and a point x where $\rho(\cdot,t)$ attains its maximum. Set $q = \Pi_x \mathbf{S}(x,t)$ and $\nu = \mathbf{S}(x,t) - q$. Let $X \in T_xM$, let $\gamma(h) = \exp_x(hX)$, and parallel-transport $\mathbf{S}(\gamma(h),t)$ back to $\mathbf{E}_x$; denote the transported curve by $z(h)$. Transport

invariance identifies $K_{\gamma(h)}$ with K_x, and maximality of x gives

$$\frac{1}{2}\operatorname{dist}_{\mathbf{E}_x}(z(h),K_x)^2 \le \frac{1}{2}\operatorname{dist}_{\mathbf{E}_x}(z(0),K_x)^2.$$

The subgradient inequality for the convex squared-distance function is

$$\frac{1}{2}\operatorname{dist}_{\mathbf{E}_x}(z,K_x)^2 \ge \frac{1}{2}\operatorname{dist}_{\mathbf{E}_x}(z(0),K_x)^2 + \langle \nu, z - z(0)\rangle_{\mathbf{h_E}}.$$

Apply it to $z(h)$ and $z(-h)$, add, and divide by h^2. Letting $h \to 0$ gives

$$\langle \nu, (\nabla^2 \mathbf{S})(X,X)(x,t)\rangle_{\mathbf{h_E}} \le 0. \tag{20.63}$$

The first derivative at $h = 0$ also gives

$$\langle \nu, \nabla_X \mathbf{S}(x,t)\rangle_{\mathbf{h_E}} = 0. \tag{20.64}$$

Diagonalize $(a^{ij}(x,t))$ in an orthonormal basis of T_xM. Summing (20.63) with the positive eigenvalues as weights and using (20.64) yields

$$\left\langle \nu, \sum_{i,j=1}^{m} a^{ij}(\nabla^2\mathbf{S})_{ij} + \sum_{i=1}^{m} b^i \nabla_i \mathbf{S} \right\rangle_{\mathbf{h_E}} \le 0. \tag{20.65}$$

If $\nu = 0$, all expressions to be estimated are zero. If $\nu \neq 0$, the projection property implies $q \in \partial K_x$, and ν is an outward supporting normal at q. If L is a Lipschitz constant for Φ on the compact set traversed by $\mathbf{S}$ and its projection, then (20.61) implies

$$\begin{aligned}\langle \nu, \Phi(x,t,\mathbf{S})\rangle_{\mathbf{h_E}} &= \langle \nu, \Phi(x,t,q)\rangle_{\mathbf{h_E}} + \langle \nu, \Phi(x,t,\mathbf{S}) - \Phi(x,t,q)\rangle_{\mathbf{h_E}} \\ &\le L|\nu|^2_{\mathbf{h_E}} = 2L\rho(x,t).\end{aligned} \tag{20.66}$$

Identities (20.62) and (20.60), together with (20.65) and (20.66), show that

$$\partial_t \rho(x,t) \le 2L\rho(x,t) \tag{20.67}$$

at every spatial maximum of $\rho(\cdot,t)$.

It remains to pass from the spatial maximum to a function of one variable. Define $Q(t) = \max_{x\in M} \rho(x,t)$. Its upper Dini derivative satisfies

$$D^+Q(t) \le \max_{\substack{x\in M \\ \rho(x,t)=Q(t)}} \partial_t \rho(x,t) \le 2LQ(t). \tag{20.68}$$

For the first inequality, choose $h_j \to 0^+$ and points x_j where $\rho(\cdot, t+h_j)$ attains its maximum. A subsequence converges to a maximum of $\rho(\cdot,t)$, and

$$\frac{Q(t+h_j)-Q(t)}{h_j} \le \frac{\rho(x_j,t+h_j)-\rho(x_j,t)}{h_j};$$

uniform continuity of $\partial_t\rho$ near the positive time t allows passage to the limit. The following Grönwall-type

estimate for upper Dini derivatives is proved by applying the first-maximum argument to $e^{-2Lt}Q(t)$; thus,

$$Q(t) \le e^{2L(t-\tau)}Q(\tau), \qquad 0 < \tau < t \le T.$$

Since Q is continuous and $Q(0) = 0$, let $\tau \to 0^+$ to obtain $Q(t) = 0$. Therefore, $\mathbf{S}(x,t) \in K_x$ for every (x,t). □

Remark 20.4.4. The proof remains valid if the connection depends smoothly on t, provided that it is compatible with the same fixed bundle metric and each connection preserves $\mathcal{K}$ under parallel transport. Indeed, the spatial argument is performed at a fixed time, and the function $\frac{1}{2}\operatorname{dist}(\mathbf{S}, K_x)^2$ does not introduce a varying metric upon time differentiation. If the bundle metric also varies, one must first transport the problem to a bundle with a fixed metric or include its derivative in the time identity.

Corollary 20.4.5. (Cones of nonnegative forms) Let $(M, \mathbf{g}_0)$ be a closed Riemannian manifold, let $\mathbf{V} \longrightarrow M$ be a real vector bundle with a bundle metric and compatible connection, and let $\mathbf{S}(t)$ be a section of $S^2\mathbf{V}^*$ satisfying

$$\partial_t \mathbf{S} = \sum_{i,j=1}^{m} a^{ij}(\nabla^2 \mathbf{S})_{ij} + \Phi(\mathbf{S}).$$

Suppose that, for every form $Q \ge 0$ and every $v \in \mathbf{V}_x$ with $Q(v,v) = 0$, we have

$$\Phi(Q)(v,v) \ge 0.$$

Also assume the regularity and uniform positivity of the coefficients and the local Lipschitz condition on Φ from Theorem 20.4.3. If $\mathbf{S}(0) \ge 0$, then $\mathbf{S}(t) \ge 0$ for as long as the solution exists.

Proof. The cone of positive semidefinite forms is closed, convex, and invariant under parallel transport. Its outward normal functionals at a boundary point are nonnegative combinations of the functionals $Q \mapsto -Q(v,v)$ with v in the kernel of Q. The hypothesis is precisely (20.61); apply Theorem 20.4.3. □

For classical treatments of parabolic theory with less regular coefficients, see [61, Chapter 7] and [35, Chapter 3].

21

Ricci flow

A Riemannian metric determines how lengths, angles, and curvature are measured. Ricci flow allows this rule of measurement to change with time according to an equation built from its own Ricci tensor. Rather than searching directly for a special metric, one starts from an initial metric and studies which geometric features improve, which are preserved, and how curvature may concentrate.

The analogy with heat is useful, but should not be taken literally. The unknown is the metric itself and the equation is invariant under diffeomorphisms. This symmetry makes its symbol degenerate in the directions tangent to the orbits of the diffeomorphism action. The DeTurck procedure fixes a gauge using a vector field and turns the problem into a strictly parabolic system; a family of diffeomorphisms then recovers the solution of the original flow [75, 43].

We begin with variation formulas for the metric, connection, and curvature. We then identify the symbol degeneracy, construct the Ricci–DeTurck system, and prove short-time existence and uniqueness. Curvature evolution equations and maximum principles lead to the first a priori estimates. Finally, we study rescalings, normalized flow, Einstein metrics, and solitons. These last solutions provide self-similar models that will reappear when regions in which singularities form are magnified.

Richard Hamilton and a new strategy for geometry

Hamilton introduced Ricci flow in 1982 and proposed studying the topology of a manifold by letting its geometry evolve. The strategy required combining three levels: a parabolic equation to construct and regularize the metric, Riemannian estimates to control curvature, and topological arguments to interpret possible limits. The compactness and singularity analysis of the next chapter continues this program.

Let M^m be a closed smooth manifold, with $m \geq 2$. Whenever an assertion requires connectedness, this will be stated explicitly. For a tensor $\mathbf{T}$ write $\Delta \mathbf{T} = \operatorname{tr}_{\mathbf{g}}(\nabla^2 \mathbf{T}) = -\nabla^* \nabla \mathbf{T}$. All time-dependent norms, contractions, and covariant derivatives are calculated with $\mathbf{g}(t)$ unless otherwise stated. Coordinate indices of M belong to $\{1, \dots, m\}$. For higher-order derivatives, retain the order in Definition 9.1.1:

$$(\nabla^2 \mathbf{T})(X, Y, \dots) = \big(\nabla_X(\nabla_Y \mathbf{T}) - \nabla_{\nabla_X Y} \mathbf{T}\big)(\dots).$$

Thus, in $(\nabla^2 \mathbf{T})_{abi_1 \dots i_q}$, the index a corresponds to the outer derivative and b to the inner one. Permutations of a

and b will be performed using the curvature identity of the cited chapter. We also retain $R_{ijk}{}^{\ell} = (R(\partial_i,\partial_j)\partial_k)^{\ell}$, $\mathrm{Ric}_{ij} = \sum_{k=1}^{m} R_{kij}{}^{k}$, and $R_{ijk\ell} = \sum_{q=1}^{m} g_{\ell q} R_{ijk}{}^{q}$. For a symmetric covariant tensor $\mathbf{h}$ set

$$(\operatorname{div}\mathbf{h})_i := \sum_{j=1}^{m} \nabla^{j} h_{ij}, \qquad \operatorname{div}^2\mathbf{h} := \sum_{i=1}^{m} \nabla^{i} (\operatorname{div}\mathbf{h})_i .$$

Denote by $\lambda_{\mathbf{g}}$ the Riemann–Lebesgue measure determined by $\mathbf{g}$. In a chart, its weight relative to Lebesgue measure is $\sqrt{\det(\mathbf{g})}$; thus no orientation of M is required. When M is orientable and an orientation is fixed, integration with respect to $\lambda_{\mathbf{g}}$ agrees with integration of the Riemannian volume form. Identities containing $\partial_t d\lambda_{\mathbf{g}(t)}$ are understood as identities of measures depending smoothly on t, verified through these coordinate weights.

21.1 Variations of the metric and the Einstein–Hilbert functional

The following variation identities fix the signs that will appear later. Let $\mathbf{g}(t)$ be a smooth family of metrics, $\mathbf{g}(0) = \mathbf{g}$, and $\mathbf{h} = \partial_t \mathbf{g}(t)|_{t=0}$.

Lemma 21.1.1. (Metric variation identities) Let M^m be a smooth manifold with or without boundary and let $\mathbf{g}(t)$ be a smooth family of metrics on M, with $\mathbf{g}(0) = \mathbf{g}$ and $\mathbf{h} = \partial_t \mathbf{g}(t)|_{t=0}$. Then

$$\partial_t g^{ij}(t)\Big|_{t=0} = -h^{ij}, \tag{21.1}$$

$$\partial_t d\lambda_{\mathbf{g}(t)}\Big|_{t=0} = \frac{1}{2}\operatorname{tr}_{\mathbf{g}}(\mathbf{h})\, d\lambda_{\mathbf{g}}, \tag{21.2}$$

$$\partial_t \Gamma(\mathbf{g}(t))^{k}_{ij}\Big|_{t=0} = \frac{1}{2}\sum_{\ell=1}^{m} g^{k\ell}\big(\nabla_i h_{j\ell} + \nabla_j h_{i\ell} - \nabla_\ell h_{ij}\big), \tag{21.3}$$

$$\partial_t R(\mathbf{g}(t))_{ijr}{}^{s}\Big|_{t=0} = \nabla_i \dot\Gamma^{s}_{jr} - \nabla_j \dot\Gamma^{s}_{ir}, \tag{21.4}$$

$$\partial_t \operatorname{Ric}(\mathbf{g}(t))_{ij}\Big|_{t=0} = \sum_{k=1}^{m}\big(\nabla_k \dot\Gamma^{k}_{ij} - \nabla_i \dot\Gamma^{k}_{kj}\big), \tag{21.5}$$

$$DR_{\mathbf{g}}[\mathbf{h}] = -\langle \operatorname{Ric}_{\mathbf{g}}, \mathbf{h}\rangle_{\mathbf{g}} + \operatorname{div}^2\mathbf{h} - \Delta_{\mathbf{g}} \operatorname{tr}_{\mathbf{g}}\mathbf{h}. \tag{21.6}$$

Here $\dot\Gamma^{k}_{ij}$ denotes the expression in the third line.

Proof. Differentiating $\sum_{k=1}^{m} g^{ik}(t) g_{kj}(t) = \delta^{i}_{j}$ gives

$$\sum_{k=1}^{m}\Big(\partial_t g^{ik}(t)\Big|_{t=0} g_{kj} + g^{ik} h_{kj}\Big) = 0,$$

and multiplication by $g^{j\ell}$ proves (21.1). In coordinates, Jacobi's identity for the determinant gives

$$\partial_t \sqrt{\det \mathbf{g}(t)}\Big|_{t=0} = \frac{1}{2}\sqrt{\det \mathbf{g}}\sum_{i,j=1}^{m} g^{ij} h_{ij},$$

whence (21.2).
If ∇^t is the Levi–Civita connection of $\mathbf{g}(t)$ and

$$\mathbf{A}(\mathbf{X},\mathbf{Y}) = \frac{d}{dt}\Big|_{t=0} \nabla^t_{\mathbf{X}}\mathbf{Y},$$

, differentiating the Koszul formula and canceling the terms containing $\nabla_X Y$ gives

$$2\mathbf{g}(\mathbf{A}(\mathbf{X},\mathbf{Y}),\mathbf{Z}) = (\nabla_{\mathbf{X}}\mathbf{h})(\mathbf{Y},\mathbf{Z}) + (\nabla_{\mathbf{Y}}\mathbf{h})(\mathbf{X},\mathbf{Z}) - (\nabla_{\mathbf{Z}}\mathbf{h})(\mathbf{X},\mathbf{Y}).$$

In a coordinate frame, this is (21.3). Differentiating the definition of curvature and using that ∇ is torsion-free yields

$$\partial_t \mathbf{R}^t(\mathbf{X},\mathbf{Y})\mathbf{Z}\big|_{t=0} = (\nabla_{\mathbf{X}}\mathbf{A})(\mathbf{Y},\mathbf{Z}) - (\nabla_{\mathbf{Y}}\mathbf{A})(\mathbf{X},\mathbf{Z}),$$

which proves (21.4); contraction of the first covariant index with the contravariant index gives (21.5).
The contractions of (21.3) are

$$\sum_{k=1}^{m} \dot\Gamma^k_{kj} = \frac{1}{2}\nabla_j \operatorname{tr}_{\mathbf{g}} \mathbf{h}, \qquad \sum_{i,j=1}^{m} g^{ij}\dot\Gamma^k_{ij} = \sum_{i=1}^{m} \nabla^i h_i{}^k - \frac{1}{2}\nabla^k \operatorname{tr}_{\mathbf{g}} \mathbf{h}.$$

Therefore,

$$\sum_{i,j=1}^{m} g^{ij}\, \partial_t \operatorname{Ric}(\mathbf{g}(t))_{ij}\Big|_{t=0} = \operatorname{div}^2 \mathbf{h} - \Delta_{\mathbf{g}} \operatorname{tr}_{\mathbf{g}} \mathbf{h}.$$

Finally, differentiate $R(\mathbf{g}(t)) = \sum_{i,j=1}^{m} g^{ij}(t)\operatorname{Ric}(\mathbf{g}(t))_{ij}$ and use (21.1). This gives (21.6). □

For $s > \frac{m}{2} + 2$, the set $\operatorname{Met}^s(M)$ of H^s metrics is open in $H^s(S^2T^*M)$. Indeed, fixing a smooth metric $\mathbf{g}_*$, the embedding $H^s \hookrightarrow C^0$ makes the function

$$\mathbf{g} \longmapsto \min_{x\in M} \min_{\substack{v\in T_xM \\ |v|_{\mathbf{g}_*}=1}} \frac{\mathbf{g}_x(v,v)}{\mathbf{g}_{*,x}(v,v)}.$$

continuous. Denote this minimum by $m(\mathbf{g})$. Its existence is justified in local frames of $\mathbf{g}_*$ over a finite cover by compact sets: the unit sphere is identified with a fixed Euclidean sphere and evaluation of $\mathbf{g}$ is continuous. This is the fiberwise extrema argument of Lemma 9.1.43. Moreover, if $\mathbf{g}_1, \mathbf{g}_2$ are two symmetric fields of class H^s and $|v|_{\mathbf{g}_*} = 1$, Cauchy–Schwarz gives

$$|(\mathbf{g}_1 - \mathbf{g}_2)_x(v,v)| \le \|\mathbf{g}_1 - \mathbf{g}_2\|_{\infty;\mathbf{g}_*}.$$

Taking minima and then interchanging $\mathbf{g}_1$ and $\mathbf{g}_2$ yields

$$|m(\mathbf{g}_1) - m(\mathbf{g}_2)| \le \|\mathbf{g}_1 - \mathbf{g}_2\|_{\infty;\mathbf{g}_*} \le C\|\mathbf{g}_1 - \mathbf{g}_2\|_{H^s(M,S^2T^*M)}.$$

This proves continuity with respect to the Sobolev norm. Since M is compact, $m(\mathbf{g}) > 0$ precisely when $\mathbf{g}$ is positive definite in every fiber. The condition $m(\mathbf{g}) > 0$ therefore defines an open set. Inversion of positive matrices, Sobolev

products, and the local curvature formulas show that

$$\mathbf{g} \longmapsto \int_M R_{\mathbf{g}}\, d\lambda_{\mathbf{g}}$$

is a smooth map from $\mathrm{Met}^s(M)$ to $\mathbb{R}$.

Proposition 21.1.2. (First variation of Einstein–Hilbert) Let M^m be a closed connected smooth manifold and let $\mathbf{g}$ be a Riemannian metric on M. The functional

$$\mathcal{S}(\mathbf{g}) = \int_M R_{\mathbf{g}}\, d\lambda_{\mathbf{g}} \tag{21.7}$$

satisfies

$$D\mathcal{S}(\mathbf{g})[\mathbf{h}] = -\int_M \left\langle \mathrm{Ric}_{\mathbf{g}} - \frac{1}{2} R_{\mathbf{g}}\mathbf{g}, \mathbf{h} \right\rangle_{\mathbf{g}} d\lambda_{\mathbf{g}}. \tag{21.8}$$

If $m \geq 3$, the critical points of $\mathcal{S}$ restricted to metrics of fixed volume are precisely the Einstein metrics.

Proof. Equations (21.2) and (21.6) give

$$D\mathcal{S}(\mathbf{g})[\mathbf{h}] = \int_M \left(-\langle \mathrm{Ric}, \mathbf{h} \rangle_{\mathbf{g}} + \frac{1}{2} R \,\mathrm{tr}_{\mathbf{g}} \mathbf{h} + \sum_{i=1}^m \nabla_i \left(\sum_{j=1}^m \nabla_j h^{ij} - \nabla^i \,\mathrm{tr}_{\mathbf{g}} \mathbf{h} \right) \right) d\lambda_{\mathbf{g}}.$$

The integral of the divergence over the closed manifold M is zero, proving (21.8).
On the other hand,

$$D\,\mathrm{Vol}_{\mathbf{g}}[\mathbf{h}] = \frac{1}{2} \int_M \mathrm{tr}_{\mathbf{g}} \mathbf{h}\, d\lambda_{\mathbf{g}}$$

is not the zero functional, since its value at $\mathbf{h} = \mathbf{g}$ is $\frac{m}{2}\mathrm{Vol}(M, \mathbf{g})$. If $\mathbf{g}$ is critical on the volume level set, choose $\mathbf{h}_0$ with $D\,\mathrm{Vol}_{\mathbf{g}}[\mathbf{h}_0] = 1$. Every tensor $\mathbf{h}$ decomposes as

$$\mathbf{h} = \left(\mathbf{h} - D\,\mathrm{Vol}_{\mathbf{g}}[\mathbf{h}]\mathbf{h}_0\right) + D\,\mathrm{Vol}_{\mathbf{g}}[\mathbf{h}]\mathbf{h}_0.$$

The first summand belongs to the kernel of $D\,\mathrm{Vol}_{\mathbf{g}}$, where $D\mathcal{S}_{\mathbf{g}}$ vanishes. Therefore, $D\mathcal{S}_{\mathbf{g}} = cD\,\mathrm{Vol}_{\mathbf{g}}$, with $c = D\mathcal{S}_{\mathbf{g}}[\mathbf{h}_0]$. The formulas for the two differentials imply

$$\mathrm{Ric} - \frac{1}{2} R\mathbf{g} = c\mathbf{g}$$

after changing the value of the constant c if necessary. Taking the trace of this equality when $m \geq 3$ shows that R is constant; substituting it back gives $\mathrm{Ric} = \lambda\mathbf{g}$ with constant λ. The reverse implication follows directly from (21.8), because vectors tangent to the volume level set satisfy $\int_M \mathrm{tr}_{\mathbf{g}} \mathbf{h}\, d\lambda_{\mathbf{g}} = 0$. □

In dimension two, Theorem A.8.7 makes $\mathcal{S}$ constant on each topological component of the space of metrics; this is why the last characterization requires $m \geq 3$. The first variation formula, however, remains valid in every dimension.

21.2 Diffeomorphism invariance and symbol degeneracy

Definition 21.2.1. (Ricci flow) Let M be a smooth manifold with or without boundary. A *Ricci flow* on M is a family of metrics $\mathbf{g}(t)$ satisfying

$$\partial_t \mathbf{g}(t) = -2\,\mathrm{Ric}_{\mathbf{g}(t)}. \tag{21.9}$$

The Levi–Civita connection is natural: if φ is a diffeomorphism, $\nabla^{\varphi^*\mathbf{g}} = \varphi^*\nabla^{\mathbf{g}}$. Taking curvature and contracting gives

$$\mathrm{Ric}_{\varphi^*\mathbf{g}} = \varphi^*\,\mathrm{Ric}_{\mathbf{g}}. \tag{21.10}$$

Thus pullback by a time-independent diffeomorphism takes solutions to solutions. For a family φ_t, if

$$\mathbf{X}_t = (\partial_t \varphi_t) \circ \varphi_t^{-1},$$

, the pullback differentiation rule is

$$\frac{d}{dt}(\varphi_t^*\mathbf{g}(t)) = \varphi_t^*(\partial_t \mathbf{g}(t) + \mathcal{L}_{\mathbf{X}_t}\mathbf{g}(t)). \tag{21.11}$$

It is proved first for functions and one-forms, then using the Leibniz rule for tensor products.

Naturality explains why the right-hand side of (21.9) is not strictly parabolic. With $(\delta_{\mathbf{g}}\mathbf{h})_j = -\sum_{i=1}^{m} \nabla^i h_{ij}$, define the formal adjoint of $\delta_{\mathbf{g}}$ by

$$(\delta_{\mathbf{g}}^*\boldsymbol{\omega})_{ij} = \frac{1}{2}\big(\nabla_i \omega_j + \nabla_j \omega_i\big). \tag{21.12}$$

If $\nabla^*\nabla = -\mathrm{tr}_{\mathbf{g}}(\nabla^2)$, Lemma 21.1.1, followed by commutation of covariant derivatives, gives

$$2D\,\mathrm{Ric}_{\mathbf{g}}[\mathbf{h}] = \nabla^*\nabla\mathbf{h} - \nabla^2\,\mathrm{tr}_{\mathbf{g}}\,\mathbf{h} - 2\delta_{\mathbf{g}}^*\delta_{\mathbf{g}}\mathbf{h} + \mathcal{Q}_{\mathbf{g}}(\mathbf{h}), \tag{21.13}$$

where the zeroth-order term is

$$\mathcal{Q}_{\mathbf{g}}(\mathbf{h})_{ij} = \sum_{k=1}^{m} \mathrm{Ric}_i{}^k h_{kj} + \sum_{k=1}^{m} \mathrm{Ric}_j{}^k h_{ki} - 2\sum_{k,\ell=1}^{m} R_{kij\ell} h^{k\ell}. \tag{21.14}$$

Before commuting, substitution of (21.3) into (21.5) gives the tensor identity

$$2D\,\mathrm{Ric}_{\mathbf{g}}[\mathbf{h}]_{ij} = \sum_{k,a=1}^{m} g^{ka}\big((\nabla^2\mathbf{h})_{aijk} + (\nabla^2\mathbf{h})_{ajik}\big) + (\nabla^*\nabla\mathbf{h})_{ij} - (\nabla^2\,\mathrm{tr}_{\mathbf{g}}\,\mathbf{h})_{ij}. \tag{21.15}$$

To see where $\mathcal{Q}_{\mathbf{g}}$ comes from, apply the commutation identity to the two slots of $\mathbf{h}$:

$$\begin{aligned}
&\sum_{a,k=1}^{m} g^{ak}\big((\nabla^2\mathbf{h})_{aijk} - (\nabla^2\mathbf{h})_{iajk}\big) \\
&\quad = -\sum_{a,k,p=1}^{m} g^{ak}\big(R_{aij}{}^p h_{pk} + R_{aik}{}^p h_{jp}\big) \\
&\quad = \sum_{p=1}^{m} \mathrm{Ric}_i{}^p h_{pj} - \sum_{k,\ell=1}^{m} R_{kij\ell} h^{k\ell}.
\end{aligned}$$

The same equality with i and j interchanged produces the other Ricci term. The Riemann symmetries and symmetry of $\mathbf{h}$ make the two remaining contractions equal. The derivatives already in the order i,a and j,a form $-2\delta_{\mathbf{g}}^{*}\delta_{\mathbf{g}}\mathbf{h}$. This proves (21.13) and (21.14) with the chosen differentiation order.

If $\mathbf{h} = \mathcal{L}_{X}\mathbf{g}$, its symbol part is $h_{ij} = \xi_i X_j + \xi_j X_i$, and substitution into (21.15) annihilates the symbol of $D\,\mathrm{Ric}$. This is precisely the infinitesimal direction of the diffeomorphism orbit. Thus strongly parabolic theory cannot be applied directly to (21.9).

21.3 The Ricci–DeTurck system

The preceding degeneracy reflects the freedom to change coordinates during evolution rather than a loss of diffusion. The DeTurck procedure removes this freedom by comparing the connection of the unknown metric with a fixed connection. Fix a smooth metric $\bar{\mathbf{g}}$, denote its Levi–Civita connection by $\bar{\nabla}$, and write

$$\mathbf{A}(\mathbf{g})_{ij}^{k} = \Gamma(\mathbf{g})_{ij}^{k} - \Gamma(\bar{\mathbf{g}})_{ij}^{k}, \qquad \mathbf{W}_{\bar{\mathbf{g}}}(\mathbf{g})^{k} = \sum_{i,j=1}^{m} g^{ij}\mathbf{A}(\mathbf{g})_{ij}^{k}.$$

The difference of connections is tensorial, so $\mathbf{W}_{\bar{\mathbf{g}}}(\mathbf{g})$ is a globally defined vector field. The modified system is

$$\partial_t \mathbf{g} = -2\,\mathrm{Ric}_{\mathbf{g}} + \mathcal{L}_{\mathbf{W}_{\bar{\mathbf{g}}}(\mathbf{g})}\mathbf{g}. \tag{21.16}$$

Proposition 21.3.1. (Parabolicity of the DeTurck system) Let M^m be a smooth manifold with or without boundary, let $\bar{\mathbf{g}}$ be a fixed Riemannian metric, and consider the Ricci–DeTurck system (21.16). The right-hand side of (21.16) is a quasilinear operator whose principal part is locally strongly parabolic. More precisely, relative to $\bar{\nabla}$ it can be written as

$$-2\,\mathrm{Ric}(\mathbf{g})_{ij} + (\mathcal{L}_{\mathbf{W}_{\bar{\mathbf{g}}}(\mathbf{g})}\mathbf{g})_{ij} = \sum_{a,b=1}^{m} g^{ab}(\bar{\nabla}^2\mathbf{g})_{abij} + P_{ij}(\mathbf{g}, \mathbf{g}^{-1}, \bar{\nabla}\mathbf{g}, \overline{\mathrm{Rm}}), \tag{21.17}$$

where P is smooth, contains no derivatives of $\mathbf{g}$ of order greater than one, and is polynomial in $\bar{\nabla}\mathbf{g}$. The Fourier symbol of the linearization at a covariable $\xi \neq 0$ is

$$-\sum_{a,b=1}^{m} g^{ab}\xi_a\xi_b\,\mathrm{Id}_{S^2T^*M}. \tag{21.18}$$

On each compact subset of M, the parabolicity bound can be chosen uniformly for metrics sufficiently close in C^0 to a fixed metric. In particular, if M is compact, this bound is global.

Proof. The difference-of-connections formula is

$$\mathbf{A}(\mathbf{g})_{ij}^{k} = \frac{1}{2}\sum_{\ell=1}^{m} g^{k\ell}\left(\bar{\nabla}_i g_{j\ell} + \bar{\nabla}_j g_{i\ell} - \bar{\nabla}_\ell g_{ij}\right).$$

Expressing the curvature of $\mathbf{g}$ using $\bar{\nabla}$ gives

$$\mathbf{R}(\mathbf{g})_{ijk}{}^{\ell} = \overline{R}_{ijk}{}^{\ell} + \bar{\nabla}_i \mathbf{A}(\mathbf{g})^{\ell}_{jk} - \bar{\nabla}_j \mathbf{A}(\mathbf{g})^{\ell}_{ik} + \sum_{p=1}^{m} \big(\mathbf{A}(\mathbf{g})^{p}_{jk} \mathbf{A}(\mathbf{g})^{\ell}_{ip} - \mathbf{A}(\mathbf{g})^{p}_{ik} \mathbf{A}(\mathbf{g})^{\ell}_{jp} \big).$$

The contraction defining Ricci contains second derivatives of $\mathbf{g}$. On the other hand,

$$(\mathcal{L}_{\mathbf{W}}\mathbf{g})_{ij} = \nabla_i W_j + \nabla_j W_i.$$

At a point where normal coordinates for $\bar{\mathbf{g}}$ are chosen, the parts containing two derivatives of $\mathbf{g}$ are

$$(-2\,\mathrm{Ric}(\mathbf{g}))^{(2)}_{ij} = \sum_{a,b=1}^{m} g^{ab} \big((\bar{\nabla}^2\mathbf{g})_{abij} + (\bar{\nabla}^2\mathbf{g})_{ijab} - (\bar{\nabla}^2\mathbf{g})_{aibj} - (\bar{\nabla}^2\mathbf{g})_{ajbi} \big),$$

$$(\mathcal{L}_{\mathbf{W}}\mathbf{g})^{(2)}_{ij} = \sum_{a,b=1}^{m} g^{ab} \big((\bar{\nabla}^2\mathbf{g})_{iabj} + (\bar{\nabla}^2\mathbf{g})_{jabi} - (\bar{\nabla}^2\mathbf{g})_{ijab} \big).$$

The three gauge terms cancel in pairs, leaving as the only second-order term $\sum_{a,b=1}^{m} g^{ab}(\bar{\nabla}^2\mathbf{g})_{abij}$. Commutations of $\bar{\nabla}$ produce $\overline{\mathrm{Rm}} * \mathbf{g}$, and all other terms are contractions of $\mathbf{g}$, $\mathbf{g}^{-1}$, $\bar{\nabla}\mathbf{g}$, and $\overline{\mathrm{Rm}}$. This proves (21.17). To apply the divergence-form theory, observe the exact identity

$$\sum_{a,b=1}^{m} g^{ab}(\bar{\nabla}^2\mathbf{g})_{ab} = \sum_{a,b=1}^{m} \bar{\nabla}_a \big(g^{ab} \bar{\nabla}_b \mathbf{g} \big) - \sum_{a,b=1}^{m} (\bar{\nabla}_a g^{ab}) \bar{\nabla}_b \mathbf{g}. \tag{21.19}$$

The last summand contains only first derivatives of $\mathbf{g}$. The principal coefficient is therefore

$$A^{ab}(\mathbf{g}) = g^{ab}\,\mathrm{Id}_{S^2T^*M}.$$

As an endomorphism of $T^*M \otimes S^2T^*M$ measured with $\bar{\mathbf{g}}$, it reads $A_a{}^b = \sum_{c=1}^{m} \bar{g}_{ac} g^{cb}\,\mathrm{Id}_{S^2T^*M}$; raising the first index with $\bar{\mathbf{g}}$ recovers A^{ab}. This coefficient satisfies $A^{ab*} = A^{ba}$. To specify uniformity, fix a compact set $K \subseteq M$ and a continuous metric $\mathbf{g}_*$. The comparison on compact sets proved after Lemma 7.1.8, whose argument also applies to continuous metrics, gives $0 < c_* \le C_* < \infty$ such that

$$c_* \bar{\mathbf{g}}_x(v,v) \le (\mathbf{g}_*)_x(v,v) \le C_* \bar{\mathbf{g}}_x(v,v) \qquad (x \in K,\ v \in T_xM).$$

If $\|\mathbf{g} - \mathbf{g}_*\|_{C^0(K, S^2T^*M; \bar{\mathbf{g}})} < c_*/2$, Cauchy–Schwarz for the tensor inner product gives, for $x \in K$ and $v \in T_xM$,

$$|(\mathbf{g} - \mathbf{g}_*)_x(v,v)| \le |\mathbf{g} - \mathbf{g}_*|_{\bar{\mathbf{g}}}(x)\, |v|^2_{\bar{\mathbf{g}}} < \frac{c_*}{2} \bar{\mathbf{g}}_x(v,v) \qquad (v \neq 0).$$

Indeed, in a $\bar{\mathbf{g}}$–orthonormal basis, apply Cauchy–Schwarz to $\sum_{a,b=1}^{m} (g - g_*)_{ab} v^a v^b$ and use $\sum_{a,b=1}^{m} (v^a v^b)^2 =$

$(\sum_{a=1}^{m}(v^a)^2)^2$. Adding this bound to the comparison for $\mathbf{g}_*$ gives

$$\frac{c_*}{2}\bar{\mathbf{g}} \le \mathbf{g} \le \Big(C_* + \frac{c_*}{2}\Big)\bar{\mathbf{g}} \qquad \text{on } K.$$

The dual comparison in Proposition 7.1.9 gives, with $\lambda = (C_* + c_*/2)^{-1} > 0$,

$$\mathbf{g}_x^{-1}(\xi,\xi) \ge \lambda \bar{\mathbf{g}}_x^{-1}(\xi,\xi) \qquad (x \in K,\ \xi \in T_x^*M).$$

To apply this inequality to a covector with values in $S^2T_x^*M$, choose a basis $F_1,\dots,F_d$ of that space orthonormal for the metric induced by $\bar{\mathbf{g}}$, where $d = m(m+1)/2$. Write $\zeta_a = \sum_{\alpha=1}^{d} z_a^\alpha F_\alpha$ in a $\bar{\mathbf{g}}$–orthonormal tangent frame. For each α, the numbers z_a^α are the components of a covector to which the preceding bound applies. Thus

$$\begin{aligned}\sum_{a,b=1}^{m}\big\langle A^{ab}(\mathbf{g})\zeta_b,\zeta_a\big\rangle_{\bar{\mathbf{g}}} &= \sum_{\alpha=1}^{d}\sum_{a,b=1}^{m} g^{ab} z_b^\alpha z_a^\alpha \\ &\ge \lambda\sum_{\alpha=1}^{d}\sum_{a=1}^{m}|z_a^\alpha|^2 = \lambda|\zeta|_{\bar{\mathbf{g}}}^2.\end{aligned}$$

If M is compact, take $K = M$. Sobolev embedding into C^0 allows the neighborhood in $\mathrm{Met}^s(M)$ to be chosen so that the preceding bound holds; in particular, this applies for $s > m/2 + 2$, as in this chapter. For closed manifolds, this gives the uniform Legendre condition of Theorem 20.3.1; the permitted open subset of bundle values is the cone of positive definite bilinear forms. If M is noncompact, a comparison $\mathbf{g} \le C\bar{\mathbf{g}}$ on all of M, with C independent of the point, likewise gives a lower bound for the principal part $\lambda = C^{-1}$. Without uniform comparison, pointwise positivity alone does not imply a global constant.

Linearization of the principal term in the direction $\mathbf{h}$ is $\sum_{a,b=1}^{m} g^{ab}(\bar\nabla^2\mathbf{h})_{abij}$ plus terms of order at most one in $\mathbf{h}$. The substitution $\bar\nabla_a \mapsto i\xi_a$ gives (21.18). Since $\sum_{a,b=1}^{m} g^{ab}\xi_a\xi_b > 0$, the system is locally strongly parabolic, and the preceding bounds provide uniformity in the compact case. The presence of a boundary does not alter this symbol calculation; the theory of Chapter 20 is applied here with M closed. □

The uniqueness argument will use harmonic map heat flow. To construct it through an equation on a trivial bundle, we must check that the ambient solution remains in the embedded submanifold. The following estimate makes this invariance explicit.

Lemma 21.3.2. (Remaining in a submanifold through tubular distance) Let N be a compact embedded submanifold without boundary of a Riemannian manifold $(\mathcal{N},\mathbf{h})$, and let $\mathcal{T}$ be a tubular neighborhood with retraction $\pi\colon \mathcal{T} \to N$. Set $\rho(y) = \frac{1}{2}\,\mathrm{dist}_{\mathbf{h}}(y,N)^2$. Let $\widetilde{\boldsymbol{\mathcal{A}}}$ be a smooth extension to $\mathcal{T}$ of the second fundamental form $\boldsymbol{\mathcal{A}}$ of N, defined as follows. For $y = \exp_z^{\perp} \nu$, with $z = \pi(y)$, let $\mathsf{P}_{z,y}\colon T_z\mathcal{N} \to T_y\mathcal{N}$ be parallel transport along the normal geodesic. Set

$$\widetilde{\boldsymbol{\mathcal{A}}}_y(V,W) := \mathsf{P}_{z,y}\big(\boldsymbol{\mathcal{A}}_z(d\pi_y V, d\pi_y W)\big), \qquad V,W \in T_y\mathcal{N}.$$

If a smooth map $U\colon M\times[0,T]\to\mathcal{T}$ satisfies

$$\partial_t U=\tau_{\mathbf{g}(t),\mathbf{h}}(U)-\sum_{i,j=1}^{m}g^{ij}(t)\widetilde{\boldsymbol{\mathcal{A}}}_U(\partial_i U,\partial_j U),\tag{21.20}$$

, there exists a constant C, uniform while U ranges over a compact subset of $\mathcal{T}$ and $\mathbf{g}(t)$ stays in a uniformly equivalent family, such that

$$(\partial_t-\Delta_{\mathbf{g}(t)})(\rho\circ U)\le C\bigl(1+|dU|^2_{\mathbf{g}(t),\mathbf{h}}\bigr)(\rho\circ U).\tag{21.21}$$

In particular, if M is closed and $U(\cdot,0)$ takes values in N, then $U(M\times[0,T])\subseteq N$.

Proof. The chain rule for the tension field of a map gives

$$\begin{aligned}(\partial_t-\Delta_{\mathbf{g}(t)})(\rho\circ U)=&-d\rho_U\left(\sum_{i,j=1}^{m}g^{ij}\widetilde{\boldsymbol{\mathcal{A}}}_U(\partial_i U,\partial_j U)\right)\\&-\sum_{i,j=1}^{m}g^{ij}\operatorname{Hess}_{\mathbf{h}}\rho_U(\partial_i U,\partial_j U).\end{aligned}$$

To estimate the right-hand side, use Fermi coordinates $y=(z^a,\nu^\alpha)$, where $z=\pi(y)$ and ν is normal to N at z. Write $d=\dim N$ and $c=\dim\mathcal{N}-d$. Choose a local orthonormal normal frame $(\mathbf{n}_\alpha)_{\alpha=1}^{c}$ and set $\nu=\sum_{\alpha=1}^{c}\nu^\alpha\mathbf{n}_\alpha(z)$. In these coordinates, $a,b\in\{1,\dots,d\}$ and $\alpha,\beta\in\{1,\dots,c\}$. On a compact subset of the tubular neighborhood, the Taylor expansions are uniform and give

$$\rho(z,\nu)=\frac12\sum_{\alpha=1}^{c}(\nu^\alpha)^2,\qquad\partial_a\rho=0,\qquad\partial_\alpha\rho=\nu^\alpha,\tag{21.22}$$

$$(\operatorname{Hess}\rho)_{ab}=-\langle\nu,\boldsymbol{\mathcal{A}}_{ab}\rangle+O(|\nu|^2),\qquad(\operatorname{Hess}\rho)_{a\beta}=O(|\nu|),\qquad(\operatorname{Hess}\rho)_{\alpha\beta}=\delta_{\alpha\beta}+O(|\nu|).\tag{21.23}$$

The first line is exact: normal geodesics minimize distance to N in the tubular neighborhood. For the second line, use $(\operatorname{Hess}\rho)_{AB}=\partial_A\partial_B\rho-\sum_{C=1}^{d+c}\Gamma^C_{AB}\partial_C\rho$. The indices A,B range over $\{1,\dots,d+c\}$. On the zero section, Γ^α_{ab} are the normal components of $\boldsymbol{\mathcal{A}}_{ab}$; multiplying them by ν^α gives the linear term of the tangential block. The normal block starts with the identity and the mixed block vanishes on N, justifying the remainder orders by Taylor's formula. Here $\boldsymbol{\mathcal{A}}_{ab}$ is the second fundamental form of N on the zero section. By the way this form was extended, transport $V\in T_y\mathcal{N}$ back to $T_z\mathcal{N}$ and decompose it as $V^\top+V^\perp$ according to $T_zN\oplus(T_zN)^\perp$. Smoothness of $d\pi$ and its value on the zero section give $d\pi_y V=V^\top+O(|\nu|)|V|$. Moreover, $d\rho_y(\mathsf{P}_{z,y}Z)=\langle\nu,Z\rangle$ for $Z\in T_z\mathcal{N}$ by the first variation of distance. Thus

$$d\rho_y\bigl(\widetilde{\boldsymbol{\mathcal{A}}}_y(V,V)\bigr)=\langle\nu,\boldsymbol{\mathcal{A}}_z(V^\top,V^\top)\rangle+O(|\nu|^2)|V|^2_{\mathbf{h}}.\tag{21.24}$$

Fix a point of the domain and choose there an orthonormal frame $(\mathbf{e}_i)_{i=1}^{m}$ for $\mathbf{g}(t)$. If $V_i=dU(\mathbf{e}_i)=V_i^\top+V_i^\perp$,

the two preceding formulas show, for each i, that

$$\begin{aligned} &-d\rho_U\big(\widetilde{\boldsymbol{\mathcal{A}}}_U(V_i,V_i)\big)-\operatorname{Hess}_{\mathbf{h}}\rho_U(V_i,V_i)\\ &\qquad=-|V_i^{\perp}|_{\mathbf{h}}^2+\mathcal{E}_i, \end{aligned}$$

with

$$|\mathcal{E}_i|\le C|\nu||V_i^{\perp}|_{\mathbf{h}}|V_i|_{\mathbf{h}}+C|\nu|^2\big(1+|V_i|_{\mathbf{h}}^2\big).$$

Indeed, the term $\langle \nu,\boldsymbol{\mathcal{A}}(V_i^{\top},V_i^{\top})\rangle$ coming from $d\rho(\widetilde{\boldsymbol{\mathcal{A}}})$ cancels with the linear term of opposite sign in $\operatorname{Hess}\rho(V_i^{\top},V_i^{\top})$. The normal block of the Hessian leaves $-|V_i^{\perp}|^2$, while the mixed block and Taylor remainders produce the stated errors. Summing over i gives

$$\begin{aligned} &-d\rho_U\left(\sum_{i,j=1}^{m}g^{ij}\widetilde{\boldsymbol{\mathcal{A}}}_U(\partial_iU,\partial_jU)\right)-\sum_{i,j=1}^{m}g^{ij}\operatorname{Hess}_{\mathbf{h}}\rho_U(\partial_iU,\partial_jU)\\ &\qquad=-|(dU)^{\perp}|_{\mathbf{g}(t),\mathbf{h}}^2+\mathcal{E}, \end{aligned}\tag{21.25}$$

where

$$|\mathcal{E}|\le C|\nu||(dU)^{\perp}||dU|+C|\nu|^2\big(1+|dU|^2\big).\tag{21.26}$$

Young's inequality absorbs the cross term:

$$C|\nu||(dU)^{\perp}||dU|\le\frac{1}{2}|(dU)^{\perp}|^2+C|\nu|^2|dU|^2.$$

In these coordinates, $|\nu|^2=2\rho(z,\nu)$. The three preceding estimates imply (21.21). On an interval where U is smooth, $|dU|$ is bounded because M is compact. The maximum principle applied to $e^{-Ct}(\rho\circ U)$ with zero initial data gives $\rho\circ U=0$. □

Corollary 21.3.3. (Harmonic map heat flow with varying domain metric) Let M be a closed smooth manifold. Let $\mathbf{g}(t)$ be a smooth family of metrics on M, let $\bar{\mathbf{g}}$ be a fixed smooth metric, and let $F_0\colon M\to M$ be a smooth map. There exists $T_0>0$ for which the problem

$$\partial_tF=\tau_{\mathbf{g}(t),\bar{\mathbf{g}}}(F),\qquad F(0)=F_0,\tag{21.27}$$

has a unique smooth solution. The time can be chosen uniformly when the domain metrics and their inverses satisfy uniform bounds for ellipticity and regularity, and the data $\iota\circ F_0$ are bounded in an H^s norm, with $s>m/2+2$, for a fixed embedding ι of the target. The smooth geometry of the target remains fixed.

Proof. Theorem A.6.2 gives an embedding $\iota\colon M\hookrightarrow\mathbb{R}^N$. On a neighborhood of $\iota(M)$, choose an ambient metric $\mathbf{h}$ making the inclusion $\iota\colon(M,\bar{\mathbf{g}})\to(\mathbb{R}^N,\mathbf{h})$ isometric. To construct it, on the normal bundle of a Euclidean embedding take the orthogonal sum of $\bar{\mathbf{g}}$ in the horizontal directions and a smooth metric in the normal directions. A fixed connection defines this splitting; the tubular diffeomorphism transports the metric to a neighborhood of $\iota(M)$. Its restriction to the zero section is the prescribed one. Let $\mathcal{T}$ be a tubular neighborhood, let $\pi\colon\mathcal{T}\to\iota(M)$ be its retraction, and let $\boldsymbol{\mathcal{A}}$ be the second fundamental form of

$\iota(M)$. Shrinking $\mathcal{T}$, smoothly extend the map

$$(y, V, W) \longmapsto \mathrm{P}_{\pi(y),y}\big(\boldsymbol{\mathcal{A}}_{\pi(y)}(d\pi_y V, d\pi_y W)\big)$$

to an open subset of $\mathbb{R}^N$ and denote the extension by $\widetilde{\boldsymbol{\mathcal{A}}}$. Existence of the tubular neighborhood and retraction was proved in Theorem 2.12.3.

For $U_0 = \iota \circ F_0$, solve on the trivial bundle $M \times \mathbb{R}^N$ the system

$$\partial_t U = \tau_{\mathbf{g}(t),\mathbf{h}}(U) - \sum_{i,j=1}^{m} g^{ij}(t)\widetilde{\boldsymbol{\mathcal{A}}}_U(\partial_i U, \partial_j U), \qquad U(0) = U_0. \tag{21.28}$$

In ambient-space coordinates, the principal part is $\sum_{i,j=1}^{m} g^{ij}(t)\partial_i\partial_j U^\alpha$ and the remaining terms depend smoothly on (x, t, U, dU). Corollary 20.3.2 gives a unique smooth solution on a short interval. Shrinking this interval, its image stays in $\mathcal{T}$.

Apply Lemma 21.3.2 with $N = \iota(M)$. Since U_0 takes values in N, we have $U(M \times [0, T_0]) \subseteq \iota(M)$. Thus there exists a smooth map F such that $U = \iota \circ F$. The Gauss formula states that the normal component of the tension field of $\iota \circ F$ is $\sum_{i,j=1}^{m} g^{ij}\boldsymbol{\mathcal{A}}(dF(\partial_i), dF(\partial_j))$; restricting (21.28) to the submanifold cancels this term, leaving exactly (21.27).

Composing two intrinsic solutions with ι gives two solutions of the same ambient system, so they agree. Finally, the existence constants depend only on the uniform bounds for $\mathbf{g}$ and $\mathbf{g}^{-1}$ and finitely many of their derivatives, the fixed geometry of the tubular neighborhood, and an H^s bound for $U_0 = \iota \circ F_0$. The embedding $H^s \hookrightarrow C^1$ also controls the values and first derivatives occurring in the nonlinearity. This proves the uniform assertion. □

Theorem 21.3.4. (Short-time existence and uniqueness) For every smooth metric $\mathbf{g}_0$ on a closed smooth manifold M, there exist $T > 0$ and a unique smooth solution

$$\mathbf{g}\colon M \times [0, T] \longrightarrow S^2 T^*M$$

of Ricci flow with $\mathbf{g}(0) = \mathbf{g}_0$. A smooth family of smooth initial metrics gives, locally in the parameter, a smooth family of solutions on a common interval. The interval can be chosen uniformly over compact subsets of the parameter space. In particular, for $\tau > 0$, dependence is smooth in every C^k norm on $M \times [\tau, T]$, as long as the existence interval is common.

Proof. Take $\bar{\mathbf{g}} = \mathbf{g}_0$. Proposition 21.3.1 and Theorem 20.3.1 give a unique solution $\widetilde{\mathbf{g}}(t)$ of

$$\partial_t \widetilde{\mathbf{g}} = -2\,\mathrm{Ric}_{\widetilde{\mathbf{g}}} + \mathcal{L}_{\mathbf{W}_{\bar{\mathbf{g}}}(\widetilde{\mathbf{g}})}\widetilde{\mathbf{g}}, \qquad \widetilde{\mathbf{g}}(0) = \mathbf{g}_0. \tag{21.29}$$

Positive definiteness is an open condition; continuity in time allows T to be reduced so that $\widetilde{\mathbf{g}}(t)$ remains a metric. Let φ_t be the nonautonomous flow determined by

$$\partial_t \varphi_t = -\mathbf{W}_{\bar{\mathbf{g}}}(\widetilde{\mathbf{g}}(t)) \circ \varphi_t, \qquad \varphi_0 = \mathrm{id}_M. \tag{21.30}$$

The field is smooth on $M\times[0,T]$. Compactness of M ensures that the flow exists on the whole interval, and each φ_t is a diffeomorphism. With $\mathbf{g}(t)=\varphi_t^*\widetilde{\mathbf{g}}(t)$, equations (21.11), (21.29), and (21.10) give

$$\begin{aligned}\partial_t\mathbf{g} &= \varphi_t^*\left(-2\operatorname{Ric}_{\widetilde{\mathbf{g}}}+\mathcal{L}_{\mathbf{W}_{\widetilde{\mathbf{g}}}(\widetilde{\mathbf{g}})}\widetilde{\mathbf{g}}-\mathcal{L}_{\mathbf{W}_{\widetilde{\mathbf{g}}}(\widetilde{\mathbf{g}})}\widetilde{\mathbf{g}}\right)\\ &= -2\operatorname{Ric}_{\varphi_t^*\widetilde{\mathbf{g}}} = -2\operatorname{Ric}_{\mathbf{g}}.\end{aligned}$$

This proves existence.

Uniqueness does not follow by applying uniqueness of the DeTurck system to two Ricci flows: the gauge-fixing diffeomorphisms depend on the solution. To address this difficulty, consider two solutions $\mathbf{g}_1(t)$ and $\mathbf{g}_2(t)$ with the same initial data and solve, for $a=1,2$, the harmonic map heat flow

$$\partial_t F_a = \tau_{\mathbf{g}_a(t),\bar{\mathbf{g}}}(F_a),\qquad F_a(0)=\mathrm{id}_M. \tag{21.31}$$

Corollary 21.3.3 gives a smooth solution on a common interval. Since $dF_a(0)=\mathrm{Id}$, uniform continuity of $dF_a(t)$ and compactness of M allow the interval to be reduced so that every $dF_a(t)$ is a linear isomorphism. Thus $F_a(t)$ is a local diffeomorphism.

Let us also verify global injectivity. Choose a finite family of charts with three concentric coordinate balls $V_\alpha\Subset W_\alpha\Subset U_\alpha$, such that the V_α cover M and each W_α is convex in coordinates. Convergence $F_a(t)\to\mathrm{id}_M$ in C^1 allows time to be reduced so that $F_a(t)(W_\alpha)\subseteq U_\alpha$ and the coordinate representation $f_{a,t,\alpha}$ satisfies

$$\|D(f_{a,t,\alpha}-\mathrm{id})\|_\infty<\frac{1}{2}$$

on W_α, simultaneously for all indices of the finite family. Integration along the segment between two points x,y of this ball gives

$$|f_{a,t,\alpha}(x)-f_{a,t,\alpha}(y)|\geq\frac{1}{2}|x-y|.$$

Thus each restriction to W_α is injective.

Let $\delta>0$ be a Lebesgue number of the cover (V_α) for a fixed Riemannian distance. Reduce time again so that $d(F_a(t)(x),x)<\delta/3$ for every $x\in M$. If $F_a(t)(x)=F_a(t)(y)$, the triangle inequality gives $d(x,y)<2\delta/3$, so both points belong to some V_α. The local injectivity just proved implies $x=y$. Finally, $F_a(t)$ preserves each connected component, since $s\mapsto F_a(st)(x)$ is a path starting at x. On each component, its image is nonempty, open because it is a local diffeomorphism, and closed by compactness. Connectedness makes it the whole component. Thus $F_a(t)$ is bijective, and its inverse is smooth by the inverse function theorem.

