Global Analysis

An introduction to nonlinear analysis and its variational methods on Riemannian manifolds

$$\int_M \left\langle \nabla^s F, G \right\rangle_{g,h_E} d\lambda_g = (-1)^s \int_M \left\langle F, \left(\operatorname{tr}_g \circ \nabla\right)^s G \right\rangle_{g,h_E} d\lambda_g + \sum_{j=0}^{s-1} (-1)^{s-1-j} \int_{\partial M} \left\langle \nabla^j F, \iota_\nu \left(\left(\operatorname{tr}_g \circ \nabla\right)^{s-1-j} G \right) \right\rangle_{g,h_E} d\lambda_{\widetilde{g}}$$

Integration-by-parts formula for vector bundles

> *"It is well known that geometry presupposes not only the concept of space but also the first fundamental notions for constructions in space as given in advance. It only gives nominal definitions for them, while the essential means of determining them appear in the form of axioms. The relationship of these presumptions is left in the dark; one sees neither whether and in how far their connection is necessary, nor a priori whether it is possible. From Euclid to Legendre, to name the most renowned of modern writers on geometry, this darkness has been lifted neither by the mathematicians nor the philosophers who have laboured upon it."*

> — **Bernhard Riemann**

List of symbols

Sets and general conventions

$\mathbb{K}$ Scalar field, equal to $\mathbb{R}$ or $\mathbb{C}$

$\mathbb{N}$ Set of natural numbers

$\mathbb{N}_0$ The set $\mathbb{N} \cup \{0\}$

$\mathbb{Z}$ Set of integers

$\mathbb{R}^n$ Real Euclidean space of dimension n

$\mathbb{C}^n$ Complex vector space of dimension n

$\mathbb{H}^n$ Upper Euclidean half-space of dimension n

$\mathbb{S}^n$ Unit sphere of dimension n

e_j The jth vector of the standard basis of $\mathbb{R}^n$

$B_d(x, r)$ Open ball with center x and radius r for the metric d

$\overline{B}_d(x, r)$ Closed ball with center x and radius r for the metric d

$A \Subset U$ The set A is compactly contained in U

$\operatorname{supp}(f)$, $\operatorname{supp}(\mathbf{f})$ Support of the function f or the section $\mathbf{f}$

$\mathbf{1}_A$ Indicator function of the set A

$\operatorname{span}(A)$ Vector subspace spanned by A

$\sum_{i=1}^{k} a_i$ Sum of the terms a_i

$\prod_{i=1}^{k} a_i$ Product of the terms a_i

$\coprod_{j \in I} A_j$ Disjoint union of the family $(A_j)_{j \in I}$

$\binom{n}{k}$ Binomial coefficient

α Multi-index, in the context of coordinate calculations

$D^\alpha u$ Partial derivative of u associated with the multi-index α

Topology and functional analysis

(X, τ) Topological space X with topology τ

$\overline{A}$ Closure of the set A

$\sim$ Equivalence relation

$\overline{X}^{\|\cdot\|}$ Completion of the normed space $(X, \|\cdot\|)$

X' Continuous dual of the topological vector space X

V^* Algebraic dual of the vector space V

$\overline{V}$ Complex conjugate vector space of V

$\mathrm{Hom}(V, W)$ Space of linear transformations from V to W

$\mathcal{L}(X, Y)$ Space of continuous linear operators from X to Y

$\langle \cdot, \cdot \rangle$ Inner product or duality pairing, according to context

$\|\cdot\|$ Norm of the space under consideration

$\|\cdot\|_p$ Norm of a Lebesgue space

$x_j \rightharpoonup x$ Weak convergence of x_j to x

$x_j \overset{*}{\rightharpoonup} x$ Weak-$*$ convergence of x_j to x

$\sigma(X, Y)$ Weak topology on X induced by duality with Y

$(X, \mathcal{A}, \mu)$ Measure space with σ-algebra $\mathcal{A}$ and measure μ

λ_n Lebesgue measure on $\mathbb{R}^n$

$L^p(X, \mathcal{A}, \mu)$ Lebesgue space on the measure space $(X, \mathcal{A}, \mu)$

$M_{m\times n}(\mathbb{K})$ Matrices of size $m \times n$ with entries in $\mathbb{K}$

A^T Transpose of the matrix A

A^* Hermitian adjoint of a matrix; for operators, only when the context specifies the Hilbert inner products

$T^\dagger$ Bounded Hilbert space adjoint of T when it must be distinguished from the differential formal adjoint