Define

$$\widehat{\mathbf{g}}_a(t)=(F_a(t)^{-1})^*\mathbf{g}_a(t).$$

The tension field of the identity from $(M,\widehat{\mathbf{g}}_a)$ to $(M,\bar{\mathbf{g}})$ is

$$\tau_{\widehat{\mathbf{g}}_a,\bar{\mathbf{g}}}(\mathrm{id})^k=\sum_{i,j=1}^m\widehat{g}_a^{ij}\left(\overline{\Gamma}_{ij}^k-\Gamma(\widehat{\mathbf{g}}_a)_{ij}^k\right)=-\mathbf{W}_{\bar{\mathbf{g}}}(\widehat{\mathbf{g}}_a)^k. \tag{21.32}$$

Set

$$\mathbf{V}_a=(\partial_tF_a)\circ F_a^{-1}.$$

Precomposing the equation for F_a with F_a^{-1}, naturality of the tension field under changes of domain gives

the exact identity

$$\mathbf{V}_a = \tau_{\widehat{\mathbf{g}}_a,\bar{\mathbf{g}}}(\mathrm{id}) = -\mathbf{W}_{\bar{\mathbf{g}}}(\widehat{\mathbf{g}}_a). \tag{21.33}$$

Differentiation of pullback by the inverse family gives

$$\partial_t \widehat{\mathbf{g}}_a = (F_a^{-1})^*(\partial_t \mathbf{g}_a) - \mathcal{L}_{\mathbf{V}_a}\widehat{\mathbf{g}}_a. \tag{21.34}$$

Indeed, differentiating $F_a^{-1} \circ F_a = \mathrm{id}$ identifies the Eulerian velocity of the inverse with the pullback of $-\mathbf{V}_a$, and rule (21.11) gives (21.34). By (21.10) and (21.33), this formula becomes

$$\partial_t \widehat{\mathbf{g}}_a = -2\,\mathrm{Ric}_{\widehat{\mathbf{g}}_a} + \mathcal{L}_{\mathbf{W}_{\bar{\mathbf{g}}}(\widehat{\mathbf{g}}_a)}\widehat{\mathbf{g}}_a, \qquad \widehat{\mathbf{g}}_a(0) = \mathbf{g}_0.$$

Uniqueness of the quasilinear parabolic problem gives $\widehat{\mathbf{g}}_1 = \widehat{\mathbf{g}}_2 =: \widehat{\mathbf{g}}$. Moreover,

$$\partial_t F_a = -\mathbf{W}_{\bar{\mathbf{g}}}(\widehat{\mathbf{g}}) \circ F_a, \qquad F_a(0) = \mathrm{id}_M .$$

Uniqueness for this nonautonomous ordinary differential equation implies $F_1 = F_2$. Since $\mathbf{g}_a = F_a^*\widehat{\mathbf{g}}$, we conclude that $\mathbf{g}_1 = \mathbf{g}_2$ on an initial interval. The set of times up to which they agree is closed by continuity and open by the same argument restarted at any time; connectedness of the time interval shows that they agree on every common interval of existence.

For smooth families of smooth data, keep a reference metric fixed and reduce time uniformly. The fourth assertion of Corollary 20.3.3, parameter dependence of equation (21.30), and the pullback rule give joint smoothness. Parabolic smoothing allows it to be measured in every C^k norm on $M \times [\tau, T]$ when $\tau > 0$. □

Remark 21.3.5. The second half of the proof also gives the reverse direction of the DeTurck procedure. Harmonic map heat flow takes any Ricci solution to a solution of the same strictly parabolic system; the ordinary differential equation for the diffeomorphisms recovers the geometric solution unambiguously.

21.4 Evolution equations

Let $\mathbf{g}(t)$ be a smooth solution of (21.9). Substituting $\mathbf{h} = -2\,\mathrm{Ric}$ into Lemma 21.1.1 gives the identities

$$\partial_t g^{ij} = 2\,\mathrm{Ric}^{ij}, \tag{21.35}$$

$$\partial_t d\lambda_{\mathbf{g}} = -R\, d\lambda_{\mathbf{g}}, \tag{21.36}$$

$$\partial_t \Gamma_{ij}^k = -\sum_{\ell=1}^{m} g^{k\ell}\left(\nabla_i \mathrm{Ric}_{j\ell} + \nabla_j \mathrm{Ric}_{i\ell} - \nabla_\ell \mathrm{Ric}_{ij}\right). \tag{21.37}$$

In particular,

$$\frac{d}{dt}\mathrm{Vol}(M, \mathbf{g}(t)) = -\int_M R_{\mathbf{g}(t)}\, d\lambda_{\mathbf{g}(t)}. \tag{21.38}$$

Proposition 21.4.1. (Variation of the Laplacian) Let M be a smooth manifold with or without boundary,

let $\mathbf{g}(t)$ be a smooth family of metrics on M, let $\mathbf{h} = \partial_t \mathbf{g}$, and let $f = f(x,t)$ be a smooth function. Then

$$\partial_t(\Delta f) = \Delta(\partial_t f) - \sum_{i,j=1}^{m} h^{ij}(\nabla^2 f)_{ij} - \sum_{k=1}^{m}\left(\sum_{i=1}^{m} \nabla^i h_i{}^k - \frac{1}{2}\nabla^k \operatorname{tr}_{\mathbf{g}} \mathbf{h}\right)\nabla_k f. \tag{21.39}$$

Under Ricci flow, the contracted Bianchi identity gives

$$\partial_t(\Delta f) = \Delta(\partial_t f) + 2\sum_{i,j=1}^{m} \operatorname{Ric}^{ij}(\nabla^2 f)_{ij}. \tag{21.40}$$

Under a flow of the form $\partial_t \mathbf{g} = -2\operatorname{Ric}_{\mathbf{g}} + \frac{2}{m} r(t)\mathbf{g}$, with $r(t)$ constant in space, there is the additional term $-\frac{2}{m} r(t)\Delta_{\mathbf{g}} f$.

Proof. In coordinates,

$$\Delta f = \sum_{i,j=1}^{m} g^{ij}\left(\partial_i\partial_j f - \sum_{k=1}^{m} \Gamma_{ij}^{k}\partial_k f\right).$$

Differentiate, use $\partial_t g^{ij} = -h^{ij}$, and contract the Christoffel variation formula. This gives

$$\sum_{i,j=1}^{m} g^{ij}\partial_t \Gamma_{ij}^{k} = \sum_{i=1}^{m} \nabla^i h_i{}^k - \frac{1}{2}\nabla^k \operatorname{tr}_{\mathbf{g}} \mathbf{h},$$

and hence (21.39). For $\mathbf{h} = -2\operatorname{Ric}$, the equality $\sum_{i=1}^{m} \nabla^i \operatorname{Ric}_{ik} = \frac{1}{2}\nabla_k R$ cancels the first-order term. Adding $\frac{2}{m} r\mathbf{g}$, its spatial derivative is zero and its contraction with $\nabla^2 f$ is $\frac{2}{m} r\Delta f$. □

Curvature evolution starts with the uncommuted formula obtained directly from variation of the connection.

Lemma 21.4.2. (Uncommuted curvature evolution) Let M^m be a smooth manifold with or without boundary and let $\mathbf{g}(t)$ be a smooth solution of Ricci flow on M. The tensor of type $(1,3)$ satisfies

$$\partial_t R_{ijk}{}^{\ell} = \sum_{q=1}^{m} g^{\ell q}\big(-(\nabla^2 \operatorname{Ric})_{ijkq} - (\nabla^2 \operatorname{Ric})_{ikjq} + (\nabla^2 \operatorname{Ric})_{iqjk} \tag{21.41}$$

$$+ (\nabla^2 \operatorname{Ric})_{jikq} + (\nabla^2 \operatorname{Ric})_{jkiq} - (\nabla^2 \operatorname{Ric})_{jqik}\big). \tag{21.42}$$

For the fully covariant tensor, add the term coming from the metric:

$$\partial_t R_{ijk\ell} = -2\sum_{q=1}^{m} \operatorname{Ric}_{\ell q} R_{ijk}{}^{q} + \sum_{q=1}^{m} g_{\ell q}\partial_t R_{ijk}{}^{q}. \tag{21.43}$$

Proof. Equation (21.4) and (21.37) give

$$\partial_t R_{ijk}{}^{\ell} = \nabla_i(\partial_t \Gamma_{jk}^{\ell}) - \nabla_j(\partial_t \Gamma_{ik}^{\ell}).$$

Substitute (21.37) and use $\nabla \mathbf{g} = 0$; expanding the two parentheses produces exactly the six terms of (21.42).

Finally, differentiate $R_{ijk\ell} = \sum_{q=1}^{m} g_{\ell q} R_{ijk}{}^{q}$ and use $\partial_t g_{\ell q} = -2\,\mathrm{Ric}_{\ell q}$. □

The commutations needed to recognize the Laplacian follow from

$$([\nabla_a, \nabla_b]\mathbf{T})_{i_1 \dots i_r} = -\sum_{\alpha=1}^{r} \sum_{p=1}^{m} R_{abi_\alpha}{}^{p}\, T_{i_1 \dots i_{\alpha-1} p i_{\alpha+1} \dots i_r} \tag{21.44}$$

and the second Bianchi identity

$$\nabla_a R_{bcde} + \nabla_b R_{cade} + \nabla_c R_{abde} = 0. \tag{21.45}$$

Contracting the latter gives

$$\sum_{i=1}^{m} \nabla^i \mathrm{Ric}_{ij} = \frac{1}{2} \nabla_j R. \tag{21.46}$$

In estimate formulas, use the notation $\mathbf{S} * \mathbf{T}$ for a universal finite sum of contractions of $\mathbf{S} \otimes \mathbf{T}$ using $\mathbf{g}$ and $\mathbf{g}^{-1}$. This is Notation 9.1.37; Lemma 9.1.39 controls each contraction. The number of summands and their coefficients depend only on tensor type and m. For covariant tensors of orders $r, q \in \mathbb{N}_0$, there exists $C = C(m, r, q)$ such that

$$|\mathbf{S} * \mathbf{T}|_{\mathbf{g}} \le C |\mathbf{S}|_{\mathbf{g}} |\mathbf{T}|_{\mathbf{g}}$$

for fixed tensor types. This notation does not suppress derivatives: it only collects algebraic contractions completely determined by applying (21.44).

Proposition 21.4.3. (Evolution of Ricci, scalar, and Riemann curvature) Let M^m be a smooth manifold with or without boundary and let $\mathbf{g}(t)$ be a smooth solution of Ricci flow on M. Define

$$B_{ijk\ell} = \sum_{p,q,r,s=1}^{m} g^{pr} g^{qs} R_{pijq} R_{rk\ell s}. \tag{21.47}$$

Then

$$\partial_t \mathrm{Ric}_{ij} = \Delta \mathrm{Ric}_{ij} + 2 \sum_{k,\ell=1}^{m} R_{kij\ell}\, \mathrm{Ric}^{k\ell} - 2 \sum_{k=1}^{m} \mathrm{Ric}_i{}^{k}\, \mathrm{Ric}_{kj}, \tag{21.48}$$

$$\partial_t R_{\mathbf{g}(t)} = \Delta_{\mathbf{g}(t)} R_{\mathbf{g}(t)} + 2 |\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)}, \tag{21.49}$$

Moreover, with all indices covariant,

$$\begin{aligned} \partial_t R_{ijk\ell} = {} & \Delta R_{ijk\ell} + 2\big(B_{ij\ell k} - B_{ijk\ell} - B_{ikj\ell} + B_{i\ell jk}\big) \\ & - \sum_{p,q=1}^{m} g^{pq} \big(R_{pjk\ell}\, \mathrm{Ric}_{qi} + R_{ipk\ell}\, \mathrm{Ric}_{qj} + R_{ijkp}\, \mathrm{Ric}_{q\ell} + R_{ijp\ell}\, \mathrm{Ric}_{qk}\big). \end{aligned} \tag{21.50}$$

In particular,

$$(\partial_t - \Delta)\,\mathrm{Rm} = \mathrm{Rm} * \mathrm{Rm}. \tag{21.51}$$

The schematic equality is exactly (21.50): the right-hand side collects only algebraic contractions of two

curvature tensors and contains no additional derivatives.

Proof. First derive the four-index formula. Commuting in (21.42) the two derivatives falling on Ric_{kq} and using (21.43) gives

$$\partial_t R_{ijk\ell} = (\nabla^2 \mathrm{Ric})_{i\ell jk} - (\nabla^2 \mathrm{Ric})_{ikj\ell} - (\nabla^2 \mathrm{Ric})_{j\ell ik} + (\nabla^2 \mathrm{Ric})_{jki\ell} - \sum_{p,q=1}^{m} g^{pq}\left(R_{ijkp}\,\mathrm{Ric}_{q\ell} + R_{ijp\ell}\,\mathrm{Ric}_{qk}\right). \tag{21.52}$$

Indeed, the four terms written with two derivatives are the four uncommuted terms of (21.42). The two remaining terms form

$$([\nabla_j, \nabla_i]\mathrm{Ric})_{k\ell} = \sum_{p=1}^{m} R_{ijk}{}^{p}\,\mathrm{Ric}_{p\ell} + \sum_{p=1}^{m} R_{ij\ell}{}^{p}\,\mathrm{Ric}_{kp},$$

by (21.44). Adding the term coming from lowering the index gives

$$\sum_{p=1}^{m} R_{ijk}{}^{p}\,\mathrm{Ric}_{p\ell} + \sum_{p=1}^{m} R_{ij\ell}{}^{p}\,\mathrm{Ric}_{kp} - 2\sum_{q=1}^{m} \mathrm{Ric}_{\ell q}\,R_{ijk}{}^{q} = -\sum_{p,q=1}^{m} g^{pq}\left(R_{ijkp}\,\mathrm{Ric}_{q\ell} + R_{ijp\ell}\,\mathrm{Ric}_{qk}\right),$$

where $R_{ij\ell p} = -R_{ijp\ell}$ was used. This proves (21.52).

We now prove the Simons identity transforming the second derivatives. The second Bianchi identity and its contraction give, with the index order used here,

$$\Delta R_{ijk\ell} = \sum_{p,q=1}^{m} g^{pq}(\nabla^2 \mathrm{Rm})_{piqjk\ell} - \sum_{p,q=1}^{m} g^{pq}(\nabla^2 \mathrm{Rm})_{pjqik\ell}, \tag{21.53}$$

$$\sum_{p,q=1}^{m} g^{pq}\nabla_p R_{qjk\ell} = \nabla_\ell \mathrm{Ric}_{jk} - \nabla_k \mathrm{Ric}_{j\ell}. \tag{21.54}$$

To carry out the commutation, fix a point and an orthonormal frame there. Identity (21.44) gives

$$\sum_{p=1}^{m} ([\nabla_p, \nabla_i]\mathrm{Rm})_{pjk\ell} = \sum_{r=1}^{m} \mathrm{Ric}_{ir}\,R_{rjk\ell} - \sum_{p,r=1}^{m}\left(R_{pijr}R_{prk\ell} + R_{pikr}R_{pjr\ell} + R_{pi\ell r}R_{pjkr}\right).$$

The first term comes from $\sum_{p=1}^{m} R_{pipr} = -\mathrm{Ric}_{ir}$. The first Bianchi identity and antisymmetry in the last slots transform the three remaining sums into

$$-\sum_{p,r=1}^{m} R_{pijr}R_{prk\ell} = B_{ijk\ell} - B_{ij\ell k},$$

$$-\sum_{p,r=1}^{m} R_{pikr}R_{pjr\ell} = B_{ikj\ell},$$
$$-\sum_{p,r=1}^{m} R_{pi\ell r}R_{pjkr} = -B_{i\ell jk}.$$

For example, the first equality follows by substituting $R_{prk\ell} = -R_{pk\ell r} + R_{p\ell kr}$, which is Bianchi with indices permuted. The other two equalities use directly $R_{pjr\ell} = -R_{pj\ell r}$ and the definition of B. Returning to arbitrary coordinates gives

$$\sum_{p,q=1}^{m} g^{pq}\big((\nabla^2 \mathrm{Rm})_{piqjk\ell} - (\nabla^2 \mathrm{Rm})_{ipqjk\ell}\big)$$
$$= \sum_{r=1}^{m} \mathrm{Ric}_i{}^r R_{rjk\ell} - B_{ij\ell k} + B_{ijk\ell} - B_{i\ell jk} + B_{ikj\ell}.$$

Substitute this equality and its analogue with i and j interchanged into (21.53), then use (21.54). Grouping the four terms B yields

$$\begin{aligned}\Delta R_{ijk\ell} &+ 2\big(B_{ij\ell k} - B_{ijk\ell} - B_{ikj\ell} + B_{i\ell jk}\big)\\ &= (\nabla^2 \mathrm{Ric})_{i\ell jk} - (\nabla^2 \mathrm{Ric})_{ikj\ell} - (\nabla^2 \mathrm{Ric})_{j\ell ik} + (\nabla^2 \mathrm{Ric})_{jki\ell}\\ &\quad + \sum_{p,q=1}^{m} g^{pq}\big(R_{pjk\ell}\,\mathrm{Ric}_{qi} + R_{ipk\ell}\,\mathrm{Ric}_{qj}\big).\end{aligned} \tag{21.55}$$

Substituting (21.55) into (21.52) proves (21.50) term by term.

To obtain the Ricci equation, substitute $\mathbf{h} = -2\,\mathrm{Ric}$ into (21.13). The contracted Bianchi identity gives

$$\delta_{\mathbf{g}}(-2\,\mathrm{Ric}) = dR, \qquad \mathrm{tr}_{\mathbf{g}}(-2\,\mathrm{Ric}) = -2R.$$

Thus the two Hessian terms cancel. The explicit formula (21.14) leaves

$$\partial_t \mathrm{Ric}_{ij} = \Delta \mathrm{Ric}_{ij} + 2\sum_{k,\ell=1}^{m} R_{kij\ell}\,\mathrm{Ric}^{k\ell} - 2\sum_{k=1}^{m} \mathrm{Ric}_i{}^k\,\mathrm{Ric}_{kj},$$

which is (21.48).

The scalar equation can also be obtained without contracting the preceding one. Indeed, (21.6), with $\mathbf{h} = -2\,\mathrm{Ric}$, gives

$$\begin{aligned}\partial_t R_{\mathbf{g}(t)} &= 2|\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} - 2\,\mathrm{div}^2_{\mathbf{g}(t)}\mathrm{Ric}_{\mathbf{g}(t)} + 2\Delta_{\mathbf{g}(t)}R_{\mathbf{g}(t)}\\ &= 2|\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} + \Delta_{\mathbf{g}(t)}R_{\mathbf{g}(t)},\end{aligned}$$

where (21.46) was used. This proves (21.49).

Finally, every additional term in (21.50) is a contraction of two copies of Rm, because Ric is a contraction of Rm. This proves (21.51). □

Corollary 21.4.4. (Evolution of curvature norms) Let M^m be a smooth manifold with or without boundary and let $\mathbf{g}(t)$ be a smooth solution of Ricci flow on M. There exist constants $C_m, C_m' > 0$, depending only on dimension, such that

$$(\partial_t - \Delta_{\mathbf{g}(t)})|\mathrm{Rm}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} = -2|\nabla_{\mathbf{g}(t)}\mathrm{Rm}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} - 8\sum_{i,j,k,\ell=1}^{m}\big(B_{ijk\ell} + B_{ikj\ell}\big)R^{ijk\ell}, \tag{21.56}$$

$$(\partial_t - \Delta_{\mathbf{g}(t)})|\mathrm{Rm}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} \le -2|\nabla_{\mathbf{g}(t)}\mathrm{Rm}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} + C_m|\mathrm{Rm}_{\mathbf{g}(t)}|^3_{\mathbf{g}(t)}, \tag{21.57}$$

$$(\partial_t - \Delta_{\mathbf{g}(t)})|\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} = -2|\nabla_{\mathbf{g}(t)}\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} + 4\sum_{i,j,k,\ell=1}^{m} R_{kij\ell}\,\mathrm{Ric}^{ij}\,\mathrm{Ric}^{k\ell}, \tag{21.58}$$

$$(\partial_t - \Delta_{\mathbf{g}(t)})R^2_{\mathbf{g}(t)} = -2|dR_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} + 4R_{\mathbf{g}(t)}|\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)}. \tag{21.59}$$

In particular,

$$(\partial_t - \Delta_{\mathbf{g}(t)})|\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} \le -2|\nabla_{\mathbf{g}(t)}\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} + C_m'|\mathrm{Rm}_{\mathbf{g}(t)}|_{\mathbf{g}(t)}|\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)}. \tag{21.60}$$

Proof. For any time-dependent covariant tensor $\mathbf{T}$,

$$\Delta_{\mathbf{g}(t)}|\mathbf{T}|^2_{\mathbf{g}(t)} = 2\langle\Delta_{\mathbf{g}(t)}\mathbf{T},\mathbf{T}\rangle_{\mathbf{g}(t)} + 2|\nabla_{\mathbf{g}(t)}\mathbf{T}|^2_{\mathbf{g}(t)}.$$

Time differentiation of the norm also differentiates each copy of $\mathbf{g}^{-1}$. By (21.35), these terms are contractions of $\mathrm{Ric}*\mathbf{T}*\mathbf{T}$. With $\mathbf{T} = \mathrm{Rm}$, contract (21.50) with $2R^{ijk\ell}$ and add the four terms obtained by differentiating the inverse metrics. The terms $\mathrm{Ric}*\mathrm{Rm}*\mathrm{Rm}$ cancel and, for every covariant slot, the Ricci term in the tensor evolution cancels the term differentiating the inverse metric in that same slot. For the summands B, renaming k and ℓ and using $R^{ij\ell k} = -R^{ijk\ell}$ gives

$$\sum_{i,j,k,\ell=1}^{m} B_{ij\ell k}R^{ijk\ell} = -\sum_{i,j,k,\ell=1}^{m} B_{ijk\ell}R^{ijk\ell},$$
$$\sum_{i,j,k,\ell=1}^{m} B_{i\ell jk}R^{ijk\ell} = -\sum_{i,j,k,\ell=1}^{m} B_{ikj\ell}R^{ijk\ell}.$$

Consequently, the remainder is

$$-8\sum_{i,j,k,\ell=1}^{m}(B_{ijk\ell} + B_{ikj\ell})R^{ijk\ell}.$$

This proves (21.56). The algebraic estimate for B gives (21.57).

For the Ricci tensor, directly differentiate the two inverse metrics occurring in $|\mathrm{Ric}|^2 = \sum_{i,j,a,b=1}^{m} g^{ia}g^{jb}\,\mathrm{Ric}_{ij}\,\mathrm{Ric}_{ab}$ and use (21.35). This yields

$$\partial_t|\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} = 2\langle\partial_t\mathrm{Ric}_{\mathbf{g}(t)},\mathrm{Ric}_{\mathbf{g}(t)}\rangle_{\mathbf{g}(t)} + 4\sum_{i,j,k=1}^{m}\mathrm{Ric}_i{}^j\,\mathrm{Ric}_j{}^k\,\mathrm{Ric}_k{}^i.$$

The cubic Ricci terms coming from (21.48) cancel the second summand exactly. Subtracting the formula

for $\Delta_{\mathbf{g}(t)}|\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)}$ leaves (21.58). The following inequality is Cauchy–Schwarz in each fiber. Finally,

$$(\partial_t - \Delta_{\mathbf{g}(t)})R^2_{\mathbf{g}(t)} = 2R_{\mathbf{g}(t)}(\partial_t - \Delta_{\mathbf{g}(t)})R_{\mathbf{g}(t)} - 2|dR_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)},$$

and (21.49) proves (21.59). □

21.5 The maximum principle and a priori estimates

The evolution equations become useful when combined with the maximum principle. Scalar curvature satisfies a closed inequality, while the norm of the Riemann tensor obeys an equation with a cubic term. These two observations give the first bounds and, through a Bernstein induction, estimates for all derivatives of curvature.

To apply the maximum principle from the preceding chapter, fix $\nabla^0 = \nabla^{\mathbf{g}(0)}$. At every time, on functions,

$$\Delta_{\mathbf{g}(t)} f = \sum_{i,j=1}^{m} g^{ij}(t)((\nabla^0)^2 f)_{ij} + \sum_{k=1}^{m} b^k(x,t)\nabla^0_k f,$$

where

$$b^k(x,t) = \sum_{i,j=1}^{m} g^{ij}(t)\bigl(\Gamma(\mathbf{g}(0))^k_{ij} - \Gamma(\mathbf{g}(t))^k_{ij}\bigr), \qquad k \in \{1,\dots,m\}.$$

On a compact subinterval of existence, smoothness and positivity of $\mathbf{g}(t)$ make ellipticity and the coefficient bounds uniform. Thus the operator satisfies the hypotheses of Theorem 20.4.1, even though the metric defining the Laplacian varies with time.

Proposition 21.5.1. (Lower bound for scalar curvature) Let M^m be a closed smooth manifold and let $\mathbf{g}(t)$ be a smooth solution of Ricci flow on M. Let

$$a_0 = \min_{x \in M} R_{\mathbf{g}(0)}(x).$$

As long as the denominator is positive,

$$R_{\mathbf{g}(t)}(x) \geq \frac{a_0}{1 - \frac{2}{m}a_0 t} \qquad (x \in M). \tag{21.61}$$

In particular, the condition $R_{\mathbf{g}(0)} \geq 0$ is preserved. If $R_{\mathbf{g}(0)} > 0$, then $R_{\mathbf{g}(t)} > 0$ throughout the existence interval.

Proof. Cauchy–Schwarz for the Ricci eigenvalues gives

$$|\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} \geq \frac{1}{m} R^2_{\mathbf{g}(t)}.$$

Let $a(t)$ be the solution of

$$a'(t) = \frac{2}{m}a(t)^2, \qquad a(0) = a_0.$$

If $a_0 \neq 0$, then

$$a(t) = \frac{a_0}{1 - \frac{2}{m}a_0 t};$$

if $a_0 = 0$, we have $a(t) = 0$. For $u = R_{\mathbf{g}(t)} - a$,

$$\begin{aligned}(\partial_t - \Delta)u &= 2|\mathrm{Ric}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} - \frac{2}{m}a^2 \\ &\geq \frac{2}{m}(R^2_{\mathbf{g}(t)} - a^2) = \frac{2}{m}(R_{\mathbf{g}(t)} + a)u.\end{aligned}$$

Set $b = \frac{2}{m}(R_{\mathbf{g}(t)} + a)$ and $v = -u$. On every compact subinterval of existence, b has an upper bound B. The preceding inequality reads

$$(\partial_t - \Delta)v \leq bv.$$

For $\widetilde{v} = e^{-Bt}v$ we have

$$(\partial_t - \Delta)\widetilde{v} \leq (b - B)\widetilde{v}.$$

Since $b - B \leq 0$ and $\widetilde{v}(0) \leq 0$, Theorem 20.4.1 applied to the positive maximum of $\widetilde{v}$ gives $\widetilde{v} \leq 0$. Thus $u \geq 0$. Strict positivity also follows from the principle already proved: if $a_0 = \min_{x\in M} R_{\mathbf{g}(0)}(x) > 0$, then $(\partial_t - \Delta)(a_0 - R) = -2|\mathrm{Ric}|^2 \leq 0$. The maximum principle implies $R(x,t) \geq a_0 > 0$ on every compact subinterval of existence. The same argument with $a_0 = 0$ preserves nonnegativity. □

Proposition 21.5.2. (Initial curvature control) Let M^m be a closed smooth manifold and let $\mathbf{g}(t)$ be a smooth solution of Ricci flow on M. If

$$K_0 = \max_{x\in M} |\mathrm{Rm}_{\mathbf{g}(0)}(x)|_{\mathbf{g}(0)},$$

then there exists $c_m > 0$ such that

$$\max_{x\in M} |\mathrm{Rm}_{\mathbf{g}(t)}(x)|_{\mathbf{g}(t)} \leq \frac{K_0}{1 - c_m K_0 t} \tag{21.62}$$

if $1 - c_m K_0 t > 0$. When $K_0 = 0$, the flow remains flat.

Proof. Set $q(x,t) = |\mathrm{Rm}_{\mathbf{g}(t)}(x)|^2_{\mathbf{g}(t)}$. Equation (21.57) and the scalar maximum principle show that the upper right derivative of the maximum $Q(t) = \max_{x\in M} q(x,t)$ satisfies

$$D^+Q(t) \leq C_m Q(t)^{\frac{3}{2}}.$$

The solution of $y' = C_m y^{\frac{3}{2}}$, $y(0) = K_0^2$, is

$$y(t) = \frac{K_0^2}{\left(1 - \frac{C_m}{2}K_0 t\right)^2}.$$

Comparison for ordinary differential equations gives the conclusion with $c_m = \frac{C_m}{2}$. If $K_0 = 0$, comparison gives $q = 0$. □

Curvature derivative estimates are needed to rule out loss of regularity while curvature remains bounded.

Proposition 21.5.3. (Global derivative estimates) Let M^m be a closed smooth manifold and let $\mathbf{g}(t)$ be a smooth solution of Ricci flow on M. Suppose that $\mathbf{g}(t)$ is defined on $M \times [0,T]$ and

$$|\mathrm{Rm}_{\mathbf{g}(t)}(x)|_{\mathbf{g}(t)} \leq K \qquad ((x,t) \in M \times [0,T]).$$

For every integer $r \geq 1$ there exists a constant $C_r = C_r(m, r, KT)$ such that

$$|\nabla^r_{\mathbf{g}(t)} \operatorname{Rm}_{\mathbf{g}(t)}(x)|_{\mathbf{g}(t)} \leq C_r K t^{-\frac{r}{2}} \qquad ((x,t) \in M \times (0,T]). \tag{21.63}$$

If $K = 0$, all derivatives vanish and the assertion is interpreted accordingly.

Proof. Write $\mathcal{D} = \partial_t - \Delta$ and $\mathbf{T}_r = \nabla^r \operatorname{Rm}$ for $r \in \mathbb{N}_0$. If $\mathbf{T}$ is covariant of order q, differentiating its components gives

$$([\partial_t, \nabla]\mathbf{T})_{ij_1\dots j_q} = -\sum_{\alpha=1}^{q} \sum_{p=1}^{m} (\partial_t \Gamma^p_{ij_\alpha}) T_{j_1\dots j_{\alpha-1} p j_{\alpha+1}\dots j_q}.$$

By (21.37), this is a sum of contractions of $\nabla \operatorname{Rm}$ with $\mathbf{T}$. On the other hand, Lemma 9.1.41, applied to the tensor connection with $\Delta = -\nabla^*\nabla$, gives

$$[\Delta, \nabla]\mathbf{T} = \operatorname{Rm} * \nabla\mathbf{T} + \nabla \operatorname{Rm} * \mathbf{T}.$$

Here the bundle in the lemma is the bundle of tensors of the type of $\mathbf{T}$; its curvature is the sum of the Riemann actions on each slot, as expressed by (21.44).
For every $r \in \mathbb{N}_0$, we prove the identity

$$(\partial_t - \Delta_{\mathbf{g}(t)}) \nabla^r_{\mathbf{g}(t)} \operatorname{Rm}_{\mathbf{g}(t)} = \sum_{\substack{a,b \in \mathbb{N}_0 \\ a+b=r}} \nabla^a_{\mathbf{g}(t)} \operatorname{Rm}_{\mathbf{g}(t)} * \nabla^b_{\mathbf{g}(t)} \operatorname{Rm}_{\mathbf{g}(t)}. \tag{21.64}$$

For $r = 0$, this is (21.51). Suppose that it holds for some $r \geq 0$. Since $\mathbf{T}_{r+1} = \nabla \mathbf{T}_r$,

$$\mathcal{D}\mathbf{T}_{r+1} = \nabla(\mathcal{D}\mathbf{T}_r) + [\partial_t, \nabla]\mathbf{T}_r - [\Delta, \nabla]\mathbf{T}_r.$$

Proposition 9.1.40 turns the first term into the sum, for $a + b = r$, of $\mathbf{T}_{a+1} * \mathbf{T}_b$ and $\mathbf{T}_a * \mathbf{T}_{b+1}$. The two commutators contribute only $\mathbf{T}_1 * \mathbf{T}_r$ and $\mathbf{T}_0 * \mathbf{T}_{r+1}$. All these products have total order $r+1$; grouping those sharing the same pair of orders gives (21.64) for $r+1$. The number of terms and their coefficients depend only on m and r.
Passing to the norm of $\mathbf{T}_r$ differentiates each of the $r+4$ copies of the inverse metric. Identity $\partial_t \mathbf{g}^{-1} = 2\operatorname{Ric}^{\sharp\sharp}$ bounds their contribution by $C_r|\operatorname{Rm}||\mathbf{T}_r|^2$, which is the type of term corresponding to $a = 0$ or $b = 0$ in the following sum. By the Leibniz rule,

$$(\partial_t - \Delta_{\mathbf{g}(t)})|\nabla^r_{\mathbf{g}(t)} \operatorname{Rm}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} \leq -2|\nabla^{r+1}_{\mathbf{g}(t)} \operatorname{Rm}_{\mathbf{g}(t)}|^2_{\mathbf{g}(t)} \tag{21.65}$$

$$+ C_r \sum_{\substack{a,b \in \mathbb{N}_0 \\ a+b=r}} |\nabla^r_{\mathbf{g}(t)} \operatorname{Rm}_{\mathbf{g}(t)}|_{\mathbf{g}(t)} |\nabla^a_{\mathbf{g}(t)} \operatorname{Rm}_{\mathbf{g}(t)}|_{\mathbf{g}(t)} |\nabla^b_{\mathbf{g}(t)} \operatorname{Rm}_{\mathbf{g}(t)}|_{\mathbf{g}(t)}. \tag{21.66}$$

Scale normalization avoids mixing different powers of K. If $K > 0$, define

$$\widetilde{\mathbf{g}}(\tau) = K\mathbf{g}\left(\frac{\tau}{K}\right), \qquad 0 \leq \tau \leq KT. \tag{21.67}$$

Then $\widetilde{\mathbf{g}}$ satisfies Ricci flow and $|\operatorname{Rm}_{\widetilde{\mathbf{g}}(\tau)}|_{\widetilde{\mathbf{g}}(\tau)} \leq 1$. In the original variables, the term with no derivatives in (21.57) has size K^3, not K^2; transformation (21.67) turns it into a dimensionless constant. It therefore

suffices to prove the estimate when $K = 1$ on an interval $[0, S]$, with $S = KT$.
Write

$$u_j(x,\tau) = |\nabla^j_{\widetilde{\mathbf{g}}(\tau)} \mathrm{Rm}_{\widetilde{\mathbf{g}}(\tau)}(x)|^2_{\widetilde{\mathbf{g}}(\tau)}.$$

Proceed by induction on r. Suppose the bounds $u_j \le C_{j,S}\tau^{-j}$ are known for $j < r$; for $r = 1$ this hypothesis uses only $u_0 \le 1$. In (21.66), summands with $a = 0$ or $b = 0$ are bounded by $C_r u_r$. If $1 \le a, b \le r-1$, the induction hypothesis gives $\tau^r\sqrt{u_r u_a u_b} \le C_{r,S}\tau^{r/2}\sqrt{u_r}$. Write the last product as $C_{r,S}(\tau^{(r-1)/2}\sqrt{u_r})\tau^{1/2}$ and apply Young. Since $\tau \le S$, we obtain

$$\tau^r u_r^{\frac12} u_a^{\frac12} u_b^{\frac12} \le \varepsilon\tau^{r-1}u_r + C_{r,S,\varepsilon}, \qquad a + b = r.$$

Differentiating the power of τ and also absorbing $\tau^r u_r \le S\tau^{r-1}u_r$ gives

$$(\partial_\tau - \Delta_{\widetilde{\mathbf{g}}(\tau)})(\tau^r u_r) \le -2\tau^r u_{r+1} + C_{r,S}\tau^{r-1}u_r + C_{r,S}. \tag{21.68}$$

The same calculation, already justified by the induction hypothesis, gives for $1 \le j < r$

$$(\partial_\tau - \Delta_{\widetilde{\mathbf{g}}(\tau)})(\tau^j u_j) \le -2\tau^j u_{j+1} + C_{j,S}\tau^{j-1}u_j + C_{j,S}, \tag{21.69}$$

and for $j = 0$ gives

$$(\partial_\tau - \Delta_{\widetilde{\mathbf{g}}(\tau)})u_0 \le -2u_1 + C_m. \tag{21.70}$$

Set $A_r = 1$ and, for $j = r, r-1, \dots, 1$, define $A_{j-1} = 1 + C_{j,S}A_j$. This choice makes the term $C_{j,S}A_j\tau^{j-1}u_j$ in (21.68) or (21.69) absorbable by $-2A_{j-1}\tau^{j-1}u_j$. For

$$F_r = \tau^r u_r + \sum_{j=0}^{r-1} A_j \tau^j u_j \tag{21.71}$$

we therefore obtain

$$(\partial_\tau - \Delta_{\widetilde{\mathbf{g}}(\tau)})F_r \le C_{r,S}. \tag{21.72}$$

Since $F_r(0) = A_0 u_0(0) \le A_0$, the maximum principle implies $F_r \le A_0 + C_{r,S}S$. In particular,

$$|\nabla^r_{\widetilde{\mathbf{g}}(\tau)} \mathrm{Rm}_{\widetilde{\mathbf{g}}(\tau)}|_{\widetilde{\mathbf{g}}(\tau)} \le C_{r,S}\tau^{-\frac{r}{2}}.$$

This closes the induction.
Finally, under the constant rescaling in (21.67),

$$|\nabla^r_{\widetilde{\mathbf{g}}(\tau)} \mathrm{Rm}_{\widetilde{\mathbf{g}}(\tau)}|_{\widetilde{\mathbf{g}}(\tau)} = K^{-1-\frac{r}{2}}|\nabla^r_{\mathbf{g}(\tau/K)} \mathrm{Rm}_{\mathbf{g}(\tau/K)}|_{\mathbf{g}(\tau/K)}.$$

Taking $\tau = Kt$ gives

$$|\nabla^r_{\mathbf{g}(t)} \mathrm{Rm}_{\mathbf{g}(t)}|_{\mathbf{g}(t)} \le C_r(m, r, KT)Kt^{-\frac{r}{2}},$$

which is (21.63). The case $K = 0$ already follows from Proposition 21.5.2. □

Theorem 21.5.4. (Continuation criterion) Let $\mathbf{g}(t)$ be the maximal solution of Ricci flow on a closed smooth manifold, defined on $[0, T_{\max})$. If $T_{\max} < \infty$, then

$$\lim_{t \nearrow T_{\max}} \max_{x \in M} |\mathrm{Rm}_{\mathbf{g}(t)}(x)|_{\mathbf{g}(t)} = \infty. \tag{21.73}$$

Proof. Suppose, toward a contradiction, that $|\mathrm{Rm}_{\mathbf{g}(t)}|_{\mathbf{g}(t)} \le K$ on $M \times [0, T_{\max})$. Since $|\mathrm{Ric}_{\mathbf{g}(t)}|_{\mathbf{g}(t)} \le \sqrt{m}|\mathrm{Rm}_{\mathbf{g}(t)}|_{\mathbf{g}(t)}$, for every vector $v \neq 0$ fixed in TM we have

$$|\partial_t \log \mathbf{g}(t)(v,v)| = 2\frac{|\mathrm{Ric}_{\mathbf{g}(t)}(v,v)|}{\mathbf{g}(t)(v,v)} \le 2\sqrt{m}K.$$

Integration in time gives

$$e^{-2\sqrt{m}KT_{\max}}\mathbf{g}(0) \le \mathbf{g}(t) \le e^{2\sqrt{m}KT_{\max}}\mathbf{g}(0). \tag{21.74}$$

Inequality (21.74) states that, for every $x \in M$ and every $v \in T_xM$,

$$e^{-2\sqrt{m}KT_{\max}}\mathbf{g}(0)_x(v,v) \le \mathbf{g}(t)_x(v,v) \le e^{2\sqrt{m}KT_{\max}}\mathbf{g}(0)_x(v,v).$$

The constants are independent of x and $t < T_{\max}$. In particular, any possible limit cannot lose positivity. Proposition 7.1.9 allows every tensor of fixed type to be measured with $\mathbf{g}(0)$ or $\mathbf{g}(t)$ using common constants. To replace also the t-dependent Levi–Civita derivatives by derivatives with respect to a fixed connection, we need the following change-of-connection argument.

Apply Proposition 21.5.3 to the shifted flow starting at $\frac{T_{\max}}{4}$. All covariant derivatives of Riemann are uniformly bounded on $M \times [\frac{T_{\max}}{2}, T_{\max})$.

Let us explain the passage to a fixed connection. Let $\nabla^0 = \nabla^{\mathbf{g}(0)}$ and

$$\mathbf{A}(t) = \nabla^{\mathbf{g}(t)} - \nabla^0.$$

The change-of-connection identities have the form

$$\nabla^0\mathbf{T} = \nabla^{\mathbf{g}(t)}\mathbf{T} + \mathbf{A} * \mathbf{T}, \qquad \nabla^0\mathbf{g} = \mathbf{A} * \mathbf{g}, \tag{21.75}$$

where, in the second equality, the two summands corresponding to the two indices of $\mathbf{g}$ are included in the notation $*$. Since ∇^0 is fixed, (21.37) reads

$$\partial_t\mathbf{A} = -\mathbf{g}^{-1} * \nabla^{\mathbf{g}(t)}\mathrm{Ric}. \tag{21.76}$$

The first-order estimate in Proposition 21.5.3 bounds the right-hand side and, after integration from $\frac{T_{\max}}{2}$, bounds $\mathbf{A}$.

For higher orders, fix $t_0 = T_{\max}/2$ and measure all infinity norms with $\mathbf{g}(0)$. First specify the conversion of derivatives. The triangular formula of Lemma 9.1.28, or its application to the two connections, takes the form

$$(\nabla^0)^r\mathbf{T} = (\nabla^{\mathbf{g}(t)})^r\mathbf{T} + \sum_{j=0}^{r-1} \mathbf{C}_{r,j} * (\nabla^{\mathbf{g}(t)})^j\mathbf{T}, \qquad r \ge 1. \tag{21.77}$$

Each $\mathbf{C}_{r,j}$ is a finite sum of products of $\mathbf{A}, \nabla^0\mathbf{A}, \dots, (\nabla^0)^{r-j-1}\mathbf{A}$. For $r = 1$ the formula is (21.75). If it holds for

r, apply ∇^0: when the derivative falls on $\mathbf{C}_{r,j}$, it raises by at most one the order of a derivative of $\mathbf{A}$; when it falls on $(\nabla^{\mathbf{g}})^j\mathbf{T}$, the first identity in (21.75) gives $(\nabla^{\mathbf{g}})^{j+1}\mathbf{T}$ and $\mathbf{A}*(\nabla^{\mathbf{g}})^j\mathbf{T}$. These are precisely the terms allowed for $r+1$. Contractions are understood as the natural actions of a difference of connections on every tensor slot; they introduce no new metric derivatives.

Now suppose that $(\nabla^0)^j\mathbf{A}$ are bounded for $j \in \{0,\dots,r-1\}$, with $r \geq 1$. Identity $\nabla^0\mathbf{g} = \mathbf{A}*\mathbf{g}$ shows that derivatives of $\mathbf{g}$ up to order r are bounded: in the step from order k to $k+1$, distribute k derivatives between $\mathbf{A}$ and $\mathbf{g}$, so at most $(\nabla^0)^k\mathbf{A}$ and the already controlled derivatives of $\mathbf{g}$ occur. For $0 \leq k \leq r-1$ all these factors are available. Differentiating $\mathbf{g}^{-1}\mathbf{g} = I$ in the same way controls derivatives of $\mathbf{g}^{-1}$ up to order r, also using uniform equivalence of metrics.

Apply $(\nabla^0)^r$ to (21.76). The Leibniz rule distributes derivatives between $\mathbf{g}^{-1}$ and $\nabla^{\mathbf{g}(t)}\mathrm{Ric}$. For the second factor, (21.77) uses only derivatives of $\mathbf{A}$ up to order $r-1$ and derivatives of Riemann with respect to $\nabla^{\mathbf{g}(t)}$ up to order $r+1$. By the induction hypothesis and curvature estimates, all are bounded. Consequently,

$$\|\partial_t(\nabla^0)^r\mathbf{A}(t)\|_{L^\infty(M,T^{(1,r+2)}(TM);\mathbf{g}(0))} \leq C_r, \qquad t \in [t_0, T_{\max}).$$

If $a_r(t) := \|(\nabla^0)^r\mathbf{A}(t)\|_{L^\infty(M,T^{(1,r+2)}(TM);\mathbf{g}(0))}$, integration even gives $a_r(t) \leq a_r(t_0) + C_r(t-t_0)$ and, in particular,

$$a_r(t) \leq a_r(t_0) + C_r\int_{t_0}^{t}(1+a_r(\rho))\,d\rho. \tag{21.78}$$

This proves the inductive step. The case $r = 0$ was already obtained by integrating the evolution of $\mathbf{A}$. All derivatives of $\mathbf{A}$ with the fixed connection are bounded; the preceding identities then give those of $\mathbf{g}$, $\mathbf{g}^{-1}$, and Rm.

In particular, conversion of connections gives, for every r, a constant C_r such that

$$\|(\nabla^0)^r\partial_t\mathbf{g}(t)\|_{C^0(M,(T^*M)^{\otimes(r+2)};\mathbf{g}(0))} = 2\|(\nabla^0)^r\,\mathrm{Ric}_{\mathbf{g}(t)}\|_{C^0(M,(T^*M)^{\otimes(r+2)};\mathbf{g}(0))} \leq C_r.$$

Consequently, if $t_0 \leq t_1 < t_2 < T_{\max}$,

$$\|\mathbf{g}(t_2) - \mathbf{g}(t_1)\|_{C^r(M,S^2T^*M;\mathbf{g}(0))} \leq C_r|t_2 - t_1|. \tag{21.79}$$

Completeness of each C^r space and compatibility of the limits produce a smooth metric $\mathbf{g}_*$ such that

$$\mathbf{g}(t) \longrightarrow \mathbf{g}_* \quad \text{in } C^\infty(M) \quad \text{as } t \nearrow T_{\max}.$$

Inequality (21.74) ensures that $\mathbf{g}_*$ is positive definite.

Theorem 21.3.4, applied to $\mathbf{g}_*$, gives a solution on $[T_{\max}, T_{\max}+\varepsilon)$ with initial data $\mathbf{g}_*$. The piecewise definition is continuous, and its first time derivative agrees on both sides, since it equals $-2\,\mathrm{Ric}_{\mathbf{g}_*}$. To check all derivatives, define the differential operators $\mathcal{P}_1(\mathbf{g}) = -2\,\mathrm{Ric}_{\mathbf{g}}$ and

$$\mathcal{P}_{k+1}(\mathbf{g}) := D\mathcal{P}_k(\mathbf{g})[-2\,\mathrm{Ric}_{\mathbf{g}}], \qquad k \in \mathbb{N}.$$

If $\partial_t^k\mathbf{g} = \mathcal{P}_k(\mathbf{g})$, the chain rule gives $\partial_t^{k+1}\mathbf{g} = \mathcal{P}_{k+1}(\mathbf{g})$. Thus every time derivative is a smooth expression in the inverse metric and finitely many spatial derivatives of the metric. Convergence in all C^r spaces makes these expressions and their spatial derivatives agree with those of the new solution at $T_{\max}$. This gives a smooth

extension, contradicting maximality. This proof is also the geometric application of Theorem 20.3.4: the derivative estimates verify that no coefficient norm of the DeTurck system diverges while curvature remains bounded. This first proves that the limit superior is infinite.
If the full limit were not infinite, there would exist $K < \infty$ and $t_j \nearrow T_{\max}$ such that

$$\max_{x\in M} |\operatorname{Rm}_{\mathbf{g}(t_j)}(x)|_{\mathbf{g}(t_j)} \le K.$$

Replacing K by $\max\{K,1\}$, we may assume $K > 0$. Apply Proposition 21.5.2 to the shifted flow starting at t_j. For j large enough that $T_{\max} - t_j < (2c_m K)^{-1}$, we obtain

$$\max_{x\in M} |\operatorname{Rm}_{\mathbf{g}(t)}(x)|_{\mathbf{g}(t)} \le 2K, \qquad t_j \le t < T_{\max}.$$

Curvature is also bounded on the compact interval $[0, t_j]$. Thus there is a uniform bound on all of $[0, T_{\max})$, contradicting the first part of the proof. The conclusion is the stated limit. □

21.6 Rescalings and normalized flow

If $c > 0$ is constant and $\widehat{\mathbf{g}} = c\mathbf{g}$, the Levi–Civita connections of $\mathbf{g}$ and $\widehat{\mathbf{g}}$ agree. Consequently,

$$\operatorname{Rm}^{(1,3)}_{c\mathbf{g}} = \operatorname{Rm}^{(1,3)}_{\mathbf{g}}, \qquad \operatorname{Rm}^{(0,4)}_{c\mathbf{g}} = c\operatorname{Rm}^{(0,4)}_{\mathbf{g}}, \qquad \operatorname{Ric}_{c\mathbf{g}} = \operatorname{Ric}_{\mathbf{g}}, \qquad R_{c\mathbf{g}} = c^{-1}R_{\mathbf{g}}, \qquad d\lambda_{c\mathbf{g}} = c^{\frac{m}{2}} d\lambda_{\mathbf{g}}, \tag{21.80}$$

as well as

$$d_{c\mathbf{g}} = c^{1/2} d_{\mathbf{g}}, \qquad \operatorname{inj}_{c\mathbf{g}} = c^{1/2}\operatorname{inj}_{\mathbf{g}}, \qquad |\nabla^q_{c\mathbf{g}} \operatorname{Rm}_{c\mathbf{g}}|_{c\mathbf{g}} = c^{-1-q/2}|\nabla^q_{\mathbf{g}} \operatorname{Rm}_{\mathbf{g}}|_{\mathbf{g}}. \tag{21.81}$$

The equality $\operatorname{Ric}_{c\mathbf{g}} = \operatorname{Ric}_{\mathbf{g}}$ is an equality of covariant tensors of order two; it is important not to replace it by $c^{-1}\operatorname{Ric}_{\mathbf{g}}$.

Denote by

$$r(\mathbf{g}) = \frac{1}{\operatorname{Vol}(M,\mathbf{g})}\int_M R_{\mathbf{g}}\, d\lambda_{\mathbf{g}} \tag{21.82}$$

the average scalar curvature. The volume-normalized Ricci flow is

$$\partial_t \mathbf{g} = -2\operatorname{Ric}_{\mathbf{g}} + \frac{2}{m} r(\mathbf{g})\mathbf{g}. \tag{21.83}$$

Proposition 21.6.1. (Volume and curvature of normalized flow) Let M^m be a closed smooth manifold and let $\mathbf{g}(t)$ be a smooth solution of normalized Ricci flow (21.83). Every solution of (21.83) satisfies

$$\partial_t g_{ij} = -2\operatorname{Ric}_{ij} + \frac{2}{m} r g_{ij}, \tag{21.84}$$

$$\partial_t d\lambda_{\mathbf{g}} = (-R_{\mathbf{g}} + r) d\lambda_{\mathbf{g}}, \tag{21.85}$$

$$\frac{d}{dt}\operatorname{Vol}(M,\mathbf{g}(t)) = 0, \tag{21.86}$$

$$\partial_t R_{\mathbf{g}} = \Delta_{\mathbf{g}} R_{\mathbf{g}} + 2|\operatorname{Ric}_{\mathbf{g}}|^2_{\mathbf{g}} - \frac{2}{m} r R_{\mathbf{g}}. \tag{21.87}$$

Proof. The first identity is the component expression of (21.83). The trace of $\mathbf{h} = -2\operatorname{Ric}_{\mathbf{g}} + \frac{2}{m} r\mathbf{g}$ is $-2R_{\mathbf{g}} + 2r$. By (21.2) we obtain (21.85). Integrating this identity,

$$\frac{d}{dt}\operatorname{Vol}(M, \mathbf{g}(t)) = -\int_M R_{\mathbf{g}}\, d\lambda_{\mathbf{g}} + r\int_M d\lambda_{\mathbf{g}} = 0,$$

where definition (21.82) was used. The part $-2\operatorname{Ric}$ of $\mathbf{h}$ gives $\Delta_{\mathbf{g}} R_{\mathbf{g}} + 2|\operatorname{Ric}_{\mathbf{g}}|^2_{\mathbf{g}}$ by (21.49). For the part $\frac{2}{m} r\mathbf{g}$, the number $r(t)$ is spatially constant at each time, so both derivative terms in (21.6) vanish, while

$$-\left\langle \operatorname{Ric}_{\mathbf{g}}, \frac{2}{m} r\mathbf{g} \right\rangle_{\mathbf{g}} = -\frac{2}{m} r R_{\mathbf{g}}.$$

Their sum proves (21.87). □

Normalized flow is not a different equation from the local viewpoint. A spatial rescaling by a positive function of time, together with a change of the time variable, turns an unnormalized solution into a normalized one. Indeed, if $\mathbf{g}(t)$ solves (21.9), set

$$c(t) := \left(\frac{\operatorname{Vol}(M, \mathbf{g}(0))}{\operatorname{Vol}(M, \mathbf{g}(t))}\right)^{2/m}, \qquad \tau(t) := \int_0^t c(s)\, ds, \qquad \widehat{\mathbf{g}}(\tau(t)) := c(t)\mathbf{g}(t).$$

Then $\operatorname{Vol}(\widehat{\mathbf{g}}) = \operatorname{Vol}(\mathbf{g}(0))$. Moreover, viewing c as a function of τ and $t = t(\tau)$, we have

$$\frac{dt}{d\tau} = \frac{1}{c}, \qquad \frac{1}{c}\frac{dc}{d\tau} = \frac{2}{m} r(\widehat{\mathbf{g}}),$$

since $\partial_t \log \operatorname{Vol}(\mathbf{g}) = -r(\mathbf{g})$ and $r(c\mathbf{g}) = c^{-1} r(\mathbf{g})$. Then, using (21.80),

$$\begin{aligned} \partial_\tau \widehat{\mathbf{g}} &= \frac{dc}{d\tau}\mathbf{g} + c\frac{dt}{d\tau}\partial_t \mathbf{g} \\ &= \frac{1}{c}\frac{dc}{d\tau}\widehat{\mathbf{g}} - 2\operatorname{Ric}_{\mathbf{g}} \\ &= \frac{2}{m} r(\widehat{\mathbf{g}})\widehat{\mathbf{g}} - 2\operatorname{Ric}_{\widehat{\mathbf{g}}}. \end{aligned}$$

This gives precisely (21.83).

21.7 Einstein metrics, surfaces, and solitons

The simplest solutions combine rescalings, diffeomorphisms, and special curvature structures.

Example 21.7.1. (Einstein metrics) Let M be a closed smooth manifold and let $\mathbf{g}_0$ be a Riemannian metric on M. Suppose that $\operatorname{Ric}_{\mathbf{g}_0} = \lambda \mathbf{g}_0$, with constant λ. On the interval where $1 - 2\lambda t > 0$,

$$\mathbf{g}(t) = (1 - 2\lambda t)\mathbf{g}_0 \tag{21.88}$$

solves Ricci flow. Indeed,

$$\partial_t \mathbf{g} = -2\lambda \mathbf{g}_0, \qquad \operatorname{Ric}_{\mathbf{g}(t)} = \operatorname{Ric}_{\mathbf{g}_0} = \lambda \mathbf{g}_0.$$

If $\lambda > 0$, the homothetic solution becomes extinct at $t = \frac{1}{2\lambda}$; if $\lambda = 0$, it is stationary; if $\lambda < 0$, it exists for all $t \geq 0$ and expands. The same metric $\mathbf{g}_0$ is a fixed point of normalized flow, since $r(\mathbf{g}_0) = m\lambda$.

In particular, a metric of constant sectional curvature K is Einstein with $\lambda = (m-1)K$. Formula (21.88) describes its evolution completely.

Proposition 21.7.2. (Ricci flow in dimension two) On a closed surface,

$$\partial_t \mathbf{g} = -R\mathbf{g}, \qquad \partial_t R = \Delta R + R^2 \tag{21.89}$$

for unnormalized flow. For normalized flow,

$$\partial_t \mathbf{g} = (r - R)\mathbf{g}, \qquad \partial_t R = \Delta R + R(R - r) \tag{21.90}$$

In the latter case,

$$r = \frac{4\pi\chi(M)}{\operatorname{Vol}(M, \mathbf{g}(0))} \tag{21.91}$$

is constant in time.

Proof. In dimension two, the algebraic Riemann symmetries imply

$$\operatorname{Ric} = K\mathbf{g}, \qquad R = 2K,$$

and hence $\operatorname{Ric} = \frac{1}{2}R\mathbf{g}$. Substitution into (21.9) and (21.49) gives

$$\partial_t \mathbf{g} = -R\mathbf{g}, \qquad \partial_t R = \Delta R + 2\left|\frac{1}{2}R\mathbf{g}(t)\right|^2_{\mathbf{g}(t)} = \Delta R + R^2,$$

because $|\mathbf{g}(t)|^2_{\mathbf{g}(t)} = 2$. The normalized formulas follow in the same way from (21.83) and (21.87). If M is orientable, Theorem A.8.7 states

$$\int_M K \, d\lambda_{\mathbf{g}} = 2\pi\chi(M).$$

If M is nonorientable, apply this equality to the orientable two-sheeted covering space $\pi\colon \widetilde{M} \to M$ with the lifted metric. Since

$$\int_{\widetilde{M}} K_{\pi^*\mathbf{g}} \, d\lambda_{\pi^*\mathbf{g}} = 2\int_M K_{\mathbf{g}} \, d\lambda_{\mathbf{g}}, \qquad \chi(\widetilde{M}) = 2\chi(M),$$

the same formula holds on M. Consequently, $\displaystyle\int_M R \, d\lambda_{\mathbf{g}} = 4\pi\chi(M)$. Volume is constant by (21.86), proving (21.91). □

Definition 21.7.3. (Ricci soliton) Let M be a smooth manifold with or without boundary. A *Ricci soliton* on M is a metric $\mathbf{g}_0$ for which there exist a smooth vector field $\mathbf{X}$ and a constant λ such that

$$\operatorname{Ric}_{\mathbf{g}_0} + \frac{1}{2}\mathcal{L}_{\mathbf{X}}\mathbf{g}_0 = \lambda\mathbf{g}_0. \tag{21.92}$$

It is called shrinking, steady, or expanding according as $\lambda > 0$, $\lambda = 0$, or $\lambda < 0$. If $\mathbf{X} = \nabla^{\mathbf{g}_0} f$, the equation is

equivalent to

$$\mathrm{Ric}_{\mathbf{g}_0} + \nabla^2 f = \lambda \mathbf{g}_0 \tag{21.93}$$

and it is called a gradient soliton.

Proposition 21.7.4. (Self-similar solutions) Let M be a closed smooth manifold and let $(\mathbf{g}_0, \mathbf{X}, \lambda)$ be a Ricci soliton on M. Set

$$\sigma(t) = 1 - 2\lambda t$$

and, while $\sigma(t) > 0$, let φ_t be the family of diffeomorphisms generated by the time-dependent field

$$\mathbf{Y}_t = \frac{1}{\sigma(t)} \mathbf{X}, \qquad \varphi_0 = \mathrm{id}_M . \tag{21.94}$$

Then

$$\mathbf{g}(t) = \sigma(t) \varphi_t^* \mathbf{g}_0 \tag{21.95}$$

is a solution of Ricci flow.

Proof. The pullback differentiation rule and $\sigma'(t) = -2\lambda$ give

$$\begin{aligned} \partial_t \mathbf{g}(t) &= -2\lambda \varphi_t^* \mathbf{g}_0 + \sigma(t) \varphi_t^* (\mathcal{L}_{\mathbf{Y}_t} \mathbf{g}_0) \\ &= \varphi_t^* (-2\lambda \mathbf{g}_0 + \mathcal{L}_{\mathbf{X}} \mathbf{g}_0) \\ &= -2 \varphi_t^* \mathrm{Ric}_{\mathbf{g}_0}, \end{aligned}$$

where the last equality is (21.92). By naturality of Ricci and its invariance under constant rescaling,

$$\mathrm{Ric}_{\sigma(t)\varphi_t^* \mathbf{g}_0} = \mathrm{Ric}_{\varphi_t^* \mathbf{g}_0} = \varphi_t^* \mathrm{Ric}_{\mathbf{g}_0} .$$

Therefore, $\partial_t \mathbf{g} = -2 \mathrm{Ric}_{\mathbf{g}}$. □

Einstein metrics are the solitons with $\mathbf{X} = 0$. Solitons with $\mathbf{X} \neq 0$ also incorporate the motion by diffeomorphisms that the geometric equation does not detect in its principal symbol. Proposition 21.7.4 describes the combination of this motion with rescaling.

22

Compactness, singularities, and Perelman's theory

When curvature in a Ricci flow grows without bound, the relevant geometry concentrates in regions whose natural size tends to zero. To observe them, one chooses a point of large curvature, multiplies the metric by that scale, and reparametrizes time. If volume does not collapse and curvature derivatives remain controlled, a subsequence of these rescalings converges to a complete flow retaining the geometry of the singularity at unit scale.

This is the first chain of ideas in the chapter: Shi estimates, injectivity radius, and Hamilton compactness. The second begins with conjugate heat and Perelman's monotone quantities. The functionals $\mathcal{F}$ and $\mathcal{W}$, the quantity μ, and reduced volume prevent regions of controlled curvature from losing all their volume. In dimension three, Hamilton–Ivey pinching turns rescaling limits into ancient solutions of nonnegative curvature, the κ–solutions.

Surgery theory additionally requires a uniform description of regions of large curvature, the standard solution inserted after cutting a neck, and an inductive argument preserving pinching, noncollapsing, and canonical neighborhoods. We first study the analytic part leading to singularity limits. In the final section, we state with precise hypotheses the structural surgery and extinction theorems used to conclude the Poincaré Conjecture; for these results we follow Chapters 12–19 of [104].

Perelman introduced these tools in his 2002 and 2003 papers [114, 116, 115]. The presentation also draws on the compactness and singularity estimates in [36] and the entropy approach of [154].

Grisha Perelman and the geometry of singularities

Perelman's contribution went beyond continuing the flow through a singularity. He first found quantities distinguishing an irreversible direction of evolution; he then used noncollapsing and compactness to prove that magnifying a region of large curvature can produce only very rigid models. Surgery relies on this rigidity: one cuts where the geometry is nearly cylindrical and replaces the singular region by a cap whose behavior can be controlled. In this way, a singularity ceases to be the point where the argument ends and becomes an organized part of the evolution.

Throughout this chapter, dimension is denoted by m.

22.1 Pointed smooth convergence

A rescaled sequence rarely converges on the entire original manifold. The appropriate notion fixes a base point and requires smooth convergence only on increasingly large compact subsets of the limit space. For flows, spatial identifications must be time-independent; otherwise the limiting equation would acquire additional Lie derivative terms.

Definition 22.1.1. (Pointed smooth convergence) A sequence of pointed complete Riemannian manifolds without boundary $(M_i, \mathbf{g}_i, p_i)$ *converges smoothly in the pointed sense* to $(M_\infty, \mathbf{g}_\infty, p_\infty)$ if there exist an exhaustion

$$p_\infty \in U_1 \Subset U_2 \Subset \cdots \Subset M_\infty, \qquad \bigcup_{a=1}^{\infty} U_a = M_\infty,$$

, a sequence of integers $a_i \to \infty$, and embeddings $\Phi_i \colon U_{a_i} \to M_i$. For every $a \in \mathbb{N}$ and every i with $a \le a_i$, denote their restrictions by

$$\Phi_{i,a} \colon U_a \longrightarrow M_i, \qquad \Phi_{i,a}(p_\infty) = p_i,$$

such that

$$\Phi_{i,a}^{*}\mathbf{g}_i \longrightarrow \mathbf{g}_\infty \quad \text{in } C^\infty(U_a).$$

We also require that the images exhaust the pointed balls of the approximating spaces: for every $R > 0$ there exists $a(R)$ such that, for all sufficiently large i,

$$\overline{B_{\mathbf{g}_\infty}(p_\infty, R)} \subseteq U_{a(R)}, \qquad B_{\mathbf{g}_i}(p_i, R) \subseteq \Phi_{i,a(R)}(U_{a(R)}). \tag{22.1}$$

The notation $C^\infty(U_a)$ means uniform convergence of every derivative on each compact subset of U_a. Since $\Phi_{i,a} = \Phi_i|_{U_a}$, the identifications are compatible under restriction of domains. We work in the connected component of each base point, and the limit manifold is also taken to be connected and without boundary.

Definition 22.1.2. (Pointed convergence of flows) Let M_i and M_∞ be smooth manifolds without boundary and let $\mathbf{g}_i(t)$ be complete Ricci flows on M_i, defined on a common interval I. We say that

$$(M_i, \mathbf{g}_i(t), p_i) \longrightarrow (M_\infty, \mathbf{g}_\infty(t), p_\infty)$$

smoothly on compact spacetime subsets if the embeddings in the preceding definition are independent of t and, for every $J \Subset I$,

$$\Phi_{i,a}^{*}\mathbf{g}_i(t) \longrightarrow \mathbf{g}_\infty(t) \quad \text{in } C^\infty(U_a \times J).$$

Exhaustion of balls is also required uniformly on compact time intervals: given $J \Subset I$ and $R > 0$, one can choose $a = a(J, R)$ so that, for sufficiently large i and every $t \in J$,

$$\overline{B_{\mathbf{g}_\infty(t)}(p_\infty, R)} \subseteq U_a, \qquad B_{\mathbf{g}_i(t)}(p_i, R) \subseteq \Phi_{i,a}(U_a). \tag{22.2}$$

Lemma 22.1.3. (Passing geometry to the limit) Let M_i and M_∞ be smooth manifolds without boundary and suppose that $(M_i, \mathbf{g}_i(t), p_i)$ converges smoothly in the pointed sense to $(M_\infty, \mathbf{g}_\infty(t), p_\infty)$. Then, on every identified compact subset, the Levi–Civita connections, the Rm and Ric tensors, scalar curvatures, and all their covariant derivatives converge. Convergence also commutes with tensor products, contractions, and

traces. If the $\mathbf{g}_i(t)$ are Ricci flows and convergence is in spacetime, the limit satisfies $\partial_t \mathbf{g}_\infty = -2\operatorname{Ric}_{\mathbf{g}_\infty}$.

Proof. In a fixed chart, Christoffel symbols are smooth rational functions of g_{ij}, g^{ij}, and ∂g_{ij}. Curvature and its derivatives are obtained by iterating derivatives and products of these coefficients. C^∞ convergence allows passage to the limit in all these expressions. Tensor operations are continuous in each C^k space on compact subsets. Finally, C^∞ convergence in the time variable allows passage to the limit in the flow equation. □

The injectivity radius prevents a curvature bound from concealing collapse.

Lemma 22.1.4. (Volume, curvature, and injectivity radius) For every $m \in \mathbb{N}$ and $v > 0$ there exists $c = c(m, v) > 0$ with the following property. If $(N^m, \mathbf{h})$ is a complete Riemannian manifold without boundary,

$$|\operatorname{Rm}_{\mathbf{h}}|_{\mathbf{h}} \le r^{-2} \quad \text{en } B_{\mathbf{h}}(x, r), \qquad \operatorname{Vol}_{\mathbf{h}} B_{\mathbf{h}}(x, r) \ge v r^m,$$

then $\operatorname{inj}_{\mathbf{h}}(x) \ge cr$.

The preceding estimate is local: it involves only the geometry of the ball $B_{\mathbf{h}}(x, r)$ and completeness of the metric. Its proof, based on the short-loop lemma and comparison of the exponential Jacobian, can be found in Chapter 1, in the section *Local volume and the injectivity radius*, of [104].

Lemma 22.1.5. (Local propagation of injectivity radius) Given $m \in \mathbb{N}$, $R > 0$, $\iota_0 > 0$, and $0 \le K < \infty$, there exists $\iota = \iota(m, R, \iota_0, K) > 0$ with the following property. If $(N^m, \mathbf{h}, p)$ is a complete Riemannian manifold without boundary,

$$\operatorname{inj}_{\mathbf{h}}(p) \ge \iota_0, \qquad |\operatorname{Rm}_{\mathbf{h}}|_{\mathbf{h}} \le K \quad \text{on } B_{\mathbf{h}}(p, 2R + 2),$$

then

$$\operatorname{inj}_{\mathbf{h}}(x) \ge \iota \qquad \text{for every } x \in B_{\mathbf{h}}(p, R).$$

Proof. After increasing K by a constant depending only on dimension, we may assume that

$$\operatorname{Sec}_{\mathbf{h}} \le K, \qquad \operatorname{Ric}_{\mathbf{h}} \ge -(m-1)K\mathbf{h}$$

on the indicated ball. Choose

$$0 < r_0 < \min\left\{\frac{\iota_0}{2}, 1, \frac{\pi}{4\sqrt{K+1}}\right\}.$$

The exponential map at p is a diffeomorphism on the tangent ball of radius $2r_0$. The local Jacobi-field argument used in the proof of Theorem 13.1.8, applied on this ball, gives a constant $c_0 = c_0(m, K, r_0) > 0$ such that

$$\operatorname{Vol}_{\mathbf{h}} B_{\mathbf{h}}(p, r_0) \ge c_0 r_0^m.$$

Let $x \in B_{\mathbf{h}}(p, R)$. Since $B_{\mathbf{h}}(p, r_0) \subseteq B_{\mathbf{h}}(x, R + r_0)$, we have

$$\operatorname{Vol}_{\mathbf{h}} B_{\mathbf{h}}(x, R + r_0) \ge c_0 r_0^m.$$

Denote by $V_{-K}(s)$ the volume of a ball of radius s in the simply connected space of constant sectional

curvature $-K$. Relative Bishop–Gromov comparison, valid because $\mathrm{Ric}_{\mathbf{h}} \geq -(m-1)K\mathbf{h}$, gives

$$\frac{\mathrm{Vol}_{\mathbf{h}} B_{\mathbf{h}}(x,\rho)}{V_{-K}(\rho)} \geq \frac{\mathrm{Vol}_{\mathbf{h}} B_{\mathbf{h}}(x,R+r_0)}{V_{-K}(R+r_0)}$$

for $0 < \rho \leq R + r_0$. For this form of comparison, see [104, Chapter 1]. Take

$$\rho := \min\{1, (K+1)^{-1/2}, R+r_0\}.$$

The preceding estimate implies

$$\mathrm{Vol}_{\mathbf{h}} B_{\mathbf{h}}(x,\rho) \geq v\rho^m$$

with $v = v(m,R,\iota_0,K) > 0$. Moreover, $B_{\mathbf{h}}(x,\rho) \subseteq B_{\mathbf{h}}(p,R+1)$ and $|\mathrm{Rm}_{\mathbf{h}}| \leq K \leq \rho^{-2}$ on this ball. Lemma 22.1.4 gives

$$\mathrm{inj}_{\mathbf{h}}(x) \geq c(m,v)\rho.$$

The constant on the right is independent of x and the manifold. □

The version of Shi's estimates proved in the preceding chapter was formulated for closed manifolds. For compactness we will need the complete noncompact version.

Theorem 22.1.6. (Shi estimates for complete flows) Let $(M^m, \mathbf{g}(t))$, $t \in [s_0, s_1]$, be a complete Ricci flow and suppose that

$$\sup_{t\in[s_0,s_1]} \|\mathrm{Rm}_{\mathbf{g}(t)}\|_{L^\infty(M,\mathbf{g}(t))} \leq K < \infty.$$

For every $q \in \mathbb{N}$ and every $\delta \in (0, s_1 - s_0]$ there exists a constant $C_q = C_q(m,q,K,s_1-s_0,\delta) > 0$ such that

$$\sup_{t\in[s_0+\delta,s_1]} \|\nabla^q_{\mathbf{g}(t)} \mathrm{Rm}_{\mathbf{g}(t)}\|_{L^\infty(M,\mathbf{g}(t))} \leq C_q.$$

In particular, if $J \Subset I$ and there exists $s < \min J$ such that $[s, \max J] \subseteq I$, a uniform curvature bound on this interval gives uniform bounds for all its covariant derivatives on $M \times J$.

We will use this theorem in its complete version, proved through local estimates in [104, Chapter 3, Section 7]. The Bernstein quantities are those of Proposition 21.5.3; localization allows the maximum principle to be applied on compact domains before their radius is sent to infinity. The time margin $\delta > 0$ is essential: the constant may diverge as $\delta \to 0^+$. In particular, a curvature bound with no initial bounds for its derivatives only gives smooth convergence at times later than the initial time.

We separate from the parabolic argument the compactness theorem for a single metric.

Theorem 22.1.7. (Cheeger–Gromov pointed smooth compactness) Let $(M_i^m, \mathbf{h}_i, p_i)$ be a sequence of complete Riemannian manifolds without boundary. Suppose that there exists $\iota_0 > 0$ such that

$$\mathrm{inj}_{\mathbf{h}_i}(p_i) \geq \iota_0 \qquad \text{for every } i,$$

and that, for every $R > 0$ and $q \in \mathbb{N}_0$, there exists $C_{q,R} < \infty$ such that

$$\sup_{i\in\mathbb{N}} \|\nabla^q_{\mathbf{h}_i} \operatorname{Rm}_{\mathbf{h}_i}\|_{L^\infty(B_{\mathbf{h}_i}(p_i,R),\mathbf{h}_i)} \le C_{q,R}.$$

Then there exist a complete Riemannian manifold without boundary $(M_\infty, \mathbf{h}_\infty, p_\infty)$ and a subsequence converging smoothly to it in the pointed sense. The convergence embeddings can be chosen compatibly on an exhaustion

$$p_\infty \in U_1 \Subset U_2 \Subset \cdots \Subset M_\infty$$

satisfying the ball-exhaustion property (22.1).

Proof. Replace each M_i by the connected component of p_i. Fix $R > 0$. The hypothesis with radius $2R+4$ and Lemma 22.1.5 give $\iota_R > 0$ such that

$$\operatorname{inj}_{\mathbf{h}_i}(x) \ge \iota_R \qquad \big(x \in B_{\mathbf{h}_i}(p_i, R+1)\big)$$

for every i. Bounds for curvature derivatives on the ball of radius $R+2$, together with the local part of the proof of Theorem 13.1.8, allow a radius $\rho_R > 0$ to be chosen independently of i and the center $x \in B_{\mathbf{h}_i}(p_i, R+1)$, such that normal coordinates of radius $4\rho_R$ are defined and the coefficients of $\mathbf{h}_i$, its inverse, and all their jets are uniformly bounded in them. The same bounds hold for transitions between two such charts.

Choose in $B_{\mathbf{h}_i}(p_i, R)$ a maximal net of points separated by ρ_R. The balls of radius ρ_R centered at net points cover the pointed ball, while the concentric balls of radius $\rho_R/2$ are disjoint. The Bishop–Gromov argument used in the preceding lemma gives a uniform lower bound for the volume of each small ball. The Ricci lower bound gives, by the same comparison, a uniform upper bound for the volume of $B_{\mathbf{h}_i}(p_i, R+1)$. Consequently, the number of net points is bounded by a constant N_R independent of i. Thus, for every R, we obtain a finite atlas with uniformly bounded number of charts, common radius, and uniform bounds for all jets of the metrics and transitions.

To turn these uniform atlases into a limit manifold, apply the geometric convergence theorem of [104, Theorem 5.6]. In the complete case under consideration, its hypotheses are: a nondegenerate base point, upper volume bounds on fixed-radius balls, bounds for all curvature derivatives on these balls, and lower volume bounds at small radii. The injectivity bound verifies the first; Bishop–Gromov comparison and the preceding paragraph's construction verify the second and fourth; the third is our hypothesis. Completeness also ensures that closed balls in every approximating manifold are compact.

The theorem gives a smooth Hausdorff manifold M_∞, a metric $\mathbf{h}_\infty$, relatively compact open subsets $U_1 \Subset U_2 \Subset \cdots$, and, after choosing a subsequence, embeddings $\Phi_i \colon U_{a_i} \to M_i$, with $a_i \to \infty$. For every $a \in \mathbb{N}$, the restrictions $\Phi_{i,a} = \Phi_i|_{U_a}$ satisfy

$$\Phi_{i,a}^* \mathbf{h}_i \longrightarrow \mathbf{h}_\infty \quad \text{in } C^\infty(U_a).$$

The topological part of that theorem constructs the transition domains and embeddings simultaneously; it therefore also preserves exhaustion of balls in the approximating manifolds. This is the complete form of Cheeger–Gromov compactness stated in [104, Theorem 5.9].

In the cited construction, the atlases of radius $R+1$ cover the ball $B_{\mathbf{h}_i}(p_i, R+1)$ before the charts are restricted.

Reindexing the exhaustion gives, for every $R \in \mathbb{N}$ and all sufficiently large i,

$$\overline{B_{\mathbf{h}_\infty}(p_\infty, R)} \subseteq U_{R+1}, \qquad B_{\mathbf{h}_i}(p_i, R) \subseteq \Phi_{i,R+1}(U_{R+1}). \tag{22.3}$$

The second inclusion follows by retaining all net charts meeting the ball of radius R; the unit margin allows their domains to be restricted without leaving points of that ball outside the image. This verifies (22.1). The first inclusion also shows that every closed bounded ball in $(M_\infty, \mathbf{h}_\infty)$ is compact. The Hopf–Rinow theorem implies that $\mathbf{h}_\infty$ is complete. □

The next estimate compares different time slices of a flow.

Lemma 22.1.8. (Metric and distance distortion) Let $(M, \mathbf{g}(t))$, $t \in J$, be a Ricci flow and suppose that

$$|\mathrm{Ric}_{\mathbf{g}(t)}|_{\mathbf{g}(t)} \le K \qquad \text{on } M \times J.$$

For $s, t \in J$ we have

$$e^{-2K|t-s|}\mathbf{g}(s) \le \mathbf{g}(t) \le e^{2K|t-s|}\mathbf{g}(s), \tag{22.4}$$

and, if the distances are finite,

$$e^{-K|t-s|}d_{\mathbf{g}(s)}(x,y) \le d_{\mathbf{g}(t)}(x,y) \le e^{K|t-s|}d_{\mathbf{g}(s)}(x,y). \tag{22.5}$$

In particular,

$$B_{\mathbf{g}(s)}\big(x, e^{-K|t-s|}r\big) \subseteq B_{\mathbf{g}(t)}(x,r) \subseteq B_{\mathbf{g}(s)}\big(x, e^{K|t-s|}r\big). \tag{22.6}$$

If one metric $\mathbf{g}(s)$ is complete, every metric in the family is complete.

Proof. Fix $v \in T_xM \setminus \{0\}$. Since $\partial_t \mathbf{g} = -2\,\mathrm{Ric}_{\mathbf{g}(t)}$,

$$\left|\frac{d}{dt}\log \mathbf{g}(t)(v,v)\right| = 2\frac{|\mathrm{Ric}_{\mathbf{g}(t)}(v,v)|}{\mathbf{g}(t)(v,v)} \le 2K.$$

Integration between s and t gives

$$-2K|t-s| \le \log \frac{\mathbf{g}(t)_x(v,v)}{\mathbf{g}(s)_x(v,v)} \le 2K|t-s|.$$

The exponential function is increasing. Applying it and multiplying by $\mathbf{g}(s)_x(v,v) > 0$ yields

$$e^{-2K|t-s|}\mathbf{g}(s)_x(v,v) \le \mathbf{g}(t)_x(v,v) \le e^{2K|t-s|}\mathbf{g}(s)_x(v,v).$$

The inequality also holds for $v = 0$. Since the constants are independent of x and v, this is precisely (22.4) with the interpretation of Definition 2.1.5.
Taking square roots gives

$$e^{-K|t-s|}|v|_{\mathbf{g}(s)} \le |v|_{\mathbf{g}(t)} \le e^{K|t-s|}|v|_{\mathbf{g}(s)}.$$

For a piecewise smooth curve $\gamma\colon [a,b] \to M$, apply this bound to $v = \dot\gamma(r)$ on each smooth segment and

integrate with respect to r. The identity $L_{\mathbf{g}(t)}(\gamma) = \int_a^b |\dot\gamma(r)|_{\mathbf{g}(t)}\,dr$ gives

$$e^{-K|t-s|}L_{\mathbf{g}(s)}(\gamma) \le L_{\mathbf{g}(t)}(\gamma) \le e^{K|t-s|}L_{\mathbf{g}(s)}(\gamma).$$

Taking the infimum over curves joining x to y yields (22.5); the ball inclusions are an immediate consequence.

Suppose that $\mathbf{g}(s)$ is complete. A Cauchy sequence for $d_{\mathbf{g}(t)}$ is Cauchy for $d_{\mathbf{g}(s)}$ by (22.5) and therefore converges with respect to $d_{\mathbf{g}(s)}$. The two distances induce the same topology, and the second inequality in (22.5) gives convergence with respect to $d_{\mathbf{g}(t)}$. Thus $\mathbf{g}(t)$ is complete. □

We also need to turn Shi's covariant bounds into coefficient bounds in time-independent coordinates.

Lemma 22.1.9. (Control with respect to a reference connection) Let $J \subseteq \mathbb{R}$ be a compact interval containing 0 and let $\mathbf{g}_i(t)$ be Ricci flows defined on open subsets V_i, with $\mathbf{h}_i := \mathbf{g}_i(0)$. Suppose that the metrics $\mathbf{h}_i$ have uniform bounds for all jets of their coefficients and inverses in fixed charts over V_i. Also suppose that, for every $q \in \mathbb{N}_0$, there exists C_q such that

$$\sup_{i\in\mathbb{N}}\sup_{t\in J}\|\nabla^q_{\mathbf{g}_i(t)}\operatorname{Rm}_{\mathbf{g}_i(t)}\|_{L^\infty(V_i,\mathbf{g}_i(t))} \le C_q.$$

Then, in each coordinate subdomain whose closure lies within the fixed charts, all coefficients of $\mathbf{g}_i(t)$ and $\mathbf{g}_i(t)^{-1}$ and all their spatial and time derivatives are uniformly bounded on J.

Proof. The order-zero curvature bound gives $|\operatorname{Ric}_{\mathbf{g}_i(t)}|_{\mathbf{g}_i(t)} \le K := \sqrt{m}\,C_0$ for all indices and times. Since $0 \in J$, Lemma 22.1.8 implies, with $Q = e^{2K\operatorname{diam} J}$,

$$Q^{-1}(\mathbf{h}_i)_x(v,v) \le \mathbf{g}_i(t)_x(v,v) \le Q(\mathbf{h}_i)_x(v,v) \qquad (i\in\mathbb{N},\ t\in J,\ x\in V_i,\ v\in T_xV_i).$$

By Proposition 7.1.9, norms of the same tensor of fixed type are comparable with constants independent of i,x,t. This allows the metric used in a tensor bound to be changed; to change covariant derivatives, we study the difference of connections. Let $\nabla^i(t)$ and $\nabla^{i,0}$ be their Levi–Civita connections and set

$$\mathbf{A}_i(t) := \nabla^i(t) - \nabla^{i,0}.$$

Then $\mathbf{A}_i(0) = 0$, and identity (21.37) takes the form

$$\partial_t\mathbf{A}_i = -\mathbf{g}_i(t)^{-1} * \nabla^i(t)\operatorname{Ric}_{\mathbf{g}_i(t)}. \tag{22.7}$$

Moreover,

$$\nabla^{i,0}\mathbf{T} = \nabla^i(t)\mathbf{T} + \mathbf{A}_i * \mathbf{T}, \qquad \nabla^{i,0}\mathbf{g}_i(t) = \mathbf{A}_i * \mathbf{g}_i(t). \tag{22.8}$$

Write $D_i = \nabla^{i,0}$ and $\nabla_i = \nabla^i(t)$. The difference of connections acts on every tensor slot as in Chapter 9. Apply the formula already proved in (21.77): for every integer $r \ge 1$,

$$D_i^r\mathbf{T} = \nabla_i^r\mathbf{T} + \sum_{j=0}^{r-1}\mathbf{C}_{i,r,j} * \nabla_i^j\mathbf{T}. \tag{22.9}$$

Each coefficient $\mathbf{C}_{i,r,j}$ is a finite sum of products of $D_i^b \mathbf{A}_i$ with $b \in \{0,\dots,r-j-1\}$; the number of terms depends only on r, dimension, and the type of $\mathbf{T}$. The Leibniz rule of Proposition 9.1.40 and the contraction estimates in the chapter on bundles bound these products by the norms of their factors.

The induction starts at $r = 0$. The evolution of $\mathbf{A}_i$ and the bound for $\nabla_i \operatorname{Ric}$ give $\|\partial_t \mathbf{A}_i(t)\|_{L^\infty(V_i, T^{(1,2)}(TV_i); \mathbf{h}_i)} \le C$. Integrating from 0 and using $\mathbf{A}_i(0) = 0$ yields $\|\mathbf{A}_i(t)\|_{L^\infty(V_i, T^{(1,2)}(TV_i); \mathbf{h}_i)} \le C|J|$.

Now let $r \ge 1$ and suppose that the derivatives $D_i^b \mathbf{A}_i$ are bounded uniformly in i and $t \in J$ for $b \in \{0,\dots,r-1\}$. Define $\mathbf{F}_i = \partial_t \mathbf{A}_i$. Equation (22.7) expresses $\mathbf{F}_i$ as contractions of $\mathbf{g}_i^{-1}$ and $\nabla_i \operatorname{Ric}$. Since $\nabla_i \mathbf{g}_i = 0$, for each $j \in \{0,\dots,r\}$, $\nabla_i^j \mathbf{F}_i$ contains only Ricci derivatives of order $j+1$ contracted with the inverse metric. All are bounded by the curvature hypothesis. Applying (22.9) to $\mathbf{T} = \mathbf{F}_i$, the additional coefficients contain only derivatives of $\mathbf{A}_i$ of order at most $r-1$. By the induction hypothesis,

$$\|\partial_t D_i^r \mathbf{A}_i(t)\|_{L^\infty(V_i, T^{(1,r+2)}(TV_i); \mathbf{h}_i)} = \|D_i^r \mathbf{F}_i(t)\|_{L^\infty(V_i, T^{(1,r+2)}(TV_i); \mathbf{h}_i)} \le C_r, \qquad i \in \mathbb{N}, \quad t \in J.$$

Since $D_i^r \mathbf{A}_i(0) = 0$, integration toward either endpoint of J gives $\|D_i^r \mathbf{A}_i(t)\|_{L^\infty(V_i, T^{(1,r+2)}(TV_i); \mathbf{h}_i)} \le C_r|J|$. This proves the step from $r-1$ to r without introducing a derivative of $\mathbf{A}_i$ of higher order than the one controlled.

Now apply (22.9) to $\mathbf{T} = \mathbf{g}_i$ and $\mathbf{T} = \mathbf{g}_i^{-1}$. All their positive-order derivatives with respect to ∇_i vanish. Thus $D_i^r \mathbf{g}_i$ and $D_i^r \mathbf{g}_i^{-1}$ are expressed in terms of $\mathbf{C}_{i,r,0}$ and already bounded order-zero tensors. The local expression for higher covariant derivatives in Lemma 9.1.28, applied to the fixed connection D_i, converts these bounds into coordinate derivative bounds. Its coefficients are uniform because the jets of $\mathbf{h}_i$ and $\mathbf{h}_i^{-1}$ are uniform by hypothesis.

For time derivatives, use the coordinate expression for Ricci: it is a finite sum of products of coefficients of $\mathbf{g}_i^{-1}$, first derivatives of $\mathbf{g}_i$, and second derivatives of $\mathbf{g}_i$. Suppose that all spatial derivatives of $\partial_t^b \mathbf{g}_i$ and $\partial_t^b \mathbf{g}_i^{-1}$ are controlled for $b \in \{0,\dots,a\}$. Applying ∂_t^a to $\partial_t \mathbf{g}_i = -2\operatorname{Ric}_{\mathbf{g}_i}$, each product of d factors is differentiated by

$$\partial_t^a (F_1 \cdots F_d) = \sum_{\substack{(b_1,\dots,b_d) \in \mathbb{N}_0^d \\ b_1+\cdots+b_d = a}} \frac{a!}{b_1! \cdots b_d!} (\partial_t^{b_1} F_1) \cdots (\partial_t^{b_d} F_d).$$

All time indices on the right-hand side are at most a. The induction hypothesis therefore bounds all spatial derivatives of $\partial_t^{a+1} \mathbf{g}_i$. Differentiating the matrix identity $\mathbf{g}_i^{-1} \mathbf{g}_i = I$ then gives

$$\partial_t^{a+1} \mathbf{g}_i^{-1} = -\sum_{b=0}^{a} \binom{a+1}{b} (\partial_t^b \mathbf{g}_i^{-1})(\partial_t^{a+1-b} \mathbf{g}_i) \mathbf{g}_i^{-1}.$$

All factors here are also controlled, even after spatial derivatives are applied. The initial case $a = 0$ is the spatial control already proved. Bounds for all mixed orders follow. □

Theorem 22.1.10. (Hamilton compactness) Let M_i be smooth manifolds without boundary of dimension m and let $(M_i, \mathbf{g}_i(t), p_i)$ be complete Ricci flows defined on a common interval I, open on the left, with $0 \in I$ and $\inf I < 0$. The interval I may contain its right endpoint, in particular $I = (a, 0]$ with $-\infty \le a < 0$. In this statement, $J \Subset I$ denotes a compact interval contained in I; it may include the right endpoint if this belongs to I. Suppose that

$$\operatorname{inj}_{\mathbf{g}_i(0)}(p_i) \ge \iota_0 > 0.$$

Also suppose that, for every $J \Subset I$, there exists $C(J) < \infty$ such that

$$\sup_{i\in\mathbb{N}} \sup_{t\in J} \|\operatorname{Rm}_{\mathbf{g}_i(t)}\|_{L^\infty(M_i,\mathbf{g}_i(t))} \le C(J).$$

Then a subsequence converges smoothly, in the pointed sense and on compact spacetime subsets, to a complete Ricci flow

$$(M_\infty, \mathbf{g}_\infty(t), p_\infty), \qquad t \in I,$$

where M_∞ is a smooth manifold without boundary and $\mathbf{g}_\infty(t)$ is complete for every t.

Proof. Set $\mathbf{h}_i := \mathbf{g}_i(0)$. First extract a limit of the time slices at $t = 0$. Fix $q \in \mathbb{N}_0$ and choose $s < 0$ with $[s, 0] \subseteq I$. The hypothesis gives a uniform curvature bound on $M_i \times [s, 0]$. If $q \ge 1$, apply Theorem 22.1.6 to the shifted flow starting at s and evaluate at $t = 0$; for $q = 0$, use the hypothesis directly. We obtain a constant C_q independent of i such that

$$\|\nabla^q_{\mathbf{h}_i} \operatorname{Rm}_{\mathbf{h}_i}\|_{L^\infty(M_i,\mathbf{h}_i)} \le C_q, \qquad i \in \mathbb{N}.$$

Together with the injectivity radius bound at p_i, these estimates verify the hypotheses of Theorem 22.1.7. After passing to a subsequence, there exist a complete Riemannian manifold $(M_\infty, \mathbf{h}_\infty, p_\infty)$, an exhaustion

$$p_\infty \in U_1 \Subset U_2 \Subset \cdots \Subset M_\infty$$

, and compatible embeddings

$$\Phi_{i,a} \colon U_a \longrightarrow M_i, \qquad \Phi_{i,a}(p_\infty) = p_i,$$

such that

$$\Phi^*_{i,a}\mathbf{h}_i \longrightarrow \mathbf{h}_\infty \quad \text{in } C^\infty(U_a). \tag{22.10}$$

Now fix $a \in \mathbb{N}$, a compact set $K \Subset U_a$, and a compact interval $J \Subset I$. Let $\widetilde{J} \Subset I$ be a compact interval containing $J \cup \{0\}$. Choose $s < \min \widetilde{J}$ so that $[s, \max \widetilde{J}] \subseteq I$. The curvature bound on this interval and Theorem 22.1.6 give, for every $q \in \mathbb{N}_0$, constants $C_{q,\widetilde{J}}$ such that

$$\sup_{i\in\mathbb{N}} \sup_{t\in\widetilde{J}} \|\nabla^q_{\mathbf{g}_i(t)} \operatorname{Rm}_{\mathbf{g}_i(t)}\|_{L^\infty(M_i,\mathbf{g}_i(t))} \le C_{q,\widetilde{J}}. \tag{22.11}$$

Consider on U_a the metrics

$$\widehat{\mathbf{g}}_{i,a}(t) := \Phi^*_{i,a}\mathbf{g}_i(t), \qquad \widehat{\mathbf{h}}_{i,a} := \widehat{\mathbf{g}}_{i,a}(0).$$

By (22.10), in any finite atlas covering K, the coefficients of $\widehat{\mathbf{h}}_{i,a}$ and their inverses have uniform bounds of all orders. The estimates (22.11) are preserved under pullback. Lemma 22.1.9, applied on $\widetilde{J}$, then shows that on $K \times J$ all coefficients of $\widehat{\mathbf{g}}_{i,a}(t)$ and all their spatial and time derivatives are uniformly bounded. Metric distortion also ensures a uniform lower bound for these positive definite tensors.
Exhaust each U_a by compact sets and I by compact intervals. Arzelà–Ascoli, applied successively to all coefficient derivatives in finitely many charts, and a diagonal argument give a subsequence for which

$$\Phi^*_{i,a}\mathbf{g}_i(t) \longrightarrow \mathbf{g}_\infty(t) \quad \text{in } C^\infty(K \times J) \tag{22.12}$$

for every a, every $K \Subset U_a$, and every $J \Subset I$. Compatibility of the embeddings $\Phi_{i,a}$ makes the limits obtained on U_a and U_{a+1} agree on U_a; they therefore define a global family of smooth metrics $\mathbf{g}_\infty(t)$ on M_∞. At $t = 0$, identity (22.10) gives $\mathbf{g}_\infty(0) = \mathbf{h}_\infty$. Lemma 22.1.3, applied to (22.12), shows that

$$\partial_t \mathbf{g}_\infty(t) = -2\,\mathrm{Ric}_{\mathbf{g}_\infty(t)}.$$

Let us also verify uniform exhaustion of balls. Fix $J \Subset I$ and $R > 0$. Let $\widehat{J}$ be the compact interval joining J to 0. The curvature bound on $M_i \times \widehat{J}$ bounds $|\mathrm{Ric}|$ by a constant K_J independent of i. By (22.5), for every $t \in J$,

$$B_{\mathbf{g}_i(t)}(p_i, R) \subseteq B_{\mathbf{h}_i}(p_i, e^{K_J|t|}R).$$

The exhaustion property of the static limit allows a common U_a to be chosen whose image contains the balls on the right for all $t \in J$. Passing to the limit, the analogous inequality between $\mathbf{g}_\infty(t)$ and $\mathbf{h}_\infty$ shows that the same U_a contains $\overline{B_{\mathbf{g}_\infty(t)}(p_\infty, R)}$. Thus (22.2) holds, establishing pointed smooth convergence on compact spacetime subsets.

It remains to prove completeness of each slice. Fix $t \in I$ and choose a compact interval $J \Subset I$ containing 0 and t. The curvature bound gives $K_J < \infty$ such that

$$|\mathrm{Ric}_{\mathbf{g}_i(\rho)}|_{\mathbf{g}_i(\rho)} \le K_J \qquad ((x,\rho) \in M_i \times J)$$

for every i. By Lemma 22.1.8,

$$e^{-2K_J|t|}\mathbf{h}_i \le \mathbf{g}_i(t) \le e^{2K_J|t|}\mathbf{h}_i.$$

Pull back by $\Phi_{i,a}$ and pass to the limit. Since the U_a cover M_∞, we obtain

$$e^{-2K_J|t|}\mathbf{h}_\infty \le \mathbf{g}_\infty(t) \le e^{2K_J|t|}\mathbf{h}_\infty \quad \text{on } M_\infty.$$

The metric $\mathbf{h}_\infty$ is complete by the static compactness theorem; the last assertion of Lemma 22.1.8 implies that $\mathbf{g}_\infty(t)$ is also complete. □

22.2 Rescalings and singularity models

The preceding compactness theorem becomes useful once the correct scale is chosen. At a point where $|\mathrm{Rm}| = Q$, the metric $Q\mathbf{g}$ makes the curvature have size one. Time must be multiplied by the same factor to preserve the Ricci equation. The following formulas fix all conventions used for singularity limits.

Definition 22.2.1. (Temporal types of solutions) Let M be a smooth manifold without boundary and let $\mathbf{g}(t)$ be a solution of Ricci flow on M. For a problem with initial data at $t = 0$, the solution is *forward maximal* if it admits no smooth extension beyond its right time endpoint. This is the meaning of maximality used for flows on $[0, T)$. Independently of this property, a solution is called *ancient* if its time interval has left endpoint $-\infty$, for example $(-\infty, T]$; *eternal* if defined on $\mathbb{R}$, and *immortal* if defined on $[0, \infty)$. A *rescaling limit model* is a nonflat pointed smooth limit of parabolic rescalings about points whose curvature tends to infinity.

Suppose the original flow is defined on $[0,T)$. Let $(x_i,t_i)\in M\times[0,T)$, with $i\in\mathbb{N}$, and set

$$Q_i := |\mathrm{Rm}_{\mathbf{g}(t_i)}|_{\mathbf{g}(t_i)}(x_i) > 0.$$

The parabolic rescaling centered at (x_i,t_i) is

$$\mathbf{g}_i(s) := Q_i\,\mathbf{g}\Big(t_i+\frac{s}{Q_i}\Big), \qquad s\in\big[-Q_i t_i, Q_i(T-t_i)\big). \tag{22.13}$$

For each $i\in\mathbb{N}$ and $q\in\mathbb{N}_0$, the scaling laws are

$$\begin{aligned}
s &= Q_i(t-t_i), & \mathbf{g}_i &= Q_i\mathbf{g}, & d_{\mathbf{g}_i} &= Q_i^{1/2} d_{\mathbf{g}},\\
d\lambda_{\mathbf{g}_i} &= Q_i^{m/2} d\lambda_{\mathbf{g}}, & \mathrm{inj}_{\mathbf{g}_i} &= Q_i^{1/2}\,\mathrm{inj}_{\mathbf{g}}, & R_{\mathbf{g}_i} &= Q_i^{-1} R_{\mathbf{g}},\\
\mathrm{Rm}^{(1,3)}_{\mathbf{g}_i} &= \mathrm{Rm}^{(1,3)}_{\mathbf{g}}, & \mathrm{Rm}^{(0,4)}_{\mathbf{g}_i} &= Q_i\,\mathrm{Rm}^{(0,4)}_{\mathbf{g}}, & \mathrm{Ric}_{\mathbf{g}_i} &= \mathrm{Ric}_{\mathbf{g}},\\
|\nabla^q_{\mathbf{g}_i(s)}\mathrm{Rm}_{\mathbf{g}_i(s)}|_{\mathbf{g}_i(s)} &= Q_i^{-1-q/2}|\nabla^q_{\mathbf{g}(t_i+s/Q_i)}\mathrm{Rm}_{\mathbf{g}(t_i+s/Q_i)}|_{\mathbf{g}(t_i+s/Q_i)}.
\end{aligned} \tag{22.14}$$

In particular, $|\mathrm{Rm}_{\mathbf{g}_i(0)}|_{\mathbf{g}_i(0)}(x_i)=1$. Moreover,

$$\partial_s\mathbf{g}_i = Q_i\frac{1}{Q_i}\partial_t\mathbf{g}\Big(t_i+\frac{s}{Q_i}\Big) = -2\,\mathrm{Ric}_{\mathbf{g}(t_i+s/Q_i)} = -2\,\mathrm{Ric}_{\mathbf{g}_i},$$

so the flow is invariant.

The choice of points cannot be arbitrary. If

$$Q_i = |\mathrm{Rm}_{\mathbf{g}(t_i)}|_{\mathbf{g}(t_i)}(x_i) = \max_{(x,t)\in M\times[0,t_i]}|\mathrm{Rm}_{\mathbf{g}(t)}|_{\mathbf{g}(t)}(x), \qquad t_i\nearrow T, \tag{22.15}$$

then

$$|\mathrm{Rm}_{\mathbf{g}_i(s)}|_{\mathbf{g}_i(s)}\le 1 \quad \text{for } -Q_i t_i\le s\le 0, \qquad |\mathrm{Rm}_{\mathbf{g}_i(0)}|_{\mathbf{g}_i(0)}(x_i)=1.$$

Shi estimates control all derivatives on compact subintervals of $(-\infty,0]$. A lower injectivity radius bound is still needed; we will obtain it from Perelman's noncollapsing. Hamilton compactness will then produce a complete nonflat ancient solution.

22.3 Heat with a time-dependent metric

Perelman's monotone quantities are constructed by coupling Ricci flow with a backward heat equation. Since Riemannian measure is also time-dependent, the spacetime adjoint is not $-\partial_t-\Delta$; a scalar curvature term appears to compensate for volume variation.

For a Ricci flow define

$$\Box := \partial_t - \Delta_{\mathbf{g}(t)}.$$

The measure evolution, proved in (21.36), is $\partial_t d\lambda_{\mathbf{g}(t)} = -R_{\mathbf{g}(t)}\,d\lambda_{\mathbf{g}(t)}$.

Proposition 22.3.1. (Spacetime adjoint) If u, v are smooth and M is closed, then

$$\int_{t_1}^{t_2}\int_M v\,\Box u\,d\lambda_{\mathbf{g}(t)}dt = \Big[\int_M uv\,d\lambda_{\mathbf{g}(t)}\Big]_{t_1}^{t_2} + \int_{t_1}^{t_2}\int_M u\,\Box^* v\,d\lambda_{\mathbf{g}(t)}dt, \tag{22.16}$$

where

$$\Box^* := -\partial_t - \Delta_{\mathbf{g}(t)} + R_{\mathbf{g}(t)}. \tag{22.17}$$

Thus the conjugate equation is

$$\Box^* u = 0, \qquad \partial_t u = -\Delta_{\mathbf{g}(t)}u + R_{\mathbf{g}(t)}u.$$

Every positive solution of this equation preserves $\int_M u\,d\lambda_{\mathbf{g}(t)}$.

Proof. Differentiating the time pairing gives

$$\frac{d}{dt}\int_M uv\,d\lambda_{\mathbf{g}(t)} = \int_M (u_t v + u v_t - R_{\mathbf{g}(t)}uv)\,d\lambda_{\mathbf{g}(t)}.$$

Spatial self-adjointness of $\Delta_{\mathbf{g}(t)}$ and integration in time give (22.16). If $\Box^* u = 0$, then

$$\frac{d}{dt}\int_M u\,d\lambda_{\mathbf{g}(t)} = \int_M \big(-\Delta_{\mathbf{g}(t)}u + R_{\mathbf{g}(t)}u - R_{\mathbf{g}(t)}u\big)\,d\lambda_{\mathbf{g}(t)} = 0.$$

□

Time dependence prevents use of an autonomous semigroup. For $s \le t$ write $U(t,s)$ for the propagator of $\partial_t u = \Delta_{\mathbf{g}(t)}u$. It satisfies

$$U(t,r)U(r,s) = U(t,s), \qquad s \le r \le t,$$

but does not depend only on $t-s$. Its two-time kernel $H(x,t;y,s)$ satisfies the same composition law, integrating over the intermediate slice. The adjoint of $U(t,s)$ propagates backward through $\Box^*$; in general there is no symmetry under simultaneous interchange of (x,t) and (y,s). The construction follows by applying the parabolic theory of Chapter 20 on short intervals and composing the evolution operators.

22.4 The functional $\mathcal{F}$

Perelman's variational description considers a metric and a density simultaneously. The auxiliary function f allows the weighted measure to be fixed and introduces an energy whose derivative along the flow is a square.

Let M be closed. For $f \in C^\infty(M)$ define

$$\mathcal{F}(\mathbf{g}, f) := \int_M \big(R_{\mathbf{g}} + |\nabla f|_{\mathbf{g}}^2\big)e^{-f}\,d\lambda_{\mathbf{g}}. \tag{22.18}$$

The natural normalization is $\int_M e^{-f}\,d\lambda_{\mathbf{g}} = 1$.

Before differentiating $\mathcal{F}$, collect the integrations by parts explaining the Hessian terms that will appear.

Lemma 22.4.1. (Integration by parts with the weighted measure) Let M be a closed smooth manifold, let $f \in C^\infty(M)$, and let $\mathbf{h}$ be a symmetric covariant tensor of order two. Then

$$\int_M \operatorname{div}_{\mathbf{g}}^2 \mathbf{h}\, e^{-f}\, d\lambda_{\mathbf{g}} = \int_M \left[-\langle \mathbf{h}, \nabla_{\mathbf{g}}^2 f\rangle_{\mathbf{g}} + \mathbf{h}(\nabla^{\mathbf{g}} f, \nabla^{\mathbf{g}} f)\right] e^{-f}\, d\lambda_{\mathbf{g}}, \tag{22.19}$$

$$-\int_M \Delta_{\mathbf{g}}(\operatorname{tr}_{\mathbf{g}} \mathbf{h}) e^{-f}\, d\lambda_{\mathbf{g}} = \int_M \operatorname{tr}_{\mathbf{g}} \mathbf{h}\left(\Delta_{\mathbf{g}} f - |\nabla f|_{\mathbf{g}}^2\right) e^{-f}\, d\lambda_{\mathbf{g}}, \tag{22.20}$$

$$2\int_M \langle \nabla^{\mathbf{g}} f, \nabla^{\mathbf{g}} \varphi\rangle_{\mathbf{g}} e^{-f}\, d\lambda_{\mathbf{g}} = -2\int_M \varphi\left(\Delta_{\mathbf{g}} f - |\nabla f|_{\mathbf{g}}^2\right) e^{-f}\, d\lambda_{\mathbf{g}}. \tag{22.21}$$

Proof. For the first identity, integrate the two divergences successively:

$$\begin{aligned}\int_M \sum_{i,j=1}^m \nabla^i \nabla^j h_{ij}\, e^{-f}\, d\lambda_{\mathbf{g}} &= \int_M \sum_{i,j=1}^m (\nabla^j h_{ij}) \nabla^i f\, e^{-f}\, d\lambda_{\mathbf{g}} \\ &= -\int_M \sum_{i,j=1}^m h_{ij} \nabla^j (\nabla^i f\, e^{-f})\, d\lambda_{\mathbf{g}}.\end{aligned}$$

Since $\nabla^j(\nabla^i f\, e^{-f}) = (\nabla^2 f)^{ij} e^{-f} - \nabla^i f \nabla^j f\, e^{-f}$, we obtain (22.19). If $q = \operatorname{tr}_{\mathbf{g}} \mathbf{h}$, then

$$-\int_M (\Delta_{\mathbf{g}} q) e^{-f}\, d\lambda_{\mathbf{g}} = -\int_M \langle \nabla q, \nabla f\rangle_{\mathbf{g}} e^{-f}\, d\lambda_{\mathbf{g}}.$$

Integrating the divergence of $q e^{-f} \nabla^{\mathbf{g}} f$ gives (22.20). The same calculation with $q = 2\varphi$ proves (22.21). □

Proposition 22.4.2. (First variation of $\mathcal{F}$) Let M be a closed smooth manifold. For a metric $\mathbf{g}$, a function $f \in C^\infty(M)$, and variations $\mathbf{h} = \delta\mathbf{g}$, $\varphi = \delta f$, we have

$$D\mathcal{F}_{(\mathbf{g},f)}[\mathbf{h}, \varphi] = \int_M \left[-\langle \mathbf{h}, \operatorname{Ric}_{\mathbf{g}} + \nabla_{\mathbf{g}}^2 f\rangle_{\mathbf{g}} + \left(\frac{1}{2}\operatorname{tr}_{\mathbf{g}} \mathbf{h} - \varphi\right)\left(2\Delta_{\mathbf{g}} f - |\nabla f|_{\mathbf{g}}^2 + R_{\mathbf{g}}\right)\right] e^{-f}\, d\lambda_{\mathbf{g}}. \tag{22.22}$$

Proof. The variation formulas of the preceding chapter give

$$\begin{aligned}\delta R_{\mathbf{g}} &= -\langle \mathbf{h}, \operatorname{Ric}_{\mathbf{g}}\rangle_{\mathbf{g}} + \operatorname{div}_{\mathbf{g}}^2 \mathbf{h} - \Delta_{\mathbf{g}} \operatorname{tr}_{\mathbf{g}} \mathbf{h}, \\ \delta|\nabla f|_{\mathbf{g}}^2 &= -\mathbf{h}(\nabla^{\mathbf{g}} f, \nabla^{\mathbf{g}} f) + 2\langle \nabla^{\mathbf{g}} f, \nabla^{\mathbf{g}} \varphi\rangle_{\mathbf{g}}, \\ \delta(e^{-f}\, d\lambda_{\mathbf{g}}) &= \left(\frac{1}{2}\operatorname{tr}_{\mathbf{g}} \mathbf{h} - \varphi\right) e^{-f}\, d\lambda_{\mathbf{g}}.\end{aligned}$$

Substituting into (22.18), the sum of terms containing derivatives of $\mathbf{h}$ becomes, by (22.19) and (22.20),

$$-\langle \mathbf{h}, \nabla^2 f\rangle + \mathbf{h}(\nabla f, \nabla f) + \operatorname{tr}_{\mathbf{g}} \mathbf{h}(\Delta f - |\nabla f|^2).$$

The second summand cancels the metric variation in $|\nabla f|^2$ exactly. By (22.21), the term containing $\nabla\varphi$ becomes $-2\varphi(\Delta f - |\nabla f|^2)$. Adding the measure variation, the coefficients of $\operatorname{tr}_{\mathbf{g}} \mathbf{h}$ and φ are, respectively,

$$\frac{1}{2}(2\Delta f - |\nabla f|^2 + R), \qquad -(2\Delta f - |\nabla f|^2 + R).$$

This proves (22.22). □

Theorem 22.4.3. (Monotonicity of $\mathcal{F}$) Let M be a closed smooth manifold and suppose that

$$\partial_t \mathbf{g} = -2\,\mathrm{Ric}_{\mathbf{g}(t)}, \qquad \partial_t f = -\Delta_{\mathbf{g}(t)} f + |\nabla f|^2_{\mathbf{g}(t)} - R_{\mathbf{g}(t)}. \tag{22.23}$$

Then $u = e^{-f}$ satisfies $\Box^* u = 0$ and

$$\frac{d}{dt}\mathcal{F}(\mathbf{g}(t), f(t)) = 2\int_M |\mathrm{Ric}_{\mathbf{g}(t)} + \nabla^2_{\mathbf{g}(t)} f|^2_{\mathbf{g}(t)} e^{-f}\, d\lambda_{\mathbf{g}(t)} \geq 0. \tag{22.24}$$

Equality on an interval characterizes, modulo diffeomorphisms, a steady gradient soliton. On a closed manifold, such a soliton is Ricci-flat and f is constant on every connected component.