$\mathcal{D}(A)$ Domain of the linear operator A

$\mathcal{G}(A)$ Graph of the linear operator A

$M^\perp$ Orthogonal complement of the subset M in a Hilbert space

$\mathcal{K}(X, Y)$ Space of compact linear operators from X to Y

$\mathcal{L}^m(X_1,\dots,X_m;Y)$ Space of continuous m-linear operators from $X_1\times\cdots\times X_m$ to Y

$\mathcal{L}^m_s(X;Y)$ Subspace of continuous symmetric m-linear operators

$D^m f(x)$ Fréchet derivative of order m of f at x

$\delta^m f(x)$ Gâteaux derivative of order m of f at x

$\mathrm{Car}(\Omega\times\mathbb{R}^m,\mathbb{R}^\ell)$ Carathéodory functions with the indicated domains and codomains

$\delta_j f(x)$ Partial Gâteaux derivative of f with respect to the jth variable

$D_j f(x)$ Partial Fréchet derivative of f with respect to the jth variable

$\mathcal{N}_f$ Nemytski or superposition operator associated with f

$\mathrm{Iso}(X,Y)$ Set of continuous linear isomorphisms from X onto Y

$(X_0,X_1)_{\theta,q}$ Real interpolation space of the compatible couple (X_0,X_1)

$[X_0,X_1]_\theta$ Complex interpolation space of the compatible couple (X_0,X_1)

$K(t,u;X_0,X_1)$ Lions–Peetre K-functional

$J(t,u;X_0,X_1)$ Lions–Peetre J-functional

$\mathcal{S}(\mathbb{R}^n)$ Schwartz class on $\mathbb{R}^n$

$\mathcal{S}'(\mathbb{R}^n)$ Space of tempered distributions

$\mathcal{F}u=\widehat{u}$ Fourier transform of u with unitary normalization

X/Y Quotient of the normed space X by the closed subspace Y

$BC^j(U,F)$, $BC^\infty(U,F)$ Functions of class C^j with bounded derivatives up to order j; the infinite-order class is the intersection over all orders

$BUC^j(U,F)$, $BUC^\infty(U,F)$ Subspaces of BC^j whose derivatives up to order j are uniformly continuous

Differential geometry

$C^k(M,N)$ Maps of class C^k between the smooth manifolds M and N

$C^k_c(M)$ Functions of class C^k with compact support in M

$C^\infty(M)$ Smooth real-valued functions on M

TM Tangent bundle of the smooth manifold M

T^*M Cotangent bundle of the smooth manifold M

T_pM Tangent space of M at the point p

$\mathfrak{X}(M)$ Space of smooth vector fields on M

∂_i Coordinate vector field $\frac{\partial}{\partial}x^i$

$\mathbf{d}x^i$ Coordinate covector field

df Differential of the function f

$T^{(k,l)}(TM)$ Bundle of k-contravariant and l-covariant tensors

$F^{i_1\dots i_k}_{j_1\dots j_l}$ Coordinate components of a tensor of type (k,l)

$\otimes$ Tensor product

$\wedge$ Wedge product

$\bigwedge^k(T^*M)$ Bundle of alternating k-tensors

$\Omega^k(M)$ Space of differential k-forms on M

$d\omega$ Exterior derivative of the differential form ω

$F\restriction_A$ Restriction of F to the subset A

∂M Boundary of a manifold with boundary M

Riemannian geometry

$(M,\mathbf{g})$ Riemannian manifold M with metric $\mathbf{g}$

g_{ij} Local coefficients of the Riemannian metric $\mathbf{g}$

g^{ij} Coefficients of the inverse matrix of (g_{ij})

$\langle\cdot,\cdot\rangle_{\mathbf{g}}$ Inner product induced by the metric $\mathbf{g}$

$|\cdot|_{\mathbf{g}}$ Pointwise norm induced by the metric $\mathbf{g}$

$\lambda_{\mathbf{g}}$ Riemann–Lebesgue measure associated with $\mathbf{g}$

$d\lambda_{\mathbf{g}}$ Integration element with respect to the Riemann–Lebesgue measure

$dV_{\mathbf{g}}$ Volume form of $\mathbf{g}$ when an orientation has been fixed

$d_{\mathbf{g}}$ Riemannian distance

$L_{\mathbf{g}}(\gamma)$ Riemannian length of the curve γ

$\mathrm{inj}(M,\mathbf{g})$ Injectivity radius of the Riemannian manifold

$\mathrm{grad}_{\mathbf{g}} f$ Riemannian gradient of f

$\mathrm{div}_{\mathbf{g}} X$ Riemannian divergence of the vector field X

$\Delta_{\mathbf{g}}$ Laplace–Beltrami operator, $\mathrm{div}_{\mathbf{g}}\,\mathrm{grad}_{\mathbf{g}}$