Proof. The equation for f implies

$$\partial_t(e^{-f}) = (\Delta f - |\nabla f|^2 + R)e^{-f} = -\Delta(e^{-f}) + Re^{-f},$$

so $\Box^* u = 0$. Let φ_t be the diffeomorphisms generated by $-\nabla^{\mathbf{g}(t)} f$. By naturality of Ricci and the Hessian, the pullback of $(\mathbf{g}, f)$ satisfies

$$\partial_t \mathbf{g} = -2(\mathrm{Ric}_{\mathbf{g}} + \nabla^2_{\mathbf{g}} f), \qquad \partial_t f = -\Delta_{\mathbf{g}} f - R_{\mathbf{g}}.$$

In this gauge, $\frac{1}{2}\,\mathrm{tr}_{\mathbf{g}}(\partial_t \mathbf{g}) - \partial_t f = 0$; thus the measure $e^{-f} d\lambda_{\mathbf{g}}$ remains fixed pointwise. Apply (22.22) with $\mathbf{h} = -2(\mathrm{Ric} + \nabla^2 f)$ and $\varphi = -\Delta f - R$. The second variation term vanishes, and the first is the right-hand side of (22.24). Diffeomorphism invariance of $\mathcal{F}$ returns the formula to the original flow.

If equality holds, then $\mathrm{Ric} + \nabla^2 f = 0$. Taking the trace and integrating gives $\int_M R\, d\lambda_{\mathbf{g}} = 0$. Naturality of scalar curvature and its evolution equation give

$$\Delta_f R := \Delta R - \langle \nabla f, \nabla R \rangle = -2|\mathrm{Ric}|^2.$$

The measure $e^{-f} d\lambda_{\mathbf{g}}$ makes Δ_f symmetric, so the integral of the left-hand side is zero. We conclude that $\mathrm{Ric} = 0$ and then $\nabla^2 f = 0$. A function with zero Hessian on a closed manifold is constant on every connected component. □

22.5 The entropy $\mathcal{W}$ and the quantity μ

The functional $\mathcal{F}$ is not invariant under parabolic rescaling. The entropy $\mathcal{W}$ incorporates a time scale $\tau > 0$ and a Boltzmann entropy term so that the entire expression remains invariant when $\mathbf{g}$ and τ are multiplied by the same constant.

Let

$$u = (4\pi\tau)^{-m/2} e^{-f}, \qquad \int_M u\, d\lambda_{\mathbf{g}} = 1,$$

and define

$$\mathcal{W}(\mathbf{g}, f, \tau) := \int_M \left[\tau(R_{\mathbf{g}} + |\nabla f|^2_{\mathbf{g}}) + f - m\right] u\, d\lambda_{\mathbf{g}}. \tag{22.25}$$

Lemma 22.5.1. (Boltzmann entropy and $\mathcal{F}$) Suppose that $\mathbf{g}(t)$ solves Ricci flow and a positive function u satisfies $\Box^* u = 0$ and $\int_M u \, d\lambda_{\mathbf{g}(t)} = 1$. If

$$\mathcal{B}(t) := \int_M u \log u \, d\lambda_{\mathbf{g}(t)}, \qquad \mathcal{F}(t) := \int_M \left(\frac{|\nabla u|^2}{u} + Ru \right) d\lambda_{\mathbf{g}(t)},$$

then $\mathcal{B}'(t) = \mathcal{F}(t)$.

Proof. Use $u_t = -\Delta u + Ru$ and $\partial_t d\lambda_{\mathbf{g}} = -R \, d\lambda_{\mathbf{g}}$. Differentiation under the integral gives

$$\mathcal{B}'(t) = \int_M \left[u_t (1 + \log u) - Ru \log u \right] d\lambda_{\mathbf{g}} = \int_M \left[-\Delta u (1 + \log u) + Ru \right] d\lambda_{\mathbf{g}}.$$

The integral of Δu is zero and $-\int_M (\Delta u) \log u = \int_M |\nabla u|^2 / u$. This proves the identity. □

Theorem 22.5.2. (Monotonicity of $\mathcal{W}$) Let M^m be a closed smooth manifold. Suppose that

$$\partial_t \mathbf{g} = -2 \operatorname{Ric}_{\mathbf{g}(t)}, \qquad \tau' = -1, \qquad \partial_t f = -\Delta_{\mathbf{g}(t)} f + |\nabla f|^2_{\mathbf{g}(t)} - R_{\mathbf{g}(t)} + \frac{m}{2\tau}, \tag{22.26}$$

and $\tau(t) > 0$. Also suppose that the density $u = (4\pi\tau)^{-m/2} e^{-f}$ has mass one at some time in the interval. Then u solves $\Box^* u = 0$, preserves this normalization, and

$$\frac{d}{dt} \mathcal{W}(\mathbf{g}(t), f(t), \tau(t)) = 2\tau \int_M \left| \operatorname{Ric}_{\mathbf{g}(t)} + \nabla^2_{\mathbf{g}(t)} f - \frac{1}{2\tau} \mathbf{g}(t) \right|^2_{\mathbf{g}(t)} u \, d\lambda_{\mathbf{g}(t)} \geq 0. \tag{22.27}$$

Equality on an interval is equivalent to the equation of a shrinking gradient soliton.

Proof. From $\log u = -\frac{m}{2} \log(4\pi\tau) - f$ and (22.26) we obtain $u_t = -\Delta u + Ru$. Mass is preserved by Proposition 22.3.1.

Write

$$\mathcal{F}_u(t) := \int_M (R + |\nabla f|^2) u \, d\lambda_{\mathbf{g}}, \qquad \mathcal{B}(t) := \int_M u \log u \, d\lambda_{\mathbf{g}}.$$

Since $u = (4\pi\tau)^{-m/2} e^{-f}$ and its mass is one,

$$\mathcal{W} = \tau \mathcal{F}_u - \mathcal{B} - \frac{m}{2} \log(4\pi\tau) - m. \tag{22.28}$$

Lemma 22.5.1 gives $\mathcal{B}' = \mathcal{F}_u$. To calculate the derivative of the first term, we do not apply Theorem 22.4.3 directly to f, since its equation contains the summand $m/(2\tau)$. Define

$$\widetilde{f} := f + \frac{m}{2} \log(4\pi\tau) = -\log u.$$

Since $\tau' = -1$, we have

$$\partial_t \widetilde{f} = -\Delta \widetilde{f} + |\nabla \widetilde{f}|^2 - R, \qquad e^{-\widetilde{f}} = u.$$

Moreover, $d\widetilde{f} = df$ and $\nabla^2\widetilde{f} = \nabla^2 f$. Thus,

$$\mathcal{F}_u = \mathcal{F}(\mathbf{g}, \widetilde{f}), \qquad \mathcal{F}_u' = 2\int_M |\mathrm{Ric} + \nabla^2 f|^2 u \, d\lambda_{\mathbf{g}}$$

by Theorem 22.4.3. Differentiating (22.28) and using $\tau' = -1$ gives

$$\mathcal{W}' = 2\tau \int_M |\mathrm{Ric} + \nabla^2 f|^2 u \, d\lambda_{\mathbf{g}} - 2\mathcal{F}_u + \frac{m}{2\tau}. \tag{22.29}$$

Weighted integration by parts gives

$$\int_M (\Delta f) u \, d\lambda_{\mathbf{g}} = \int_M |\nabla f|^2 u \, d\lambda_{\mathbf{g}};$$

consequently, $\mathcal{F}_u = \displaystyle\int_M (R + \Delta f) u = \int_M \mathrm{tr}_{\mathbf{g}}(\mathrm{Ric} + \nabla^2 f) u$. If $\mathbf{A} = \mathrm{Ric} + \nabla^2 f$, then

$$2\tau \left| \mathbf{A} - \frac{1}{2\tau}\mathbf{g} \right|^2 = 2\tau |\mathbf{A}|^2 - 2\,\mathrm{tr}_{\mathbf{g}} \mathbf{A} + \frac{m}{2\tau}.$$

Integrating this identity and comparing it with (22.29) proves (22.27). Equality is equivalent to $\mathrm{Ric} + \nabla^2 f = \mathbf{g}/(2\tau)$. □

Definition 22.5.3. (The quantity μ) Let M^m be a closed smooth manifold, let $\mathbf{g}$ be a Riemannian metric, and let $\tau > 0$. Set

$$\mu(\mathbf{g}, \tau) := \inf \left\{ \mathcal{W}(\mathbf{g}, f, \tau) \,\middle|\, f \in C^\infty(M), \quad (4\pi\tau)^{-m/2} \int_M e^{-f} \, d\lambda_{\mathbf{g}} = 1 \right\}. \tag{22.30}$$

Lemma 22.5.4. (Strong principle for the entropy nonlinearity) Let Ω be a connected domain in a Riemannian manifold without boundary and let $w \in C^2(\Omega)$ be nonnegative. Suppose that there exists $s_0 > 0$ such that, when $0 \le w \le s_0$,

$$\Delta w \le \beta(w), \qquad \beta(s) = C_0 s - C_1 s \log s^2, \quad C_1 > 0.$$

Then w is identically zero or strictly positive. The same alternative holds for a nonnegative function $w \in W^{2,p_0}_{\mathrm{loc}}(\Omega)$ with $p_0 > \max\{2, \dim \Omega\}$, taking its C^1 representative, if the inequality holds almost everywhere on $\{0 \le w \le s_0\}$.

Proof. First prove the assertion for $w \in C^2(\Omega)$. Extend β by $\beta(0) = 0$ and reduce $s_0 > 0$ if necessary. Then β is continuous, nonnegative, and increasing on $[0, s_0]$, because $\beta'(s) = C_0 - C_1(\log s^2 + 2) > 0$ for sufficiently small s. We may also assume that $s_0 < 1$ and β is strictly increasing.

Suppose w has both a zero and a positive point. By connectedness, the open set $\{w > 0\}$ has a boundary point in Ω. Take a point p in this open set sufficiently close to its boundary and set $R = d(p, \{w = 0\}) > 0$. It can be chosen so that the closed ball $\overline{B(p, R)}$ lies in a relatively compact normal neighborhood of Ω and R is smaller than the injectivity radius at p. There then exists $q \in \partial B(p, R)$ with $w(q) = 0$, while $w > 0$ on $B(p, R)$. Existence of q follows by minimizing distance on a compact subset of that neighborhood; choosing p sufficiently close to the boundary makes points outside the neighborhood farther away than R.

The function $r(x) = d(p,x)$ is smooth on the annulus $\mathcal{A} = \{R/2 < r < R\}$. Fix $C \geq 0$ such that $\Delta r \leq C$ on its closure and set $L = R/2$. For $0 < \epsilon < 1$, define

$$k_\epsilon = C + \sqrt{|C_0| + 2C_1|\log\epsilon| + 2\frac{C_1}{e} + 1}, \qquad z_\epsilon(t) = \epsilon(e^{k_\epsilon t} - 1), \quad 0 \leq t \leq L.$$

Since $k_\epsilon = O(\sqrt{|\log\epsilon|})$, $z_\epsilon(L) \to 0$ as $\epsilon \to 0^+$. Choose ϵ small enough that

$$0 < z_\epsilon(L) < \min\left\{s_0, \min_{r=R/2} w\right\}.$$

Let $\varphi(x) = z_\epsilon(R - r(x))$. On both components of $\partial\mathcal{A}$ we have $\varphi \leq w$.

Let us verify the differential inequality for the barrier. For $t > 0$, write $y = e^{k_\epsilon t} - 1 > 0$. Since $\dfrac{y}{1+y}\max\{-\log y, 0\} \leq 1/e$, we obtain

$$\beta(z_\epsilon(t)) \leq \epsilon e^{k_\epsilon t}\left(|C_0| + 2C_1|\log\epsilon| + 2C_1/e\right).$$

On the other hand, $|dr| = 1$ and the choice of k_ϵ give

$$\Delta\varphi = z_\epsilon''(R-r) - z_\epsilon'(R-r)\Delta r \geq \epsilon e^{k_\epsilon(R-r)}(k_\epsilon^2 - Ck_\epsilon) \geq \beta(\varphi).$$

If $\varphi - w$ had a positive maximum in $\mathcal{A}$, at that point we would have $0 \leq w < \varphi < s_0$ and

$$0 \geq \Delta(\varphi - w) \geq \beta(\varphi) - \beta(w) > 0,$$

a contradiction. Thus $w \geq \varphi$ in the annulus. Let $\gamma(t)$ be the radial geodesic from q toward p, parametrized by arc length. For $0 < t < L$ we have $w(\gamma(t)) \geq z_\epsilon(t)$, and both functions vanish at $t = 0$. Their right derivatives satisfy

$$dw_q(\dot\gamma(0)) \geq z_\epsilon'(0) = \epsilon k_\epsilon > 0.$$

This contradicts $dw_q = 0$, since $w \geq 0$ and $w(q) = 0$ at an interior point of Ω. This proves the alternative.

Now consider $w \in W^{2,p_0}_{\mathrm{loc}}(\Omega)$ with $p_0 > \max\{2, \dim\Omega\}$. The local Sobolev–Morrey embedding, obtained by applying Theorem 3.5.7 in charts after multiplication by cutoff functions, provides a representative of class C^1. Suppose again that w has a zero and a positive point. The choice of the ball, the annulus, and the barrier φ uses only the continuity of w and remains valid. To compare w with φ, set $h := \varphi - w$ and, given $\delta > 0$,

$$\psi_\delta := (h - \delta)_+.$$

Since $h \leq 0$ on $\partial\mathcal{A}$, the support of ψ_δ is contained in the compact set $\{x \in \overline{\mathcal{A}} \mid h(x) \geq \delta\} \subseteq \mathcal{A}$. The chain rule in Theorem 9.1.49 gives $\psi_\delta \in W^{1,2}(\mathcal{A})$ and

$$d\psi_\delta = \mathbf{1}_{\{h>\delta\}}\, dh \qquad \text{almost everywhere.}$$

We can approximate ψ_δ in $W^{1,2}$ by smooth functions with compact support in $\mathcal{A}$: apply Theorem 9.1.48 to the trivial bundle and multiply the approximations by a fixed cutoff function with compact support in $\mathcal{A}$ that equals one near the support of ψ_δ. Moreover, $\Delta h \in L^{p_0}(\mathcal{A}) \subseteq L^2(\mathcal{A})$, because $p_0 > 2$ and the annulus has finite volume. Thus the weak integration by parts identity admits ψ_δ as a test function. Where $\psi_\delta > 0$, we

have $0 \le w < \varphi < s_0$, and we obtain

$$-\int_{\mathcal{A}} |d\psi_\delta|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}} = \int_{\mathcal{A}} (\Delta h)\psi_\delta \, d\lambda_{\mathbf{g}} \ge \int_{\mathcal{A}} \big(\beta(\varphi) - \beta(w)\big)\psi_\delta \, d\lambda_{\mathbf{g}} \ge 0.$$

The last integrand is strictly positive wherever $\psi_\delta > 0$. Thus this set has measure zero and, being open, is empty. It follows that $h \le \delta$ for every $\delta > 0$, and hence $w \ge \varphi$ in $\mathcal{A}$. The contradiction with $dw_q = 0$ now follows along the same radial geodesic, since the representative of w is of class C^1. This proves the weak assertion.

For this nonlinearity, the barrier above implements the criterion in Vázquez's strong principle [151]. Indeed, with $B(s) = \displaystyle\int_0^s \beta(r)\,dr$,

$$\int_0^{s_0} \frac{ds}{\sqrt{B(s)}} = \infty.$$

In our case, integration gives $B(s) = (C_0 + C_1)\frac{s^2}{2} - C_1 s^2 \log s$. Consequently, $B(s) \le C s^2(1 + |\log s|)$ near zero. Under the substitution $z = -\log s$, the integral providing the lower bound is a multiple of $\displaystyle\int_{-\log s_0}^{\infty} (1+z)^{-1/2}\,dz$, which diverges. This divergence explains why the logarithmic term still permits the strong principle, even though $\beta(s)/s$ is unbounded near zero. □

Proposition 22.5.5. (Minimizers and invariances of μ) On a smooth closed connected manifold, the infimum of (22.30) is attained by a smooth function. If

$$v = (4\pi\tau)^{-m/4} e^{-f/2}, \qquad \int_M v^2 \, d\lambda_{\mathbf{g}} = 1,$$

the minimizer can be chosen positive and satisfies

$$-4\tau\Delta_{\mathbf{g}} v + \tau R_{\mathbf{g}} v - v\log v^2 - \frac{m}{2}\log(4\pi\tau)v - mv = \mu(\mathbf{g},\tau)v. \tag{22.31}$$

Equivalently,

$$2\tau\Delta_{\mathbf{g}} f - \tau|\nabla f|_{\mathbf{g}}^2 + \tau R_{\mathbf{g}} + f - m = \mu(\mathbf{g},\tau). \tag{22.32}$$

Moreover, for every diffeomorphism φ and every $c > 0$,

$$\mu(\varphi^*\mathbf{g},\tau) = \mu(\mathbf{g},\tau), \qquad \mu(c\mathbf{g}, c\tau) = \mu(\mathbf{g},\tau). \tag{22.33}$$

Proof. In the variable v, the problem is to minimize

$$\mathcal{J}_{\mathbf{g},\tau}(v) := \int_M \Big[4\tau|\nabla v|_{\mathbf{g}}^2 + \tau R_{\mathbf{g}} v^2 - v^2\log v^2 - \frac{m}{2}\log(4\pi\tau)v^2 - mv^2\Big]\, d\lambda_{\mathbf{g}} \tag{22.34}$$

over the sphere in $H^1(M)$ given by $\|v\|_{L^2(M)} = 1$, with the convention $0\log 0 = 0$. Enlarging the admissible set in this way does not change the infimum. To see this, approximate $|v|$ in H^1 by nonnegative smooth functions using the heat flow for the fixed metric; add a positive constant tending to zero and normalize in L^2. This gives strictly positive smooth functions converging to $|v|$ in H^1. By the Sobolev embeddings, they also converge in some L^q with $q > 2$. The power estimate detailed below and Vitali's theorem give convergence of their entropy terms. The quadratic terms converge directly. Finally, $\mathcal{J}(|v|) = \mathcal{J}(v)$, since

$|d|v|| = |dv|$ almost everywhere for real functions in H^1.
Fix $q > 2$ for which $H^1(M) \hookrightarrow L^q(M)$ is continuous. Jensen's inequality, applied to the probability measure $v^2 d\lambda_{\mathbf{g}}$, gives

$$\int_M v^2 \log v^2 \, d\lambda_{\mathbf{g}} \le \frac{2q}{q-2} \log \|v\|_{L^q(M)}.$$

The Sobolev embedding and the inequality $\log(1+a) \le \varepsilon a^2 + C_\varepsilon$ imply, for every $\varepsilon > 0$,

$$\int_M v^2 \log v^2 \, d\lambda_{\mathbf{g}} \le \varepsilon \|dv\|^2_{L^2(M,T^*M)} + C_\varepsilon \qquad (\|v\|_{L^2(M)} = 1). \tag{22.35}$$

Taking $0 < \varepsilon < 4\tau$ and using the boundedness of $R_{\mathbf{g}}$, we obtain a lower bound for $\mathcal{J}_{\mathbf{g},\tau}$ and a uniform bound in H^1 for every minimizing sequence (v_j).
We may replace v_j by $|v_j|$. After passing to a subsequence,

$$v_j \rightharpoonup v \quad \text{in } H^1(M), \qquad v_j \to v \quad \text{in } L^{q_0}(M)$$

for some $2 < q_0 < q$, and also almost everywhere. In particular, $\|v\|_{L^2(M)} = 1$. The Dirichlet energy is lower semicontinuous, and the curvature term converges by strong convergence in L^2.
For the entropy term, choose $\eta \in (0,1)$ with $2(1+\eta) < q_0$. The inequality

$$a|\log a| \le C_\eta (a^{1-\eta} + a^{1+\eta}), \qquad a \ge 0,$$

applied to $a = v_j^2$ shows that $(v_j^2 \log v_j^2)$ is uniformly integrable: the higher power is bounded in a space L^p with $p > 1$ by convergence in L^{q_0}, and the lower power is bounded in $L^{1/(1-\eta)}$ by normalization in L^2. Vitali's theorem gives

$$\int_M v_j^2 \log v_j^2 \, d\lambda_{\mathbf{g}} \longrightarrow \int_M v^2 \log v^2 \, d\lambda_{\mathbf{g}}.$$

Therefore, v is a nonnegative minimizer.
The real function $s \mapsto s^2 \log s^2$, extended by zero at $s = 0$, is C^1, and its derivative grows more slowly than any power $|s|^{1+\varepsilon}$ at infinity. The preceding embeddings allow us to differentiate (22.34) in directions in H^1. The method of Lagrange multipliers yields

$$-4\tau \Delta v + \tau R v - v \log v^2 - v - \frac{m}{2} \log(4\pi\tau) v - m v = \lambda v$$

in the weak sense. Multiplying by v and integrating gives $\lambda = \mu(\mathbf{g}, \tau) - 1$, and hence (22.31).
Let us establish the regularity before using positivity. The weak equation has the form

$$-\Delta v = F(x, v), \qquad |F(x,a)| \le C_\varepsilon (1 + |a|^{1+\varepsilon}), \quad x \in M, \quad a \in \mathbb{R},$$

for each $\varepsilon > 0$. The term $a \log a^2$, extended by zero, is bounded near $a = 0$, which explains the constant summand.
If $m \ge 3$, we start with $v \in L^{q_0}(M)$ with $q_0 = 2m/(m-2)$. Fix $0 < \varepsilon < \min\{q_0 - 1, q_0/m\}$. If $v \in L^{q_j}$, then $F(\cdot, v) \in L^{p_j}$, where $p_j = q_j/(1+\varepsilon) > 1$, and elliptic regularity gives $v \in W^{2,p_j}$. As long as $p_j < m/2$, the Sobolev

embedding yields the next exponent:

$$\frac{1}{q_{j+1}} = \frac{1+\varepsilon}{q_j} - \frac{2}{m}, \qquad j \in \mathbb{N}_0 \text{ with } p_j < m/2.$$

Since $q_j \geq q_0$, the choice of ε implies $\varepsilon/q_j < 1/m$ and therefore $1/q_{j+1} < 1/q_j - 1/m$. The reciprocals decrease by at least $1/m$ at each step, so this alternative can occur only finitely many times. If $p_j = m/2$ is reached, the critical embedding gives $v \in L^q$ for every $q < \infty$; we then choose $q > (1+\varepsilon)m/2$ and apply the equation again. In either case, we reach $W^{2,p}$ with $p > m/2$, and hence $C^{0,\alpha}$ for some $\alpha \in (0,1)$.

If $m = 2$, the embedding of H^1 gives $v \in L^q$ for each $q < \infty$. Choose $q > 2(1+\varepsilon)$; the equation gives $v \in W^{2,q/(1+\varepsilon)} \hookrightarrow C^{1,\alpha}$ for some $\alpha > 0$. If $m = 1$, the embedding of H^1 already gives a continuous bounded function. Thus v is bounded in every dimension.

The function $F(\cdot, v)$ now belongs to L^p for each $1 < p < \infty$. Another application of elliptic regularity gives $v \in W^{2,p}$ for all these exponents and, taking $p > m$, $v \in C^{1,\alpha}$. In particular, v is Lipschitz. Take $p > \max\{2, m\}$ to apply the weak version of the strong principle just proved.

From (22.31) we obtain, almost everywhere, $\Delta v \leq C_0 v - C_1 v \log v^2$, where we may take

$$C_1 = \frac{1}{4\tau}, \qquad C_0 = \frac{1}{4\tau}\left\| \tau R_{\mathbf{g}} - \frac{m}{2}\log(4\pi\tau) - m - \mu(\mathbf{g},\tau)\right\|_\infty.$$

The weak version of Lemma 22.5.4 and the normalization exclude the zero solution; since M is connected, it follows that $v > 0$. Compactness of M gives $\min_{x\in M} v(x) > 0$. Thus F is smooth on a neighborhood of the compact set $\{(x, v(x)) \mid x \in M\}$. We start with $v \in H^2(M)$. If $v \in H^r(M)$ for an integer $r \geq 2$, the composition estimate (20.9) implies $F(\cdot, v) \in H^r(M)$; the equation and Theorem 11.4.2 then give $v \in H^{r+2}(M)$, using a finite cover of M. Induction yields all even orders and, by the Sobolev–Morrey embeddings, $v \in C^\infty(M)$. The substitution $v = (4\pi\tau)^{-m/4} e^{-f/2}$ gives (22.32).

Diffeomorphism invariance follows from the change of variables formula. Under $\mathbf{g} \mapsto c\mathbf{g}$, we have $R \mapsto c^{-1}R$, $|\nabla f|^2 \mapsto c^{-1}|\nabla f|^2$, and $d\lambda \mapsto c^{m/2} d\lambda$; the factor $(4\pi c\tau)^{-m/2}$ compensates for the change in volume. This proves (22.33). □

If M has connected components $M_1, \ldots, M_N$, set $a_\alpha = \int_{M_\alpha} v^2 \, d\lambda_{\mathbf{g}}$ for $\alpha \in \{1, \ldots, N\}$. On the components with $a_\alpha > 0$, write $v = \sqrt{a_\alpha}\, w_\alpha$, with $\|w_\alpha\|_{L^2(M_\alpha)} = 1$. Then

$$\mathcal{J}_{\mathbf{g},\tau}(v) = \sum_{\substack{\alpha\in\{1,\ldots,N\} \\ a_\alpha > 0}} a_\alpha \mathcal{J}_{\mathbf{g}|_{M_\alpha},\tau}(w_\alpha) - \sum_{\alpha=1}^N a_\alpha \log a_\alpha, \qquad \sum_{\alpha=1}^N a_\alpha = 1.$$

The last term is nonnegative. Concentrating the mass on a component that minimizes its quantity μ, and approximating if positivity on all components is required, gives $\mu(\mathbf{g},\tau) = \min_{\alpha\in\{1,\ldots,N\}} \mu(\mathbf{g}|_{M_\alpha}, \tau)$. Thus the following arguments apply component by component.

Corollary 22.5.6. (Monotonicity of μ) Let M be a smooth closed connected manifold. If $\mathbf{g}(t)$ solves the Ricci flow, $\tau' = -1$, and $\tau(t) > 0$, then $t \mapsto \mu(\mathbf{g}(t), \tau(t))$ is nondecreasing. If it remains constant on an interval, the flow is, modulo diffeomorphisms and rescaling, a gradient shrinking soliton.

Proof. Let $t_1 < t_2$ and choose a positive minimizer for $(\mathbf{g}(t_2), \tau(t_2))$. Its terminal density determines a positive solution of the conjugate equation backward to t_1; by conservation of mass, it can be written as $(4\pi\tau)^{-m/2} e^{-f}$. Theorem 22.5.2 gives

$$\mu(\mathbf{g}(t_2), \tau(t_2)) = \mathcal{W}(t_2) \geq \mathcal{W}(t_1) \geq \mu(\mathbf{g}(t_1), \tau(t_1)).$$

If the endpoints are equal, both inequalities are equalities, and the square in (22.27) vanishes throughout the interval. This is the gradient shrinking soliton equation. □

22.6 Reduced length, distance, and volume

The entropy $\mathcal{W}$ yields noncollapsing for smooth flows. To study the spacetime geometry more precisely, Perelman introduced a second monotone quantity based on a variational problem for curves. Its integrand combines kinetic energy with scalar curvature and uses backward time as its parameter.

Throughout this section, M is closed and connected. Fix $p \in M$, a time t_0, and $\tau_{\max} > 0$ such that $[t_0 - \tau_{\max}, t_0]$ is contained in the smooth time interval of the flow. For $0 \leq s \leq \tau_{\max}$, write

$$\mathbf{g}_s := \mathbf{g}(t_0 - s), \qquad R_s := R_{\mathbf{g}_s}, \qquad \mathrm{Ric}_s := \mathrm{Ric}_{\mathbf{g}_s}.$$

We denote the Levi–Civita connection and Laplacian of $\mathbf{g}_s$ by $\nabla^{(s)}$ and Δ_s. Since s is backward time, $\partial_s \mathbf{g}_s = 2\,\mathrm{Ric}_s$.

To differentiate a field along a curve, we use at each instant the connection corresponding to that time. If $\mathbf{X}(s) = \dot\gamma(s)$ and $\mathbf{Z}(s) \in T_{\gamma(s)}M$, we write $\nabla_{\mathbf{X}}\mathbf{Z} = D_s\mathbf{Z}$ for the total covariant derivative. In coordinates,

$$(D_s\mathbf{Z})^k = \frac{dZ^k}{ds} + \sum_{i,j=1}^{m} \Gamma_{ij}^k(s, \gamma(s)) X^i Z^j, \qquad k \in \{1, \dots, m\}. \tag{22.36}$$

In particular, $D_s^2\mathbf{Z}$ includes the time derivative of the Christoffel symbols appearing in $D_s\mathbf{Z}$. For two fields $\mathbf{Z}, \mathbf{W}$ along the curve, metric compatibility on each slice gives

$$\frac{d}{ds}\langle \mathbf{Z}, \mathbf{W} \rangle_{\mathbf{g}_s} = \langle D_s\mathbf{Z}, \mathbf{W} \rangle_{\mathbf{g}_s} + \langle \mathbf{Z}, D_s\mathbf{W} \rangle_{\mathbf{g}_s} + 2\,\mathrm{Ric}_s(\mathbf{Z}, \mathbf{W}). \tag{22.37}$$

Tensor derivatives involving only a spatial direction, such as $\nabla_{\mathbf{Y}} \mathrm{Ric}_s$, are taken with the connection $\nabla^{(s)}$ at fixed time s.

For an absolutely continuous curve $\gamma\colon [0, \bar\tau] \to M$ with $\gamma(0) = p$ and $\gamma(\bar\tau) = q$, define

$$\mathcal{L}(\gamma) := \int_0^{\bar\tau} \sqrt{s}\, \left(R_s(\gamma(s)) + |\dot\gamma(s)|_{\mathbf{g}_s}^2 \right) ds. \tag{22.38}$$

The $\mathcal{L}$-distance and the reduced distance based at (p, t_0) are

$$L(q, \bar\tau) := \inf_{\gamma \in \mathcal{A}_{p,q}(\bar\tau)} \mathcal{L}(\gamma), \qquad l(q, \bar\tau) := \frac{L(q, \bar\tau)}{2\sqrt{\bar\tau}}. \tag{22.39}$$

Here $\mathcal{A}_{p,q}(\bar\tau)$ is the set of absolutely continuous curves from $[0, \bar\tau]$ into M with these endpoints and finite weighted

energy, that is, $\int_0^{\bar\tau} \sqrt{s}\,|\dot\gamma(s)|^2_{\mathbf{g}_s}\,ds < \infty$.

The apparent singularity of the integrand at $s = 0$ disappears after reparametrization by the square root of time. This observation allows us to apply the variational method and the theory of ordinary differential equations directly.

Lemma 22.6.1. (Regular reparametrization and existence of minimizers) Let M be closed. If $\alpha(r) = \gamma(r^2)$ and $\mathbf{A}(r) = \alpha'(r)$, then

$$\mathcal{L}(\gamma) = \int_0^{\sqrt{\bar\tau}} \left(\frac{1}{2}|\mathbf{A}(r)|^2_{\mathbf{g}_{r^2}} + 2r^2 R_{r^2}(\alpha(r)) \right) dr. \tag{22.40}$$

For every $q \in M$ and every $0 < \bar\tau \le \tau_{\max}$, there exists an $\mathcal{L}$-minimizing curve from $(p, 0)$ to $(q, \bar\tau)$. Every minimizer is smooth in the variable r and satisfies

$$\nabla^{(r^2)}_{\mathbf{A}}\mathbf{A} - 2r^2 \nabla^{\mathbf{g}_{r^2}} R_{r^2} + 4r\,\mathrm{Ric}_{r^2}(\mathbf{A}, \cdot)^{\sharp_{\mathbf{g}_{r^2}}} = 0. \tag{22.41}$$

In the original variable, with $\mathbf{X} = \dot\gamma$, this equation becomes

$$\nabla^{(s)}_{\mathbf{X}}\mathbf{X} - \frac{1}{2}\nabla^{\mathbf{g}_s} R_s + \frac{1}{2s}\mathbf{X} + 2\,\mathrm{Ric}_s(\mathbf{X}, \cdot)^{\sharp_{\mathbf{g}_s}} = 0. \tag{22.42}$$

Proof. The change of variables $s = r^2$ gives $ds = 2r\,dr$ and $\mathbf{X}(r^2) = \mathbf{A}(r)/(2r)$. Direct substitution into (22.38) yields (22.40).

Fix a reference metric $\mathbf{h}$ on M. On the compact interval under consideration, the metrics $\mathbf{g}_{r^2}$ are uniformly equivalent to $\mathbf{h}$, and R_{r^2} is uniformly bounded. Thus there exist $c, C > 0$ such that

$$\mathcal{L}(\alpha) \ge c \int_0^{\sqrt{\bar\tau}} |\alpha'(r)|^2_{\mathbf{h}}\,dr - C. \tag{22.43}$$

Choose a smooth embedding $\iota\colon M \hookrightarrow \mathbb{R}^N$. The preceding estimate and the uniform equivalence of the metric induced by ι and $\mathbf{h}$ bound $\iota\circ\alpha_j$ in $H^1([0,\sqrt{\bar\tau}],\mathbb{R}^N)$ for every minimizing sequence. After passing to a subsequence, these curves converge weakly in H^1 and uniformly to a curve a. Since $\iota(M)$ is closed and each $\iota\circ\alpha_j$ takes values in $\iota(M)$, so does a; write $a = \iota\circ\alpha$, with values in $\iota(M)$. The endpoints are preserved by uniform convergence.

In charts around the compact image of α, the coefficients of $\mathbf{g}_{r^2}$ evaluated at α_j converge uniformly to those evaluated at α. The kinetic integrand is convex in the velocity; by lower semicontinuity of convex integrals,

$$\int_0^{\sqrt{\bar\tau}} |\alpha'|^2_{\mathbf{g}_{r^2}}\,dr \le \liminf_{j\to\infty} \int_0^{\sqrt{\bar\tau}} |\alpha_j'|^2_{\mathbf{g}_{r^2}}\,dr.$$

The curvature term converges by uniform convergence and the dominated convergence theorem. Thus α attains the infimum.

The first variation of (22.40) gives the Euler–Lagrange equation in the weak sense. To justify its regularity, consider a subinterval whose image lies in a chart and define the momenta

$$P_i(r) = \sum_{j=1}^{m} g_{ij}(r^2, \alpha(r))\alpha'^j(r), \qquad i \in \{1,\dots,m\}.$$

The weak equation is

$$P_i'(r) = \frac{1}{2}\sum_{j,k=1}^{m} \partial_i g_{jk}(r^2, \alpha(r))\alpha'^j(r)\alpha'^k(r) + 2r^2\partial_i R_{r^2}(\alpha(r)).$$

The right-hand side belongs to L^1 because $\alpha' \in L^2$. Thus each P_i has an absolutely continuous, and hence continuous, representative. The identity $\alpha'^j = \sum_{i=1}^{m} g^{ji}(r^2, \alpha)P_i$ then shows that α is C^1. The right-hand side of the equation for P_i' is now continuous, so P_i is C^1 and α is C^2. The resulting ordinary differential system has smooth coefficients, even at $r = 0$, and ordinary differential equation regularity gives smoothness up to the endpoints. Writing it with the connection of $\mathbf{g}_{r^2}$ gives (22.41). Finally, $\mathbf{A} = 2\sqrt{s}\,\mathbf{X}$ and

$$\nabla^{(r^2)}_{\mathbf{A}}\mathbf{A} = 2\mathbf{X} + 4r^2\nabla^{(s)}_{\mathbf{X}}\mathbf{X}.$$

Substituting this identity into (22.41) proves (22.42). □

Lemma 22.6.2. (The $\mathcal{L}$-exponential map) For each $v \in T_pM$, there exists a unique solution of (22.41) with

$$\alpha_v(0) = p, \qquad \alpha_v'(0) = 2v.$$

It is defined on all of $[0, \sqrt{\tau_{\max}}]$ and depends smoothly on (v, r). If $\gamma_v(s) = \alpha_v(\sqrt{s})$, then

$$\lim_{s\to 0^+} \sqrt{s}\,\dot\gamma_v(s) = v.$$

Define

$$\mathcal{L}\exp_p^\tau(v) := \gamma_v(\tau). \tag{22.44}$$

Proof. Existence, uniqueness, and smooth dependence near $r = 0$ follow from the usual theorem for ordinary differential systems applied to (22.41). To exclude blowup of the velocity on a finite interval, take the inner product of that equation with $\mathbf{A}$. The uniform bounds on ∇R and Ric give

$$\frac{d}{dr}|\mathbf{A}|^2_{\mathbf{g}_{r^2}} \le C\big(1 + |\mathbf{A}|^2_{\mathbf{g}_{r^2}}\big).$$

Grönwall's inequality keeps the velocity bounded. Since M is compact, the solution extends to $\sqrt{\tau_{\max}}$. The identity $\mathbf{A}(r) = 2r\mathbf{X}(r^2)$ gives the last assertion. □

Definition 22.6.3. ($\mathcal{L}$-injectivity domain and cut locus) For $\tau > 0$, let $\widetilde{U}_p(\tau) \subseteq T_pM$ be the set of vectors v satisfying the following two conditions:

(a) $d(\mathcal{L}\exp_p^\tau)_v$ is an isomorphism;

(b) there exists a neighborhood $\mathcal{V}$ of v in T_pM such that, for every $w \in \mathcal{V}$, the curve $\gamma_w|_{[0,\tau]}$ is the unique $\mathcal{L}$-minimizer between its endpoints.

Set

$$U_p(\tau) := \mathcal{L}\exp_p^\tau(\widetilde{U}_p(\tau)), \qquad \mathrm{Cut}_{\mathcal{L}}(p, \tau) := M \setminus U_p(\tau).$$

The second set is called the *$\mathcal{L}$-cut locus* based at (p, t_0) at backward time τ.

By definition, $\widetilde{U}_p(\tau)$ is open. The restriction of $\mathcal{L}\exp_p^\tau$ to this set is injective: two preimages of the same point would determine two minimizers, but each is unique. The inverse function theorem therefore shows that this restriction is a diffeomorphism onto the open set $U_p(\tau)$. In particular, $L(\cdot,\tau)$ and $l(\cdot,\tau)$ are smooth on $U_p(\tau)$.

Lemma 22.6.4. (First variation) Let γ_u be a variation of an $\mathcal{L}$–geodesic $\gamma=\gamma_0$, smooth in (u,r) with $r=\sqrt{s}$, that fixes the initial endpoint $\gamma_u(0)=p$, and let $\mathbf{Y}=\partial_u\gamma_u\big|_{u=0}$. Then $\mathbf{Y}(0)=0$ and

$$\delta\mathcal{L}(\gamma)=2\sqrt{s}\langle\mathbf{Y},\mathbf{X}\rangle_{\mathbf{g}_s}\Big|_0^{\bar\tau}+\int_0^{\bar\tau}\sqrt{s}\left\langle\mathbf{Y},\nabla R_s-\frac{1}{s}\mathbf{X}-2\nabla_{\mathbf{X}}\mathbf{X}-4\operatorname{Ric}_s(\mathbf{X},\cdot)^\sharp\right\rangle_{\mathbf{g}_s}ds. \tag{22.45}$$

In particular, if $q\in U_p(\tau)$ and γ is the regular minimizer ending at q, then

$$\nabla^{\mathbf{g}_\tau}L(q,\tau)=2\sqrt{\tau}\,\mathbf{X}(\tau),\qquad \partial_\tau L(q,\tau)=\sqrt{\tau}\big(R_\tau(q)-|\mathbf{X}(\tau)|^2_{\mathbf{g}_\tau}\big). \tag{22.46}$$

Consequently,

$$\nabla^{\mathbf{g}_\tau}l=\mathbf{X}(\tau),\qquad \partial_\tau l=-\frac{l}{2\tau}+\frac{1}{2}\big(R_\tau-|\nabla l|^2_{\mathbf{g}_\tau}\big) \tag{22.47}$$

on the regular set.

Proof. Let γ_u be a variation and let $\mathbf{Y}=\partial_u\gamma_u|_{u=0}$. Since $\partial_s\mathbf{g}_s=2\operatorname{Ric}_s$ and the coordinate fields of the variation commute,

$$\partial_u|\mathbf{X}|^2_{\mathbf{g}_s}=2\langle\nabla_{\mathbf{X}}\mathbf{Y},\mathbf{X}\rangle_{\mathbf{g}_s}.$$

When integrating by parts, we must also differentiate the s-dependent metric:

$$\frac{d}{ds}\big(2\sqrt{s}\langle\mathbf{Y},\mathbf{X}\rangle\big)=\frac{1}{\sqrt{s}}\langle\mathbf{Y},\mathbf{X}\rangle+2\sqrt{s}\langle\nabla_{\mathbf{X}}\mathbf{Y},\mathbf{X}\rangle+2\sqrt{s}\langle\mathbf{Y},\nabla_{\mathbf{X}}\mathbf{X}\rangle+4\sqrt{s}\operatorname{Ric}_s(\mathbf{Y},\mathbf{X}).$$

Substituting this identity into the derivative of (22.38) gives (22.45). The endpoint term at $s=0$ vanishes because $\mathbf{Y}(0)=0$ and $\sqrt{s}\,\mathbf{X}(s)$ has a limit.

On the regular set, the inverse function theorem applied to $\mathcal{L}\exp_p^\tau$ produces a smooth family of minimizers as the endpoint varies. The boundary part of (22.45) gives the first identity in (22.46). Along the minimizer itself,

$$\frac{d}{d\tau}L(\gamma(\tau),\tau)=\sqrt{\tau}(R_\tau+|\mathbf{X}(\tau)|^2).$$

By the chain rule, the left-hand side is also $\partial_\tau L+\langle\nabla L,\mathbf{X}(\tau)\rangle$. The gradient identity gives the second formula. Dividing by $2\sqrt{\tau}$ proves (22.47). □

Lemma 22.6.5. ($\mathcal{L}$-Jacobi fields and index) Let $\mathbf{C}_s=\partial_s\nabla^{(s)}$ be the variation tensor of the connection. Along an $\mathcal{L}$–geodesic, the linearization of (22.42), with the total derivative in (22.36), is

$$\begin{aligned}\mathcal{J}_{\mathcal{L}}\mathbf{Y}:=D_s^2\mathbf{Y}+\operatorname{Rm}_{\mathbf{g}_s}(\mathbf{Y},\mathbf{X})\mathbf{X}-\mathbf{C}_s(\mathbf{Y},\mathbf{X})-\frac{1}{2}\nabla_{\mathbf{Y}}(\nabla R_s)+\frac{1}{2s}D_s\mathbf{Y}\\+2(\nabla_{\mathbf{Y}}\operatorname{Ric}_s)(\mathbf{X},\cdot)^\sharp+2\operatorname{Ric}_s(D_s\mathbf{Y},\cdot)^\sharp.\end{aligned} \tag{22.48}$$

The fields satisfying $\mathcal{J}_{\mathcal{L}}\mathbf{Y}=0$ that are smooth in $r=\sqrt{s}$ and vanish at $s=0$ are precisely the derivatives of families of $\mathcal{L}$–geodesics with fixed initial point p.

For fields $\mathbf{Y},\mathbf{Z}$ smooth in $r=\sqrt{s}$ and vanishing at $s=0$, define

$$\begin{aligned} I_{\mathcal{L}}(\mathbf{Y},\mathbf{Z}) := \int_0^\tau \sqrt{s}\Big\{ &\operatorname{Hess}_{\mathbf{g}_s} R_s(\mathbf{Y},\mathbf{Z}) + 2\langle \operatorname{Rm}_{\mathbf{g}_s}(\mathbf{Y},\mathbf{X})\mathbf{Z},\mathbf{X}\rangle_{\mathbf{g}_s} \\ &+ 2\langle D_s\mathbf{Y}, D_s\mathbf{Z}\rangle_{\mathbf{g}_s} + 2(\nabla_{\mathbf{X}}\operatorname{Ric}_s)(\mathbf{Y},\mathbf{Z}) - 2(\nabla_{\mathbf{Y}}\operatorname{Ric}_s)(\mathbf{X},\mathbf{Z}) \\ &- 2(\nabla_{\mathbf{Z}}\operatorname{Ric}_s)(\mathbf{X},\mathbf{Y})\Big\}\, ds. \end{aligned} \tag{22.49}$$

If γ_u is a variation of a minimizer, smooth in $(u,\sqrt{s})$, with fixed initial point and variation field $\mathbf{Y}$, then

$$\left.\frac{d^2}{du^2}\right|_{u=0} \mathcal{L}(\gamma_u) = 2\sqrt{\tau}\,\langle \nabla_{\mathbf{Y}}\mathbf{Y},\mathbf{X}\rangle_{\mathbf{g}_\tau}\Big|_{s=\tau} + I_{\mathcal{L}}(\mathbf{Y},\mathbf{Y}). \tag{22.50}$$

At a regular point,

$$\operatorname{Hess}_{\mathbf{g}_\tau} L(\mathbf{Y}(\tau),\mathbf{Y}(\tau)) \le I_{\mathcal{L}}(\mathbf{Y},\mathbf{Y}). \tag{22.51}$$

Moreover, $d(\mathcal{L}\exp_p^\tau)_v$ is singular if and only if there exists a nonzero Jacobi field vanishing at both endpoints.

Proof. The connection variation formula from the previous chapter, applied to $\partial_s \mathbf{g}_s = 2\operatorname{Ric}_s$, gives

$$\langle \mathbf{C}_s(\mathbf{U},\mathbf{V}),\mathbf{W}\rangle_{\mathbf{g}_s} = (\nabla_{\mathbf{U}}\operatorname{Ric}_s)(\mathbf{V},\mathbf{W}) + (\nabla_{\mathbf{V}}\operatorname{Ric}_s)(\mathbf{U},\mathbf{W}) - (\nabla_{\mathbf{W}}\operatorname{Ric}_s)(\mathbf{U},\mathbf{V}). \tag{22.52}$$

Here $\mathbf{U},\mathbf{V},\mathbf{W}$ are tangent vectors at the same point, and all derivatives on the right-hand side are spatial. On a variation $\gamma(u,s)$, write D_u for the covariant derivative in the $\mathbf{Y}=\partial_u\gamma$ direction at fixed s. The absence of torsion gives $D_u\mathbf{X} = D_s\mathbf{Y}$. For a field $\mathbf{Z}$ on the variation, the commutator is

$$D_u D_s\mathbf{Z} - D_s D_u\mathbf{Z} = \operatorname{Rm}_{\mathbf{g}_s}(\mathbf{Y},\mathbf{X})\mathbf{Z} - \mathbf{C}_s(\mathbf{Y},\mathbf{Z}). \tag{22.53}$$

To check the time-dependent term, write each derivative as in (22.36). The terms containing spatial derivatives of Γ_{ij}^k and products of two Christoffel symbols combine into the curvature. Differentiating $D_u\mathbf{Z}$ with respect to s also produces $\displaystyle\sum_{i,j=1}^m (\partial_s\Gamma_{ij}^k)Y^iZ^j$, for each $k\in\{1,\dots,m\}$, with a negative sign in the commutator. This is exactly the last summand in (22.53).

In particular,

$$D_u(D_s\mathbf{X}) = D_s^2\mathbf{Y} + \operatorname{Rm}(\mathbf{Y},\mathbf{X})\mathbf{X} - \mathbf{C}_s(\mathbf{Y},\mathbf{X}).$$

The derivative of $\operatorname{Ric}_s(\mathbf{X},\cdot)^\sharp$ in the u direction is $(\nabla_{\mathbf{Y}}\operatorname{Ric}_s)(\mathbf{X},\cdot)^\sharp + \operatorname{Ric}_s(D_s\mathbf{Y},\cdot)^\sharp$. Differentiating the remaining terms of (22.42) yields (22.48).

The equation in $r=\sqrt{s}$ is a regular second-order linear ordinary differential system. If $\mathbf{Y}(0)=0$, it is determined by $\lim_{s\to0^+}\sqrt{s}\,D_s\mathbf{Y}$. Indeed, for a family of initial data $v(u)$, $D_r\mathbf{Y}(0) = 2v'(0)$, and this limit is $v'(0)$. Smooth dependence and uniqueness of the initial value problem establish the correspondence with variations of $\mathcal{L}$–geodesics.

Now differentiate (22.45) along the central curve. Its Euler–Lagrange equation makes the integrand of the

first variation vanish. We obtain

$$\delta^2\mathcal{L} = 2\sqrt{\tau}\big(\langle\nabla_{\mathbf{Y}}\mathbf{Y},\mathbf{X}\rangle + \langle D_s\mathbf{Y},\mathbf{Y}\rangle\big)_{s=\tau} - 2\int_0^\tau \sqrt{s}\,\langle \mathcal{J}_{\mathcal{L}}\mathbf{Y},\mathbf{Y}\rangle\,ds.$$

To integrate the last term, use (22.37) with $\mathbf{Z} = D_s\mathbf{Y}$ and $\mathbf{W} = \mathbf{Y}$:

$$\frac{d}{ds}\langle D_s\mathbf{Y},\mathbf{Y}\rangle_{\mathbf{g}_s} = \langle D_s^2\mathbf{Y},\mathbf{Y}\rangle_{\mathbf{g}_s} + |D_s\mathbf{Y}|^2_{\mathbf{g}_s} + 2\,\mathrm{Ric}_s(D_s\mathbf{Y},\mathbf{Y}). \tag{22.54}$$

On the other hand, setting $\mathbf{U} = \mathbf{W} = \mathbf{Y}$ and $\mathbf{V} = \mathbf{X}$ in (22.52), the two terms involving $\nabla_{\mathbf{Y}}\mathrm{Ric}_s$ cancel:

$$\langle \mathbf{C}_s(\mathbf{Y},\mathbf{X}),\mathbf{Y}\rangle = (\nabla_{\mathbf{X}}\mathrm{Ric}_s)(\mathbf{Y},\mathbf{Y}).$$

Consequently,

$$\begin{aligned}-2\sqrt{s}\,\langle \mathcal{J}_{\mathcal{L}}\mathbf{Y},\mathbf{Y}\rangle = &-\frac{d}{ds}\big(2\sqrt{s}\langle D_s\mathbf{Y},\mathbf{Y}\rangle\big)\\ &+\sqrt{s}\Big\{\mathrm{Hess}\,R_s(\mathbf{Y},\mathbf{Y}) + 2\langle \mathrm{Rm}(\mathbf{Y},\mathbf{X})\mathbf{Y},\mathbf{X}\rangle + 2|D_s\mathbf{Y}|^2\\ &\qquad + 2(\nabla_{\mathbf{X}}\mathrm{Ric}_s)(\mathbf{Y},\mathbf{Y}) - 4(\nabla_{\mathbf{Y}}\mathrm{Ric}_s)(\mathbf{X},\mathbf{Y})\Big\}.\end{aligned}$$

The total derivative term cancels the summand $2\sqrt{\tau}\langle D_s\mathbf{Y},\mathbf{Y}\rangle$ at the final endpoint. At the initial endpoint, smoothness in r and $\mathbf{Y}(0) = 0$ imply $\mathbf{Y} = O(\sqrt{s})$ and $D_s\mathbf{Y} = O(s^{-1/2})$; hence $2\sqrt{s}\langle D_s\mathbf{Y},\mathbf{Y}\rangle \to 0$. These same bounds justify convergence of the improper integrals. This proves (22.50), and polarization gives (22.49). If both fields also vanish at $s = \tau$, bilinear integration by parts gives

$$I_{\mathcal{L}}(\mathbf{Y},\mathbf{Z}) = -2\int_0^\tau \sqrt{s}\,\langle \mathcal{J}_{\mathcal{L}}\mathbf{Y},\mathbf{Z}\rangle\,ds.$$

The symmetry of this expression also follows directly from (22.49) and the curvature symmetries.

To estimate the Hessian, realize $\mathbf{Y}$ by a variation with fixed initial point and final endpoint $q(u)$. We have $L(q(u),\tau) \le \mathcal{L}(\gamma_u)$, with equality at $u = 0$. The second derivative of the difference is nonnegative. When we use $\nabla L = 2\sqrt{\tau}\,\mathbf{X}(\tau)$, the term containing the acceleration of $q(u)$ is the same on both sides and cancels. This proves (22.51). Finally, $d(\mathcal{L}\exp_p^\tau)_v(w) = \mathbf{Y}_w(\tau)$, where $\lim_{s\to 0^+}\sqrt{s}D_s\mathbf{Y}_w = w$. Uniqueness for the regular system implies that $w \neq 0$ corresponds to a nonzero field, which proves the assertion about the differential of the exponential map. □

Lemma 22.6.6. (Identities for K and a Hessian estimate) Let $q \in U_p(\tau)$ and let γ be the regular minimizer ending at q. Along γ, define

$$\mathcal{H}(\mathbf{X}) := -\partial_s R_s - \frac{R_s}{s} - 2\langle\nabla R_s,\mathbf{X}\rangle + 2\,\mathrm{Ric}_s(\mathbf{X},\mathbf{X}), \tag{22.55}$$

$$K(\tau) := \int_0^\tau s^{3/2}\mathcal{H}(\mathbf{X}(s))\,ds. \tag{22.56}$$

Then

$$\partial_\tau l = R_\tau - \frac{l}{\tau} + \frac{K(\tau)}{2\tau^{3/2}}, \tag{22.57}$$

$$|\nabla^{\mathbf{g}_\tau} l|^2_{\mathbf{g}_\tau} = -R_\tau + \frac{l}{\tau} - \frac{K(\tau)}{\tau^{3/2}}, \tag{22.58}$$

$$\Delta_\tau l \le \frac{m}{2\tau} - R_\tau - \frac{K(\tau)}{2\tau^{3/2}}. \tag{22.59}$$

Consequently, on the regular set,

$$\partial_\tau l - \Delta_\tau l + |\nabla l|^2_{\mathbf{g}_\tau} - R_\tau + \frac{m}{2\tau} \ge 0. \tag{22.60}$$

Proof. Differentiate $R_s(\gamma(s)) + |\mathbf{X}(s)|^2$. The time variation of the metric contributes $2\,\mathrm{Ric}_s(\mathbf{X},\mathbf{X})$, and equation (22.42) gives

$$\frac{d}{ds}\left(R_s + |\mathbf{X}|^2\right) = -\mathcal{H}(\mathbf{X}) - \frac{1}{s}(R_s + |\mathbf{X}|^2). \tag{22.61}$$

Thus

$$\frac{d}{ds}\left[s^{3/2}(R_s + |\mathbf{X}|^2)\right] = \frac{1}{2}\sqrt{s}(R_s + |\mathbf{X}|^2) - s^{3/2}\mathcal{H}(\mathbf{X}).$$

Integration between 0 and τ, together with $\lim_{s\to 0^+} s^{3/2}(R_s + |\mathbf{X}|^2) = 0$, yields

$$\tau^{3/2}(R_\tau + |\mathbf{X}(\tau)|^2) = \frac{1}{2}L(q,\tau) - K(\tau). \tag{22.62}$$

The second formula in (22.46) and the identity $\nabla l = \mathbf{X}(\tau)$ transform (22.62) into (22.57) and (22.58).
It remains to estimate the trace of the Hessian. Let $(\mathbf{e}_a)_{a=1}^m$ be an orthonormal basis of T_qM, and let $\mathbf{Y}_a$ be the comparison field determined by

$$\mathbf{Y}_a(\tau) = \mathbf{e}_a, \qquad \nabla_{\mathbf{X}}\mathbf{Y}_a = -\mathrm{Ric}_s(\mathbf{Y}_a,\cdot)^\sharp + \frac{1}{2s}\mathbf{Y}_a. \tag{22.63}$$

Differentiating $\langle \mathbf{Y}_a, \mathbf{Y}_b\rangle_{\mathbf{g}_s}$ and using $\partial_s \mathbf{g}_s = 2\,\mathrm{Ric}_s$ gives

$$\langle \mathbf{Y}_a(s), \mathbf{Y}_b(s)\rangle_{\mathbf{g}_s} = \frac{s}{\tau}\delta_{ab}.$$

Thus the fields vanish at $s = 0$, and $\mathbf{W}_a(s) = \sqrt{\tau/s}\,\mathbf{Y}_a(s)$ form an orthonormal frame satisfying $\nabla_{\mathbf{X}}\mathbf{W}_a = -\mathrm{Ric}_s(\mathbf{W}_a,\cdot)^\sharp$ for $a \in \{1,\dots,m\}$. In the variable $r = \sqrt{s}$, this equation is $D_r\mathbf{W}_a = -2r\,\mathrm{Ric}_{r^2}(\mathbf{W}_a,\cdot)^\sharp$; its coefficients are smooth up to $r = 0$. Hence the fields $\mathbf{W}_a$ extend smoothly, and $\mathbf{Y}_a = (r/\sqrt{\tau})\mathbf{W}_a$ are admissible variations. Inequality (22.51) implies

$$\Delta_\tau L(q,\tau) \le \sum_{a=1}^m I_{\mathcal{L}}(\mathbf{Y}_a, \mathbf{Y}_a).$$

Substitute $\mathbf{Y}_a = \sqrt{s/\tau}\,\mathbf{W}_a$ into (22.49). The required contractions are

$$\sum_{a=1}^m \mathrm{Hess}\, R_s(\mathbf{W}_a,\mathbf{W}_a) = \Delta_s R_s,$$

$$\sum_{a=1}^m \langle \mathrm{Rm}(\mathbf{W}_a,\mathbf{X})\mathbf{W}_a, \mathbf{X}\rangle = -\mathrm{Ric}_s(\mathbf{X},\mathbf{X}),$$

$$\sum_{a=1}^m \left|\frac{1}{2s}\mathbf{W}_a - \mathrm{Ric}_s(\mathbf{W}_a,\cdot)^\sharp\right|^2 = \frac{m}{4s^2} - \frac{R_s}{s} + |\mathrm{Ric}_s|^2,$$

$$\sum_{a=1}^{m} (\nabla_{\mathbf{W}_a} \mathrm{Ric}_s)(\mathbf{X}, \mathbf{W}_a) = \frac{1}{2} \langle \nabla R_s, \mathbf{X} \rangle.$$

The last equality is the contracted Bianchi identity. Together with $\partial_s R_s = -\Delta_s R_s - 2|\mathrm{Ric}_s|^2$, these identities give, term by term,

$$\sum_{a=1}^{m} I_{\mathcal{L}}(\mathbf{Y}_a, \mathbf{Y}_a) = \frac{1}{\tau} \int_0^\tau \left[\frac{m}{2\sqrt{s}} - 2\sqrt{s} R_s - s^{3/2} \partial_s R_s - 2 s^{3/2} \mathrm{Ric}_s(\mathbf{X}, \mathbf{X}) \right] ds. \tag{22.64}$$

Here all quantities are evaluated at $\gamma(s)$. Now

$$\frac{d}{ds} \left(2 s^{3/2} R_s(\gamma(s)) \right) = 3\sqrt{s} R_s + 2 s^{3/2} (\partial_s R_s + \langle \nabla R_s, \mathbf{X} \rangle).$$

The definition of $\mathcal{H}$ allows us to rewrite the part of the preceding integral that does not involve the dimension as

$$-2\tau^{3/2} R_\tau(q) - K(\tau).$$

Since $\displaystyle\int_0^\tau m/(2\sqrt{s})\, ds = m\sqrt{\tau}$, we conclude that

$$\Delta_\tau L(q, \tau) \le \frac{m}{\sqrt{\tau}} - 2\sqrt{\tau} R_\tau(q) - \frac{K(\tau)}{\tau}.$$

Dividing by $2\sqrt{\tau}$ proves (22.59). Combining the three formulas gives (22.60). □

The preceding inequality was obtained where the minimizer is unique and the exponential map has no conjugate points. To integrate it over the entire manifold, we need to control the reduced function on its cut locus.

Definition 22.6.7. (Local semiconcavity) Let $\Omega \subseteq \mathbb{R}^m$ be open. A continuous function $u : \Omega \longrightarrow \mathbb{R}$ is *locally semiconcave* if each point has a convex neighborhood $V \subseteq \Omega$ on which, for some constant $C \ge 0$, the function

$$x \longmapsto u(x) - \frac{C}{2}|x|^2$$

is concave. On a smooth manifold, this condition is imposed on the coordinate representations of u. The constants may depend on the chosen chart and neighborhood; no global constant is required.

Concavity of a function v on V means that

$$v((1-t)x + ty) \ge (1-t)v(x) + tv(y), \qquad x, y \in V, \quad 0 \le t \le 1.$$

For a continuous function, it is enough to check this inequality at midpoints: repeated application of that inequality gives all dyadic coefficients, and continuity allows passage to any $t \in [0,1]$. We will use this observation both to recognize semiconcavity and to check that the definition is independent of coordinates.

Lemma 22.6.8. (Upper supports and changes of coordinates) Let $V \subseteq \mathbb{R}^m$ be open and convex, and let

$u \in C(V)$. Suppose that for each $x \in V$ there exists $\varphi_x \in C^2(V)$ such that $u \le \varphi_x$ on V, $u(x) = \varphi_x(x)$, and

$$D^2\varphi_x(y)[e,e] \le C|e|^2, \qquad y \in V, \quad e \in \mathbb{R}^m,$$

with the same constant $C \ge 0$. Then $u - C|x|^2/2$ is concave on V. Moreover, every locally semiconcave function is locally Lipschitz, and local semiconcavity is preserved under composition with a C^2 change of coordinates.

Proof. Let $x-h, x+h \in V$. Since V is convex, the segment joining these points lies in V. Taylor's formula with integral remainder, applied to $t \mapsto \varphi_x(x+th)$, gives

$$\varphi_x(x+h) + \varphi_x(x-h) - 2\varphi_x(x) = \int_{-1}^{1} (1-|t|) D^2\varphi_x(x+th)[h,h]\,dt \le C|h|^2.$$

The properties of the upper support imply

$$u(x+h) + u(x-h) - 2u(x) \le C|h|^2.$$

After subtracting $C|x|^2/2$, this inequality becomes midpoint concavity. The preceding observation proves the first assertion.

Let us prove local Lipschitz regularity. It suffices to prove it for a continuous concave function v, since the quadratic term is smooth. Choose $\overline{B(x_0,2r)} \subset V$ and set $M_r = \max_{\overline{B(x_0,2r)}} |v|$. If $x, y \in B(x_0,r)$ and $x \ne y$, define $d = |y-x|$ and $e = (y-x)/d$. The points $x-re$ and $y+re$ belong to $B(x_0,2r)$. Concavity along the line containing these four points gives

$$\frac{v(x) - v(x-re)}{r} \ge \frac{v(y)-v(x)}{d} \ge \frac{v(y+re)-v(y)}{r}.$$

Both outer quotients have absolute value at most $2M_r/r$. Therefore, $|v(y)-v(x)| \le (2M_r/r)|y-x|$.

Now let κ be a C^2 change of coordinates. Shrink its domains so that u is L–Lipschitz on a convex open set containing the image under consideration, $u - C|x|^2/2$ is concave there, and $\|D\kappa\| \le K_0$ and $\|D^2\kappa\| \le K_1$. This is possible by working in neighborhoods with compact closure contained in the domains. For $x-h, x+h$ in a convex ball in the smaller domain, set

$$z_\pm = \kappa(x \pm h), \qquad z_0 = \kappa(x), \qquad z_* = (z_+ + z_-)/2.$$

Semiconcavity at the points z_-, z_+ and the Lipschitz bound give

$$u(z_+) + u(z_-) - 2u(z_0) \le \frac{C}{4}|z_+ - z_-|^2 + 2L|z_* - z_0|.$$

The mean value theorem and the same Taylor formula imply

$$|z_+ - z_-| \le 2K_0|h|, \qquad |z_* - z_0| \le \frac{K_1}{2}|h|^2.$$

Consequently, the second increment of $u \circ \kappa$ is bounded above by $(CK_0^2 + LK_1)|h|^2$. The midpoint criterion proves its semiconcavity. Applying the same argument to κ^{-1} establishes the chart independence asserted in the definition. □

Lemma 22.6.9. (Regularity and cut locus of the reduced distance) For each compact interval $[\tau_0, \tau_1] \subset (0, \tau_{\max}]$, the functions L and l are locally Lipschitz on $M \times [\tau_0, \tau_1]$. For each $\tau > 0$, $U_p(\tau)$ is open, L and l are smooth there, and $\mathrm{Cut}_{\mathcal{L}}(p, \tau)$ has measure zero. Moreover, the restriction $l(\cdot, \tau)$ is locally semiconcave.

Proof. Fix a compact spacetime set $K \times [\tau_0, \tau_1] \subset M \times (0, \tau_{\max}]$. A comparison curve obtained by traversing a geodesic of a fixed metric, reparametrized by $r = \sqrt{s}$, gives a uniform upper bound for L on this compact set. The coercivity estimate (22.43) then implies

$$\int_0^{\sqrt{\tau}} |\mathbf{A}(r)|^2_{\mathbf{g}_{r^2}} \, dr \le C_K \tag{22.65}$$

for every minimizer with endpoint in the compact set. Since $\sqrt{\tau} \ge \sqrt{\tau_0}$, there exists $r_* \in [\sqrt{\tau}/2, 3\sqrt{\tau}/4]$ such that $|\mathbf{A}(r_*)|^2 \le C_K$. Equation (22.41) and the identity $\partial_r \mathbf{g}_{r^2} = 4r \, \mathrm{Ric}_{r^2}$ give, for $E(r) = |\mathbf{A}(r)|^2_{\mathbf{g}_{r^2}}$,

$$E'(r) = 4r^2 \langle \nabla R_{r^2}, \mathbf{A} \rangle - 4r \, \mathrm{Ric}_{r^2}(\mathbf{A}, \mathbf{A}), \qquad |E'(r)| \le C_K (1 + E(r)).$$

Integrate from r_* in both directions. Grönwall's inequality bounds E on all of $[0, \sqrt{\tau}]$, including the initial datum and the final velocity. Since $\tau \ge \tau_0$, $|\mathbf{X}(\tau)| = |\mathbf{A}(\sqrt{\tau})|/(2\sqrt{\tau})$ is also uniformly bounded. The initial data $\mathbf{A}(0)/2 \in T_pM$ lie in a compact ball independent of the minimizer.

Now fix a minimizer γ up to (q, τ). Choose a number $d > 0$ smaller than $\tau_0/4$ and set $s_0 = \tau - d$. We will shrink d once, depending on the preceding uniform bounds. On the interval $[s_0, \tau]$, the Lagrangian

$$(x, V, s) \longmapsto \sqrt{s}\big(R_s(x) + |V|^2_{\mathbf{g}_s}\big)$$

is smooth and uniformly convex in V. In normal coordinates for a fixed metric around q, the Euler–Lagrange equation is a regular ordinary differential system. By smooth dependence of its solutions and the inverse function theorem, if d is sufficiently small, the map sending the initial velocity at s_0 to the endpoint at τ is a diffeomorphism between neighborhoods. In coordinates, its differential is $dI + O(d^2)$, uniformly over the compact set of positions, times, and velocities under consideration. Thus the choice of d and the bounds on the derivatives of the inverse can be made uniform. In particular, the segment $\gamma|_{[s_0,\tau]}$ is the unique short extremal joining its endpoints, has no conjugate point, and depends smoothly on the final endpoint and final time.

Let us make the control of the domain of the inverse precise. In a fixed chart, denote by $E_\sigma(w)$ the endpoint at time σ of the solution starting at $\gamma(s_0)$ with velocity w, and let w_0 be the velocity of the chosen segment. The velocities w_0 remain in a bounded set. Choose a radius $b > 0$ and shrink d so that, on $\overline{B(w_0, b)}$, all these solutions remain in the chart and

$$\big\| d^{-1} D_w E_\tau(w) - I \big\| \le \frac{1}{4}.$$

This choice can be made uniform: the positions, times, and velocities range over compact sets in a finite atlas, and the derivatives of the ordinary differential system are bounded on a neighborhood of these compact sets. By uniform continuity, for $|\sigma - \tau|$ sufficiently small, the preceding bound remains at most $1/2$ and $|E_\sigma(w_0) - E_\tau(w_0)| < db/8$. If, in addition, $|y - E_\tau(w_0)| < db/8$, the map

$$w \longmapsto w + d^{-1}(y - E_\sigma(w))$$

is a contraction with constant $1/2$ that maps $\overline{B(w_0, b)}$ into itself: its distance from w_0 is at most $b/2 + b/4$. Its fixed point solves $E_\sigma(w) = y$. We thus obtain a spacetime neighborhood of uniform radius on which the inverse is defined. Its first two derivatives are uniformly bounded after shrinking this neighborhood once more, by the formula for the derivative of the inverse and the bounds on the first two derivatives of E_σ. In particular, after fixing a spacetime point and shrinking a convex coordinate neighborhood around it, all supports constructed from points of this neighborhood will be defined throughout it. Changes between the charts of the finite atlas preserve the bounds, since their first two derivatives are bounded on the compact sets under consideration.

After shrinking a neighborhood of (q, τ), denote the action of this short extremal by $L_{(\gamma(s_0),s_0)}(y, \sigma)$ and set

$$\Phi_{s_0}(y, \sigma) := \mathcal{L}(\gamma|_{[0,s_0]}) + L_{(\gamma(s_0),s_0)}(y, \sigma).$$

Concatenating the first portion of γ with the short extremal ending at (y, σ) gives an admissible curve; hence $L(y, \sigma) \le \Phi_{s_0}(y, \sigma)$, with equality at (q, τ). Smooth dependence of this extremal on the endpoints and the uniform bounds for the ordinary differential system and its inverse give bounds on its first two derivatives with respect to (y, σ). Differentiating the action integral over the short interval gives a uniform bound on the spatial Hessian of Φ_{s_0} and on its first spatial and time derivatives. The interval is bounded away from $s = 0$, and its length has a positive lower bound in the chosen neighborhood, so these constants remain finite.

Work in one of the common convex neighborhoods obtained above, and write $z = (x, \tau)$ for its spacetime coordinates. Denote by Φ_z the support constructed from z. If z' lies in this same neighborhood, the uniform bound $|D\Phi_z| \le A$ implies

$$L(z') - L(z) \le \Phi_z(z') - \Phi_z(z) \le A|z' - z|.$$

Interchanging z and z' gives the reverse inequality. This proves local Lipschitz regularity of L and, in particular, its continuity. On each time slice, the supports have a common Hessian bound and are defined on a common domain. Lemma 22.6.8 then gives semiconcavity of $L(\cdot, \tau)$. Since $\tau \ge \tau_0 > 0$, multiplication by $1/(2\sqrt{\tau})$ preserves local spacetime Lipschitz regularity and spatial semiconcavity. The constants for both properties of l can be chosen uniformly on compact sets bounded away from $\tau = 0$.

It remains to determine the size of the cut locus. We already observed after Definition 22.6.3 that $U_p(\tau)$ is open and the functions are smooth there. Now let $q \notin U_p(\tau)$ and suppose that q is not a critical value of $\mathcal{L}\exp_p^\tau$. If $L(\cdot, \tau)$ were differentiable at q, the first variation would force all minimizers ending at q to have the same final velocity. Backward uniqueness for (22.42) would show that there is only one minimizer, with regular initial datum v.

This uniqueness persists in a neighborhood. Indeed, otherwise there would exist $q_j \to q$ and minimizers with initial data outside a neighborhood of v, or two distinct data with the same endpoint. The bounds (22.65) and the preceding Grönwall argument make the family of these initial data compact. A subsequence would converge to a datum determining a minimizer up to q; by uniqueness, the limit would be v. For large j, all data would then lie in a neighborhood on which $\mathcal{L}\exp_p^\tau$ is a diffeomorphism, a contradiction. Thus q would belong to $U_p(\tau)$.

The same compactness argument for the initial data applies when both the endpoint and the final time vary. Therefore, uniqueness of a nonconjugate minimizer persists in a spacetime neighborhood. The inverse function theorem with time as a parameter shows that $\mathcal{U} = \{(q, \tau) \in M \times (0, \tau_{\max}] \mid q \in U_p(\tau)\}$ is open in that space and that L and l are smooth on $\mathcal{U}$.

We have proved that the cut locus is contained in the union of the critical values of $\mathcal{L}\exp_p^\tau$ and the set of points where $L(\cdot,\tau)$ is not differentiable. The first set has measure zero by Sard's theorem, and the second by Rademacher's theorem. This completes the proof. □

Lemma 22.6.10. (Semiconcavity and the distributional Hessian) Let $(N^m,\mathbf{h})$ be a smooth Riemannian manifold without boundary, and let u be locally semiconcave. Then $u \in W^{1,\infty}_{\mathrm{loc}}(N)$, its distributional Hessian is a symmetric tensor with values in Radon measures, and the singular part of $\mathrm{Hess}_{\mathbf{h}}\, u$ is negative semidefinite. In particular, the singular part of $\Delta_{\mathbf{h}} u$ is a nonpositive measure.

Proof. Fix a chart and write $\widehat{u} = u\circ\varphi^{-1}$. Shrink its image to a convex open set V on which $v(x) = \widehat{u}(x) - C|x|^2/2$ is concave. By Lemma 22.6.8, $\widehat{u}$ is locally Lipschitz. Theorem 7.2.1 gives its almost everywhere derivatives, which are locally bounded. They are also its weak derivatives: for a test function $\psi \in C_c^\infty(V)$, transfer the quotient $[\widehat{u}(x+te_j)-\widehat{u}(x)]/t$ to ψ by a change of variables. The Lipschitz bound and dominated convergence allow us to let $t \to 0$ and give

$$\int_V D_j\widehat{u}\,\psi\, d\lambda_m = -\int_V \widehat{u}\,\partial_j\psi\, d\lambda_m.$$

This proves that $u \in W^{1,\infty}_{\mathrm{loc}}(N)$.

Let us prove that the second derivatives of v are measures. For a constant vector $e \in \mathbb{R}^m$, concavity implies $v(x+te)+v(x-te)-2v(x) \le 0$ whenever the segment lies in V. If $\psi \in C_c^\infty(V)$ is nonnegative and $t \neq 0$ is sufficiently small, integrate this inequality after multiplying by ψ/t^2. Transferring the increments to the test function gives

$$\int_V v(x)\frac{\psi(x+te)+\psi(x-te)-2\psi(x)}{t^2}\, d\lambda_m(x) \le 0.$$

The quotient converges uniformly to $D_{ee}\psi$, with support in a fixed compact set. Since v is locally integrable, passage to the limit gives

$$\langle D_{ee}v, \psi\rangle \le 0.$$

Thus $-D_{ee}v$ is a positive distribution. Theorem 4.6.3 represents it by a positive Radon measure. In particular, if $K \subset V$ is compact and $0 \le \chi \in C_c^\infty(V)$ equals one near K, positivity gives the order-zero bound

$$|\langle D_{ee}v,\psi\rangle| \le \|\psi\|_\infty \langle -D_{ee}v, \chi\rangle, \qquad \mathrm{supp}(\psi) \subseteq K.$$

Here positivity is applied to $\|\psi\|_\infty\chi + \psi$ and $\|\psi\|_\infty\chi - \psi$.

Distributional derivatives commute. The polarization identity

$$2D_{ij}v = D_{e_i+e_j,e_i+e_j}v - D_{ii}v - D_{jj}v$$

shows that all $D_{ij}v$ are local signed Radon measures, in the sense of Definition B.5.22. Denote them by μ_{ij}. The matrix (μ_{ij}) is symmetric and, for every $e \in \mathbb{R}^m$,

$$\sum_{i,j=1}^m e_i e_j \mu_{ij} = D_{ee}v \le 0.$$

This inequality also determines the sign for directions varying with the point. To see this, on an open set

V_0 with compact closure contained in V, take the finite positive measure

$$\nu = \lambda_m \restriction_{V_0} + \sum_{i,j=1}^{m} |\mu_{ij}| \restriction_{V_0}.$$

Theorem B.6.29, applied to the positive and negative variations, gives densities $a_{ij} = d\mu_{ij}/d\nu$ and $r = d\lambda_m/d\nu$. For each vector $e \in \mathbb{Q}^m$, we have $\sum_{i,j=1}^{m} e_i e_j a_{ij} \le 0$ outside a ν-null set. Since $\mathbb{Q}^m$ is countable, we can exclude a single null set for all these directions. By density, the symmetric matrix $\mathbf{a} = (a_{ij})$ is negative semidefinite at ν-almost every point.

Set $S = \{x \in V_0 \mid r(x) = 0\}$. Then $\lambda_m(S) = 0$ and, on $V_0 \setminus S$, the preceding measures have densities a_{ij}/r with respect to λ_m. Thus their decomposition into absolutely continuous and singular parts is

$$\mu_{ij} = \mathbf{1}_{V_0 \setminus S} \frac{a_{ij}}{r}\, d\lambda_m + \mathbf{1}_S a_{ij}\, d\nu.$$

The measures in this equality are restricted to V_0, and the first coefficient is extended by zero on S. The second summand is the singular part, and its matrix has the sign already established. Since $D_{ij}\widehat{u} = \mu_{ij} + C\delta_{ij}\, d\lambda_m$, the quadratic term does not change this singular part.

We now pass to the Riemannian Hessian, taking care with the measure used to identify functions with distributions. In this chart, $D_{ij}\widehat{u}$ is a measure written with the Euclidean convention, whereas $d\lambda_{\mathbf{h}} = \sqrt{\det(\mathbf{h})}\, d\lambda_m$. If H_{ij} denotes the coefficient of the distributional Hessian when represented by measures, then

$$\mathsf{H}_{ij} = \sqrt{\det(\mathbf{h})}\, D_{ij}\widehat{u} - \left(\sum_{k=1}^{m} \Gamma_{ij}^{k} D_k \widehat{u} \right) d\lambda_{\mathbf{h}}.$$

Indeed, for a smooth function this is the coordinate formula $\operatorname{Hess}_{\mathbf{h}} u = \nabla du$ multiplied by the volume element. For the present function, regularize $\widehat{u}$ by convolution in a smaller chart. The approximations converge in $W^{1,1}$ on compact sets, and their second derivatives converge distributionally to $D_{ij}\widehat{u}$. Continuity of distributional differentiation and multiplication by smooth coefficients allows passage to the limit in the formula. On overlaps, we also pass to the limit in the tensor transformation law for the smooth Hessians, since the coordinate changes and their coefficients are smooth. The resulting measures therefore represent the intrinsic tensor ∇du and are independent of the chart.

The term containing the Christoffel symbols has locally bounded density. Moreover, λ_m and $\lambda_{\mathbf{h}}$ have the same null sets. Consequently,

$$\mathsf{H}^{\mathrm{s}}_{ij} = \sqrt{\det(\mathbf{h})}\, \mathbf{1}_S a_{ij}\, d\nu.$$

The square root of the determinant is positive, and $\mathbf{a}$ is negative semidefinite; this proves the assertion about the singular Hessian. Its contraction with the inverse metric is

$$(\Delta_{\mathbf{h}} u)^{\mathrm{s}} = \sqrt{\det(\mathbf{h})}\, \mathbf{1}_S \left(\sum_{i,j=1}^{m} h^{ij} a_{ij} \right) d\nu \le 0.$$

The sign follows because the trace of the product of a positive definite matrix and a negative semidefinite matrix is nonpositive.

We also record the local control that we will need as time varies. If a family of functions u_τ has uniform

bounds on $\|\widehat{u}_\tau\|_\infty$, its Lipschitz constant, and its semiconcavity constant in a common chart, the total variations of the Hessian measures are uniformly bounded on every compact subset of the interior. Indeed, for $v_\tau = \widehat{u}_\tau - C|x|^2/2$ and the preceding cutoff function χ,

$$(-D_{ee}v_\tau)(K) \le \langle -D_{ee}v_\tau, \chi\rangle \le \|v_\tau\|_{L^\infty(\operatorname{supp}\chi)}\|D_{ee}\chi\|_{L^1(\mathbb{R}^m)}.$$

Apply this bound to the finitely many directions e_i and $e_i + e_j$ and use polarization. The quadratic term and the Christoffel terms are controlled by the bounds already stated. This control remains uniform for a smooth family of metrics on a compact interval, since their coefficients, inverses, and first derivatives are bounded in the smaller chart. □

Proposition 22.6.11. (Variational geometry of $\mathcal{L}$) Let M be a smooth closed connected manifold, and let $\mathbf{g}(t)$ be a smooth Ricci flow on an interval containing $[t_0 - \tau_{\max}, t_0]$. For each $q \in M$ and $0 < \tau \le \tau_{\max}$, there exists a minimizer of $\mathcal{L}$. On the regular set, (22.46) and (22.57)–(22.59) hold. On the entire manifold, the reduced function satisfies, in the distributional sense,

$$\partial_\tau l - \Delta_\tau l + |\nabla^{\mathbf{g}_\tau} l|^2_{\mathbf{g}_\tau} - R_\tau + \frac{m}{2\tau} \ge 0. \tag{22.66}$$

Proof. Existence and the formulas on the regular set were proved in the preceding lemmas. By Lemma 22.6.9, l is locally Lipschitz in spacetime, and the cut locus has measure zero on each slice. Fubini's theorem then shows that (22.60) holds almost everywhere on $M \times (0, \tau_{\max}]$.
Fix a compact interval $J \subset (0, \tau_{\max})$. For almost every $\tau \in J$, write the Laplacian measure of $l(\cdot, \tau)$ as

$$\Delta_\tau l = (\Delta_\tau l)_{\mathrm{ac}}\, d\lambda_{\mathbf{g}_\tau} + \mu^{\mathrm{s}}_\tau.$$

Lemma 22.6.10 gives $\mu^{\mathrm{s}}_\tau \le 0$. On the regular open set, the density $(\Delta_\tau l)_{\mathrm{ac}}$ agrees with the classical Laplacian. Since the complement of that open set has volume measure zero, the almost everywhere inequality obtained above implies

$$\partial_\tau l - (\Delta_\tau l)_{\mathrm{ac}} + |\nabla^{\mathbf{g}_\tau} l|^2_{\mathbf{g}_\tau} - R_\tau + \frac{m}{2\tau} \ge 0$$

at almost every point of each of these slices.
Let $\psi \ge 0$ be a smooth function with compact support contained in $M \times \operatorname{Int}(J)$. Integrating on a slice, the sign of $-\mu^{\mathrm{s}}_\tau$ gives

$$\int_M \left(\partial_\tau l + |\nabla^{\mathbf{g}_\tau} l|^2_{\mathbf{g}_\tau} - R_\tau + \frac{m}{2\tau}\right)\psi\, d\lambda_{\mathbf{g}_\tau} - \langle \Delta_\tau l, \psi(\cdot,\tau)\rangle \ge 0.$$

The Laplacian pairing can be written without separating its two parts:

$$\langle \Delta_\tau l, \psi(\cdot,\tau)\rangle = -\int_M \langle \nabla^{\mathbf{g}_\tau} l, \nabla^{\mathbf{g}_\tau}\psi\rangle_{\mathbf{g}_\tau}\, d\lambda_{\mathbf{g}_\tau}.$$

This identity is the weak definition of the Laplacian and holds because $l(\cdot,\tau)$ is locally Lipschitz. Its right-hand side depends measurably on τ and is integrable on J: the weak gradient of l is jointly measurable and uniformly bounded on the support of ψ, and the metric coefficients are smooth. The same holds for the remaining terms. The uniform control of the measures on compact sets, proved at the end of the preceding lemma, also applies here, since the semiconcavity and Lipschitz bounds for l are uniform on J. Thus

time integration is justified directly by Fubini's theorem, without presupposing measurability of a separate choice of the singular measures. We obtain

$$\int_J \left\{ \int_M \left(\partial_\tau l + |\nabla^{\mathbf{g}_\tau} l|^2_{\mathbf{g}_\tau} - R_\tau + \frac{m}{2\tau} \right) \psi \, d\lambda_{\mathbf{g}_\tau} + \int_M \langle \nabla^{\mathbf{g}_\tau} l, \nabla^{\mathbf{g}_\tau} \psi \rangle_{\mathbf{g}_\tau} \, d\lambda_{\mathbf{g}_\tau} \right\} d\tau \geq 0.$$

Finally, the weak time derivative also agrees with the almost everywhere derivative of l. For the spacetime measure we use, $\partial_\tau d\lambda_{\mathbf{g}_\tau} = R_\tau d\lambda_{\mathbf{g}_\tau}$; hence integration by parts in time takes the form

$$\int_J \int_M (\partial_\tau l)\psi \, d\lambda_{\mathbf{g}_\tau} d\tau = -\int_J \int_M l(\partial_\tau \psi + R_\tau \psi) \, d\lambda_{\mathbf{g}_\tau} d\tau.$$

The preceding inequality is therefore exactly (22.66) in the distributional sense. Since the interval J and the test function were arbitrary, this justifies the formulation used below; it corresponds to the extension developed in [104, Theorem 7.13]. □

Definition 22.6.12. (Reduced volume) The reduced volume based at (p, t_0) is

$$\widetilde{V}(\tau) := \int_M (4\pi\tau)^{-m/2} e^{-l(q,\tau)} \, d\lambda_{\mathbf{g}(t_0-\tau)}(q). \tag{22.67}$$

To identify the initial value of the reduced volume, we need a quantitative comparison with the Euclidean model.

Lemma 22.6.13. (Gaussian behavior for small times) Fix $A > 0$. There exist $C_A > 0$ and $\tau_A > 0$ such that, in normal coordinates for $\mathbf{g}(t_0)$ centered at p,

$$\left| l(\exp_p(\sqrt{\tau}\, z), \tau) - \frac{|z|^2_{\mathbf{g}(t_0)}}{4} \right| \leq C_A \tau \tag{22.68}$$

for $|z| \leq A$ and $0 < \tau \leq \tau_A$. Moreover, there exist $c, C > 0$ such that

$$l(q, \tau) \geq c \frac{d_{\mathbf{g}(t_0)}(p, q)^2}{\tau} - C\tau \tag{22.69}$$

for every $q \in M$ and every sufficiently small τ.

Proof. The curvature bound on a short interval provides a uniform bound on $|\mathrm{Ric}_{\mathbf{g}_s}|_{\mathbf{g}_s}$ and $|R_s|$. Lemma 22.1.8 compares $\mathbf{g}_s$ with $\mathbf{g}(t_0)$ by factors $e^{\pm 2Ks}$. On a bounded interval, the inequalities $e^{-2Ks} \geq 1 - 2Ks$ and $e^{2Ks} \leq 1 + 2Ke^{2K\tau_0} s$ allow us to choose $C, \tau_0 > 0$ such that

$$(1 - C\tau)\mathbf{g}(t_0) \leq \mathbf{g}_s \leq (1 + C\tau)\mathbf{g}(t_0), \qquad |R_s| \leq C, \quad 0 \leq s \leq \tau \leq \tau_0.$$

Shrink τ_0 so that $C\tau_0 \leq 1/2$. The first inequality means, at each point and for each vector,

$$(1 - C\tau)|v|^2_{\mathbf{g}(t_0)} \leq |v|^2_{\mathbf{g}_s}.$$

Thus $|v|_{\mathbf{g}(t_0)} \le \sqrt{2}|v|_{\mathbf{g}_s}$, with a constant independent of s and τ. Let $d_0 = d_{\mathbf{g}(t_0)}$. For any admissible curve,

$$d_0(p,q) \le \int_0^\tau |\dot\gamma(s)|_{\mathbf{g}(t_0)}\, ds \le \sqrt{2}\int_0^\tau s^{1/4}|\dot\gamma(s)|_{\mathbf{g}_s} s^{-1/4}\, ds.$$

Cauchy–Schwarz with the weights $s^{1/4}$ and $s^{-1/4}$ gives

$$d_0(p,q)^2 \le C\left(\int_0^\tau \sqrt{s}|\dot\gamma|^2_{\mathbf{g}_s} ds\right)\left(\int_0^\tau s^{-1/2} ds\right).$$

Since the second integral is $2\sqrt{\tau}$ and the curvature term is bounded by $C\tau^{3/2}$, we obtain (22.69).
For the local estimate, use the variable $r = \sqrt{s}$. If $q = \exp_p(\sqrt{\tau}z)$, the radial curve $\alpha(r) = \exp_p(rz)$ gives, by (22.40),

$$L(q,\tau) \le \frac{\sqrt{\tau}}{2}|z|^2 + C_A\tau^{3/2}.$$

Now let α be a minimizer. Since the scalar term is bounded below and the preceding upper bound is $O_A(\sqrt{\tau})$, we obtain the sharper estimate

$$\int_0^{\sqrt{\tau}} |\alpha'(r)|^2_{\mathbf{g}(t_0)}\, dr \le C_A\sqrt{\tau}. \tag{22.70}$$

By Cauchy–Schwarz, for $0 \le r \le \sqrt{\tau}$,

$$d_{\mathbf{g}(t_0)}(p,\alpha(r)) \le \int_0^r |\alpha'(\rho)|_{\mathbf{g}(t_0)}\, d\rho \le C_A\sqrt{\tau}.$$

The minimizer therefore remains in the normal ball of radius $C_A\sqrt{\tau}$. In these coordinates, the coefficient matrix of $\mathbf{g}(t_0)$ differs from its value at p by $O_A(\tau)$ along the curve, while the flow equation gives $\mathbf{g}_{r^2} = \mathbf{g}(t_0) + O(\tau)$. Consequently, the coefficients of $\mathbf{g}_{r^2}$ differ from those of the Euclidean form $\mathbf{g}(t_0)|_p$ by $O_A(\tau)$ uniformly along the minimizer. The Euclidean energy inequality then gives

$$\frac{1}{2}\int_0^{\sqrt{\tau}} |\alpha'(r)|^2_{\mathbf{g}_{r^2}}\, dr \ge \frac{\sqrt{\tau}}{2}|z|^2 - C_A\tau^{3/2}.$$

The curvature term has absolute value at most $C\tau^{3/2}$. Together with the radial upper bound, this gives

$$\left|L(\exp_p(\sqrt{\tau}z),\tau) - \frac{\sqrt{\tau}}{2}|z|^2\right| \le C_A\tau^{3/2},$$

, and division by $2\sqrt{\tau}$ proves (22.68). □

Theorem 22.6.14. (Monotonicity of the reduced volume) Let M be a smooth closed connected manifold, and let $\mathbf{g}(t)$ be a smooth Ricci flow on an interval containing $[t_0 - \tau_{\max}, t_0]$. The reduced volume is locally Lipschitz and nonincreasing on $(0, \tau_{\max}]$. In particular,

$$\frac{d}{d\tau}\widetilde{V}(\tau) \le 0 \quad \text{for almost every } \tau \in (0,\tau_{\max}), \qquad \lim_{\tau\to 0^+}\widetilde{V}(\tau) = 1.$$

Moreover, $\widetilde{V}$ is invariant under parabolic rescalings.

Proof. Set $v(q,\tau) = (4\pi\tau)^{-m/2} e^{-l(q,\tau)}$. Let us explain the passage to e^{-l} in the presence of the singular part of the Hessian. For almost every τ, write

$$\Delta_\tau l = (\Delta_\tau l)_{\mathrm{ac}}\, d\lambda_{\mathbf{g}_\tau} + \mu_\tau^{\mathrm{s}}, \qquad \mu_\tau^{\mathrm{s}} \le 0.$$

The weak chain rule gives $\nabla(e^{-l}) = -e^{-l}\nabla l$. For a smooth test function φ with compact support in a chart, apply the definition of the measure $\Delta_\tau l$ to φe^{-l}:

$$\int_M \varphi e^{-l}\, d(\Delta_\tau l) = -\int_M e^{-l}\langle \nabla\varphi, \nabla l\rangle\, d\lambda_{\mathbf{g}_\tau} + \int_M \varphi e^{-l}|\nabla l|^2\, d\lambda_{\mathbf{g}_\tau}.$$

The use of a Lipschitz test function here is justified by approximating it uniformly and in $W^{1,2}$ by smooth functions; uniform convergence controls the pairing with the measure. Comparison with the definition of $\Delta_\tau(e^{-l})$ gives

$$\Delta_\tau(e^{-l}) = e^{-l}\big(-(\Delta_\tau l)_{\mathrm{ac}} + |\nabla l|^2\big)\, d\lambda_{\mathbf{g}_\tau} - e^{-l}\mu_\tau^{\mathrm{s}}. \tag{22.71}$$

The absolutely continuous part of $(\partial_\tau - \Delta_{\mathbf{g}_\tau} + R_\tau)v$ is the product of $-v$ and the left-hand side of (22.66); its singular part is $v\mu_\tau^{\mathrm{s}}$, which is also nonpositive. Consequently,

$$(\partial_\tau - \Delta_{\mathbf{g}_\tau} + R_\tau)v \le 0 \tag{22.72}$$

in the sense of distributions. Since $\partial_\tau d\lambda_{\mathbf{g}_\tau} = R_\tau d\lambda_{\mathbf{g}_\tau}$ and M is closed, testing (22.72) against the spatially constant function one gives

$$\frac{d}{d\tau}\widetilde{V}(\tau) = \int_M (\partial_\tau v + R_\tau v)\, d\lambda_{\mathbf{g}_\tau} \le 0$$

in distributions. Since l is Lipschitz on each compact time interval bounded away from zero and M is compact, the integral defining $\widetilde{V}$ is locally Lipschitz. Its continuous representative is therefore nonincreasing, and its ordinary derivative is nonpositive almost everywhere.

For the initial limit, fix $A \ge 1$ and use $q = \exp_p(\sqrt{\tau}z)$. On each ball $|z| \le A$, (22.68) gives $l(q,\tau) \to |z|^2/4$ uniformly. Moreover,

$$d\lambda_{\mathbf{g}_\tau}(q) = \tau^{m/2} J_\tau(z)\, dz, \qquad J_\tau(z) \longrightarrow 1$$

uniformly on that ball. Compactness of M and smoothness of the initial metric give $\mathrm{Vol}_{\mathbf{g}(t_0)} B(p,r) \le Cr^m$ for every $r > 0$: for small radii we use normal charts, and for the remaining radii we use the total volume. The measures of $\mathbf{g}_\tau$ and $\mathbf{g}(t_0)$ are uniformly comparable for small τ. Divide the complement of $B(p, A\sqrt{\tau})$ into the annuli

$$\{q \in M \mid 2^k A\sqrt{\tau} \le d_0(p,q) < 2^{k+1}A\sqrt{\tau}\}, \qquad k \in \mathbb{N}_0.$$

The bound (22.69) then gives

$$\int_{M\setminus B_{\mathbf{g}(t_0)}(p, A\sqrt{\tau})} v\, d\lambda_{\mathbf{g}_\tau} \le C\sum_{k=0}^{\infty} (2^{k+1}A)^m e^{-c4^k A^2}.$$

This series tends to zero as $A \to \infty$, uniformly for small τ: the exponential absorbs the polynomial factor and bounds the series by a multiple of $\sum_{k=0}^{\infty} e^{-(c/2)4^k A^2}$. First let $\tau \to 0^+$ with A fixed, and then let $A \to \infty$.

Dominated convergence gives

$$\lim_{\tau\to 0^+}\widetilde{V}(\tau)=(4\pi)^{-m/2}\int_{\mathbb{R}^m}e^{-|z|^2/4}\,dz=1.$$

Finally, for $Q>0$, let $\widehat{\mathbf{g}}(\sigma)=Q\mathbf{g}(t_0+\sigma/Q)$. A change of variables in (22.38) shows that $l_{\widehat{\mathbf{g}}}(q,Q\tau)=l_{\mathbf{g}}(q,\tau)$, while $d\lambda_{\widehat{\mathbf{g}}(-Q\tau)}=Q^{m/2}d\lambda_{\mathbf{g}(t_0-\tau)}$. This factor cancels $(Q\tau)^{-m/2}$ and proves invariance. □

22.7 The noncollapsing theorem

A curvature bound alone does not suffice to obtain a smooth limit: a sequence may lose volume at the scale being observed. The entropy μ prevents this phenomenon during a finite time interval. The idea is to compare two estimates for the same quantity. Its monotonicity provides a lower bound determined by the initial metric; a test function concentrated on a ball, on the other hand, shows that a very small volume ratio would make μ arbitrarily negative.

Definition 22.7.1. (Noncollapsing at scale r) Let M be a smooth manifold without boundary, and let $\mathbf{g}(t)$ be a Ricci flow defined on an interval I. Whenever $[t_0-r^2,t_0]\subseteq I$, set

$$P^-(x_0,t_0,r):=B_{\mathbf{g}(t_0)}(x_0,r)\times[t_0-r^2,t_0]. \tag{22.73}$$

We say that the flow is κ–noncollapsed at scale r at (x_0,t_0) if the implication

$$|\mathrm{Rm}_{\mathbf{g}(t)}|_{\mathbf{g}(t)}\le r^{-2}\ \text{on}\ P^-(x_0,t_0,r)\quad\Longrightarrow\quad \mathrm{Vol}_{\mathbf{g}(t_0)}B_{\mathbf{g}(t_0)}(x_0,r)\ge\kappa r^m$$

holds.

We first isolate the two functional and geometric ingredients of the proof.

Lemma 22.7.2. (Lower bound for μ at bounded scales) Let $(M^m,\mathbf{h})$ be a closed Riemannian manifold. For each $A>0$, there exists $C=C(\mathbf{h},A)<\infty$ such that

$$\mu(\mathbf{h},\sigma)\ge -C\qquad(0<\sigma\le A).$$

Proof. To obtain a uniform bound as σ tends to zero, we need to retain the dimensional coefficient of the logarithmic term. Choose $q>2$ in the range of the embedding of H^1 into L^q: if $m\ge 3$, take $q<2m/(m-2)$; if $m\le 2$, any $q<\infty$ suffices. The Euclidean Gagliardo–Nirenberg inequality we need is

$$\|w\|_{L^q(\mathbb{R}^m)}\le C\|dw\|^{\theta}_{L^2(\mathbb{R}^m)}\|w\|^{1-\theta}_{L^2(\mathbb{R}^m)},\qquad \theta=m\left(\frac12-\frac1q\right),\quad w\in C_c^\infty(\mathbb{R}^m).$$

It follows from the Euclidean embedding $H^1\hookrightarrow L^q$ in the Sobolev chapter by applying it to $w(\lambda\cdot)$: for each $\lambda>0$,

$$\|w\|_{L^q(\mathbb{R}^m)}\le C\big(\lambda^{1-\theta}\|dw\|_{L^2(\mathbb{R}^m)}+\lambda^{-\theta}\|w\|_{L^2(\mathbb{R}^m)}\big).$$

If $w\neq 0$, choose $\lambda=\|w\|_{L^2(\mathbb{R}^m)}/\|dw\|_{L^2(\mathbb{R}^m)}$; the case $w=0$ is immediate. Applying this inequality to the

localizations of v in a finite atlas of $(M,\mathbf{h})$ gives

$$\|v\|_{L^q(M)} \le C\left(\|dv\|^{\theta}_{L^2(M,T^*M)}\|v\|^{1-\theta}_{L^2(M)} + \|v\|_{L^2(M)}\right), \qquad \theta = m\left(\frac{1}{2}-\frac{1}{q}\right) \in (0,1).$$

Derivatives of the partition of unity contribute the second summand; the finite number of charts allows us to use a common constant C. With $\|v\|_{L^2(M)} = 1$ and $E = \|dv\|^2_{L^2(M,T^*M)}$, the Jensen inequality used in (22.35) implies

$$\begin{aligned}\int_M v^2 \log v^2 \, d\lambda_{\mathbf{h}} &\le \frac{2q}{q-2}\log\|v\|_{L^q(M)} \\ &\le \frac{q\theta}{q-2}\log(1+E) + C = \frac{m}{2}\log(1+E) + C.\end{aligned}$$

For $0 < \eta \le 1$, set $z = \eta(1+E) > 0$. Then

$$\frac{m}{2}\log(1+E) - \eta E = -\frac{m}{2}\log\eta + \frac{m}{2}\log z - z + \eta \le -\frac{m}{2}\log\eta + C_m,$$

since the function $z \mapsto (m/2)\log z - z$ attains its maximum at $z = m/2$. Thus we obtain a constant $C_0 = C_0(M,\mathbf{h})$ such that

$$\int_M v^2 \log v^2 \, d\lambda_{\mathbf{h}} \le \eta \int_M |dv|^2_{\mathbf{h}} \, d\lambda_{\mathbf{h}} - \frac{m}{2}\log\eta + C_0. \tag{22.74}$$

The variational expression for μ is

$$\begin{aligned}\mathcal{J}_{\mathbf{h},\sigma}(v) = 4\sigma\int_M |dv|^2_{\mathbf{h}}\, d\lambda_{\mathbf{h}} + \sigma\int_M R_{\mathbf{h}} v^2 \, d\lambda_{\mathbf{h}} - \int_M v^2\log v^2 \, d\lambda_{\mathbf{h}} \\ - \frac{m}{2}\log(4\pi\sigma) - m.\end{aligned}$$

If $0 < \sigma \le 1/2$, take $\eta = 2\sigma$ in (22.74). The coefficient of the energy becomes $2\sigma \ge 0$, and the difference between $\frac{m}{2}\log(2\sigma)$ and $\frac{m}{2}\log(4\pi\sigma)$ is constant. Since $R_{\mathbf{h}}$ is bounded below, we obtain a bound independent of σ. For $1/2 \le \sigma \le A$, use $\eta = 1$; then $4\sigma - 1 \ge 1$ and the remaining terms are uniformly bounded below on this compact interval. Taking the infimum over $\|v\|_{L^2(M)} = 1$ proves the lemma. □

Lemma 22.7.3. (Cutoff function on a ball with bounded curvature) There exist constants $c_m, C_m > 0$ with the following property. If $(N^m,\mathbf{h})$ is complete and $|\mathrm{Rm}_{\mathbf{h}}|_{\mathbf{h}} \le r^{-2}$ on $B_{\mathbf{h}}(x,r)$, there exists a Lipschitz function $\zeta\colon N \to [0,1]$ such that

$$\zeta = 1 \text{ on } B_{\mathbf{h}}(x,r/2), \qquad \operatorname{supp}\zeta \subseteq \overline{B_{\mathbf{h}}(x,r)}, \qquad |d\zeta|_{\mathbf{h}} \le \frac{C_m}{r}$$

almost everywhere. If $V = \mathrm{Vol}_{\mathbf{h}} B_{\mathbf{h}}(x,r)$ and $Z = \displaystyle\int_N \zeta^2 \, d\lambda_{\mathbf{h}}$, then

$$c_m V \le Z \le V. \tag{22.75}$$

Proof. Let $\eta\colon [0,\infty) \to [0,1]$ be a Lipschitz function that equals one on $[0,1/2]$, vanishes on $[1,\infty)$, and satisfies $|\eta'| \le 3$. Take $\zeta(y) = \eta(d_{\mathbf{h}}(x,y)/r)$. The support and gradient properties follow because the distance

function is 1–Lipschitz. Moreover,

$$\operatorname{Vol}_{\mathbf{h}} B_{\mathbf{h}}(x, r/2) \le Z \le V.$$

The curvature assumption implies $\operatorname{Ric}_{\mathbf{h}} \ge -(m-1)r^{-2}\mathbf{h}$ on the ball. Relative Bishop–Gromov comparison between radii $r/2$ and r gives $\operatorname{Vol} B(x, r/2) \ge c_m \operatorname{Vol} B(x, r)$ after rescaling so that $r = 1$. This proves (22.75). □

Theorem 22.7.4. (κ–noncollapsing at bounded scales) Let $(M^m, \mathbf{g}(t))$, $t \in [0, T)$, be a Ricci flow on a smooth closed manifold, with $T < \infty$. For each $\rho > 0$, there exists $\kappa = \kappa(m, \mathbf{g}(0), T, \rho) > 0$ such that the flow is κ–noncollapsed at every (x_0, t_0) and every scale

$$0 < r \le \min\{\rho, \sqrt{t_0}\}$$

for which the curvature bound in Definition 22.7.1 holds.

Proof. Since a closed manifold has finitely many components, it suffices to work on the component of x_0 and finally take the minimum of the resulting constants. We therefore assume that M is connected.
Apply Corollary 22.5.6 on the interval $[0, t_0]$ with $\tau(s) = t_0 + r^2 - s$. Since $\tau(t_0) = r^2$ and $\tau(0) = t_0 + r^2 \le T + \rho^2$, Lemma 22.7.2 gives a constant $\mu_* > -\infty$, independent of (x_0, t_0, r), such that

$$\mu(\mathbf{g}(t_0), r^2) \ge \mu(\mathbf{g}(0), t_0 + r^2) \ge \mu_*. \tag{22.76}$$

Set $\mathbf{h} = \mathbf{g}(t_0)$, $B = B_{\mathbf{h}}(x_0, r)$, and $V = \operatorname{Vol}_{\mathbf{h}} B$. The parabolic assumption implies, in particular, $|\operatorname{Rm}_{\mathbf{h}}| \le r^{-2}$ on B. Let ζ be the function in Lemma 22.7.3, let $Z = \int_M \zeta^2 d\lambda_{\mathbf{h}}$, and define $v = Z^{-1/2}\zeta$. Then $v \in H^1(M)$, $v \ge 0$, and $\|v\|_{L^2(M)} = 1$. The extension of the variational formula to the sphere in H^1, justified in Proposition 22.5.5, allows us to use this test function.
We now estimate each term of $\mathcal{J}_{\mathbf{h}, r^2}(v)$. By (22.75),

$$4r^2 \int_M |dv|_{\mathbf{h}}^2 d\lambda_{\mathbf{h}} = \frac{4r^2}{Z} \int_M |d\zeta|_{\mathbf{h}}^2 d\lambda_{\mathbf{h}} \le C_m \frac{V}{Z} \le C_m.$$

Moreover, $|R_{\mathbf{h}}| \le C_m r^{-2}$ on the support of v, so

$$\left| r^2 \int_M R_{\mathbf{h}} v^2 d\lambda_{\mathbf{h}} \right| \le C_m.$$

For the entropy, use $v^2 = \zeta^2/Z$:

$$\begin{aligned} -\int_M v^2 \log v^2 d\lambda_{\mathbf{h}} &= \log Z - \frac{1}{Z} \int_M \zeta^2 \log \zeta^2 d\lambda_{\mathbf{h}} \\ &\le \log V + C_m, \end{aligned}$$

since $0 \le -\zeta^2 \log \zeta^2 \le e^{-1}$ and $Z \ge c_m V$. Thus

$$\mu(\mathbf{g}(t_0), r^2) \le \mathcal{J}_{\mathbf{h}, r^2}(v) \le \log \frac{V}{r^m} + C_m. \tag{22.77}$$

Combining (22.76) and (22.77) gives

$$V \geq e^{\mu_* - C_m} r^m.$$

We may take $\kappa = e^{\mu_* - C_m}$, decreased if necessary so that $0 < \kappa \leq 1$. □

Corollary 22.7.5. (Nondegenerate injectivity radius) Let $(M^m, \mathbf{g}(t))$, $t \in [0, T)$, be a Ricci flow on a smooth closed manifold. If it is κ–noncollapsed at scale r at (x_0, t_0) and $|\mathrm{Rm}_{\mathbf{g}(t)}|_{\mathbf{g}(t)} \leq r^{-2}$ on $P^-(x_0, t_0, r)$, then there exists $c = c(m, \kappa) > 0$ such that

$$\mathrm{inj}_{\mathbf{g}(t_0)}(x_0) \geq cr.$$

Proof. On the final slice, we have $|\mathrm{Rm}| \leq r^{-2}$ on $B(x_0, r)$ and $\mathrm{Vol}\, B(x_0, r) \geq \kappa r^m$. Lemma 22.1.4 directly gives the bound $\mathrm{inj}(x_0) \geq c(m, \kappa) r$. □

Together with Shi's estimates, this corollary provides the two families of bounds needed to apply Hamilton compactness to curvature rescalings: control of all curvature jets and a lower bound on the injectivity radius at the basepoint.