$\mathrm{Rm}_{\mathbf{g}}$ Riemann curvature tensor of the metric $\mathbf{g}$

$\mathrm{Ric}_{\mathbf{g}}$ Ricci tensor of the metric $\mathbf{g}$

$R = R_{\mathbf{g}}$ Scalar curvature of the metric $\mathbf{g}$

Vector bundles and sections

$\mathbf{E} \longrightarrow M$ Vector bundle $\mathbf{E}$ over the manifold M

$\mathbf{E}^*$ Finite-rank dual vector bundle of $\mathbf{E}$, in accordance with the finite-dimensional convention

$\overline{\mathbf{E}}$ Complex conjugate vector bundle of $\mathbf{E}$

$\Gamma(\mathbf{E})$ Space of smooth sections of $\mathbf{E}$

$\Gamma^k(\mathbf{E})$ Space of sections of class C^k of $\mathbf{E}$

$\Gamma_c^k(\mathbf{E})$ Compactly supported sections of class C^k of $\mathbf{E}$

$\Gamma_c(\mathbf{E})$ Smooth compactly supported sections of $\mathbf{E}$

$\mathbf{h}_{\mathbf{E}}$ Bundle metric on the vector bundle $\mathbf{E}$

$\boldsymbol{\mathcal{R}}_{\mathbf{E}} \colon \overline{\mathbf{E}} \to \mathbf{E}^*$ Complex-linear Riesz isomorphism, $\boldsymbol{\mathcal{R}}_{\mathbf{E}}(\overline{v})(w) = \mathbf{h}_{\mathbf{E}}(w, v)$

$\langle \cdot, \cdot \rangle_{\mathbf{h}_{\mathbf{E}}}$ Pointwise inner product induced by $\mathbf{h}_{\mathbf{E}}$

$|\cdot|_{\mathbf{h}_{\mathbf{E}}}$ Pointwise norm induced by $\mathbf{h}_{\mathbf{E}}$

$\nabla^{\mathbf{E}}$ Connection on the vector bundle $\mathbf{E}$

∇_i Covariant derivative in the direction of the coordinate vector field ∂_i

$\nabla^k \mathbf{F}$ The kth covariant derivative of the tensor field or section $\mathbf{F}$

$\nabla_w^k \mathbf{F}$ The kth weak covariant derivative of $\mathbf{F}$

$\boldsymbol{\mathcal{D}}(M, \mathbf{E})$ Space of test sections of the bundle $\mathbf{E}$

$\boldsymbol{\mathcal{D}}'(M, \mathbf{E}, W)$ W-valued distributions in the vector bundle $\mathbf{E}$

$\boldsymbol{\mathcal{E}}'$ Continuous dual bundle of a Banach vector bundle $\boldsymbol{\mathcal{E}}$

$V_e\mathbf{E}$, $V\mathbf{E}$ Vertical space at $e \in \mathbf{E}$ and vertical subbundle of $T\mathbf{E}$

w_e^{V} Vertical lift of $w \in \mathbf{E}_{\pi_{\mathbf{E}}(e)}$ at e

$K^{\nabla^{\mathbf{E}}} \colon T\mathbf{E} \longrightarrow \mathbf{E}$ Connection map induced by $\nabla^{\mathbf{E}}$

$H_e^{\nabla^{\mathbf{E}}}\mathbf{E}$, $H^{\nabla^{\mathbf{E}}}\mathbf{E}$ Horizontal space at e and horizontal subbundle induced by $\nabla^{\mathbf{E}}$

X_e^{H} Horizontal lift of $X \in T_{\pi_{\mathbf{E}}(e)}M$ at e

$\pi^*\nabla^{\mathbf{E}}$ Pullback connection on $\pi^*\mathbf{E}$

∇^{H}, ∇^{V} Horizontal and vertical covariant derivatives on the cotangent bundle

Sobolev spaces

$L^p(\Omega)$ Lebesgue space on the open subset $\Omega \subseteq \mathbb{R}^n$

$L^p(M)$ Lebesgue space with respect to the measure $\lambda_{\mathbf{g}}$

$L^p(M,\mathbf{E})$ Space of p-integrable sections of the bundle $\mathbf{E} \longrightarrow M$

$L^p(M,\mathbb{R}^n)$ Space of measurable functions from M to $\mathbb{R}^n$ whose Euclidean bundle norm is p-integrable

$W^{m,p}(\Omega)$ Sobolev space of order m on Ω

$W^{m,p}(M)$ Sobolev space of order m on the manifold M

$W^{m,p}(M,\mathbf{E})$ Sobolev space of sections of the bundle $\mathbf{E}$

$W^{m,p}_{\mathrm{loc}}(M,\mathbf{E})$ Local Sobolev space of sections of the bundle $\mathbf{E}$