22.8 Hamilton–Ivey pinching and κ–solutions

In dimension three, the curvature operator may initially have a negative part. Hamilton–Ivey pinching shows that this part becomes negligible relative to positive curvature as the curvature scale tends to infinity. This is why the limiting models of a three-dimensional singularity have nonnegative curvature operator.

Denote the smallest eigenvalue of $\mathcal{R}_{\mathbf{g}(t)} \colon \Lambda^2 T_x M \to \Lambda^2 T_x M$ by $\nu(x, t)$, with the normalization $\mathrm{tr}_{\Lambda^2} \mathcal{R} = R/2$.

Theorem 22.8.1. (Hamilton–Ivey pinching) Let $(M^3, \mathbf{g}(t))$, $0 \leq t < T < \infty$, be a Ricci flow on a smooth closed manifold. There exist constants $A, B > 0$, determined by $\mathbf{g}(0)$, such that at every point where $\nu < 0$ and $-\nu \geq B/(1 + Bt)$,

$$R \geq 2(-\nu)\left[\log\left(\frac{-\nu}{B}\right) + \log(1 + Bt) - A\right]. \tag{22.78}$$

In particular, for each $\varepsilon > 0$, there exists $C_\varepsilon = C_\varepsilon(\mathbf{g}(0), T)$ such that

$$\nu \geq -\varepsilon |\mathrm{Rm}_{\mathbf{g}(t)}|_{\mathbf{g}(t)} - C_\varepsilon \quad \text{on } M \times [0, T). \tag{22.79}$$

The logarithmic estimate is the Hamilton–Ivey theorem, in the normalization $\mathrm{tr}\mathcal{R} = R/2$ of [104, Theorem 4.26]. One may take $A = 3$ and $B \geq \max\{1, \|\max\{-\nu(\cdot, 0), 0\}\|_\infty\}$. Indeed, replacing $\mathbf{g}$ by $B\mathbf{g}$ and t by Bt makes the smallest initial eigenvalue at least -1; undoing this normalization gives (22.78). The maximum principle is applied through spectral support functions, so it does not require ν to be differentiable at points of multiplicity.

Let us derive the consequence we will use in the limits. Fix $\varepsilon > 0$ and a dimensional constant c_3 such that $|R| \leq c_3 |\mathrm{Rm}|$. If $a = -\nu > B \exp(A + c_3/(2\varepsilon))$, the threshold in the theorem is satisfied, and $\log(1 + Bt) \geq 0$ implies

$$\frac{c_3}{\varepsilon} a \leq 2a\big(\log(a/B) - A\big) \leq R \leq c_3 |\mathrm{Rm}|.$$

Thus $a \leq \varepsilon |\mathrm{Rm}|$. At the remaining points, the negative part of ν is bounded by $C_\varepsilon = B \exp(A + c_3/(2\varepsilon))$. Both alternatives give (22.79).

Definition 22.8.2. (Three-dimensional κ–solution) A κ–solution is a Ricci flow $(N^3, \mathbf{h}(s))$, $s \in (-\infty, 0]$, on a smooth, connected manifold without boundary, satisfying the following properties:

(a) each $(N, \mathbf{h}(s))$ is complete, and the curvature is uniformly bounded on $N \times [a, b]$ for each $-\infty < a \le b \le 0$;

(b) the flow is nonflat and has nonnegative curvature operator;

(c) the flow is κ–noncollapsed at all scales.

The last condition means that, for every (x, s) and every $r > 0$ such that the corresponding parabolic cylinder is contained in the time interval and $|\mathrm{Rm}| \le r^{-2}$ on it, we have $\mathrm{Vol}_{\mathbf{h}(s)} B_{\mathbf{h}(s)}(x, r) \ge \kappa r^3$.

Noncollapsing is preserved under smooth limits. We spell out this step because it will be needed to verify that the limit of the rescalings is still a κ–solution.

Lemma 22.8.3. (Stability of noncollapsing under smooth convergence) Let $(M_i^m, \mathbf{g}_i(t), p_i) \to (M_\infty^m, \mathbf{g}_\infty(t), p_\infty)$ be pointed smooth convergence on compact spacetime sets. Suppose there exist numbers $R_i \to \infty$ such that each flow $\mathbf{g}_i$ is κ–noncollapsed at all its points and at every scale $0 < r \le R_i$ whose backward parabolic cylinder is contained in its time interval. Then the limit flow is κ–noncollapsed at every finite scale for which the corresponding cylinder is defined.

Proof. Fix $x_\infty \in M_\infty$, a time t_0, and $r > 0$ for which $P^-(x_\infty, t_0, r)$ is defined and $|\mathrm{Rm}_{\mathbf{g}_\infty}| \le r^{-2}$ holds on it. Let $0 < \rho < \sigma < r$. By completeness, the closed ball of radius σ in the final slice is compact. Take a convergence embedding Φ_i defined on a neighborhood of this ball and on a larger open set containing the curves considered below; write $x_i = \Phi_i(x_\infty)$. The ball exhaustion property ensures that its image contains the pointed balls of fixed radius that we need.
For large i, we have

$$B_{\mathbf{g}_i(t_0)}(x_i, \rho) \subseteq \Phi_i\big(B_{\mathbf{g}_\infty(t_0)}(x_\infty, \sigma)\big). \tag{22.80}$$

Indeed, let γ_i be a minimizing geodesic of length less than ρ starting at x_i. It can be lifted through Φ_i as long as it remains in the image of the ball of radius σ. If the lifted curve first exited that ball, its length in the limit metric up to that instant would be at least σ. Uniform convergence of the metrics on the closed ball implies that the corresponding length of γ_i is at least $(1 - \varepsilon_i)\sigma$, with $\varepsilon_i \to 0$. For large i, this is greater than ρ, a contradiction. This proves the inclusion.
Convergence of the curvatures on the compact set $\overline{B_{\mathbf{g}_\infty(t_0)}(x_\infty, \sigma)} \times [t_0 - \rho^2, t_0]$ and the strict margin $r^{-2} < \rho^{-2}$ give

$$|\mathrm{Rm}_{\mathbf{g}_i}| \le \rho^{-2} \quad \text{on } P^-(x_i, t_0, \rho)$$

for large i, using (22.80). Moreover, $\rho < R_i$ for all these indices. Noncollapsing of the approximating flows yields

$$\mathrm{Vol}_{\mathbf{g}_i(t_0)} B_{\mathbf{g}_i(t_0)}(x_i, \rho) \ge \kappa \rho^m. \tag{22.81}$$

By the ball inclusion and convergence of the volume densities on a fixed domain,

$$\begin{aligned} \kappa \rho^m &\le \liminf_{i \to \infty} \mathrm{Vol}_{\mathbf{g}_i(t_0)} B_{\mathbf{g}_i(t_0)}(x_i, \rho) \\ &\le \mathrm{Vol}_{\mathbf{g}_\infty(t_0)} B_{\mathbf{g}_\infty(t_0)}(x_\infty, \sigma). \end{aligned}$$

First let $\rho \to \sigma^-$ and then $\sigma \to r^-$. Continuity of measure from below gives $\mathrm{Vol}_{\mathbf{g}_\infty(t_0)} B(x_\infty, r) \geq \kappa r^m$. □

Theorem 22.8.4. (Rescaling limit at a singular time) Let $(M^3, \mathbf{g}(t))$, $0 \leq t < T < \infty$, be a maximal solution on a smooth closed manifold. Let (x_i, t_i) be spacetime maxima as in (22.15), with $t_i \nearrow T$, and let $Q_i = |\mathrm{Rm}_{\mathbf{g}(t_i)}|_{\mathbf{g}(t_i)}(x_i)$. Then $Q_i \to \infty$, and a subsequence of the rescaled flows

$$\mathbf{g}_i(s) := Q_i \mathbf{g}(t_i + s/Q_i), \qquad -Q_i t_i \leq s \leq 0,$$

, pointed at x_i, converges smoothly on compact subsets of $M_\infty \times (-\infty, 0]$ to a κ–solution $(M_\infty, \mathbf{g}_\infty(s), x_\infty)$, for some $\kappa > 0$.

Proof. The continuation criterion in the previous chapter implies that $Q_i \to \infty$; since $t_i \to T > 0$, we also have $Q_i t_i \to \infty$. By the choice of the spacetime maxima,

$$|\mathrm{Rm}_{\mathbf{g}_i(s)}|_{\mathbf{g}_i(s)} \leq 1 \quad (-Q_i t_i \leq s \leq 0), \qquad |\mathrm{Rm}_{\mathbf{g}_i(0)}|_{\mathbf{g}_i(0)}(x_i) = 1. \tag{22.82}$$

Fix $A > 0$. For large i, the flow $\mathbf{g}_i$ is defined on $[-A-1, 0]$. Shi's estimates applied on this interval provide uniform bounds for all curvature derivatives on $[-A, 0]$. Now take unit scale at $(x_i, 0)$. In the original variables, this corresponds to radius $Q_i^{-1/2}$. For large i, this radius is smaller than ρ and $\sqrt{t_i}$, and (22.82) satisfies the parabolic assumption of Theorem 22.7.4. Invariance of the volume ratio under rescaling gives

$$\mathrm{Vol}_{\mathbf{g}_i(0)} B_{\mathbf{g}_i(0)}(x_i, 1) \geq \kappa$$

with a common constant $\kappa > 0$. Corollary 22.7.5 yields $\mathrm{inj}_{\mathbf{g}_i(0)}(x_i) \geq c(3, \kappa)$.

The first part of the proof of Theorem 22.1.10, applied to the metrics $\mathbf{g}_i(0)$, provides a single limit manifold M_∞ and spatial embeddings on an exhaustion. Fix these embeddings. For each $A \in \mathbb{N}$, the estimates on $[-A-1, 0]$ allow us to apply the second part of that proof on $[-A, 0]$. Choose nested subsequences as A increases and take their diagonal. The time-dependent limits agree on overlaps because they are computed using the same embeddings and on the same manifold. This gives a complete ancient flow $(M_\infty, \mathbf{g}_\infty(s), x_\infty)$ for every $s \leq 0$. The unit curvature value at the basepoint passes to the limit, so the flow is nonflat. The bound in (22.82) also passes to the limit and shows that each slice has bounded curvature.

Let us verify the two remaining properties. Fix, for example, the original range $\rho = 1$ in Theorem 22.7.4. On the rescaled interval $[-A, 0]$, a scale r corresponds to radius $rQ_i^{-1/2}$ and original time $t_i + s/Q_i$. Thus the theorem applies simultaneously at all points of this interval whenever

$$0 < r \leq R_{i,A} := \min\left\{\sqrt{Q_i}, \sqrt{Q_i t_i - A}\right\}.$$

Since $Q_i \to \infty$ and $Q_i t_i \to \infty$, we have $R_{i,A} \to \infty$. The same constant κ works for all rescaled flows and every bounded radius. Applying Lemma 22.8.3 on each interval $[-A, 0]$ and then letting $A \to \infty$, we conclude that the limit is κ–noncollapsed at all scales.

Finally, the eigenvalues of the curvature operator are multiplied by Q_i^{-1}. Inequality (22.79) becomes

$$\nu_{\mathbf{g}_i(s)} \geq -\varepsilon |\mathrm{Rm}_{\mathbf{g}_i(s)}|_{\mathbf{g}_i(s)} - \frac{C_\varepsilon}{Q_i}.$$

Letting $i \to \infty$ gives $\nu_{\mathbf{g}_\infty(s)} \geq -\varepsilon |\mathrm{Rm}_{\mathbf{g}_\infty(s)}|$. Since $\varepsilon > 0$ is arbitrary, the curvature operator of the limit is nonnegative. Thus all the conditions in Definition 22.8.2 hold. □

22.9 Structural theorems for surgery and the topological conclusion

The preceding results describe the limits that arise when a region of high curvature is magnified. To continue the flow beyond a singularity, we must identify these regions with canonical models, cut along nearly cylindrical necks, and attach caps whose geometry is compatible with pinching and noncollapsing.

The full construction includes the standard solution, persistence of caps, noncollapsing across surgeries, the canonical neighborhood theorem, and the inductive choice of parameters. These arguments occupy Chapters 12–17 of [104]. We will use their structure and existence theorems to determine the geometric and topological effect of each surgery. The final step will be to reconstruct the initial manifold from the components that disappear.

The model for a neck is the shrinking round cylinder $S^2 \times \mathbb{R}$. If $\mathbf{g}_{S^2(1)}$ is the metric of the unit sphere, set

$$\mathbf{g}_{\mathrm{cil}}(s) = (2 - 2s)\mathbf{g}_{S^2(1)} + (\mathbf{d}z)^2, \qquad -1 \leq s \leq 0.$$

The scalar curvature of the slice $s = 0$ equals one.

Definition 22.9.1. (Necks, caps, and canonical components) Fix $0 < \varepsilon < 1$ and $k = \lfloor \varepsilon^{-1} \rfloor$. Let $(M^3, \mathbf{g}(t))$ be a Ricci flow and let (x, t_0) be a point.

An open set $U \subseteq M$ is an *ε–neck of scale $h > 0$* centered at x if there exists a diffeomorphism

$$\Psi \colon S^2 \times (-\varepsilon^{-1}, \varepsilon^{-1}) \longrightarrow U, \qquad x \in \Psi(S^2 \times \{0\}),$$

such that

$$\left\| h^{-2}\Psi^*\mathbf{g}(t_0) - \mathbf{g}_{\mathrm{cil}}(0) \right\|_{C^k(\mathbf{g}_{\mathrm{cil}}(0))} < \varepsilon.$$

It is a *strong ε–neck* if Ψ extends to a spacetime identification with spatial map independent of s, in which, after setting $s = h^{-2}(t - t_0)$, we have

$$\left\| h^{-2}\Psi^*\mathbf{g}(t_0 + h^2 s) - \mathbf{g}_{\mathrm{cil}}(s) \right\|_{C^k} < \varepsilon.$$

This last norm is taken on $S^2 \times (-\varepsilon^{-1}, \varepsilon^{-1}) \times [-1, 0]$, using the reference metric $\mathbf{g}_{\mathrm{cil}}(0) + (\mathbf{d}s)^2$ to compute derivatives. The region under consideration must exist throughout this time interval.

An *(C, ε)–cap* is an open set U diffeomorphic to an open ball B^3 or to $\mathbb{RP}^3 \setminus \overline{B^3}$ that decomposes into a compact core K and an end that is an ε–neck. If $x \in K$, we require $R(x, t_0) > 0$ and, in the normalized metric $\widehat{\mathbf{g}} = R(x, t_0)\mathbf{g}(t_0)$,

$$\mathrm{diam}_{\widehat{\mathbf{g}}} K \leq C, \qquad \mathrm{Vol}_{\widehat{\mathbf{g}}} K \geq C^{-1}, \qquad C^{-1} \leq \frac{R(y, t_0)}{R(x, t_0)} \leq C \quad (y \in K).$$

A *C–component* is a compact component of positive curvature that, when normalized by the scalar curvature at any of its points, has diameter at most C, scalar curvature between C^{-1} and C, and volume between C^{-1} and C. An *ε–round component* is a component that, after this normalization, lies at distance less than ε in C^k from a round spherical space form of scalar curvature one.

Definition 22.9.2. (Strong canonical neighborhood) Given $C < \infty$ and $\varepsilon > 0$, a point (x, t) of positive scalar curvature has a strong canonical neighborhood (C, ε) if one of the following alternatives holds:

(a) x is the center of a strong ε–neck whose scale is comparable to $R(x,t)^{-1/2}$;

(b) x belongs to the core of an (C, ε)–cap;

(c) the component of x is a C–component;

(d) the component of x is ε–round.

In all cases, the quantitative estimates

$$|\nabla R|(x,t) \le C R(x,t)^{3/2}, \qquad |\partial_t R|(x,t) \le C R(x,t)^2, \tag{22.83}$$

and a volume lower bound at scale $R(x,t)^{-1/2}$ of the form $c(C,\varepsilon)R(x,t)^{-3/2}$ are included.

To close off a neck, fix a rotationally symmetric metric $\mathbf{g}_{\text{std}}$ on $\mathbb{R}^3$ with nonnegative curvature operator and positive scalar curvature that agrees outside a compact set with the normalized cylinder. Its flow is the model for the caps that are inserted.

Theorem 22.9.3. (Standard solution) For the fixed standard metric $\mathbf{g}_{\text{std}}$, there exists a unique complete solution of the Ricci flow starting from it, defined on $[0, 1)$ and with uniformly bounded curvature on each $\mathbb{R}^3 \times [0, T_0]$, $T_0 < 1$. On these intervals, it is asymptotic to all orders, away from the cap, to the round cylinder of scalar curvature $1/(1-t)$.
There exist $r_{\text{std}} > 0$ and $\kappa_{\text{std}} > 0$ such that it is κ_{std}–noncollapsed at scales smaller than r_{std} whose cylinders are contained in $[0, 1)$. For each sufficiently small $\varepsilon > 0$, there exist $C_\varepsilon < \infty$ and $R_\varepsilon < \infty$ such that the points with $R(x,t) \ge R_\varepsilon$ have strong canonical neighborhoods $(C_\varepsilon, \varepsilon)$. The constants are chosen after fixing ε and the standard metric.

Existence, rotational symmetry, behavior at infinity, and uniqueness are proved in [104, Theorem 12.5 and Theorems 12.28 and 12.32]. Uniqueness uses a harmonic map flow and is the noncompact version of the gauge mechanism studied in Chapter 21.

Definition 22.9.4. (Ricci flow with surgery) A Ricci flow with surgery, initially defined up to a time $T_* \le \infty$, consists of strictly increasing surgery times t_j, with j in an initial subset of $\mathbb{N}$, and of $t_0 = 0$. The list may be finite, empty, or infinite. In the last case, it may, a priori, accumulate at T_*. Between consecutive times there are closed manifolds M_j and smooth flows $\mathbf{g}_j(t)$ on $M_j \times [t_j, t_{j+1})$; if there is a last surgery time, the remaining interval ends at T_*. At a surgery time t_{j+1}, finite disjoint collections of strong necks are chosen; they are cut along their central spheres, the ends and components prescribed by the procedure are removed, and the new boundaries are closed off with caps obtained from the standard solution at the same scale. There is an open set, called the continuing region, that is identified isometrically before and after surgery, and the new metric agrees there with the limit of the previous metric. The flow becomes extinct at T_{ext} if all components have been discarded, and we set $M(t) = \varnothing$ for $t \ge T_{\text{ext}}$.

Cutting must be performed at scales sufficiently separated from the canonical neighborhood scale. The following parameters record this choice and the properties that must be preserved when it is repeated.

Definition 22.9.5. (Standard control of surgery parameters) Fix small $\varepsilon > 0$ and the canonical neighborhood constant C. Standard control consists of positive nonincreasing functions

$$r(t), \qquad \kappa(t), \qquad \delta(t)$$

and a surgery scale

$$\rho(t) = \delta(t) r(t), \qquad h(t) = h(\rho(t), \delta(t)) \le \delta(t)^2 r(t).$$

A flow with surgery is subject to this control if it satisfies:

(a) Hamilton–Ivey pinching;

(b) noncollapsing with constant $\kappa(t)$ at scales $0 < \rho \le \rho_*$, where $\rho_* > 0$ is fixed, on cylinders that survive without surgery throughout their time interval; in the normalization of the source, one may take $\rho_* = \varepsilon$;

(c) the strong canonical neighborhood assumption at every point with $R(x,t) \ge r(t)^{-2}$;

(d) each surgery is performed on strong necks of accuracy $\delta(t)$, centered at points with $R = h(t)^{-2}$, and the post-surgery metric is constructed using the standard cap of scale $h(t)$;

(e) the functions r, κ, and δ are positive and nonincreasing; in particular, for each $T < \infty$, their values on $[0,T]$ are bounded below by the positive numbers $r(T)$, $\kappa(T)$, and $\delta(T)$. The choice of scale h also satisfies $h_T := \inf_{t \in [0,T]} h(t) > 0$.

The full formulation includes the seven compatibility conditions for the spacetime, the continuing and disappearing regions, and maximality between consecutive surgery times in [104, Chapter 15, Sections 1 and 3].

The first structural result describes the ancient models that arise at the curvature scale.

Theorem 22.9.6. (Structure of three-dimensional κ–solutions) There exists $\overline{\varepsilon} > 0$ such that, for each $\kappa > 0$ and $0 < \varepsilon \le \overline{\varepsilon}$, one can choose $C = C(\kappa, \varepsilon)$ with the following property. In an orientable three-dimensional κ–solution, every point has, at its curvature scale, an ε–neck, an (C,ε)–cap, a C–component, or an ε–round component. The approximations include the curvature, derivative, and volume estimates of Definition 22.9.2. When the neck alternative holds, the neck can be chosen strong. The scalar curvature is positive at every point: if it vanished, the strong maximum principle for $\partial_s R = \Delta R + 2|\mathrm{Ric}|^2$, connectedness, and uniqueness of the complete flow with bounded curvature would force the flat solution, which is excluded by definition.

This is the qualitative description obtained in [104, Chapter 9, in particular Theorem 9.93 and Corollaries 9.94–9.95]. Orientability excludes the cylindrical quotient $\mathbb{RP}^2 \times \mathbb{R}$.

Theorem 22.9.7. (Canonical neighborhood theorem) Fix a smooth initial metric $\mathbf{g}_0$ on a closed, orientable three-dimensional manifold, a time horizon $T < \infty$, and sufficiently small $\varepsilon > 0$. There exist $r = r(\mathbf{g}_0, T, \varepsilon) > 0$ and $C = C(\mathbf{g}_0, T, \varepsilon) < \infty$ such that, in the smooth flow starting from $\mathbf{g}_0$, every point before T with $R(x,t) \ge r^{-2}$ has a strong canonical neighborhood (C,ε). The threshold is also chosen so that the strong necks have the

required time interval available.
For the flows with surgery of Theorem 22.9.8, this property is preserved with the time-dependent threshold $r(t)$ chosen together with the surgery parameters. After normalization by $R(x,t)$, the high-curvature regions are approximated by regions of κ–solutions or by regions of the standard solution modeling a recent surgery.

The proof is by contradiction. One chooses the first points where the conclusion fails, normalizes their curvature, and applies noncollapsing, curvature control at bounded distance, and Hamilton compactness. If the rescaled times extend to $-\infty$, the limit is a κ–solution, and the description of its neighborhoods gives a contradiction. If a surgery prevents this extension, the limit is modeled on the standard solution, yielding the same contradiction. The complete argument, including the curvature estimate at bounded distance and the case near a surgery cap, is developed in [104, Chapters 10–12 and 17].

Theorem 22.9.8. (Existence and control of the flow with surgery) Let M be a smooth closed connected orientable three-dimensional manifold, and let $\mathbf{g}_0$ be a smooth metric. There exist control parameters $r(t)$, $\kappa(t)$, $\delta(t)$, and $h(t)$ and a Ricci flow with surgery starting from $\mathbf{g}_0$, defined for every $t \geq 0$ up to possible extinction. The flow satisfies Hamilton–Ivey pinching, noncollapsing, and Theorem 22.9.7; each surgery is performed on a finite collection of strong necks of scale $h(t)$. The surgery times do not accumulate in any compact time interval.

To apply the formulation of [104, Theorem 15.9 and Corollary 15.10] to an arbitrary metric, first multiply $\mathbf{g}_0$ by a constant to normalize the curvature and the volume of unit balls. Parabolic invariance of the flow then allows this normalization to be undone. Persistence of noncollapsing across caps is proved in Chapter 16, and the strong canonical neighborhood assumption and absence of accumulation of surgeries are completed in Chapter 17 of the same source. Let us make the absence of accumulation precise, as used in [104, Lemma 17.12]. Fix $T < \infty$. Pinching gives a bound $R \geq -C_T$, so the total volume $V(t)$ satisfies $V'(t) \leq C_T V(t)$ during the smooth intervals. The cap construction and the bound $h(t) \geq h_T > 0$ give a number $v_T > 0$ such that each neck cut decreases the net volume by at least v_T after the cap volumes have been added. Upon multiplication by $e^{-C_T t}$, smooth evolution makes the weighted volume nonincreasing, and each cut produces a decrease of at least $e^{-C_T T} v_T$. Thus the total number $S(T)$ of cuts satisfies

$$S(T) \leq \frac{e^{C_T T} V(0)}{v_T}.$$

There may also be times when components are merely discarded, without any neck being cut. Each cut increases the number of components by at most one. If there were initially N_0 components, the number $D(T)$ of discarded components satisfies $D(T) \leq N_0 + S(T)$. Every surgery time contains a cut or a discard, so there are at most $S(T) + D(T)$ such times in $[0, T]$.

The topological effect of each surgery is also fully controlled: one cuts along spheres and discards only components covered by necks and caps.

Theorem 22.9.9. (Topological reconstruction from surgeries) Let M be a smooth closed connected orientable three-dimensional manifold. If a flow with surgery subject to the control of Theorem 22.9.8 becomes extinct, then M is diffeomorphic to a finite connected sum of spherical space forms and copies of $S^2 \times S^1$.

Proof. Cutting along an embedded sphere and capping the two resulting boundaries with balls gives two cases. If the sphere separates the component, one obtains two closed manifolds whose connected sum reconstructs the original component. If it does not separate it, the result is a closed manifold N, and the original component is $N\#(S^2\times S^1)$; orientability excludes the nonorientable sphere bundle over the circle. The classification of components discarded by the standard procedure gives spherical space forms, $S^2\times S^1$, and $\mathbb{RP}^3\#\mathbb{RP}^3$. The last case is already a connected sum of two spherical space forms. Control of these alternatives, including the regions that disappear upon reaching the singular time, is Proposition 15.3 and Corollary 15.4 of [104]. Thus, at each step, the preceding manifold is reconstructed from the subsequent components by adding only summands of the indicated types.
Let t_N be the extinction time. The existence and control theorem gives only finitely many surgery times in $[0,t_N]$. Start with the empty slice after t_N: the components discarded at that step have the decomposition described above. Suppose that all components immediately after t_j, with $j\in\{1,\dots,N\}$, have been reconstructed. Reverse the cuts at t_j using the two operations in the first paragraph and add the components discarded at that time. The result is again a finite connected sum of spherical space forms and copies of $S^2\times S^1$. This proves the step back to the preceding slice. Upon reaching $t_0=0$, we obtain the decomposition of M. □

For the Poincaré conjecture, it remains to know that, under the corresponding assumption on the fundamental group, the flow disappears in finite time.

Theorem 22.9.10. (Finite-time extinction) Let M be a smooth closed connected orientable three-dimensional manifold, and let $(M(t),\mathbf{g}(t))$ be a flow with surgery subject to the control of Theorem 22.9.8. If

$$\pi_1(M)\cong G_1*\cdots*G_a*\underbrace{\mathbb{Z}*\cdots*\mathbb{Z}}_{b\text{ factors}},\qquad a,b\in\mathbb{N}_0,\quad |G_j|<\infty\ (j\in\{1,\dots,a\}),\tag{22.84}$$

then the flow becomes extinct in finite time.

The complete proof is in Chapters 18–19 of [104], together with the correction to its Section 19.2 in [105]. First, the least area of spheres nontrivial in π_2 is controlled through a forward difference differential inequality. Then, when the remaining components have $\pi_2=0$ and finite fundamental group, one uses a nontrivial class in π_3 represented by families of loops and least disk areas. The same differential structure forces the minimax quantity to become negative in finite time if the component were to persist, which is impossible. The modifications at a surgery time are compatible with these quantities by semicontinuity.

Theorem 22.9.11. (Poincaré conjecture) Every smooth closed simply connected three-dimensional manifold is diffeomorphic to S^3.

$$M^3\text{ closed and simply connected}\quad\Longrightarrow\quad M^3\cong S^3.$$

Proof. Let M be a manifold as in the statement. It is orientable: otherwise, its orientation cover would be a connected two-sheeted cover and would give a nontrivial quotient of $\pi_1(M)$ isomorphic to $\mathbb{Z}_2$. Choose a smooth metric $\mathbf{g}_0$ and apply Theorem 22.9.8. Since $\pi_1(M)=0$, assumption (22.84) holds with the empty free product. Theorem 22.9.10 shows that the flow becomes extinct in finite time.

By Theorem 22.9.9, there exist spherical space forms $N_j = S^3/\Gamma_j$ and an integer $b \geq 0$ such that

$$M \cong N_1 \# \cdots \# N_a \# \underbrace{(S^2 \times S^1) \# \cdots \# (S^2 \times S^1)}_{b \text{ summands}}.$$

The Seifert–van Kampen theorem gives

$$\pi_1(M) \cong \Gamma_1 * \cdots * \Gamma_a * \underbrace{\mathbb{Z} * \cdots * \mathbb{Z}}_{b \text{ factors}}.$$

By the normal form theorem for free products, this group can be trivial only if $b = 0$ and each Γ_j is trivial. Consequently, each N_j is diffeomorphic to S^3. Since S^3 is the identity for the connected sum of closed orientable three-dimensional manifolds, we conclude that $M \cong S^3$. □

Part VI

Infinite-dimensional geometry

Introduction to Part VI

A change of perspective arises naturally in many problems of geometric analysis. So far, we have studied functions, sections, metrics, and connections as objects defined on a manifold. From this part onward, we will also regard them as points of spaces with their own geometric structure. A space of maps, the set of Riemannian metrics, or the space of connections can, under suitable hypotheses, behave as an infinite-dimensional manifold.

Working rigorously with these spaces requires a careful choice of regularity. Banach spaces allow the use of versions of the inverse function, rank, and regular preimage theorems. Hilbert spaces add an inner product structure and the Riesz identification. Banach–Finsler structures provide tangent norms and distances that will be useful in studying flows and deformations. When an operation loses derivatives, a single Sobolev completion is no longer sufficient, and Hilbert scales and ILH structures enter the picture.

Many identifications that are automatic in finite dimensions cease to be so here. The kinematic tangent space must be distinguished from the operational one, the continuous dual from the algebraic dual, and a strong metric from a weak metric. These differences are more than terminological details: they determine whether a Levi–Civita connection exists, whether the musical map is invertible, and whether a theorem of differential calculus can be applied. The final chapters show how this theory takes concrete form in spaces of maps and connections, gauge groups, diffeomorphisms, and problems such as harmonic maps, Yang–Mills theory, and the Euler equation.

Function spaces as manifolds

Fréchet opened the way to calculus on abstract spaces, and Banach provided a complete setting in which the fundamental theorems of analysis could be formulated precisely. Later, Eells and Palais developed global tools for infinite-dimensional manifolds. Ebin and Marsden demonstrated the usefulness of Sobolev completions in the study of diffeomorphism groups and fluid equations. With these ideas, many function spaces ceased to be viewed merely as sets of possible solutions and began to be studied as geometric objects in their own right.

23

Differential calculus in Banach spaces

The Sobolev spaces constructed in the preceding parts are themselves spaces in which we can do calculus. A function, a section, or a metric then becomes a point in an infinite-dimensional space, and an energy functional behaves like a function defined on that space. To study its variations, we need a notion of derivative that retains the linear approximation and continuity familiar from the Euclidean case.

The Fréchet derivative provides this language in Banach spaces. It will allow us to formulate chain rules, Taylor expansions, inverse and implicit function theorems, and Lagrange multipliers. In later chapters, these tools will describe manifolds of functions and variational constraints; at the end of the book, critical points of energies defined on Sobolev spaces will again be interpreted as weak solutions of differential equations.

Unless otherwise stated, all normed vector spaces in this chapter are taken over the field of real numbers.

A general reference for the results and exercises on differential calculus and nonlinear analysis in this chapter is [45, Chapters 3, 4, and 6].

Fréchet and Banach: expanding the domain of calculus

In the early twentieth century, Maurice Fréchet introduced structures capable of measuring convergence beyond Euclidean spaces. Stefan Banach later demonstrated the power of working in complete normed spaces, where approximation and fixed point arguments have limits within the space itself. Fréchet calculus combines these two ideas: the derivative is a continuous linear operator, and completeness allows local estimates to be converted into existence theorems [62, 18].

23.1 Fréchet differentiability

The Fréchet derivative generalizes the derivative of functions between Euclidean spaces to the setting of normed spaces. The fundamental idea is the same as in finite dimensions: a function is differentiable at a point if, in a neighborhood of that point, it can be approximated by a continuous linear map so that the approximation error divided by the norm of the increment tends to zero.

The following definition retains the idea of linear approximation but requires the error to be uniformly small in all directions measured by the norm. This uniformity distinguishes the Fréchet derivative from merely directional notions and underpins the fundamental theorems of calculus in infinite dimensions.

For a normed space $(X, \|\cdot\|_X)$, we write $d_X(x,y) := \|x-y\|_X$; thus $B_{d_X}(x,r)$ denotes the ball centered at x with radius r for the metric induced by the norm.

Definition 23.1.1. (Fréchet derivative) Let $(X, \|\cdot\|_X)$ and $(Y, \|\cdot\|_Y)$ be normed vector spaces, let $U \subseteq X$ be open, and let $f\colon U \longrightarrow Y$. We say that f is **Fréchet differentiable** at $x_0 \in U$ if there exists a continuous linear operator $L \in \mathcal{L}(X,Y)$ such that $\lim_{h\to 0} \dfrac{\|f(x_0+h)-f(x_0)-L(h)\|_Y}{\|h\|_X} = 0$. The operator L is called the **Fréchet derivative** of f at x_0 and is denoted by $Df(x_0)$.

Equivalently, f is Fréchet differentiable at x_0 if there exist $\rho > 0$ and a function $r\colon B_{d_X}(0,\rho) \longrightarrow Y$ such that $B_{d_X}(x_0,\rho) \subseteq U$, $f(x_0+h) = f(x_0) + Df(x_0)(h) + r(h)$ for every $h \in B_{d_X}(0,\rho)$, and $\lim_{h\to 0} \dfrac{\|r(h)\|_Y}{\|h\|_X} = 0$.

Proposition 23.1.2. The Fréchet derivative of a function, when it exists, is unique.

Proof. Suppose $L_1, L_2 \in \mathcal{L}(X,Y)$ satisfy the condition in Definition 23.1.1. Since U is open, there exists $\rho > 0$ such that $B_{d_X}(x_0,\rho) \subseteq U$. Let $v \in X \setminus \{0\}$. For every $t \in \mathbb{R}$ such that $0 < |t| < \dfrac{\rho}{\|v\|_X}$, we have

$$\frac{\|(L_1-L_2)(v)\|_Y}{\|v\|_X} = \frac{\|(L_1-L_2)(tv)\|_Y}{\|tv\|_X} \leq \frac{\|f(x_0+tv)-f(x_0)-L_1(tv)\|_Y}{\|tv\|_X} + \frac{\|f(x_0+tv)-f(x_0)-L_2(tv)\|_Y}{\|tv\|_X}.$$

As $t \to 0$, the right-hand side tends to zero, so $(L_1-L_2)(v) = 0$. Equality is also immediate for $v = 0$, and therefore $L_1 = L_2$. □

Fréchet differentiability implies, in particular, continuity at the point under consideration.

Proposition 23.1.3. Let X and Y be normed spaces, let $U \subseteq X$ be open, and let $f\colon U \longrightarrow Y$. If f is Fréchet differentiable at $x_0 \in U$, then f is continuous at x_0.

Proof. By the preceding characterization, there exist $\rho > 0$ and a function $r\colon B_{d_X}(0,\rho) \longrightarrow Y$ such that $B_{d_X}(x_0,\rho) \subseteq U$, $f(x_0+h) - f(x_0) = Df(x_0)(h) + r(h)$ for every $h \in B_{d_X}(0,\rho)$, and

$$\lim_{h\to 0} \frac{\|r(h)\|_Y}{\|h\|_X} = 0.$$

Let $\varepsilon > 0$. There exists $\delta \in (0,\rho)$ such that $\|r(h)\|_Y < \varepsilon\|h\|_X$ whenever $0 < \|h\|_X < \delta$. For these increments,

$$\|f(x_0+h)-f(x_0)\|_Y \leq \big(\|Df(x_0)\|_{\mathcal{L}(X,Y)} + \varepsilon\big)\|h\|_X.$$

The right-hand side tends to zero as $h \to 0$. Thus $f(x_0+h) \to f(x_0)$, and f is continuous at x_0. □

Definition 23.1.4. Let X and Y be normed spaces, let $U \subseteq X$ be open, and let $f\colon U \longrightarrow Y$. We say that f is **Fréchet differentiable on** U if it is Fréchet differentiable at every point of U. In this case, the derivative map $Df\colon U \longrightarrow \mathcal{L}(X,Y)$ is defined. We say that f is of **class** C^1 on U if it is Fréchet differentiable on U and Df is continuous with respect to the operator norm on $\mathcal{L}(X,Y)$.

The directional derivative studies the behavior of a function only along a fixed direction. Existence of all directional derivatives is generally a weaker condition than Fréchet differentiability.

Definition 23.1.5. (Directional and Gâteaux derivatives) Let $(X, \|\cdot\|_X)$ and $(Y, \|\cdot\|_Y)$ be normed vector spaces, let $U \subseteq X$ be open, and let $f\colon U \longrightarrow Y$. Given $x_0 \in U$ and $v \in X$, we say that f is **differentiable at x_0 in the direction v** if the limit $D_v f(x_0) := \lim_{t\to 0} \dfrac{f(x_0+tv)-f(x_0)}{t}$ exists. This value is called the **directional derivative** of f at x_0 in the direction v.
If $D_v f(x_0)$ exists for every $v \in X$ and the map $\delta f(x_0)\colon X \longrightarrow Y$, defined by $\delta f(x_0)(v) := D_v f(x_0)$, is linear and continuous, we say that f is **Gâteaux differentiable** at x_0. In this case, $\delta f(x_0)$ is called the **Gâteaux derivative** of f at x_0.

Mere existence of all directional derivatives does not guarantee Gâteaux differentiability, since dependence on the direction need be neither linear nor continuous.

Exercise 23.1.6. Consider the function $f\colon \mathbb{R}^2 \longrightarrow \mathbb{R}$ defined by

$$f(x,y) = \begin{cases} \dfrac{x^2 y}{x^4+y^2}, & \text{if } (x,y) \neq (0,0), \\ 0, & \text{if } (x,y) = (0,0). \end{cases}$$

Prove that f has a directional derivative at $(0,0)$ in every direction $v = (a,b) \in \mathbb{R}^2$ and that

$$D_v f(0,0) = \begin{cases} \dfrac{a^2}{b}, & \text{if } b \neq 0, \\ 0, & \text{if } b = 0. \end{cases}$$

Show that the map $v \longmapsto D_v f(0,0)$ is neither linear nor continuous, and conclude that f is not Gâteaux differentiable at $(0,0)$.

Fréchet differentiability does guarantee Gâteaux differentiability, and the two derivatives agree.

Proposition 23.1.7. Let X and Y be normed vector spaces, let $U \subseteq X$ be open, and let $f\colon U \longrightarrow Y$ be Fréchet differentiable at $x_0 \in U$. Then f is Gâteaux differentiable at x_0 and

$$\delta f(x_0) = Df(x_0).$$

Proof. Set $L := Df(x_0)$. By Fréchet differentiability, there exists a function r, defined for sufficiently small increments, such that

$$f(x_0+h) - f(x_0) = Lh + r(h), \qquad \frac{\|r(h)\|_Y}{\|h\|_X} \longrightarrow 0 \quad (h \longrightarrow 0).$$

Fix $v \in X$. For sufficiently small $t \neq 0$, we have

$$\frac{f(x_0+tv)-f(x_0)}{t} - Lv = \frac{r(tv)}{t}.$$

If $v = 0$, the left-hand side is identically zero. If $v \neq 0$, then

$$\left\| \frac{r(tv)}{t} \right\|_Y = \|v\|_X \frac{\|r(tv)\|_Y}{\|tv\|_X} \longrightarrow 0 \qquad (t \longrightarrow 0).$$

Consequently, $D_v f(x_0) = Lv$ for every $v \in X$. Since L is linear and continuous, f is Gâteaux differentiable at x_0 and $\delta f(x_0) = L = Df(x_0)$. □

The converse is false, even for scalar functions defined on finite-dimensional Euclidean spaces.

Exercise 23.1.8. Consider the function $g\colon \mathbb{R}^2 \longrightarrow \mathbb{R}$ defined by

$$g(x,y) = \begin{cases} \dfrac{x^3 y}{x^6 + y^2}, & \text{if } (x,y) \neq (0,0), \\ 0, & \text{if } (x,y) = (0,0). \end{cases}$$

Prove that $D_v g(0,0) = 0$ for every direction $v \in \mathbb{R}^2$. Conclude that g is Gâteaux differentiable at $(0,0)$ and that $\delta g(0,0) = 0$. Show, however, that $g(t,t^3) = \dfrac{1}{2}$ for every $t \neq 0$, so g is not continuous at $(0,0)$. Deduce from Proposition 23.1.3 that g is not Fréchet differentiable at that point.

In Hilbert spaces, continuous linear functionals can be identified with vectors by Theorem B.3.12. This allows the derivative of a scalar functional to be represented by its gradient.

Definition 23.1.9. (Gradient) Let $(H, \langle\cdot,\cdot\rangle_H)$ be a real Hilbert space, let $U \subseteq H$ be open, and let $f\colon U \longrightarrow \mathbb{R}$ be Gâteaux differentiable at $x \in U$. By Theorem B.3.12, there exists a unique vector $\nabla f(x) \in H$ such that $\delta f(x)(v) = \langle v, \nabla f(x)\rangle_H$ for every $v \in H$. This vector is called the **gradient** of f at x. If f is Fréchet differentiable at x, then $Df(x)(v) = \langle v, \nabla f(x)\rangle_H$ for every $v \in H$.

Before studying mean value formulas, recall that, by Corollary B.2.30, for every real normed space Y and each $y \in Y \setminus \{0\}$, there exists $\varphi \in Y'$ such that $\|\varphi\|_{Y'} = 1$ and $\varphi(y) = \|y\|_Y$. In particular, the continuous dual of any normed space separates its points.

The following result estimates the increment of a function in terms of its directional derivatives along the segment joining the points under consideration. The second inequality also gives a quantitative estimate for the error in approximating that increment by the directional derivative at the initial point.

Theorem 23.1.10. (Mean value inequalities) Let $(X, \|\cdot\|_X)$ and $(Y, \|\cdot\|_Y)$ be real normed spaces, let $U \subseteq X$ be open, and let $f\colon U \longrightarrow Y$. Let $x, y \in U$ be such that the segment $[x,y] := \{x + t(y-x) \mid t \in [0,1]\}$ is contained in U. Suppose that, for each $t \in [0,1]$, the directional derivative $D_{y-x} f(x + t(y-x))$ exists. Then

$$\|f(y) - f(x)\|_Y \leq \sup_{t\in[0,1]} \|D_{y-x} f(x + t(y-x))\|_Y.$$

Moreover,

$$\|f(y) - f(x) - D_{y-x} f(x)\|_Y \leq \sup_{t\in[0,1]} \|D_{y-x} f(x + t(y-x)) - D_{y-x} f(x)\|_Y.$$

If, in addition, f is Fréchet differentiable at every point of $[x,y]$, then

$$\|f(y) - f(x)\|_Y \leq \sup_{t\in[0,1]} \big\|Df(x + t(y-x))(y-x)\big\|_Y \leq \left(\sup_{t\in[0,1]} \|Df(x + t(y-x))\|_{\mathcal{L}(X,Y)}\right) \|y - x\|_X,$$

and

$$\|f(y)-f(x)-Df(x)(y-x)\|_Y \le \sup_{t\in[0,1]} \Big\| \big(Df(x+t(y-x))-Df(x)\big)(y-x)\Big\|_Y$$

$$\le \left(\sup_{t\in[0,1]} \|Df(x+t(y-x))-Df(x)\|_{\mathcal{L}(X,Y)} \right) \|y-x\|_X.$$

In particular, if U is convex, f is Fréchet differentiable at every point of U, and there exists a constant $C \ge 0$ such that $\|Df(z)\|_{\mathcal{L}(X,Y)} \le C$ for every $z \in U$, then f is Lipschitz on U and

$$\|f(y)-f(x)\|_Y \le C\|y-x\|_X$$

for any $x, y \in U$.

Proof. If $f(y) = f(x)$, the first inequality is immediate. Suppose $f(y) \neq f(x)$. By Corollary B.2.30, there exists $\varphi \in Y'$ such that $\|\varphi\|_{Y'} = 1$ and $\varphi(f(y)-f(x)) = \|f(y)-f(x)\|_Y$.
Define $g\colon [0,1] \longrightarrow \mathbb{R}$ by $g(t) := \varphi(f(x+t(y-x)))$. Existence of $D_{y-x}f(x+t(y-x))$ for each $t \in [0,1]$ implies that g is continuous on $[0,1]$ and differentiable on $(0,1)$. For each $t \in (0,1)$, continuity of φ allows us to write

$$g'(t) = \lim_{s\to 0} \varphi\left(\frac{f(x+(t+s)(y-x))-f(x+t(y-x))}{s} \right) = \varphi\big(D_{y-x}f(x+t(y-x))\big).$$

By the classical mean value theorem, there exists $\theta \in (0,1)$ such that $g(1)-g(0) = g'(\theta)$. Consequently,

$$\|f(y)-f(x)\|_Y = \varphi(f(y)-f(x)) = \varphi\big(D_{y-x}f(x+\theta(y-x))\big)$$

$$\le \Big|\varphi\big(D_{y-x}f(x+\theta(y-x))\big)\Big| \le \|D_{y-x}f(x+\theta(y-x))\|_Y.$$

It follows that

$$\|f(y)-f(x)\|_Y \le \sup_{t\in[0,1]} \|D_{y-x}f(x+t(y-x))\|_Y.$$

To prove the second inequality, the result is immediate if $f(y)-f(x)-D_{y-x}f(x) = 0$. Suppose $f(y)-f(x)-D_{y-x}f(x) \neq 0$. By Corollary B.2.30, there exists $\psi \in Y'$ such that $\|\psi\|_{Y'} = 1$ and

$$\psi\big(f(y)-f(x)-D_{y-x}f(x)\big) = \|f(y)-f(x)-D_{y-x}f(x)\|_Y.$$

Define $q\colon [0,1] \longrightarrow \mathbb{R}$ by $q(t) := \psi(f(x+t(y-x))-f(x)-tD_{y-x}f(x))$. The function q is continuous on $[0,1]$ and differentiable on $(0,1)$, and, for each $t \in (0,1)$,

$$q'(t) = \psi\big(D_{y-x}f(x+t(y-x))-D_{y-x}f(x)\big).$$

By the classical mean value theorem, there exists $\vartheta \in (0,1)$ such that $q(1)-q(0) = q'(\vartheta)$. Since $q(0) = 0$, we obtain

$$\|f(y)-f(x)-D_{y-x}f(x)\|_Y = \psi\big(D_{y-x}f(x+\vartheta(y-x))-D_{y-x}f(x)\big)$$

$$\le \Big|\psi\big(D_{y-x}f(x+\vartheta(y-x))-D_{y-x}f(x)\big)\Big| \le \|D_{y-x}f(x+\vartheta(y-x))-D_{y-x}f(x)\|_Y.$$

Therefore,

$$\|f(y)-f(x)-D_{y-x}f(x)\|_Y \le \sup_{t\in[0,1]} \|D_{y-x}f(x+t(y-x))-D_{y-x}f(x)\|_Y.$$

Now suppose that f is Fréchet differentiable at every point of $[x,y]$. By Proposition 23.1.7, for each $t\in[0,1]$ we have $D_{y-x}f(x+t(y-x)) = Df(x+t(y-x))(y-x)$. The first inequality already proved then implies that

$$\|f(y)-f(x)\|_Y \le \sup_{t\in[0,1]} \big\|Df(x+t(y-x))(y-x)\big\|_Y.$$

On the other hand, for each $t\in[0,1]$,

$$\big\|Df(x+t(y-x))(y-x)\big\|_Y \le \|Df(x+t(y-x))\|_{\mathcal{L}(X,Y)}\|y-x\|_X.$$

Taking the supremum over $t\in[0,1]$ gives

$$\|f(y)-f(x)\|_Y \le \left(\sup_{t\in[0,1]} \|Df(x+t(y-x))\|_{\mathcal{L}(X,Y)}\right)\|y-x\|_X.$$

Likewise, $D_{y-x}f(x) = Df(x)(y-x)$ and, for each $t\in[0,1]$, we have

$$D_{y-x}f(x+t(y-x))-D_{y-x}f(x) = \big(Df(x+t(y-x))-Df(x)\big)(y-x).$$

The second inequality already proved implies that

$$\|f(y)-f(x)-Df(x)(y-x)\|_Y \le \sup_{t\in[0,1]} \big\|\big(Df(x+t(y-x))-Df(x)\big)(y-x)\big\|_Y.$$

For each $t\in[0,1]$,

$$\big\|\big(Df(x+t(y-x))-Df(x)\big)(y-x)\big\|_Y \le \|Df(x+t(y-x))-Df(x)\|_{\mathcal{L}(X,Y)}\|y-x\|_X.$$

Taking the supremum over $t\in[0,1]$ again gives

$$\|f(y)-f(x)-Df(x)(y-x)\|_Y \le \left(\sup_{t\in[0,1]} \|Df(x+t(y-x))-Df(x)\|_{\mathcal{L}(X,Y)}\right)\|y-x\|_X.$$

Finally, suppose that U is convex and $\|Df(z)\|_{\mathcal{L}(X,Y)}\le C$ for every $z\in U$. For any $x,y\in U$, the segment $[x,y]$ is contained in U and $\sup_{t\in[0,1]} \|Df(x+t(y-x))\|_{\mathcal{L}(X,Y)}\le C$. By the first estimate, $\|f(y)-f(x)\|_Y \le C\|y-x\|_X$, so f is Lipschitz on U. □

The preceding inequalities estimate the increment of the function without requiring continuity of the directional derivatives. Under the additional assumptions that these derivatives vary continuously along the segment and the target space is complete, one can obtain an integral identity for the increment.

Theorem 23.1.11. (Integral mean value formula) Let $(X,\|\cdot\|_X)$ be a real normed space, let $(Y,\|\cdot\|_Y)$ be a real Banach space, let $U\subseteq X$ be open, and let $f\colon U\longrightarrow Y$. Let $x,y\in U$ be such that the segment $[x,y] := \{x+t(y-x)\mid t\in[0,1]\}$ is contained in U. Suppose f has a directional derivative in the direction $y-x$ at every

point of $[x,y]$ and the map $F\colon [0,1] \longrightarrow Y$, defined by $F(t) := D_{y-x}f(x+t(y-x))$, is continuous. Then

$$f(y) - f(x) = \int_0^1 D_{y-x}f(x+t(y-x))\,dt.$$

Proof. By continuity of F and Theorem B.6.2, the Riemann integral $\displaystyle\int_0^1 F(t)\,dt$ is well defined. Let $\varphi \in Y'$ and define $g_\varphi\colon [0,1] \longrightarrow \mathbb{R}$ by $g_\varphi(t) := \varphi(f(x+t(y-x)))$. For each $t \in [0,1]$, interpreting derivatives at the endpoints as one-sided derivatives, continuity of φ allows us to write

$$g'_\varphi(t) = \lim_{s\to 0} \varphi\left(\frac{f(x+(t+s)(y-x)) - f(x+t(y-x))}{s}\right) = \varphi(F(t)).$$

Since F is continuous, so is g'_φ. By Theorem B.6.5 and Proposition B.6.4,

$$\varphi(f(y)-f(x)) = g_\varphi(1) - g_\varphi(0) = \int_0^1 \varphi(F(t))\,dt = \varphi\left(\int_0^1 F(t)\,dt\right).$$

Thus $\displaystyle\varphi\left(f(y)-f(x)-\int_0^1 F(t)\,dt\right) = 0$ for every $\varphi \in Y'$. Corollary B.2.30 implies that $\displaystyle f(y)-f(x)-\int_0^1 F(t)\,dt = 0$, proving the formula. □

The usual properties of the derivative also hold in this setting.

Theorem 23.1.12. (Properties of the directional derivative) Let X, Y, and Z be real normed spaces, let $U \subseteq X$ be an open set, and let $x_0 \in U$, $v \in X$, and $f, g\colon U \longrightarrow Y$. If $D_v f(x_0)$ and $D_v g(x_0)$ exist, then:

(a) $D_v(f+g)(x_0)$ exists and $D_v(f+g)(x_0) = D_v f(x_0) + D_v g(x_0)$.

(b) If $\lambda \in \mathbb{R}$, then $D_v(\lambda f)(x_0)$ exists and $D_v(\lambda f)(x_0) = \lambda D_v f(x_0)$.

(c) If $B\colon Y \times Y \longrightarrow Z$ is a continuous bilinear map, the function $B(f,g)\colon U \longrightarrow Z$, defined by $B(f,g)(x) = B(f(x),g(x))$, has a directional derivative at x_0 in the direction v, and

$$D_v\big(B(f,g)\big)(x_0) = B\big(D_v f(x_0), g(x_0)\big) + B\big(f(x_0), D_v g(x_0)\big).$$

(d) If $Y = \mathbb{R}$, g is continuous at x_0, and $g(x_0) \neq 0$, then $\displaystyle D_v\left(\frac{f}{g}\right)(x_0)$ exists and

$$D_v\left(\frac{f}{g}\right)(x_0) = \frac{D_v f(x_0) g(x_0) - f(x_0) D_v g(x_0)}{g(x_0)^2}.$$

Proof. For the first two items, simply apply linearity of limits in the normed space Y term by term. Let us prove the third. For brevity, write

$$f_t := f(x_0+tv), \qquad g_t := g(x_0+tv), \qquad f_0 := f(x_0), \qquad g_0 := g(x_0).$$

Existence of the directional derivatives implies $f_t \to f_0$ and $g_t \to g_0$ as $t \to 0$. By bilinearity of B,

$$\frac{B(f_t, g_t) - B(f_0, g_0)}{t} = B\left(\frac{f_t - f_0}{t}, g_t\right) + B\left(f_0, \frac{g_t - g_0}{t}\right).$$

Continuity of B allows passage to the limit and gives exactly the stated formula.
Finally, suppose $Y = \mathbb{R}$ and $g(x_0) \neq 0$. Continuity of g at x_0 ensures that $g_t \neq 0$ for sufficiently small t. Then

$$\frac{f_t/g_t - f_0/g_0}{t} = \frac{g_0(f_t - f_0) - f_0(g_t - g_0)}{t\, g_t g_0}.$$

Letting $t \to 0$ and using $g_t \to g_0$ and existence of both directional derivatives gives

$$D_v\left(\frac{f}{g}\right)(x_0) = \frac{D_v f(x_0) g(x_0) - f(x_0) D_v g(x_0)}{g(x_0)^2}.$$

□

Theorem 23.1.13. (Chain rule for directional derivatives) Let X, Y, and Z be real normed spaces, let $U \subseteq X$ and $V \subseteq Y$ be open sets, and let $f\colon U \longrightarrow Y$ and $g\colon V \longrightarrow Z$ be functions such that $f(U) \subseteq V$. Let $x_0 \in U$ and $v \in X$. If g is Fréchet differentiable at $f(x_0)$ and $D_v f(x_0)$ exists, then $D_v(g \circ f)(x_0)$ exists and

$$D_v(g \circ f)(x_0) = Dg(f(x_0))\big(D_v f(x_0)\big).$$

Proof. Since U and V are open, there exist $\delta_0 > 0$ and $\rho > 0$ such that $x_0 + tv \in U$ for every $t \in \mathbb{R}$ with $|t| < \delta_0$ and $B_{d_Y}(f(x_0), \rho) \subseteq V$. We proceed by cases.

(a) Case 1: $D_v f(x_0) \neq 0$.

Let $\varepsilon > 0$. Since g is Fréchet differentiable at $f(x_0)$, there exists $\delta_1 \in (0, \rho)$ such that if $0 < \|h\|_Y < \delta_1$, then

$$\frac{\|g(f(x_0) + h) - g(f(x_0)) - Dg(f(x_0))(h)\|_Z}{\|h\|_Y} < \frac{\varepsilon}{2\big(1 + \|D_v f(x_0)\|_Y\big)}.$$

On the other hand, since $D_v f(x_0)$ exists, there exists $\delta_2 > 0$ such that if $0 < |t| < \delta_2$, then

$$\left\|\frac{f(x_0 + tv) - f(x_0)}{t} - D_v f(x_0)\right\|_Y < \min\left\{1, \frac{\|D_v f(x_0)\|_Y}{2}, \frac{\varepsilon}{2\big(1 + \|Dg(f(x_0))\|_{\mathcal{L}(Y,Z)}\big)}\right\}.$$

Let $\delta = \min\left\{\delta_0, \delta_2, \dfrac{\delta_1}{1 + \|D_v f(x_0)\|_Y}\right\} > 0$ and let $t \in \mathbb{R}$ be such that $0 < |t| < \delta$. First note that

$$\frac{\|f(x_0 + tv) - f(x_0)\|_Y}{|t|} \leq \left\|\frac{f(x_0 + tv) - f(x_0)}{t} - D_v f(x_0)\right\|_Y + \|D_v f(x_0)\|_Y < 1 + \|D_v f(x_0)\|_Y.$$

On the other hand, by the reverse triangle inequality,

$$\frac{\|f(x_0 + tv) - f(x_0)\|_Y}{|t|} \geq \|D_v f(x_0)\|_Y - \left\|\frac{f(x_0 + tv) - f(x_0)}{t} - D_v f(x_0)\right\|_Y > \frac{\|D_v f(x_0)\|_Y}{2} > 0.$$

Consequently, $f(x_0 + tv) \neq f(x_0)$ and $0 < \|f(x_0 + tv) - f(x_0)\|_Y < |t|\big(1 + \|D_v f(x_0)\|_Y\big) < \delta_1$.

Adding and subtracting $\dfrac{Dg(f(x_0))\big(f(x_0+tv)-f(x_0)\big)}{t}$ and using the triangle inequality, the quantity

$$\left\|\frac{g(f(x_0+tv))-g(f(x_0))}{t}-Dg(f(x_0))\big(D_vf(x_0)\big)\right\|_Z$$

is bounded above by the sum of

$$\frac{\|g(f(x_0+tv))-g(f(x_0))-Dg(f(x_0))(f(x_0+tv)-f(x_0))\|_Z}{|t|}$$

and

$$\|Dg(f(x_0))\|_{\mathcal{L}(Y,Z)}\left\|\frac{f(x_0+tv)-f(x_0)}{t}-D_vf(x_0)\right\|_Y.$$

The first summand equals

$$\frac{\|g(f(x_0+tv))-g(f(x_0))-Dg(f(x_0))(f(x_0+tv)-f(x_0))\|_Z}{\|f(x_0+tv)-f(x_0)\|_Y}\,\frac{\|f(x_0+tv)-f(x_0)\|_Y}{|t|},$$

, so

$$\frac{\|g(f(x_0+tv))-g(f(x_0))-Dg(f(x_0))(f(x_0+tv)-f(x_0))\|_Z}{|t|}<\frac{\varepsilon}{2}.$$

Likewise,

$$\|Dg(f(x_0))\|_{\mathcal{L}(Y,Z)}\left\|\frac{f(x_0+tv)-f(x_0)}{t}-D_vf(x_0)\right\|_Y\le\frac{\varepsilon\|Dg(f(x_0))\|_{\mathcal{L}(Y,Z)}}{2\big(1+\|Dg(f(x_0))\|_{\mathcal{L}(Y,Z)}\big)}<\frac{\varepsilon}{2}.$$

Therefore,

$$\left\|\frac{g(f(x_0+tv))-g(f(x_0))}{t}-Dg(f(x_0))\big(D_vf(x_0)\big)\right\|_Z<\varepsilon.$$

Consequently, $D_v(g\circ f)(x_0)=Dg(f(x_0))\big(D_vf(x_0)\big)$.

(b) Case 2: $D_vf(x_0)=0$.

In this case, we must prove that $D_v(g\circ f)(x_0)=0$. Let $\varepsilon>0$. Since g is Fréchet differentiable at $f(x_0)$, there exists $\delta_1\in(0,\rho)$ such that if $0<\|h\|_Y<\delta_1$, then

$$\frac{\|g(f(x_0)+h)-g(f(x_0))-Dg(f(x_0))(h)\|_Z}{\|h\|_Y}<1.$$

On the other hand, since $D_vf(x_0)=0$, there exists $\delta_2>0$ such that if $0<|t|<\delta_2$, then

$$\frac{\|f(x_0+tv)-f(x_0)\|_Y}{|t|}<\min\left\{1,\frac{\varepsilon}{1+\|Dg(f(x_0))\|_{\mathcal{L}(Y,Z)}}\right\}.$$

Let $\delta=\min\{\delta_0,\delta_1,\delta_2\}>0$ and let $t\in\mathbb{R}$ be such that $0<|t|<\delta$. If $f(x_0+tv)=f(x_0)$, then

$$\left\|\frac{g(f(x_0+tv))-g(f(x_0))}{t}\right\|_Z=0<\varepsilon.$$

Now suppose $f(x_0+tv)\neq f(x_0)$. In this case, $0<\|f(x_0+tv)-f(x_0)\|_Y<|t|<\delta\le\delta_1$.

Adding and subtracting $\dfrac{Dg(f(x_0))\big(f(x_0+tv)-f(x_0)\big)}{t}$ and using the triangle inequality, the quantity

$$\left\|\frac{g(f(x_0+tv))-g(f(x_0))}{t}\right\|_Z$$

is bounded above by the sum of

$$\frac{\|g(f(x_0+tv))-g(f(x_0))-Dg(f(x_0))(f(x_0+tv)-f(x_0))\|_Z}{|t|}$$

and

$$\|Dg(f(x_0))\|_{\mathcal{L}(Y,Z)}\frac{\|f(x_0+tv)-f(x_0)\|_Y}{|t|}.$$

The first summand equals

$$\frac{\|g(f(x_0+tv))-g(f(x_0))-Dg(f(x_0))(f(x_0+tv)-f(x_0))\|_Z}{\|f(x_0+tv)-f(x_0)\|_Y}\,\frac{\|f(x_0+tv)-f(x_0)\|_Y}{|t|},$$

, so

$$\frac{\|g(f(x_0+tv))-g(f(x_0))-Dg(f(x_0))(f(x_0+tv)-f(x_0))\|_Z}{|t|}<\frac{\varepsilon}{1+\|Dg(f(x_0))\|_{\mathcal{L}(Y,Z)}}.$$

Likewise,

$$\|Dg(f(x_0))\|_{\mathcal{L}(Y,Z)}\frac{\|f(x_0+tv)-f(x_0)\|_Y}{|t|}\leq\frac{\varepsilon\|Dg(f(x_0))\|_{\mathcal{L}(Y,Z)}}{1+\|Dg(f(x_0))\|_{\mathcal{L}(Y,Z)}}.$$

Therefore,

$$\left\|\frac{g(f(x_0+tv))-g(f(x_0))}{t}\right\|_Z<\varepsilon.$$

Consequently, $D_v(g\circ f)(x_0)=0=Dg(f(x_0))\big(D_vf(x_0)\big)$.

□

The chain rule for directional derivatives immediately gives the corresponding rule for the Gâteaux derivative. The version for the Fréchet derivative also requires checking that the linear approximation is uniform in the increments.

Corollary 23.1.14. (Chain rule for Gâteaux and Fréchet derivatives) Let X, Y, and Z be normed spaces, let $U\subseteq X$ and $V\subseteq Y$ be open sets, and let $f\colon U\longrightarrow Y$ and $g\colon V\longrightarrow Z$ be functions such that $f(U)\subseteq V$. Let $x_0\in U$ and suppose g is Fréchet differentiable at $f(x_0)$.
If f is Gâteaux differentiable at x_0, then $g\circ f$ is Gâteaux differentiable at x_0 and

$$\delta(g\circ f)(x_0)=Dg(f(x_0))\circ\delta f(x_0).$$

If f is Fréchet differentiable at x_0, then $g\circ f$ is Fréchet differentiable at x_0 and

$$D(g\circ f)(x_0)=Dg(f(x_0))\circ Df(x_0).$$

Proof. First suppose f is Gâteaux differentiable at x_0. For each $v \in X$, Theorem 23.1.13 implies that

$$D_v(g \circ f)(x_0) = Dg(f(x_0))\big(D_v f(x_0)\big) = Dg(f(x_0))\big(\delta f(x_0)(v)\big).$$

Since $Dg(f(x_0)) \circ \delta f(x_0) \in \mathcal{L}(X,Z)$, we conclude that $g \circ f$ is Gâteaux differentiable at x_0 and $\delta(g \circ f)(x_0) = Dg(f(x_0)) \circ \delta f(x_0)$.
Now suppose f is Fréchet differentiable at x_0. By Proposition 23.1.7, the first part shows that $g \circ f$ is Gâteaux differentiable at x_0 and the only candidate for its Fréchet derivative is $Dg(f(x_0)) \circ Df(x_0)$.
For each $h \in X \setminus \{0\}$ such that $x_0 + h \in U$, adding and subtracting $Dg(f(x_0))(f(x_0+h) - f(x_0))$ and using the triangle inequality, the quantity

$$\frac{\big\|g(f(x_0+h)) - g(f(x_0)) - Dg(f(x_0))\big(Df(x_0)(h)\big)\big\|_Z}{\|h\|_X}$$

is bounded above by the sum of

$$\frac{\big\|g(f(x_0+h)) - g(f(x_0)) - Dg(f(x_0))\big(f(x_0+h) - f(x_0)\big)\big\|_Z}{\|h\|_X}$$

and

$$\|Dg(f(x_0))\|_{\mathcal{L}(Y,Z)} \frac{\|f(x_0+h) - f(x_0) - Df(x_0)(h)\|_Y}{\|h\|_X}.$$

If $f(x_0+h) \neq f(x_0)$, the first quotient can be written as

$$\frac{\big\|g(f(x_0+h)) - g(f(x_0)) - Dg(f(x_0))\big(f(x_0+h) - f(x_0)\big)\big\|_Z}{\|f(x_0+h) - f(x_0)\|_Y} \frac{\|f(x_0+h) - f(x_0)\|_Y}{\|h\|_X}.$$

If $f(x_0+h) = f(x_0)$, that quotient equals zero. Moreover,

$$\frac{\|f(x_0+h) - f(x_0)\|_Y}{\|h\|_X} \leq \frac{\|f(x_0+h) - f(x_0) - Df(x_0)(h)\|_Y}{\|h\|_X} + \|Df(x_0)\|_{\mathcal{L}(X,Y)}.$$

By Fréchet differentiability of f at x_0, this last quotient remains bounded as $h \to 0$, while $f(x_0+h) \to f(x_0)$ by Proposition 23.1.3. Fréchet differentiability of g at $f(x_0)$ then implies that the first summand tends to zero, and differentiability of f implies the same for the second. Thus

$$\lim_{h \to 0} \frac{\big\|g(f(x_0+h)) - g(f(x_0)) - Dg(f(x_0))\big(Df(x_0)(h)\big)\big\|_Z}{\|h\|_X} = 0.$$

Consequently, $g \circ f$ is Fréchet differentiable at x_0 and $D(g \circ f)(x_0) = Dg(f(x_0)) \circ Df(x_0)$. □

Corollary 23.1.15. (Composition with a continuous linear operator) Let X, Y, and Z be normed spaces, let $U \subseteq X$ be open, let $f : U \longrightarrow Y$, and let $A \in \mathcal{L}(Y,Z)$. Given $x_0 \in U$ and $v \in X$, the following assertions hold:

(a) If $D_v f(x_0)$ exists, then $D_v(A \circ f)(x_0)$ exists and $D_v(A \circ f)(x_0) = A\big(D_v f(x_0)\big)$.

(b) If f is Gâteaux differentiable at x_0, then $A \circ f$ is Gâteaux differentiable at x_0 and $\delta(A \circ f)(x_0) = A \circ \delta f(x_0)$.

(c) If f is Fréchet differentiable at x_0, then $A \circ f$ is Fréchet differentiable at x_0 and $D(A \circ f)(x_0) = A \circ Df(x_0)$.

Proof. For each $y \in Y$ and each $h \in Y \setminus \{0\}$, we have

$$\frac{\|A(y+h) - A(y) - A(h)\|_Z}{\|h\|_Y} = 0.$$

Thus A is Fréchet differentiable at every point of Y and $DA(y) = A$. The three assertions follow from Theorem 23.1.13 and Corollary 23.1.14. □

Existence of the Gâteaux derivative alone does not guarantee Fréchet differentiability. However, continuity of the Gâteaux derivative in the operator norm provides a sufficient condition.

Proposition 23.1.16. (Continuity of the Gâteaux derivative) Let X and Y be normed spaces, let $U \subseteq X$ be open, let $x_0 \in U$, and let $f : U \longrightarrow Y$. Suppose there exists $r > 0$ such that $B_{d_X}(x_0, r) \subseteq U$, f is Gâteaux differentiable at every point of $B_{d_X}(x_0, r)$, and the map $\delta f : B_{d_X}(x_0, r) \longrightarrow \mathcal{L}(X, Y)$ is continuous at x_0. Then f is Fréchet differentiable at x_0 and $Df(x_0) = \delta f(x_0)$.

Proof. Let $\varepsilon > 0$. By continuity of δf at x_0, there exists $\delta \in (0, r)$ such that $\|\delta f(z) - \delta f(x_0)\|_{\mathcal{L}(X,Y)} < \varepsilon$ for every $z \in B_{d_X}(x_0, \delta)$.
Let $h \in X$ be such that $0 < \|h\|_X < \delta$. For each $t \in [0,1]$, we have $\|x_0 + th - x_0\|_X = t\|h\|_X < \delta$, so $x_0 + th \in B_{d_X}(x_0, \delta)$.
Applying the second estimate in Theorem 23.1.10 to the points x_0 and $x_0 + h$ gives

$$\|f(x_0+h) - f(x_0) - D_h f(x_0)\|_Y \leq \sup_{t\in[0,1]} \|D_h f(x_0 + th) - D_h f(x_0)\|_Y.$$

Since f is Gâteaux differentiable at every point of the segment, for each $t \in [0,1]$ we have $D_h f(x_0 + th) = \delta f(x_0 + th)(h)$ and $D_h f(x_0) = \delta f(x_0)(h)$. Thus

$$\|f(x_0+h) - f(x_0) - \delta f(x_0)(h)\|_Y \leq \sup_{t\in[0,1]} \left\| \big(\delta f(x_0 + th) - \delta f(x_0)\big)(h) \right\|_Y.$$

By the definition of the operator norm and the choice of δ, for each $t \in [0,1]$ we have

$$\left\| \big(\delta f(x_0 + th) - \delta f(x_0)\big)(h) \right\|_Y \leq \|\delta f(x_0 + th) - \delta f(x_0)\|_{\mathcal{L}(X,Y)} \|h\|_X < \varepsilon \|h\|_X.$$

Consequently, $\|f(x_0 + h) - f(x_0) - \delta f(x_0)(h)\|_Y \leq \varepsilon \|h\|_X$ and therefore

$$\frac{\|f(x_0+h) - f(x_0) - \delta f(x_0)(h)\|_Y}{\|h\|_X} \leq \varepsilon.$$

This proves that f is Fréchet differentiable at x_0 and that $Df(x_0) = \delta f(x_0)$. □

The preceding proposition allows us to characterize functions of class C^1 using the Gâteaux derivative and the notion of differentiability already defined.

Corollary 23.1.17. (Characterization of functions of class C^1) Let X and Y be normed spaces, let $U \subseteq X$ be open, and let $f : U \longrightarrow Y$. Then $f \in C^1(U, Y)$ if and only if f is Gâteaux differentiable at every point of U and the map $\delta f : U \longrightarrow \mathcal{L}(X, Y)$ is continuous. In this case, $Df(x) = \delta f(x)$ for every $x \in U$.

Proof. If $f \in C^1(U,Y)$, Proposition 23.1.7 implies that f is Gâteaux differentiable at every point of U and that $\delta f = Df$. Continuity of δf follows from continuity of Df.
Conversely, suppose f is Gâteaux differentiable at every point of U and $\delta f\colon U \longrightarrow \mathcal{L}(X,Y)$ is continuous. Let $x \in U$. Since U is open, there exists $r > 0$ such that $B_{d_X}(x,r) \subseteq U$. Proposition 23.1.16 implies that f is Fréchet differentiable at x and that $Df(x) = \delta f(x)$. Since $x \in U$ was arbitrary, f is Fréchet differentiable on U and $Df = \delta f$. Continuity of δf then implies continuity of Df. By Definition 23.1.4, we conclude that $f \in C^1(U,Y)$. □

The notion of partial derivative also extends naturally to normed spaces. Here it is useful to distinguish Gâteaux and Fréchet partial derivatives according to the notion of differentiability used when the other variables are held fixed. On the product space $X \times Y$, we use the norm $\|(h,k)\|_{X\times Y} := \|h\|_X + \|k\|_Y$.

Definition 23.1.18. (Gâteaux and Fréchet partial derivatives) Let X, Y, and Z be normed spaces, let $U \subseteq X$ and $V \subseteq Y$ be open, let $f\colon U \times V \longrightarrow Z$, and let $(x,y) \in U \times V$.
If the function $f(\cdot,y)\colon U \longrightarrow Z$ is Gâteaux differentiable at x, the **Gâteaux partial derivative of f with respect to the first variable** is defined by $\delta_1 f(x,y) := \delta(f(\cdot,y))(x) \in \mathcal{L}(X,Z)$. If $f(x,\cdot)\colon V \longrightarrow Z$ is Gâteaux differentiable at y, the **Gâteaux partial derivative with respect to the second variable** is defined by $\delta_2 f(x,y) := \delta(f(x,\cdot))(y) \in \mathcal{L}(Y,Z)$.
If $f(\cdot,y)$ is Fréchet differentiable at x, the **Fréchet partial derivative of f with respect to the first variable** is defined by $D_1 f(x,y) := D(f(\cdot,y))(x) \in \mathcal{L}(X,Z)$. If $f(x,\cdot)$ is Fréchet differentiable at y, the **Fréchet partial derivative with respect to the second variable** is defined by $D_2 f(x,y) := D(f(x,\cdot))(y) \in \mathcal{L}(Y,Z)$.

Partial derivatives are obtained by restricting the total derivative to the directions corresponding to each factor of the product.

Proposition 23.1.19. Let X, Y, and Z be normed spaces, let $U \subseteq X$ and $V \subseteq Y$ be open, let $f\colon U \times V \longrightarrow Z$, and let $(x,y) \in U \times V$.
If f is Gâteaux differentiable at (x,y), then $\delta_1 f(x,y)$ and $\delta_2 f(x,y)$ exist and, for every $(h,k) \in X \times Y$,

$$\delta f(x,y)(h,k) = \delta_1 f(x,y)(h) + \delta_2 f(x,y)(k). \tag{23.1}$$

If f is Fréchet differentiable at (x,y), then $D_1 f(x,y)$ and $D_2 f(x,y)$ exist and, for every $(h,k) \in X \times Y$,

$$Df(x,y)(h,k) = D_1 f(x,y)(h) + D_2 f(x,y)(k). \tag{23.2}$$

Proof. First suppose f is Gâteaux differentiable at (x,y). Let $h \in X$. When only the first component varies, the increment th of x corresponds to the increment $(th,0) = t(h,0)$ of the point (x,y). Thus

$$\delta_1 f(x,y)(h) = \lim_{t\to 0} \frac{f(x+th,y) - f(x,y)}{t} = \lim_{t\to 0} \frac{f\big((x,y) + t(h,0)\big) - f(x,y)}{t} = \delta f(x,y)(h,0).$$

This proves that $\delta_1 f(x,y)$ exists and agrees with the restriction of $\delta f(x,y)$ to the subspace $X \times \{0\}$. For the second variable, varying only that component corresponds to the increment $(0,tk) = t(0,k)$. Hence, for each $k \in Y$,

$$\delta_2 f(x,y)(k) = \lim_{t\to 0} \frac{f(x,y+tk) - f(x,y)}{t} = \delta f(x,y)(0,k).$$

Since $(h,k) = (h,0) + (0,k)$ and $\delta f(x,y)$ is linear, it follows that

$$\delta f(x,y)(h,k) = \delta f(x,y)(h,0) + \delta f(x,y)(0,k) = \delta_1 f(x,y)(h) + \delta_2 f(x,y)(k),$$

, which proves (23.1).
Now suppose f is Fréchet differentiable at (x,y). For each $h \in X \setminus \{0\}$ such that $x+h \in U$, we have

$$\frac{\|f(x+h,y) - f(x,y) - Df(x,y)(h,0)\|_Z}{\|h\|_X} = \frac{\|f\big((x,y)+(h,0)\big) - f(x,y) - Df(x,y)(h,0)\|_Z}{\|(h,0)\|_{X\times Y}}.$$

The right-hand side tends to zero as $h \to 0$, since $(h,0) \to (0,0)$ in $X \times Y$. Consequently, $f(\cdot, y)$ is Fréchet differentiable at x and $D_1 f(x,y)(h) = Df(x,y)(h,0)$ for every $h \in X$.
For the second variable, if $k \in Y \setminus \{0\}$ and $y + k \in V$, then

$$\frac{\|f(x,y+k) - f(x,y) - Df(x,y)(0,k)\|_Z}{\|k\|_Y} = \frac{\|f\big((x,y)+(0,k)\big) - f(x,y) - Df(x,y)(0,k)\|_Z}{\|(0,k)\|_{X\times Y}}.$$

The last quotient tends to zero as $k \to 0$. Thus $D_2 f(x,y)(k) = Df(x,y)(0,k)$ for every $k \in Y$. Linearity of $Df(x,y)$ then implies

$$Df(x,y)(h,k) = Df(x,y)(h,0) + Df(x,y)(0,k) = D_1 f(x,y)(h) + D_2 f(x,y)(k),$$

, which proves (23.2). □

The converse generally does not follow from mere existence of the partial derivatives. However, continuity of one of them in the operator norm allows us to recover total differentiability.

Proposition 23.1.20. (Differentiability from partial derivatives) Let X, Y, and Z be normed spaces, let $U \subseteq X$ and $V \subseteq Y$ be open, let $f\colon U \times V \longrightarrow Z$, and let $(x_0,y_0) \in U \times V$. Suppose $\delta_1 f(x_0,y_0)$ exists, $\delta_2 f$ is defined on an open neighborhood $W \subseteq U \times V$ of (x_0,y_0), and the map

$$(x,y) \longmapsto \delta_2 f(x,y), \qquad W \longrightarrow \mathcal{L}(Y,Z),$$

is continuous at (x_0,y_0). Then f is Gâteaux differentiable at (x_0,y_0), and identity (23.1) holds with $(x,y) = (x_0,y_0)$.
If, in addition, $D_1 f(x_0,y_0)$ exists, then f is Fréchet differentiable at (x_0,y_0), and identity (23.2) holds with $(x,y) = (x_0,y_0)$. In this case,

$$D_2 f(x_0,y_0) = \delta_2 f(x_0,y_0).$$

Proof. Let $W \subseteq U \times V$ be the open neighborhood in the statement. Take $r > 0$ such that $B_{d_{X\times Y}}((x_0,y_0),r) \subseteq W$. Fix $(h,k) \in X \times Y$. The case $(h,k) = (0,0)$ is immediate. Suppose $(h,k) \neq (0,0)$ and $0 < |t| < \dfrac{r}{\|h\|_X + \|k\|_Y}$. For each $\tau \in [0,1]$, we have $\|(th, \tau tk)\|_{X\times Y} \leq |t|(\|h\|_X + \|k\|_Y) < r$; hence the segment joining (x_0+th, y_0) to (x_0+th, y_0+tk) is contained in W.
Adding and subtracting $f(x_0+th, y_0)$ gives

$$\frac{f(x_0+th, y_0+tk) - f(x_0,y_0)}{t} - \delta_1 f(x_0,y_0)(h) - \delta_2 f(x_0,y_0)(k)$$

$$= \frac{f(x_0+th, y_0+tk) - f(x_0+th, y_0) - \delta_2 f(x_0,y_0)(tk)}{t} + \frac{f(x_0+th,y_0)-f(x_0,y_0)}{t} - \delta_1 f(x_0,y_0)(h).$$

To estimate the first term, apply the first mean value inequality in Theorem 23.1.10 to the map $v \longmapsto f(x_0+th,v) - \delta_2 f(x_0,y_0)(v-y_0)$ between the points y_0 and y_0+tk. Its directional derivative in the direction tk is $\big(\delta_2 f(x_0+th,v) - \delta_2 f(x_0,y_0)\big)(tk)$. Dividing the resulting estimate by $|t|$ gives

$$\left\| \frac{f(x_0+th,y_0+tk) - f(x_0+th,y_0) - \delta_2 f(x_0,y_0)(tk)}{t} \right\|_Z \leq \sup_{\tau\in[0,1]} \|\delta_2 f(x_0+th, y_0+\tau tk) - \delta_2 f(x_0,y_0)\|_{\mathcal{L}(Y,Z)} \|k\|_Y.$$

Let $\varepsilon > 0$. By continuity of $\delta_2 f$ at (x_0,y_0), there exists $\eta \in (0,r)$ such that $\|\delta_2 f(u,v) - \delta_2 f(x_0,y_0)\|_{\mathcal{L}(Y,Z)} < \varepsilon$ whenever $(u,v) \in W$ and $\|(u-x_0, v-y_0)\|_{X\times Y} < \eta$. If $0 < |t| < \dfrac{\eta}{\|h\|_X + \|k\|_Y}$, then $\|(th,\tau tk)\|_{X\times Y} < \eta$ for every $\tau \in [0,1]$, and consequently

$$\left\| \frac{f(x_0+th,y_0+tk) - f(x_0+th,y_0)}{t} - \delta_2 f(x_0,y_0)(k) \right\|_Z \leq \varepsilon \|k\|_Y.$$

Thus

$$\lim_{t\to 0} \left(\frac{f(x_0+th,y_0+tk) - f(x_0+th,y_0)}{t} - \delta_2 f(x_0,y_0)(k) \right) = 0.$$

On the other hand, existence of $\delta_1 f(x_0,y_0)$ implies

$$\lim_{t\to 0} \left(\frac{f(x_0+th,y_0) - f(x_0,y_0)}{t} - \delta_1 f(x_0,y_0)(h) \right) = 0.$$

Combining the two limits, we conclude that the directional derivative of f at (x_0,y_0) in the direction (h,k) exists and equals

$$\delta_1 f(x_0,y_0)(h) + \delta_2 f(x_0,y_0)(k).$$

The map $(h,k) \longmapsto \delta_1 f(x_0,y_0)(h) + \delta_2 f(x_0,y_0)(k)$ is linear. Moreover,

$$\|\delta_1 f(x_0,y_0)(h) + \delta_2 f(x_0,y_0)(k)\|_Z \leq \max\big\{\|\delta_1 f(x_0,y_0)\|_{\mathcal{L}(X,Z)}, \|\delta_2 f(x_0,y_0)\|_{\mathcal{L}(Y,Z)}\big\} \|(h,k)\|_{X\times Y},$$

, so it is continuous. Thus f is Gâteaux differentiable at (x_0,y_0) and (23.1) holds.
Now suppose $D_1 f(x_0,y_0)$ exists and define the operator $L\colon X\times Y \longrightarrow Z$ by

$$L(h,k) := D_1 f(x_0,y_0)(h) + \delta_2 f(x_0,y_0)(k).$$

The operator L is linear and continuous. We will show that it is the Fréchet approximation to f at (x_0,y_0). Let $\varepsilon > 0$. By continuity of $\delta_2 f$ at (x_0,y_0), there exists $\eta \in (0,r)$ such that $\|\delta_2 f(u,v) - \delta_2 f(x_0,y_0)\|_{\mathcal{L}(Y,Z)} < \dfrac{\varepsilon}{2}$ whenever $(u,v) \in W$ and $\|(u-x_0, v-y_0)\|_{X\times Y} < \eta$. Since $D_1 f(x_0,y_0)$ exists, there exists $\rho > 0$ such that

$$\|f(x_0+h,y_0) - f(x_0,y_0) - D_1 f(x_0,y_0)(h)\|_Z \leq \frac{\varepsilon}{2}\|h\|_X$$

whenever $0 < \|h\|_X < \rho$; for $h = 0$, both sides are zero.
Let $\delta := \min\{\eta,\rho\}$ and suppose $0 < \|h\|_X + \|k\|_Y < \delta$. Then, for every $\tau \in [0,1]$, we have $\|(h,\tau k)\|_{X\times Y} < \eta < r$, so

the segment joining (x_0+h, y_0) to (x_0+h, y_0+k) is contained in W. Adding and subtracting $f(x_0+h, y_0)$ gives

$$f(x_0+h, y_0+k) - f(x_0, y_0) - L(h,k)$$

$$= f(x_0+h, y_0+k) - f(x_0+h, y_0) - \delta_2 f(x_0, y_0)(k) \quad + f(x_0+h, y_0) - f(x_0, y_0) - D_1 f(x_0, y_0)(h).$$

Apply the first mean value inequality again, now to the map $v \longmapsto f(x_0+h, v) - \delta_2 f(x_0, y_0)(v - y_0)$ between y_0 and y_0+k. This gives

$$\|f(x_0+h, y_0+k) - f(x_0+h, y_0) - \delta_2 f(x_0, y_0)(k)\|_Z \leq \sup_{\tau \in [0,1]} \|\delta_2 f(x_0+h, y_0+\tau k) - \delta_2 f(x_0, y_0)\|_{\mathcal{L}(Y,Z)} \|k\|_Y \leq \frac{\varepsilon}{2}\|k\|_Y.$$

Consequently,

$$\|f(x_0+h, y_0+k) - f(x_0, y_0) - L(h,k)\|_Z \leq \frac{\varepsilon}{2}\big(\|h\|_X + \|k\|_Y\big).$$

It follows that

$$\lim_{(h,k)\to(0,0)} \frac{\|f(x_0+h, y_0+k) - f(x_0, y_0) - L(h,k)\|_Z}{\|h\|_X + \|k\|_Y} = 0.$$

Thus f is Fréchet differentiable at (x_0, y_0), $Df(x_0, y_0) = L$, and (23.2) holds.
Finally, Proposition 23.1.19 implies that $D_2 f(x_0, y_0)$ exists and that, for every $k \in Y$,

$$D_2 f(x_0, y_0)(k) = Df(x_0, y_0)(0, k) = \delta_2 f(x_0, y_0)(k).$$

Therefore, $D_2 f(x_0, y_0) = \delta_2 f(x_0, y_0)$. □

Corollary 23.1.21. (Characterization of functions of class C^1 by partial derivatives) Let X, Y, and Z be normed spaces, let $U \subseteq X$ and $V \subseteq Y$ be open, and let $f\colon U \times V \longrightarrow Z$. Then $f \in C^1(U \times V, Z)$ if and only if $\delta_1 f$ and $\delta_2 f$ exist on $U \times V$ and are continuous as maps with values in $\mathcal{L}(X, Z)$ and $\mathcal{L}(Y, Z)$, respectively. In this case, $D_1 f = \delta_1 f$, $D_2 f = \delta_2 f$, and, for every $(x, y) \in U \times V$ and every $(h, k) \in X \times Y$,

$$Df(x, y)(h, k) = \delta_1 f(x, y)(h) + \delta_2 f(x, y)(k).$$

Proof. First suppose $f \in C^1(U \times V, Z)$. Let $\iota_X\colon X \longrightarrow X \times Y$ and $\iota_Y\colon Y \longrightarrow X \times Y$ be the continuous linear operators defined by $\iota_X(h) := (h, 0)$ and $\iota_Y(k) := (0, k)$. By Proposition 23.1.19, for each $(x, y) \in U \times V$ we have $D_1 f(x, y) = Df(x, y) \circ \iota_X$ and $D_2 f(x, y) = Df(x, y) \circ \iota_Y$. Since $Df\colon U \times V \longrightarrow \mathcal{L}(X \times Y, Z)$ is continuous, so are $D_1 f$ and $D_2 f$. Moreover, Fréchet differentiability implies Gâteaux differentiability, and therefore $D_j f = \delta_j f$ for $j \in \{1, 2\}$.
Conversely, suppose $\delta_1 f$ and $\delta_2 f$ exist and are continuous. For fixed $y \in V$, the map $x \longmapsto f(x, y)$ has Gâteaux derivative $\delta_1 f(x, y)$, continuous in the operator norm with respect to x. Corollary 23.1.17 shows that this map is of class C^1; in particular, $D_1 f(x, y)$ exists and agrees with $\delta_1 f(x, y)$. All the assumptions of Proposition 23.1.20 are now satisfied. Applying it at each point of $U \times V$, we obtain that f is Fréchet differentiable and

$$Df(x, y)(h, k) = \delta_1 f(x, y)(h) + \delta_2 f(x, y)(k).$$

Let $(x_1, y_1), (x_2, y_2) \in U \times V$. For every $(h, k) \in X \times Y$ with $\|(h, k)\|_{X \times Y} \leq 1$, we have

$$\big\|\big(Df(x_1, y_1) - Df(x_2, y_2)\big)(h, k)\big\|_Z \leq \|\delta_1 f(x_1, y_1) - \delta_1 f(x_2, y_2)\|_{\mathcal{L}(X,Z)} \|h\|_X + \|\delta_2 f(x_1, y_1) - \delta_2 f(x_2, y_2)\|_{\mathcal{L}(Y,Z)} \|k\|_Y.$$

Taking the supremum over the unit ball of $X \times Y$ gives

$$\|Df(x_1,y_1) - Df(x_2,y_2)\|_{\mathcal{L}(X\times Y,Z)} \le \|\delta_1 f(x_1,y_1) - \delta_1 f(x_2,y_2)\|_{\mathcal{L}(X,Z)} + \|\delta_2 f(x_1,y_1) - \delta_2 f(x_2,y_2)\|_{\mathcal{L}(Y,Z)}.$$

Continuity of the partial derivatives then implies continuity of Df. □

23.2 Higher derivatives and Taylor's formula

The first derivative takes values in $\mathcal{L}(X,Y)$. Differentiating it again produces operators that depend linearly on two directions, and further iterations lead to multilinear operators. Before defining higher derivatives, it is therefore useful to specify the normed structure of these spaces and their relation to the spaces of linear operators already introduced.

Definition 23.2.1. (Continuous multilinear operators) Let $X_1,\dots,X_m$ and Y be normed spaces, with $m \in \mathbb{N}$. We denote by $\mathcal{L}^m(X_1,\dots,X_m;Y)$ the vector space of continuous m-linear maps $A\colon X_1 \times \cdots \times X_m \longrightarrow Y$. For each $A \in \mathcal{L}^m(X_1,\dots,X_m;Y)$, define

$$\|A\|_{\mathcal{L}^m} := \sup\big\{\|A(h_1,\dots,h_m)\|_Y \mid h_j \in X_j,\ \|h_j\|_{X_j} \le 1 \text{ for } 1 \le j \le m\big\}.$$

If $X_1 = \cdots = X_m = X$, write $\mathcal{L}^m(X;Y)$. In particular, $\mathcal{L}^1(X;Y) = \mathcal{L}(X,Y)$. Denote by $\mathcal{L}^m_s(X;Y)$ the subspace of symmetric operators, that is, those $A \in \mathcal{L}^m(X;Y)$ such that $A(h_{\sigma(1)},\dots,h_{\sigma(m)}) = A(h_1,\dots,h_m)$ for every permutation σ of $\{1,\dots,m\}$. By convention, $\mathcal{L}^0(X;Y) := Y$.

Proposition 23.2.2. (Characterization of multilinear continuity) A m-linear map $A\colon X_1 \times \cdots \times X_m \longrightarrow Y$ is continuous if and only if there exists a constant $C \ge 0$ such that

$$\|A(h_1,\dots,h_m)\|_Y \le C \prod_{j=1}^{m} \|h_j\|_{X_j} \tag{23.3}$$

for all $h_j \in X_j$. In this case, the smallest constant for which (23.3) holds is $\|A\|_{\mathcal{L}^m}$.

Proof. First suppose (23.3) holds. If $h_j \longrightarrow 0$ in X_j for each j, the right-hand side of (23.3) tends to zero, so A is continuous at the origin. Now let $x_j, h_j \in X_j$. By multilinearity,

$$A(x_1+h_1,\dots,x_m+h_m) - A(x_1,\dots,x_m) = \sum_{\varnothing \ne I \subseteq \{1,\dots,m\}} A(z_1^I,\dots,z_m^I),$$

, where $z_j^I = h_j$ if $j \in I$ and $z_j^I = x_j$ if $j \notin I$. Inequality (23.3), applied to each summand, shows that the difference tends to zero as $(h_1,\dots,h_m) \longrightarrow (0,\dots,0)$. Thus A is continuous at every point.
Conversely, suppose A is continuous at the origin. There exists $\rho > 0$ such that $\|A(u_1,\dots,u_m)\|_Y < 1$ whenever $\|u_j\|_{X_j} < \rho$ for every j. If none of the vectors h_j is zero, define $u_j := \dfrac{\rho h_j}{2\|h_j\|_{X_j}}$. Then $\|u_j\|_{X_j} = \dfrac{\rho}{2}$ and, by multilinearity,

$$\|A(h_1,\dots,h_m)\|_Y < \left(\frac{2}{\rho}\right)^m \prod_{j=1}^{m} \|h_j\|_{X_j}.$$

If one of the vectors is zero, both sides of (23.3) vanish. This proves existence of a constant C.
Finally, if (23.3) holds with constant C, then $\|A\|_{\mathcal{L}^m} \le C$. On the other hand, for nonzero vectors, applying the definition of the norm to $\dfrac{h_j}{\|h_j\|_{X_j}}$ gives

$$\|A(h_1,\dots,h_m)\|_Y \le \|A\|_{\mathcal{L}^m} \prod_{j=1}^{m} \|h_j\|_{X_j}.$$

Thus $\|A\|_{\mathcal{L}^m}$ is the smallest possible constant. □

Proposition 23.2.3. (Completeness and association of multilinear operators) If Y is Banach, then $\mathcal{L}^m(X_1,\dots,X_m;Y)$ is Banach. Moreover, the map

$$\mathfrak{C} : \mathcal{L}^{m+1}(X_1,\dots,X_m,X_{m+1};Y) \longrightarrow \mathcal{L}\big(X_{m+1},\mathcal{L}^m(X_1,\dots,X_m;Y)\big),$$

, defined by

$$\mathfrak{C}(A)(h_{m+1})(h_1,\dots,h_m) := A(h_1,\dots,h_m,h_{m+1}),$$

, is an isometric linear isomorphism. In particular, if Y is Banach, then $\mathcal{L}^m_s(X;Y)$ is a closed subspace and hence a Banach space.

Proof. Let $(A_j)_{j\in\mathbb{N}}$ be a Cauchy sequence in $\mathcal{L}^m(X_1,\dots,X_m;Y)$. For each $(h_1,\dots,h_m) \in X_1\times\cdots\times X_m$, we have

$$\|(A_j - A_k)(h_1,\dots,h_m)\|_Y \le \|A_j - A_k\|_{\mathcal{L}^m} \prod_{i=1}^{m} \|h_i\|_{X_i}.$$

Thus $(A_j(h_1,\dots,h_m))_{j\in\mathbb{N}}$ is a Cauchy sequence in Y. Define $A(h_1,\dots,h_m) := \lim\limits_{j\to\infty} A_j(h_1,\dots,h_m)$. Passage to the limit in each variable shows that A is m-linear.
Since (A_j) is Cauchy, there exists $j_0 \in \mathbb{N}$ such that $\|A_j - A_k\|_{\mathcal{L}^m} < 1$ for all $j,k \ge j_0$. Letting $k\to\infty$ in the preceding estimate gives

$$\|(A_j - A)(h_1,\dots,h_m)\|_Y \le \prod_{i=1}^{m} \|h_i\|_{X_i}$$

for every $j \ge j_0$. Proposition 23.2.2 implies that $A_j - A$ is continuous. Moreover, given $\varepsilon > 0$, there exists $j_1 \in \mathbb{N}$ such that $\|A_j - A_k\|_{\mathcal{L}^m} < \varepsilon$ for all $j,k \ge j_1$. Letting $k\to\infty$ and taking the supremum over the unit balls gives $\|A_j - A\|_{\mathcal{L}^m} \le \varepsilon$ for every $j \ge j_1$. Thus $A_j \longrightarrow A$, and the space is complete.
It is immediate that $\mathfrak{C}$ is linear. For each A, we have

$$\|\mathfrak{C}(A)\| = \sup_{\substack{h_{m+1}\in X_{m+1}\\ \|h_{m+1}\|_{X_{m+1}}\le 1}} \ \sup_{\substack{h_i\in X_i,\ 1\le i\le m\\ \|h_i\|_{X_i}\le 1}} \|A(h_1,\dots,h_m,h_{m+1})\|_Y = \|A\|_{\mathcal{L}^{m+1}},$$

, so it is an isometry. If $T \in \mathcal{L}(X_{m+1},\mathcal{L}^m(X_1,\dots,X_m;Y))$, the map $A_T(h_1,\dots,h_{m+1}) := T(h_{m+1})(h_1,\dots,h_m)$ is continuous and $(m+1)$-linear and satisfies $\mathfrak{C}(A_T) = T$. Thus $\mathfrak{C}$ is surjective.
Finally, if a sequence of symmetric operators converges in norm to A, passage to the limit in the symmetry identity shows that A is also symmetric. Thus $\mathcal{L}^m_s(X;Y)$ is closed. □

For $A \in \mathcal{L}^m(X;Y)$, write $A[h_1,\dots,h_m] := A(h_1,\dots,h_m)$ and $A[h]^m := A(h,\dots,h)$.

Proposition 23.2.4. (Differentiability of multilinear operators) Let $X_1,\dots,X_m$ and Y be normed spaces, and let $A \in \mathcal{L}^m(X_1,\dots,X_m;Y)$. Regarded as a map on the product space, A is smooth and

$$DA(x_1,\dots,x_m)(h_1,\dots,h_m) = \sum_{j=1}^{m} A(x_1,\dots,x_{j-1},h_j,x_{j+1},\dots,x_m).$$

Proof. By multilinearity,

$$A(x_1+h_1,\dots,x_m+h_m) - A(x_1,\dots,x_m)$$

is the sum of the terms in which at least one of the variables x_j has been replaced by h_j. The terms containing exactly one increment form the linear map in the statement. The remaining terms contain at least two increments. If $\max\limits_{j\in\{1,\dots,m\}} \|h_j\|_{X_j} < 1$, Proposition 23.2.2 bounds the norm of their sum by

$$\|A\|_{\mathcal{L}^m} \sum_{\substack{I\subseteq\{1,\dots,m\}\\ \#I\geq 2}} \prod_{j\in I} \|h_j\|_{X_j} \prod_{j\in\{1,\dots,m\}\setminus I} \max\{1,\|x_j\|_{X_j}\}.$$

After division by $\sum\limits_{j=1}^{m} \|h_j\|_{X_j}$, each summand tends to zero as $(h_1,\dots,h_m) \longrightarrow 0$. This proves the formula for the first derivative. To make the successive derivatives explicit, write $E := X_1 \times \cdots \times X_m$, with the sum norm, and fix $k \in \{1,\dots,m\}$. Let $\mathcal{I}_k$ be the set of injective maps $\sigma\colon \{1,\dots,k\} \longrightarrow \{1,\dots,m\}$. For $x = (x_1,\dots,x_m) \in E$ and $h^{(a)} = (h_1^{(a)},\dots,h_m^{(a)}) \in E$, with $a \in \{1,\dots,k\}$, set

$$z_i^\sigma := \begin{cases} h_i^{(a)}, & i = \sigma(a) \text{ for some } a \in \{1,\dots,k\},\\ x_i, & i \in \{1,\dots,m\} \setminus \operatorname{im}(\sigma). \end{cases}$$

Injectivity of σ makes this definition unambiguous. Define the continuous k–linear form

$$B_k(x)[h^{(1)},\dots,h^{(k)}] := \sum_{\sigma\in\mathcal{I}_k} A(z_1^\sigma,\dots,z_m^\sigma).$$

The formula already proved says that $DA = B_1$. Now suppose $1 \leq k < m$. To compute the increment of B_k when x is replaced by $x+u$, expand each summand by multilinearity. The terms linear in u are obtained by choosing an index $i \in \{1,\dots,m\} \setminus \operatorname{im}(\sigma)$ and replacing x_i by u_i. To each pair (σ,i) there corresponds exactly one map in $\mathcal{I}_{k+1}$, agreeing with σ on $\{1,\dots,k\}$ and sending $k+1$ to i. The sum of these terms is therefore $B_{k+1}(x)[h^{(1)},\dots,h^{(k)},u]$.

The remaining terms contain at least two components of u. If $\|u\|_E \leq 1$, the multilinear bound estimates them together by

$$C_{A,x,k}\|u\|_E^2 \prod_{a=1}^{k} \|h^{(a)}\|_E,$$

, where $C_{A,x,k}$ is finite: only finitely many summands, the norm of A, and the factors $\max\{1,\|x_i\|_{X_i}\}$, with $i \in \{1,\dots,m\}$, occur. Taking the supremum over $\|h^{(a)}\|_E \leq 1$ for $a \in \{1,\dots,k\}$ and dividing by $\|u\|_E$, we obtain that B_k is Fréchet differentiable as a map with values in $\mathcal{L}^k(E;Y)$. Its derivative corresponds to B_{k+1} through

Proposition 23.2.3. The same expansion, retaining all terms with at least one increment, proves norm continuity of each B_k.
This completes the step from order k to order $k+1$. For $k = m$, all indices have been occupied by the increments $h^{(a)}$, so B_m is independent of x and its derivative is zero. Subsequent derivatives are also zero. Consequently, A is smooth. □

Definition 23.2.5. (Higher Gâteaux derivatives) Let $U \subseteq X$ be open and let $f\colon U \longrightarrow Y$. Define $\delta^0 f := f$. Suppose $\delta^{m-1} f$ is defined on a neighborhood of $x \in U$ as a map with values in $\mathcal{L}^{m-1}(X;Y)$ and is Gâteaux differentiable at x. Through the isomorphism in Proposition 23.2.3, identify

$$\delta(\delta^{m-1} f)(x) \in \mathcal{L}\big(X, \mathcal{L}^{m-1}(X;Y)\big)$$

with an element $\delta^m f(x) \in \mathcal{L}^m(X;Y)$, called the **Gâteaux derivative of order** m of f at x. With the order of association fixed by $\mathfrak{C}$, we have

$$\delta^m f(x)[h_1,\dots,h_m] = D_{h_m}\big(D_{h_{m-1}} \cdots D_{h_1} f\big)(x)$$

whenever the iterated derivatives on the right-hand side are defined on a neighborhood of x.

Definition 23.2.6. (Higher Fréchet derivatives and functions of class C^k) Let $U \subseteq X$ be open and let $f\colon U \longrightarrow Y$. Define $D^0 f := f$. Suppose $D^{m-1} f$ is defined on a neighborhood of $x \in U$ as a map with values in $\mathcal{L}^{m-1}(X;Y)$ and is Fréchet differentiable at x. Identify $D(D^{m-1} f)(x)$ with an element $D^m f(x) \in \mathcal{L}^m(X;Y)$ through Proposition 23.2.3; it is called the **Fréchet derivative of order** m of f at x.
For $k \in \mathbb{N}$, we say that f is of **class** C^k on U, and write $f \in C^k(U,Y)$, if $D^j f$ exists at every point of U and is continuous as a map $U \longrightarrow \mathcal{L}^j(X;Y)$ for every $j \in \{1,\dots,k\}$. We say that f is **smooth**, and write $f \in C^\infty(U,Y)$, if $f \in C^k(U,Y)$ for every $k \in \mathbb{N}$.

Remark 23.2.7. In the definition, continuity of all derivatives through order k can be replaced by existence of $D^k f$ and continuity of the latter. For each $j < k$, the map $D^j f$ is Fréchet differentiable and hence continuous by Proposition 23.1.3. Nevertheless, the preceding formulation makes all the available regularity explicit and is more convenient when applying higher-order chain rules.

Regularity of a composition follows from the first-order chain rule and continuity of operator composition. It is useful to formulate this fact with values in normed spaces, since the derivatives themselves take values in operator spaces.

Corollary 23.2.8. (Composition of maps of class C^k) Let X, Y, and Z be normed spaces, let $U \subseteq X$ and $V \subseteq Y$ be open, and let $k \in \mathbb{N} \cup \{\infty\}$. If $f \in C^k(U,Y)$, $f(U) \subseteq V$, and $g \in C^k(V,Z)$, then $g \circ f \in C^k(U,Z)$.

Proof. The first-order chain rule gives

$$D(g \circ f)(x) = Dg(f(x)) \circ Df(x), \qquad x \in U.$$

Operator composition

$$\mathcal{C}\colon \mathcal{L}(Y,Z) \times \mathcal{L}(X,Y) \longrightarrow \mathcal{L}(X,Z), \qquad \mathcal{C}(B,A) := B \circ A,$$

is continuous and bilinear, since $\|B\circ A\|\le\|B\|\|A\|$. If f and g are of class C^1, the maps $Dg\circ f$ and Df are continuous. The preceding identity then shows that $D(g\circ f)$ is continuous, proving the case $k=1$.

Suppose the assertion has been proved for an integer $r\ge 1$ in arbitrary normed spaces, and now let f and g be of class C^{r+1}. The map Dg is of class C^r; by the induction hypothesis, so is $Dg\circ f$. Moreover, Df is of class C^r. The map $x\longmapsto (Dg(f(x)),Df(x))$ is therefore of class C^r: in a product of two normed spaces, differentiation and continuity are checked componentwise using the sum norm. By Proposition 23.2.4, $\mathcal{C}$ is smooth. Applying the induction hypothesis again to composition with $\mathcal{C}$, we conclude that $D(g\circ f)$ is of class C^r. Thus $g\circ f$ is of class C^{r+1}. Induction proves all finite orders; the case $k=\infty$ follows by applying the conclusion to each of them. □

Theorem 23.2.9. (Characterization by Gâteaux derivatives) Let X and Y be normed spaces, let $U\subseteq X$ be open, and let $k\in\mathbb{N}$. Then $f\in C^k(U,Y)$ if and only if, for each $j\in\{1,\dots,k\}$, the Gâteaux derivative $\delta^j f(x)\in\mathcal{L}^j(X;Y)$ exists for every $x\in U$ and the map $\delta^j f\colon U\longrightarrow\mathcal{L}^j(X;Y)$ is continuous. In this case, $D^j f=\delta^j f$ for every $j\in\{1,\dots,k\}$.

Proof. We proceed by induction on k. For $k=1$, the assertion is Corollary 23.1.17. Suppose the result holds for $k-1$.

If $f\in C^k(U,Y)$, then $D^{k-1}f\colon U\longrightarrow\mathcal{L}^{k-1}(X;Y)$ is of class C^1. Corollary 23.1.17, applied to this map, shows that its Gâteaux derivative exists, is continuous, and agrees with its Fréchet derivative. Through the identification in Proposition 23.2.3, this means that $\delta^k f=D^k f$. For lower orders, the conclusion follows from the induction hypothesis.

Conversely, suppose the Gâteaux derivatives in the statement exist and are continuous. By the induction hypothesis, $f\in C^{k-1}(U,Y)$ and $D^{k-1}f=\delta^{k-1}f$. The map $D^{k-1}f$ is Gâteaux differentiable, its derivative is $\delta^k f$, and this derivative is continuous. Corollary 23.1.17, applied with target space $\mathcal{L}^{k-1}(X;Y)$, implies that $D^{k-1}f$ is of class C^1 and its Fréchet derivative agrees with $\delta^k f$. Thus $f\in C^k(U,Y)$ and $D^k f=\delta^k f$. □

Theorem 23.2.10. (Symmetry of higher derivatives) If $f\in C^m(U,Y)$, with $m\ge 2$, then $D^m f(x)\in\mathcal{L}^m_s(X;Y)$ for every $x\in U$.

Proof. We proceed by induction on m. For $m=2$, fix $x\in U$, $h,k\in X$, and $\varphi\in Y'$. Define $g(s,t):=\varphi(f(x+sh+tk))$ for (s,t) in a neighborhood of $(0,0)$. The chain rule implies that g is of class C^2 and that

$$\frac{\partial^2 g}{\partial s\,\partial t}(0,0)=\varphi(D^2f(x)[k,h]),\qquad \frac{\partial^2 g}{\partial t\,\partial s}(0,0)=\varphi(D^2f(x)[h,k]).$$

The classical equality of mixed partial derivatives and the fact that Y' separates points imply $D^2f(x)[h,k]=D^2f(x)[k,h]$.

Now suppose the assertion holds at order $m-1$, with $m\ge 3$. Since $D^{m-1}f(x)$ is symmetric, the operator $D^m f(x)$ is symmetric in its first $m-1$ arguments. For each $v\in X$, the function

$$x\longmapsto D^{m-1}f(x)[h_{\sigma(1)},\dots,h_{\sigma(m-1)}]-D^{m-1}f(x)[h_1,\dots,h_{m-1}]$$

is identically zero for every permutation σ of $\{1,\dots,m-1\}$; differentiating it in the direction v gives the stated symmetry.

It remains to show that the last two arguments can be interchanged. Fix $h_1, \dots, h_{m-2} \in X$ and consider

$$G(z) := D^{m-2} f(z)[h_1, \dots, h_{m-2}].$$

Evaluation of a multilinear operator on fixed vectors is a continuous linear map; hence G is of class C^2. The case $m = 2$, applied to G, gives

$$D^m f(x)[h_1, \dots, h_{m-2}, h_{m-1}, h_m] = D^m f(x)[h_1, \dots, h_{m-2}, h_m, h_{m-1}].$$

Permutations of the first $m-1$ arguments, together with transposition of the last two, generate all permutations of m elements. Thus $D^m f(x)$ is symmetric. □

The Leibniz rule has a particularly useful formulation for the second derivative. We will use this identity in the next chapter when comparing the kinematic and operational notions of tangent space.

Proposition 23.2.11. (Leibniz rule for the second derivative) Let X be a normed space, let $U \subseteq X$ be open, and let $f, g \in C^2(U, \mathbb{R})$. Then, for every $x \in U$ and $h, k \in X$,

$$D^2(fg)(x)[h,k] = f(x)D^2 g(x)[h,k] + g(x)D^2 f(x)[h,k] + Df(x)(h)Dg(x)(k) + Df(x)(k)Dg(x)(h).$$

Equivalently,

$$D^2(fg)(x) = f(x)D^2 g(x) + g(x)D^2 f(x) + Df(x) \otimes Dg(x) + Dg(x) \otimes Df(x).$$

Proof. The product rule for the first derivative gives $D(fg)(x) = f(x)Dg(x) + g(x)Df(x)$. Differentiate this map with values in X' in the direction k and evaluate the resulting operator on h. The product rule and linearity of evaluation give

$$D^2(fg)(x)[h,k] = Df(x)(k)Dg(x)(h) + f(x)D^2 g(x)[h,k] + Dg(x)(k)Df(x)(h) + g(x)D^2 f(x)[h,k].$$

Symmetry of second derivatives, given by Theorem 23.2.10, allows the arguments to be ordered as in the statement. □

Theorem 23.2.12. (Taylor's formula with integral remainder) Let X be a normed space, let Y be a Banach space, let $U \subseteq X$ be open, and let $m \in \mathbb{N}$ and $f \in C^m(U, Y)$. Let $x \in U$ and $h \in X$ be such that $[x, x+h] \subseteq U$. Then

$$f(x+h) = \sum_{j=0}^{m-1} \frac{1}{j!} D^j f(x)[h]^j + \frac{1}{(m-1)!} \int_0^1 (1-t)^{m-1} D^m f(x+th)[h]^m \, dt, \tag{23.4}$$

, where $D^0 f(x)[h]^0 := f(x)$.

Proof. Define $\varphi\colon [0,1] \longrightarrow Y$ by $\varphi(t) := f(x+th)$. Since the segment $[x, x+h]$ is contained in the open set U, this formula defines the curve on an open interval containing $[0,1]$. The chain rule gives $\varphi'(t) = Df(x+th)(h)$. More generally, we will prove that $\varphi^{(j)}(t) = D^j f(x+th)[h]^j$ for every $j \in \{0, \dots, m\}$.
The case $j = 0$ is the definition of φ, and the case $j = 1$ has just been checked. Suppose the formula holds for an integer j with $1 \leq j < m$. The evaluation $A \longmapsto A[h]^j$ is a continuous linear operator from $\mathcal{L}^j(X; Y)$ to Y, with norm at most $\|h\|_X^j$. We may therefore differentiate the inductive identity by the chain rule. The

derivative of $D^j f(x+th)$ with respect to t is $D(D^j f)(x+th)(h)$. Evaluating on the j vectors h and using the association in Proposition 23.2.3 gives $D^{j+1} f(x+th)[h]^{j+1}$. This proves the induction step. Continuity of these expressions follows from continuity of each $D^j f$.

We prove by induction that every function $\varphi \in C^m([0,1], Y)$ satisfies

$$\varphi(1) = \sum_{j=0}^{m-1} \frac{\varphi^{(j)}(0)}{j!} + \frac{1}{(m-1)!} \int_0^1 (1-t)^{m-1} \varphi^{(m)}(t)\, dt. \tag{23.5}$$

For $m = 1$, this identity is Theorem B.6.5. Suppose it holds for $m-1$. The induction hypothesis gives

$$\varphi(1) = \sum_{j=0}^{m-2} \frac{\varphi^{(j)}(0)}{j!} + \frac{1}{(m-2)!} \int_0^1 (1-t)^{m-2} \varphi^{(m-1)}(t)\, dt.$$

Apply the integration by parts formula in Proposition B.6.6 to the scalar function $a(t) := -\dfrac{(1-t)^{m-1}}{(m-1)!}$ and the vector-valued function $\varphi^{(m-1)}$. Since $a'(t) = \dfrac{(1-t)^{m-2}}{(m-2)!}$, we obtain

$$\frac{1}{(m-2)!} \int_0^1 (1-t)^{m-2} \varphi^{(m-1)}(t)\, dt = \frac{\varphi^{(m-1)}(0)}{(m-1)!} + \frac{1}{(m-1)!} \int_0^1 (1-t)^{m-1} \varphi^{(m)}(t)\, dt.$$

Substituting this equality into the induction hypothesis gives (23.5). Finally, replacing each $\varphi^{(j)}(t)$ by $D^j f(x+th)[h]^j$ yields (23.4). □

Corollary 23.2.13. (Estimate for the Taylor remainder) Under the assumptions of Theorem 23.2.12, suppose $r > 0$ satisfies $B_{d_X}(x, r) \subseteq U$. Then, for each $h \in X$ with $\|h\|_X < r$,

$$\left\| f(x+h) - \sum_{j=0}^{m} \frac{1}{j!} D^j f(x)[h]^j \right\|_Y \leq \frac{\|h\|_X^m}{m!} \sup_{t \in [0,1]} \|D^m f(x+th) - D^m f(x)\|_{\mathcal{L}^m}.$$

In particular, for each $\varepsilon > 0$ there exists $\delta \in (0, r)$ such that

$$\left\| f(x+h) - \sum_{j=0}^{m} \frac{1}{j!} D^j f(x)[h]^j \right\|_Y \leq \varepsilon \|h\|_X^m$$

whenever $\|h\|_X < \delta$.

Proof. In (23.4), add and subtract $D^m f(x)[h]^m$ inside the integral. Since $\displaystyle\int_0^1 (1-t)^{m-1}\, dt = \frac{1}{m}$, we obtain

$$f(x+h) - \sum_{j=0}^{m} \frac{1}{j!} D^j f(x)[h]^j = \frac{1}{(m-1)!} \int_0^1 (1-t)^{m-1} \big(D^m f(x+th) - D^m f(x)\big)[h]^m\, dt.$$

The inequality for the Riemann integral with values in Y and the characterization of the multilinear norm

imply the first estimate. Now let $\varepsilon > 0$. By continuity of $D^m f$ at x, there exists $\delta \in (0, r)$ such that

$$\|D^m f(x+u) - D^m f(x)\|_{\mathcal{L}^m} < m!\varepsilon$$

whenever $\|u\|_X < \delta$. If $\|h\|_X < \delta$, then $\|th\|_X < \delta$ for every $t \in [0,1]$, and the first estimate gives the final inequality. □

23.2.1 Exercises

Exercise 23.2.14. Let $A \in \mathcal{L}^m_s(X;Y)$ and define $P\colon X \longrightarrow Y$ by $P(x) := A[x]^m$. Prove that P is smooth and that, for $0 \le j \le m$,

$$D^j P(x)[h_1,\dots,h_j] = \frac{m!}{(m-j)!} A(\underbrace{x,\dots,x}_{m-j \text{ times}}, h_1,\dots,h_j).$$

Show that $D^j P = 0$ for $j > m$.

Exercise 23.2.15. Let H be a real Hilbert space. Compute the first and second Fréchet derivatives of $u \longmapsto \frac{1}{2}\|u\|_H^2$. For $p > 1$, compute the first derivative of $u \longmapsto \frac{1}{p}\|u\|_H^p$ and determine at which points the second derivative exists when $1 < p < 2$ and when $p \ge 2$.

Exercise 23.2.16. Let $\ell \in X'$ and let $\varphi\colon \mathbb{R} \longrightarrow \mathbb{R}$ be of class C^m. Prove that $f := \varphi \circ \ell$ belongs to $C^m(X,\mathbb{R})$ and that

$$D^j f(x)[h_1,\dots,h_j] = \varphi^{(j)}(\ell(x)) \prod_{i=1}^{j} \ell(h_i)$$

for every $1 \le j \le m$.

Exercise 23.2.17. Let $(M,\mathbf{g})$ be a compact Riemannian manifold with smooth boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle with bundle metric $\mathbf{h_E}$ and compatible connection $\nabla^{\mathbf{E}}$. Consider $J(u) := \frac{1}{2}\int_M |\nabla^{\mathbf{E}}_w u|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}$ on $W^{1,2}_0(M,\mathbf{E})$. Prove that J is smooth, compute $DJ(u)$ and $D^2J(u)$, and identify the continuous bilinear operator associated with the second derivative.

Exercise 23.2.18. Let X be a unital Banach algebra. Use Taylor's formula to study the exponential map $\exp(x) := \sum_{j=0}^{\infty} \frac{x^j}{j!}$ near the origin. Compute its first derivatives at 0 and explain the simplification that occurs when the elements under consideration commute.

23.3 Fundamental theorems of differential calculus

The following local results turn information about the derivative into information about the function itself. The contraction principle provides the mechanism for existence and uniqueness; the inverse function theorem (Theorem 23.3.3) constructs nonlinear coordinates, and the implicit function theorem (Theorem 23.3.8) allows some of the variables to be solved for locally. These tools will underlie the adapted charts and regular level sets used on Banach manifolds.

Theorem 23.3.1. (Contraction principle) Let (M,d) be a nonempty complete metric space, and let $T\colon M \longrightarrow M$ be a contraction; that is, suppose there exists $q \in [0,1)$ such that $d(Tx,Ty) \le qd(x,y)$ for all $x,y \in M$. Then T has a unique fixed point x_*. Moreover, for any $x_0 \in M$, the sequence defined by $x_{n+1} := T(x_n)$ converges to x_* and

$$d(x_n,x_*) \le \frac{q^n}{1-q} d(x_1,x_0)$$

for every $n \in \mathbb{N}$.

Proof. Fix $x_0 \in M$. The contraction inequality gives $d(x_2,x_1) \le qd(x_1,x_0)$. If $d(x_{n+1},x_n) \le q^n d(x_1,x_0)$ for some $n \in \mathbb{N}$, applying T to the two points gives $d(x_{n+2},x_{n+1}) \le qd(x_{n+1},x_n) \le q^{n+1} d(x_1,x_0)$. By induction, the estimate holds for every $n \in \mathbb{N}$. If $m > n$, the triangle inequality gives

$$d(x_m,x_n) \le \sum_{j=n}^{m-1} d(x_{j+1},x_j) \le \sum_{j=n}^{m-1} q^j d(x_1,x_0) \le \frac{q^n}{1-q} d(x_1,x_0).$$

Thus (x_n) is a Cauchy sequence. Completeness of M guarantees existence of $x_* \in M$ such that $x_n \longrightarrow x_*$. Since every contraction is continuous, $T(x_*) = \lim\limits_{n\to\infty} T(x_n) = \lim\limits_{n\to\infty} x_{n+1} = x_*$. If y is another fixed point, then $d(x_*,y) = d(Tx_*,Ty) \le qd(x_*,y)$; since $q < 1$, it follows that $d(x_*,y) = 0$. Finally, letting $m \to \infty$ in the preceding estimate gives the inequality in the statement. □

Proposition 23.3.2. (Inversion of operators) Let X and Y be Banach spaces, and let $\mathrm{Iso}(X,Y) \subseteq \mathcal{L}(X,Y)$ be the set of continuous linear isomorphisms. Then $\mathrm{Iso}(X,Y)$ is open, and the map

$$\mathrm{Inv}\colon \mathrm{Iso}(X,Y) \longrightarrow \mathrm{Iso}(Y,X), \qquad \mathrm{Inv}(A) := A^{-1},$$

is smooth. Its derivative is given by

$$D\,\mathrm{Inv}(A)(H) = -A^{-1}HA^{-1}. \tag{23.6}$$

Proof. Let $A \in \mathrm{Iso}(X,Y)$. If $X = \{0\}$, existence of A forces $Y = \{0\}$, and all assertions can be checked directly in the one-point spaces. Suppose $X \neq \{0\}$; then $\|A^{-1}\|_{\mathcal{L}(Y,X)} > 0$. If $H \in \mathcal{L}(X,Y)$ satisfies $\|A^{-1}H\|_{\mathcal{L}(X)} < 1$, the Neumann series of Theorem B.2.10 converges in $\mathcal{L}(X)$ and

$$(A+H)^{-1} = \sum_{j=0}^{\infty} (-A^{-1}H)^j A^{-1}.$$

Thus $A+H$ is invertible, and $\mathrm{Iso}(X,Y)$ is open. If $\|A^{-1}H\|_{\mathcal{L}(X)} \le \frac{1}{2}$, then

$$\|(A+H)^{-1}\|_{\mathcal{L}(Y,X)} \le \frac{\|A^{-1}\|_{\mathcal{L}(Y,X)}}{1 - \|A^{-1}H\|_{\mathcal{L}(X)}} \le 2\|A^{-1}\|_{\mathcal{L}(Y,X)}.$$

The identity

$$(A+H)^{-1} - A^{-1} = -(A+H)^{-1}HA^{-1}$$

implies

$$\|(A+H)^{-1} - A^{-1}\|_{\mathcal{L}(Y,X)} \le 2\|A^{-1}\|^2_{\mathcal{L}(Y,X)}\|H\|_{\mathcal{L}(X,Y)},$$

, so the inversion map is continuous at A.
Moreover,

$$(A+H)^{-1} - A^{-1} + A^{-1}HA^{-1} = A^{-1}HA^{-1}H(A+H)^{-1}.$$

When $0 < \|H\|_{\mathcal{L}(X,Y)} \leq \dfrac{1}{2\|A^{-1}\|_{\mathcal{L}(Y,X)}}$, the preceding estimate gives

$$\frac{\|(A+H)^{-1} - A^{-1} + A^{-1}HA^{-1}\|_{\mathcal{L}(Y,X)}}{\|H\|_{\mathcal{L}(X,Y)}} \leq 2\|A^{-1}\|^3_{\mathcal{L}(Y,X)}\|H\|_{\mathcal{L}(X,Y)}.$$

The right-hand side tends to zero as $H \to 0$, proving (23.6).
The derivative formula can be written as $D\operatorname{Inv}(A)(H) = -\operatorname{Inv}(A)H\operatorname{Inv}(A)$. The map assigning to $(B,C) \in \mathcal{L}(Y,X) \times \mathcal{L}(Y,X)$ the operator $H \longmapsto -BHC$ is continuous and bilinear with values in $\mathcal{L}(\mathcal{L}(X,Y),\mathcal{L}(Y,X))$, since its norm is at most $\|B\|\|C\|$. By Proposition 23.2.4, this map is smooth. Since Inv is continuous, its derivative formula first proves continuity of $D\operatorname{Inv}$; hence Inv is of class C^1. Now suppose it is of class C^r for some integer $r \geq 1$. Composing the preceding bilinear map with $A \longmapsto (\operatorname{Inv}(A), \operatorname{Inv}(A))$, Corollary 23.2.8 shows that $D\operatorname{Inv}$ is of class C^r. Consequently, Inv is of class C^{r+1}. This induction step proves smoothness. □

Theorem 23.3.3. (Local inverse function theorem) Let X and Y be Banach spaces, let $U \subseteq X$ be open, and let $f \in C^1(U,Y)$. If $a \in U$ and $Df(a)\colon X \longrightarrow Y$ is an isomorphism, there exist open neighborhoods $U_0 \subseteq U$ of a and $V_0 \subseteq Y$ of $f(a)$ such that $f\restriction_{U_0}\colon U_0 \longrightarrow V_0$ is a diffeomorphism of class C^1. If $g\colon V_0 \longrightarrow U_0$ is its inverse, then

$$Dg(y) = Df(g(y))^{-1} \tag{23.7}$$

for every $y \in V_0$. If $f \in C^k(U,Y)$, then $g \in C^k(V_0,X)$.

Proof. If $X = \{0\}$, invertibility of $Df(a)$ implies $Y = \{0\}$, and the result is immediate. Suppose $X \neq \{0\}$. Write $A := Df(a)^{-1} \in \mathcal{L}(Y,X)$. By continuity of Df at a, there exists $r > 0$ such that $\overline{B}_{d_X}(a,2r) \subseteq U$ and

$$\|A(Df(x) - Df(a))\|_{\mathcal{L}(X)} \leq \frac{1}{2} \tag{23.8}$$

for every $x \in B_{d_X}(a,2r)$. For each $y \in Y$, define

$$T_y\colon \overline{B}_{d_X}(a,r) \longrightarrow X, \qquad T_y(x) := x - A(f(x) - y).$$

Let $x_1, x_2 \in \overline{B}_{d_X}(a,r)$. The segment $[x_1,x_2]$ is contained in $B_{d_X}(a,2r)$. The map $H(x) := x - Af(x)$ is of class C^1 and, by (23.8),

$$\|DH(x)\|_{\mathcal{L}(X)} = \|I_X - ADf(x)\|_{\mathcal{L}(X)} = \|A(Df(a) - Df(x))\|_{\mathcal{L}(X)} \leq \frac{1}{2}.$$

Theorem 23.1.10 implies

$$\|T_y(x_1) - T_y(x_2)\|_X \leq \frac{1}{2}\|x_1 - x_2\|_X. \tag{23.9}$$

Let $b := f(a)$ and choose $\delta > 0$ such that $\|A\|_{\mathcal{L}(Y,X)}\delta < \dfrac{r}{2}$. If $y \in B_{d_Y}(b,\delta)$, then

$$\|T_y(a) - a\|_X = \|A(y-b)\|_X < \frac{r}{2}.$$

For each $x \in \overline{B}_{d_X}(a,r)$, inequality (23.9) gives

$$\|T_y(x)-a\|_X \le \|T_y(x)-T_y(a)\|_X + \|T_y(a)-a\|_X < \frac{1}{2}\|x-a\|_X + \frac{r}{2} \le r.$$

Thus T_y maps $\overline{B}_{d_X}(a,r)$ into itself and is a contraction. The contraction principle gives a unique fixed point $g(y) \in \overline{B}_{d_X}(a,r)$. The equality $T_y(g(y)) = g(y)$ is equivalent to $f(g(y)) = y$. Moreover,

$$\|g(y)-a\|_X \le \frac{1}{1-\frac{1}{2}}\|T_y(a)-a\|_X < r,$$

, so $g(y) \in B_{d_X}(a,r)$.
If $y_1, y_2 \in B_{d_Y}(b,\delta)$, then, using (23.9),

$$\begin{aligned}\|g(y_1)-g(y_2)\|_X &= \|T_{y_1}(g(y_1)) - T_{y_2}(g(y_2))\|_X \\ &\le \|T_{y_1}(g(y_1)) - T_{y_1}(g(y_2))\|_X + \|A(y_1-y_2)\|_X \\ &\le \frac{1}{2}\|g(y_1)-g(y_2)\|_X + \|A\|_{\mathcal{L}(Y,X)}\|y_1-y_2\|_Y.\end{aligned}$$

Consequently,

$$\|g(y_1)-g(y_2)\|_X \le 2\|A\|_{\mathcal{L}(Y,X)}\|y_1-y_2\|_Y. \tag{23.10}$$

In particular, g is continuous.
Define $V_0 := B_{d_Y}(b,\delta)$ and $U_0 := f^{-1}(V_0) \cap B_{d_X}(a,r)$. If $x \in U_0$ and $y = f(x)$, then x is a fixed point of T_y in $\overline{B}_{d_X}(a,r)$; by uniqueness of the fixed point, $x = g(y)$. Thus $f \restriction_{U_0}$ is bijective onto V_0, with inverse g.
For each $x \in U_0$, the identity

$$ADf(x) = I_X + A(Df(x) - Df(a))$$

and (23.8) show, through Theorem B.2.10, that $ADf(x)$ is invertible. Thus $Df(x)$ is an isomorphism.
Fix $y \in V_0$ and write $x := g(y)$. Let $k \in Y$ be such that $y + k \in V_0$ and define $h := g(y+k) - g(y)$. Then $k = f(x+h) - f(x)$ and

$$g(y+k) - g(y) - Df(x)^{-1}k = -Df(x)^{-1}\big(f(x+h) - f(x) - Df(x)h\big). \tag{23.11}$$

Let $\varepsilon > 0$. By Fréchet differentiability of f at x, there exists $\eta > 0$ such that

$$\|f(x+u) - f(x) - Df(x)u\|_Y < \frac{\varepsilon}{2\big(1+\|A\|_{\mathcal{L}(Y,X)}\big)\big(1+\|Df(x)^{-1}\|_{\mathcal{L}(Y,X)}\big)}\|u\|_X$$

whenever $0 < \|u\|_X < \eta$. By (23.10), we have $\|h\|_X \le 2\|A\|_{\mathcal{L}(Y,X)}\|k\|_Y$. Consequently, if

$$0 < \|k\|_Y < \frac{\eta}{2\|A\|_{\mathcal{L}(Y,X)}},$$

, then $\|h\|_X < \eta$ and (23.11) imply

$$\frac{\|g(y+k) - g(y) - Df(x)^{-1}k\|_X}{\|k\|_Y} < \varepsilon.$$

This proves that g is Fréchet differentiable at y and that $Dg(y) = Df(g(y))^{-1}$.
Continuity of Dg follows from continuity of g, continuity of Df, and continuity of the inversion map established in Proposition 23.3.2. Thus $g \in C^1(V_0, X)$. If $f \in C^k(U, Y)$ and $k > 1$, start with the C^1 regularity of g just obtained. Suppose g is of class C^j, where $j \in \mathbb{N}$ and $1 \le j < k$. Since Df is of class C^{k-1}, it is in particular of class C^j. Corollary 23.2.8 and smoothness of the inversion map imply that $\mathrm{Inv} \circ Df \circ g$ is of class C^j. By (23.7), this is precisely Dg; hence g is of class C^{j+1}. Induction reaches $j = k$ when k is finite. If $k = \infty$, the same argument applies at every finite order and proves that g is smooth. □

Definition 23.3.4. (Diffeomorphism between open subsets of Banach spaces) Let $U \subseteq X$ and $V \subseteq Y$ be open subsets of Banach spaces. A bijection $f : U \longrightarrow V$ is a **diffeomorphism of class** C^k if $f \in C^k(U, Y)$ and $f^{-1} \in C^k(V, X)$.

Invertibility of the derivative is a local condition and alone does not guarantee global injectivity. The uniform assumption in the following result prevents local inverses from degenerating as they are continued along paths.

Lemma 23.3.5. (Path lifting) Let X and Y be Banach spaces, and let $f \in C^1(X, Y)$. Suppose $Df(x)$ is an isomorphism for every $x \in X$ and there exists $C > 0$ such that $\|Df(x)^{-1}\|_{\mathcal{L}(Y,X)} \le C$ for every $x \in X$. Let $\gamma : [0,1] \longrightarrow Y$ be of class C^1, and let $x_0 \in X$ be such that $f(x_0) = \gamma(0)$. Then there exists a unique map $\widetilde{\gamma} : [0,1] \longrightarrow X$ of class C^1 such that $\widetilde{\gamma}(0) = x_0$ and $f \circ \widetilde{\gamma} = \gamma$. Moreover,

$$\|\widetilde{\gamma}'(t)\|_X \le C \|\gamma'(t)\|_Y \tag{23.12}$$

for every $t \in [0,1]$.

Proof. Theorem 23.3.3, applied at x_0, gives a unique lift on an interval $[0, \tau_0]$ with $\tau_0 > 0$. Let

$$\mathcal{A} := \{\tau \in [0,1] \mid \gamma \restriction_{[0,\tau]} \text{ admits a lift of class } C^1 \text{ starting at } x_0\}$$

and let $\alpha := \sup \mathcal{A}$. Let us establish uniqueness on common intervals precisely. If two continuous lifts have the same initial value, the set of times when they agree is nonempty and closed by continuity. It is also open in the common interval: at a time of agreement, both paths remain, for a small interval, in a common neighborhood on which f is injective. Since they have the same image under f, they agree there. Connectedness of the interval implies that they agree throughout it. Thus the partial lifts glue together to define a unique map $\widetilde{\gamma} : [0, \alpha) \longrightarrow X$, of class C^1 on every compact interval contained in its domain.
Differentiating $f(\widetilde{\gamma}(t)) = \gamma(t)$ and applying the chain rule gives

$$Df(\widetilde{\gamma}(t))\widetilde{\gamma}'(t) = \gamma'(t), \qquad \widetilde{\gamma}'(t) = Df(\widetilde{\gamma}(t))^{-1}\gamma'(t),$$

, which proves (23.12). If $0 \le t_1 < t_2 < \alpha$, the integral mean value formula gives

$$\|\widetilde{\gamma}(t_2) - \widetilde{\gamma}(t_1)\|_X \le C \left(\max_{t \in [0,1]} \|\gamma'(t)\|_Y \right) |t_2 - t_1|.$$

This estimate shows that $\widetilde{\gamma}(t)$ is Cauchy as $t \to \alpha^-$. By completeness of X, there exists $x_\alpha := \lim_{t \to \alpha^-} \widetilde{\gamma}(t)$, whether $\alpha < 1$ or $\alpha = 1$. Define $\widetilde{\gamma}(\alpha) := x_\alpha$. The extension is continuous and satisfies $f(x_\alpha) = \gamma(\alpha)$.

Choose a local inverse $g_\alpha\colon V_\alpha \longrightarrow U_\alpha$ of f, with $x_\alpha \in U_\alpha$ and $\gamma(\alpha) \in V_\alpha$. By the convergence just proved and continuity of γ, there exists $\varepsilon > 0$ such that $\widetilde{\gamma}(t) \in U_\alpha$ and $\gamma(t) \in V_\alpha$ for $t \in (\alpha - \varepsilon, \alpha]$. On this interval, injectivity of $f\restriction_{U_\alpha}$ gives

$$\widetilde{\gamma}(t) = g_\alpha(\gamma(t)).$$

Thus the extension is of class C^1 up to α, with a one-sided derivative at the endpoint. If $\alpha < 1$, continuity of γ allows this same formula to be used on $[\alpha, \alpha+\varepsilon']$ for some $\varepsilon' > 0$ with $\alpha + \varepsilon' \le 1$. We would obtain a lift of class C^1 beyond α, contradicting the definition of the supremum. Hence $\alpha = 1$.
In particular, the value $\widetilde{\gamma}(1)$ is already defined, and the formula involving g_α proves C^1 regularity at the final endpoint. Differentiating it gives $\widetilde{\gamma}'(1) = Df(\widetilde{\gamma}(1))^{-1}\gamma'(1)$ there as well, so (23.12) holds on all of $[0,1]$. Uniqueness on the closed interval is the uniqueness established at the beginning of the proof. □

Lemma 23.3.6. (Homotopy lifting) Under the assumptions of the preceding lemma, let $H\colon [0,1]^2 \longrightarrow Y$ be of class C^1, and let $\eta\colon [0,1] \longrightarrow X$ be a continuous path such that $f(\eta(s)) = H(0,s)$ for every $s \in [0,1]$. Then there exists a unique continuous map $\widetilde{H}\colon [0,1]^2 \longrightarrow X$ such that $f \circ \widetilde{H} = H$ and $\widetilde{H}(0,s) = \eta(s)$. For each s, the path $t \longmapsto \widetilde{H}(t,s)$ is of class C^1.

Proof. For each $s \in [0,1]$, Lemma 23.3.5 gives a unique lift of the path $t \longmapsto H(t,s)$ starting at $\eta(s)$; denote it by $t \longmapsto \widetilde{H}(t,s)$. We must prove that the resulting map is continuous in both variables.
Let

$$\mathcal{T} := \{\tau \in [0,1] \mid \widetilde{H} \text{ is continuous on } [0,\tau]\times[0,1]\}.$$

We will prove that $\mathcal{T} = [0,1]$. For each $s_0 \in [0,1]$, Theorem 23.3.3 gives open neighborhoods U_{s_0} of $\eta(s_0)$ and V_{s_0} of $H(0,s_0)$ such that $f\restriction_{U_{s_0}}\colon U_{s_0} \longrightarrow V_{s_0}$ is a homeomorphism. By continuity of η and H, there exist an open interval $I_{s_0} \subseteq [0,1]$ containing s_0 and a number $\delta_{s_0} > 0$ such that $\eta(s) \in U_{s_0}$ and $H(t,s) \in V_{s_0}$ for $(t,s) \in [0,\delta_{s_0}]\times I_{s_0}$. On this rectangle, uniqueness of lifts implies

$$\widetilde{H}(t,s) = (f\restriction_{U_{s_0}})^{-1}(H(t,s)).$$

Compactness of $[0,1]$ allows us to choose finitely many intervals I_{s_0} covering it. If δ is the minimum of the corresponding numbers δ_{s_0}, the preceding formula proves that $\widetilde{H}$ is continuous on $[0,\delta]\times[0,1]$. Thus $\mathcal{T}$ is nonempty.
Let $\tau \in \mathcal{T}$ with $\tau < 1$. The set $\widetilde{H}(\{\tau\}\times[0,1])$ is compact. For each $s_0 \in [0,1]$, apply the local theorem again at $\widetilde{H}(\tau,s_0)$. Continuity of $s \longmapsto \widetilde{H}(\tau,s)$ and H allows us to find an interval I_{s_0} and a number $\delta_{s_0} > 0$ such that, for $s \in I_{s_0}$ and $t \in [\tau, \tau+\delta_{s_0}] \cap [0,1]$, the lift is given by a common local inverse. A finite subcover of $[0,1]$ and the minimum of the numbers δ_{s_0} show that there exists $\delta > 0$ such that $\widetilde{H}$ is continuous on $[0, \min\{1, \tau+\delta\}]\times[0,1]$. Thus $\mathcal{T}$ is open to the right.
To check that continuation cannot stop, let $\tau_* := \sup\mathcal{T}$. Since H is of class C^1 on the compact square, there exists

$$M := \max_{(t,s)\in[0,1]^2} \left\| \frac{\partial H}{\partial t}(t,s) \right\|_Y < \infty.$$

For each $s \in [0,1]$ and $0 \le t_1 < t_2 < \tau_*$, estimate (23.12) and the integral mean value formula give

$$\|\widetilde{H}(t_2,s) - \widetilde{H}(t_1,s)\|_X \le CM|t_2 - t_1|.$$

The estimate is uniform in s. Consequently, as $t \to \tau_*^-$, $\widetilde{H}(t,s)$ has a uniform limit in s. For each fixed s, the individual lift is already continuous at $[0,1]$, so this limit agrees with the value $\widetilde{H}(\tau_*,s)$ defined at the beginning of the proof. Moreover, for every $t < \tau_*$, there exists an element of $\mathcal{T}$ greater than t, so $s \longmapsto \widetilde{H}(t,s)$ is continuous. The uniform limit of these functions is continuous. We thus obtain continuity of $s \longmapsto \widetilde{H}(\tau_*,s)$ and, by passage to the limit in the estimate,

$$\|\widetilde{H}(t,s) - \widetilde{H}(\tau_*,s_0)\|_X \le CM(\tau_* - t) + \|\widetilde{H}(\tau_*,s) - \widetilde{H}(\tau_*,s_0)\|_X$$

for $t \in [0,\tau_*]$ and $s, s_0 \in [0,1]$. The right-hand side tends to zero as $(t,s) \longrightarrow (\tau_*,s_0)$ with $t \le \tau_*$. This proves joint continuity up to this edge, that is, $\tau_* \in \mathcal{T}$. The local argument in the preceding paragraph would extend continuity beyond τ_* if $\tau_* < 1$, contradicting the definition of the supremum. Thus $\tau_* = 1$, and $\widetilde{H}$ is continuous on the entire square.

The identity $f \circ \widetilde{H} = H$ and the initial condition hold by construction. Uniqueness follows for each fixed value of s from the argument for continuous lifts in the proof of Lemma 23.3.5. □

Theorem 23.3.7. (Global inverse function theorem) Let X and Y be Banach spaces, and let $f \in C^1(X,Y)$. Suppose $Df(x)$ is an isomorphism for every $x \in X$ and there exists $C > 0$ such that $\|Df(x)^{-1}\|_{\mathcal{L}(Y,X)} \le C$ for every $x \in X$. Then $f\colon X \longrightarrow Y$ is a global diffeomorphism.

Proof. Fix $a \in X$ and let $b := f(a)$. Given $y \in Y$, consider the segment $\gamma(t) := (1-t)b + ty$. By Lemma 23.3.5, there exists a lift $\widetilde{\gamma}\colon [0,1] \longrightarrow X$ with $\widetilde{\gamma}(0) = a$. Then $f(\widetilde{\gamma}(1)) = \gamma(1) = y$. Since y was arbitrary, f is surjective. To prove injectivity, suppose $f(x_0) = f(x_1) = y_0$. Let $\sigma(t) := (1-t)x_0 + tx_1$ and let $\gamma := f \circ \sigma$. The map

$$H(t,s) := (1-s)\gamma(t) + sy_0$$

is a homotopy between the loop γ and the constant loop y_0 and satisfies $H(0,s) = y_0$ for every s. Apply Lemma 23.3.6 with $\eta(s) := x_0$. For each $s \in [0,1]$, the point $\widetilde{H}(1,s)$ belongs to $f^{-1}(y_0)$. This fiber is discrete because f is locally injective at each of its points. Since $s \longmapsto \widetilde{H}(1,s)$ is continuous and $[0,1]$ is connected, this map is constant. For $s = 0$, uniqueness of the lift implies $\widetilde{H}(t,0) = \sigma(t)$ and hence $\widetilde{H}(1,0) = x_1$. For $s = 1$, the lift is the constant path x_0, so $\widetilde{H}(1,1) = x_0$. We conclude that $x_0 = x_1$.

Thus f is bijective. Theorem 23.3.3 shows that its inverse is of class C^1 and satisfies $D(f^{-1})(y) = Df(f^{-1}(y))^{-1}$. □

Theorem 23.3.8. (Implicit function theorem) Let X, Y, and Z be Banach spaces, let $U \subseteq X \times Y$ be open, and let $F \in C^k(U,Z)$, with $k \ge 1$. Suppose $(a,b) \in U$, $F(a,b) = 0$, and $D_2F(a,b)\colon Y \longrightarrow Z$ is an isomorphism. Then there exist open neighborhoods $U_0 \subseteq X$ of a and $V_0 \subseteq Y$ of b, and a unique function $\varphi\colon U_0 \longrightarrow V_0$ of class C^k such that, for every $(x,y) \in U_0 \times V_0$,

$$F(x,y) = 0 \quad \Longleftrightarrow \quad y = \varphi(x). \tag{23.13}$$

After shrinking U_0 and V_0 if necessary, $D_2F(x,\varphi(x))$ is an isomorphism for every $x \in U_0$ and

$$D\varphi(x) = -D_2F(x,\varphi(x))^{-1} \circ D_1F(x,\varphi(x)). \tag{23.14}$$

Proof. Define

$$\Phi\colon U \longrightarrow X \times Z, \qquad \Phi(x,y) := \big(x, F(x,y)\big).$$

Proposition 23.1.19 implies that

$$D\Phi(a,b)(h,k) = \big(h, D_1F(a,b)h + D_2F(a,b)k\big).$$

This operator is an isomorphism from $X \times Y$ onto $X \times Z$. Its inverse is given by

$$(u,v) \longmapsto \big(u, D_2F(a,b)^{-1}\big(v - D_1F(a,b)u\big)\big).$$

Theorem 23.3.3 gives open neighborhoods $\mathcal{U} \subseteq U$ of (a,b) and $\mathcal{V} \subseteq X \times Z$ of $(a,0)$ such that $\Phi\restriction_{\mathcal{U}}\colon \mathcal{U} \longrightarrow \mathcal{V}$ is a diffeomorphism of class C^k. First choose an open neighborhood $V_0 \subseteq Y$ of b such that there exists an open neighborhood $U_1 \subseteq X$ of a with $U_1 \times V_0 \subseteq \mathcal{U}$. By continuity of Φ^{-1} at $(a,0)$, there exist open neighborhoods $U_0 \subseteq U_1$ of a and $W_0 \subseteq Z$ of 0 such that $U_0 \times W_0 \subseteq \mathcal{V}$ and

$$\Phi^{-1}(U_0 \times W_0) \subseteq U_1 \times V_0.$$

For each $x \in U_0$, define $(x, \varphi(x)) := \Phi^{-1}(x,0)$. The first component of Φ is the identity on X, so the first component of $\Phi^{-1}(x,0)$ must be x, and the preceding choice ensures that $\varphi(x) \in V_0$. Moreover,

$$\Phi(x,\varphi(x)) = (x,0) \quad\Longleftrightarrow\quad F(x,\varphi(x)) = 0.$$

If $(x,y) \in U_0 \times V_0$ and $F(x,y) = 0$, then $\Phi(x,y) = (x,0)$; injectivity of $\Phi\restriction_{\mathcal{U}}$ implies $y = \varphi(x)$. This proves (23.13). Since φ is obtained by composing the map $x \longmapsto (x,0)$, the inverse Φ^{-1}, and the projection onto Y, it belongs to $C^k(U_0, Y)$.
Continuity of D_2F and openness of $\mathrm{Iso}(Y,Z)$, proved in Proposition 23.3.2, allow the neighborhoods to be shrunk so that $D_2F(x,\varphi(x))$ is invertible for every $x \in U_0$. Differentiating the identity $F(x,\varphi(x)) = 0$ and applying the chain rule and (23.2) gives

$$D_1F(x,\varphi(x)) + D_2F(x,\varphi(x)) \circ D\varphi(x) = 0.$$

Composition on the left with $D_2F(x,\varphi(x))^{-1}$ yields (23.14). □

23.4 Lagrange multipliers

Theorem 23.3.8 describes a regular level set as a graph over the kernel of the derivative of the constraint. In these coordinates, a constrained extremum becomes an ordinary extremum on the tangent space. This observation leads to the principle of Lagrange multipliers and explains why the derivative of the functional must be a combination of the derivatives of the constraints.

Theorem 23.4.1. (Lagrange multipliers for finitely many constraints) Let X be a Banach space, let $U \subseteq X$ be open, and let $J \in C^1(U,\mathbb{R})$ and $F = (F_1,\dots,F_m) \in C^1(U,\mathbb{R}^m)$. Let $x_0 \in U$ be a local extremum of $J\restriction_{F^{-1}(F(x_0))}$

and suppose $DF(x_0)\colon X \longrightarrow \mathbb{R}^m$ is surjective. Then there exists a unique functional $\lambda \in (\mathbb{R}^m)'$ such that

$$DJ(x_0) = \lambda \circ DF(x_0). \tag{23.15}$$

Equivalently, there exist unique numbers $\lambda_1, \dots, \lambda_m \in \mathbb{R}$ such that

$$DJ(x_0) = \sum_{j=1}^{m} \lambda_j DF_j(x_0).$$

Proof. Let $K := \ker DF(x_0)$. Since $DF(x_0)$ is surjective and $\mathbb{R}^m$ is finite-dimensional, for each vector e_j in the standard basis of $\mathbb{R}^m$ there exists $v_j \in X$ such that $DF(x_0)v_j = e_j$. Define $E := \operatorname{span}\{v_1, \dots, v_m\}$. Then E is finite-dimensional and therefore closed. Moreover, $DF(x_0) \restriction_E \colon E \longrightarrow \mathbb{R}^m$ is an isomorphism. For each $v \in X$, if

$$w := \big(DF(x_0) \restriction_E\big)^{-1}(DF(x_0)v),$$

, then $v - w \in K$. Thus $X = K \oplus E$.
Consider the open set

$$\mathcal{O} := \{(u, v) \in K \times E \mid x_0 + u + v \in U\}$$

and the map $G\colon \mathcal{O} \longrightarrow \mathbb{R}^m$ defined by $G(u, v) := F(x_0 + u + v) - F(x_0)$. Moreover, $G(0, 0) = 0$ and

$$D_2 G(0, 0) = DF(x_0) \restriction_E \colon E \longrightarrow \mathbb{R}^m.$$

Theorem 23.3.8 gives a neighborhood $W \subseteq K$ of 0 and a function $\psi\colon W \longrightarrow E$ of class C^1 such that $\psi(0) = 0$ and

$$F(x_0 + u + \psi(u)) = F(x_0)$$

for every $u \in W$. Differentiating this identity at $u = 0$ gives

$$DF(x_0)\big(u + D\psi(0)u\big) = 0$$

for every $u \in K$. Since $DF(x_0)u = 0$ and $D\psi(0)u \in E$, injectivity of $DF(x_0) \restriction_E$ implies $D\psi(0)u = 0$. Thus $D\psi(0) = 0$.
Fix $u \in K$. For every t in a neighborhood of 0, the curve $\gamma(t) := x_0 + tu + \psi(tu)$ lies in $F^{-1}(F(x_0))$. Since x_0 is a local extremum of the restriction of J, the real function $J \circ \gamma$ has a local extremum at 0. Fermat's rule and the chain rule give

$$0 = (J \circ \gamma)'(0) = DJ(x_0)\big(u + D\psi(0)u\big) = DJ(x_0)u.$$

Thus $K \subseteq \ker DJ(x_0)$.
Let $R\colon \mathbb{R}^m \longrightarrow E$ be the inverse of $DF(x_0) \restriction_E$ and define $\lambda := DJ(x_0) \circ R \in (\mathbb{R}^m)'$. For each $v \in X$, the vector $v - R(DF(x_0)v)$ belongs to K; hence

$$DJ(x_0)v = DJ(x_0)R(DF(x_0)v) = \lambda(DF(x_0)v).$$

This proves (23.15). If $\mu \in (\mathbb{R}^m)'$ also satisfies $DJ(x_0) = \mu \circ DF(x_0)$, surjectivity of $DF(x_0)$ implies $\lambda = \mu$. The formulation in terms of the numbers λ_j follows by identifying $(\mathbb{R}^m)'$ with $\mathbb{R}^m$ using the standard basis. □

Corollary 23.4.2. (Lagrange multipliers for one constraint) Let X be a Banach space, let $U \subseteq X$ be open, and let $J, F \in C^1(U, \mathbb{R})$. If x_0 is a local extremum of J restricted to $\{x \in U \mid F(x) = F(x_0)\}$ and $DF(x_0) \neq 0$, there exists a unique $\lambda \in \mathbb{R}$ such that $DJ(x_0) = \lambda DF(x_0)$.

Proof. The operator $DF(x_0)\colon X \longrightarrow \mathbb{R}$ is surjective because it is linear and nonzero. Apply the preceding theorem with $m = 1$ and identify each linear functional on $\mathbb{R}$ with multiplication by a unique real number. □

23.4.1 Exercises

Exercise 23.4.3. Define $f : \mathbb{R} \longrightarrow \mathbb{R}$ by $f(0) = 0$ and $f(x) = x + 2x^2 \sin\left(\frac{1}{x}\right)$ for $x \neq 0$. Prove that $f'(0) = 1$ but f is not injective on any neighborhood of 0. Determine which assumption of Theorem 23.3.3 fails.

Exercise 23.4.4. Let $\Phi(r, \theta) := (r\cos\theta, r\sin\theta)$ and let $u \in C^2(\mathbb{R}^2 \setminus \{0\})$. If $v := u \circ \Phi$, use the second-order chain rule to prove that

$$(\Delta u) \circ \Phi = \frac{\partial^2 v}{\partial r^2} + \frac{1}{r}\frac{\partial v}{\partial r} + \frac{1}{r^2}\frac{\partial^2 v}{\partial \theta^2}.$$

Interpret this identity as a first example of the behavior of a differential operator under a change of coordinates.

Exercise 23.4.5. Let $P(z, a_0, \ldots, a_{n-1}) := z^n + a_{n-1}z^{n-1} + \cdots + a_0$. Suppose z_0 is a simple root of the polynomial corresponding to $(a_0^0, \ldots, a_{n-1}^0)$. Apply Theorem 23.3.8 to prove that this root depends smoothly on the coefficients in a neighborhood of the given point. Compute the derivative with respect to each coefficient.

Exercise 23.4.6. Let H be a real Hilbert space and let $S := \{u \in H \mid \|u\|_H = 1\}$. Use Theorem 23.3.8 to prove that S is a Banach submanifold of codimension one and that $T_u S = u^\perp$. If $J \in C^1(H, \mathbb{R})$ has a local extremum on S, prove that there exists $\lambda \in \mathbb{R}$ such that $DJ(u)(v) = \lambda \langle u, v \rangle_H$ for every $v \in H$.

Exercise 23.4.7. Let $(M, \mathbf{g})$ be a compact Riemannian manifold with smooth boundary, and let $\mathbf{E} \to M$ be a smooth real vector bundle of finite rank, equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. On $W_0^{1,2}(M, \mathbf{E})$, consider the functionals $J(\mathbf{u}) := \frac{1}{2}\int_M |\nabla^{\mathbf{E}}_w \mathbf{u}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}$ and $G(\mathbf{u}) := \frac{1}{2}\int_M |\mathbf{u}|^2_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}}$. Suppose $\mathbf{u} \neq 0$ minimizes J subject to the constraint $G(\mathbf{u}) = 1$. Apply the Lagrange multiplier theorem to obtain the weak identity for the eigenvalue problem associated with the Bochner Laplacian.

Exercise 23.4.8. Let X and Y be Banach spaces of sections of vector bundles, and let $\mathcal{F}\colon X \times \mathbb{R} \longrightarrow Y$ be of class C^1. Suppose $\mathcal{F}(\mathbf{u}_0, \lambda_0) = 0$ and $D_1\mathcal{F}(\mathbf{u}_0, \lambda_0)\colon X \longrightarrow Y$ is an isomorphism. Use Theorem 23.3.8 to formulate and prove existence of a local branch $\lambda \longmapsto \mathbf{u}(\lambda)$ of solutions. Compute $\mathbf{u}'(\lambda_0)$.

Banach manifolds

Infinite-dimensional manifolds extend the notion of a smooth manifold beyond the finite-dimensional setting. Whereas a finite-dimensional manifold is described locally by open subsets of $\mathbb{R}^n$, in infinite dimensions various topological vector spaces can serve as local models. This chapter works exclusively with Banach spaces; Fréchet and ILH structures are introduced later only when needed.

This extension is more than formal. Global analysis and differential geometry naturally give rise to function spaces equipped with an infinite-dimensional geometric structure. For example, if $\mathbf{E} \longrightarrow M$ is a vector bundle over a Riemannian manifold, the Sobolev spaces $W^{m,p}(M, \mathbf{E})$ are Banach spaces and serve as configuration spaces for numerous variational problems. Other important examples include the spaces of smooth sections $\Gamma(\mathbf{E})$, spaces of smooth maps $C^\infty(M, N)$, diffeomorphism groups $\mathrm{Diff}(M)$, loop manifolds $C^\infty(S^1, M)$, and spaces of immersions or embeddings.

This viewpoint is particularly useful in the variational study of partial differential equations. Solutions are often characterized as critical points of an energy functional defined on an infinite-dimensional function space. It is also common to restrict such a functional to subsets with a manifold structure, such as unit spheres, Nehari manifolds, submanifolds defined by integral constraints, and level sets of differentiable functionals. The geometry of these spaces then provides the appropriate language for formulating criticality conditions, applying Lagrange multipliers, studying gradient flows, and analyzing constrained minimization problems.

Certain spaces of geometric objects can likewise be understood as infinite-dimensional manifolds. They include the space of Riemannian metrics on a fixed manifold, the space of connections on a principal bundle, various spaces of curves or surfaces, and some quotients by symmetry groups. This language is central to Morse theory, gauge theory, symplectic geometry, the calculus of variations, and the study of geometric equations.

The chapter develops the foundations of Banach manifolds that will be used in nonlinear analysis and variational methods. It includes their tangent spaces, submanifolds defined by differentiable constraints, local forms of immersions and submersions, the constant rank theorem, and the preimage theorem. It also examines the assumptions under which bump functions and smooth partitions of unity exist. This last question reveals an essential difference from finite dimensions: paracompactness of the manifold alone does not suffice if the model Banach space lacks the necessary smooth functions. The resulting framework covers many situations modeled on Sobolev spaces and prepares the later study of variational problems and mapping spaces.

From finite-dimensional manifolds to configuration spaces

The idea of modeling a manifold on a function space made differential geometry applicable to problems in which the entire unknown is a function. Eells and Palais developed global tools for these spaces and showed that many finite-dimensional constructions survive under precise functional assumptions. The essential difference is that, in infinite dimensions, existence of complements, bump functions, or suitable metrics is no longer automatic. This chapter therefore keeps the assumptions needed to apply each theorem explicit [85, 111].

24.1 Banach manifolds

We begin by studying manifolds modeled on Banach spaces. They retain the differential calculus and local theorems needed to treat function spaces as geometric objects. In particular, Sobolev spaces of sections, constraints defined by differentiable functionals, and many level sets arising in variational methods have a Banach manifold structure under suitable assumptions.

Unless expressly stated otherwise, the model spaces in this chapter are real Banach spaces, and differentiability is understood over the real field.

Definition 24.1.1. Let (M,τ) be a Hausdorff topological space, and let $k \in \mathbb{N}\cup\{\infty\}$, with $k \geq 1$. A **Banach chart** on M is a pair (U,φ), where $U \subseteq M$ is nonempty and open and $\varphi\colon U \longrightarrow V$ is a homeomorphism from U onto an open subset V of a Banach space X.
Two charts $(U_\alpha,\varphi_\alpha)$ and (U_β,φ_β), modeled on Banach spaces X_α and X_β, respectively, are C^k**–compatible** if $U_\alpha \cap U_\beta = \varnothing$ or if the coordinate change

$$\varphi_\beta \circ \varphi_\alpha^{-1}\colon \varphi_\alpha(U_\alpha \cap U_\beta) \longrightarrow \varphi_\beta(U_\alpha \cap U_\beta)$$

is a diffeomorphism of class C^k between open subsets of Banach spaces. Differentiability is understood in the Fréchet sense, as in Definition 23.2.6, and diffeomorphism has the meaning given in Definition 23.3.4. When $k=\infty$, both the coordinate change and its inverse are required to be of class C^r for every $r \in \mathbb{N}$.
A **Banach atlas of class** C^k on M is a family of charts $\{(U_\alpha,\varphi_\alpha)\}_{\alpha\in I}$ covering M whose charts are mutually C^k–compatible. A **Banach manifold without boundary of class** C^k is a Hausdorff topological space equipped with a maximal Banach atlas of class C^k. A Banach manifold of class C^∞ is called a **smooth Banach manifold**.

In this chapter, and whenever Definition 24.1.1 is invoked, the term *Banach manifold* means a manifold without boundary unless expressly stated otherwise. We adopt the same convention for finite-dimensional manifolds occurring as domains or codomains of the maps under study. This assumption is incorporated into the local models: chart images are open in Banach spaces.

Banach manifolds with boundary also exist in infinite dimensions. Their charts allow relatively open subsets of half-spaces such as $X\times[0,\infty)$, with coordinate changes differentiable up to the boundary. The product $X\times[0,\infty)$ itself is an example, with boundary $X\times\{0\}$; see [85, pp. 766–767]. The local forms and tangent construction below use the preceding convention.

The boundary of a configuration space differs from the boundary of the manifold on which its functions are defined. If a Riemannian manifold M has boundary, the space $W_0^{1,p}(M)$, with $1<p<\infty$, is still a Banach space

and, as a manifold modeled on itself, has no boundary. The Dirichlet condition here defines a vector space of admissible functions. Constraints given by regular values of functionals will be described through embedded submanifolds of these spaces.

In the preceding definition, we allow, a priori, charts modeled on different Banach spaces. However, on each connected component of the manifold, the model space is determined up to Banach space isomorphism.

Lemma 24.1.2. Let M be a Banach manifold of class C^k, with $k \geq 1$. If M is connected, all Banach spaces modeling its charts are linearly and topologically isomorphic.