$W^{m,p}_0(M)$ Closure of $C^\infty_c(\operatorname{Int} M)$ in $W^{m,p}(M)$

$W^{m,p}_0(M,\mathbf{E})$ Closure of $\Gamma_{c,\operatorname{Int}(M)}(\mathbf{E})$ in $W^{m,p}(M,\mathbf{E})$

$H^{s,p}(M)$ Bessel potential space of order s on the manifold M

$H^{s,p}(M,\mathbf{E})$ Bessel Sobolev space of sections, defined by uniform localization

$H^s_{\mathrm{loc}}(M,\mathbf{E})$ Local Sobolev space of sections of the bundle $\mathbf{E}$

$H^{s,p}_L(M)$ Intrinsic Bessel scale associated with $L = \Delta_B = -\Delta$

$H^{s,p}_{L_{\mathbf{E}}}(M,\mathbf{E})$ Intrinsic Bessel scale associated with the connection Laplacian $L_{\mathbf{E}}$

p^* Critical Sobolev exponent corresponding to the context

Tr, $\mathbf{Tr}^{\mathbf{E}}$ Trace operators for functions and for sections of the bundle $\mathbf{E}$, respectively

$H^{s,p}(\mathbb{R}^n)$ Bessel potential space of order s

$W^{s,p}(\Omega)$ Sobolev–Slobodeckij space of noninteger order s

$W^{s,p}(M,\mathbf{E})$ Intrinsic Sobolev–Slobodeckij space of sections of the bundle $\mathbf{E}$, defined using covariant derivatives and parallel transport

$[u]_{W^{s,p}(\Omega)}$ Gagliardo–Slobodeckij seminorm

$B^s_{p,q}(M)$, $B^s_{p,q}(M,\mathbf{E})$ Besov spaces of functions and sections on M

$F^s_{p,q}(M)$, $F^s_{p,q}(M,\mathbf{E})$ Triebel–Lizorkin spaces of functions and sections on M

$J^s = (I-\Delta)^{\frac{s}{2}}$ Bessel operator of order s

Differential operators

$\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$ Partial differential operators of order at most m from $\mathbf{E}$ to $\mathbf{F}$

P^*_h Hermitian formal adjoint of the differential operator P, with respect to the bundle metrics and the Riemannian measure

P' Complex-bilinear formal transpose, $P'\colon \Gamma(\mathbf{F}^*) \to \Gamma(\mathbf{E}^*)$

$\sigma_m(P)$ Principal symbol of order m of the operator P

$d^{\mathbf{E}}$ Exterior derivative with values in the bundle $\mathbf{E}$

$\delta^{\mathbf{E}}$ Hermitian formal adjoint of $d^{\mathbf{E}}$

Δ_B Bochner Laplacian with the positive sign convention, $(\nabla)_h^*\nabla$

Δ_H Hodge Laplacian

$\Delta_{p,g}$ p-Laplacian associated with the metric g

$S^m_{1,0}$ Hörmander symbol class of order m and type $(1,0)$

S^m_{cl} Class of classical symbols of order m

$\Psi^m(M;\mathbf{E},\mathbf{F})$ Pseudodifferential operators of order m from sections of $\mathbf{E}$ to sections of $\mathbf{F}$

$\mathrm{WF}(u)$ Wavefront set of the distribution u

$S^{-\infty}(U\times\mathbb{R}^n;\mathrm{Hom}(\mathbb{C}^r,\mathbb{C}^s))$ Euclidean smoothing symbols

$\Psi^{-\infty}(M;\mathbf{E},\mathbf{F})$ Properly supported smoothing operators on M

$\Psi^m_{\mathrm{u},\rho}(M;\mathbf{E},\mathbf{F})$ Radius-ρ stage of the uniform pseudodifferential calculus

$\Psi^{-\infty}_{\mathrm{u}}(M;\mathbf{E},\mathbf{F})$ Uniformly smoothing operators of finite propagation

Infinite-dimensional geometry

X, Y Banach spaces serving as model spaces

$DI(u)$ Fréchet derivative of the functional I at u

$T'M$ Continuous cotangent bundle of a Banach manifold

dF_p Differential of a map between Banach manifolds

$T_p^{\mathrm{kin}}M$ Kinematic tangent space of the Banach manifold M

$T_p^{\mathrm{op}}M$ Operational tangent space of the Banach manifold M

T_pN Tangent space of the Banach submanifold N at p

$\mathrm{GL}(E)$ Group of continuous invertible linear operators on the Banach space E

$\flat_{\mathbf{g}}$, $\sharp_{\mathbf{g}}$ Musical morphisms induced by a strong Riemannian metric

F_x, F_x^* Finsler norm on T_xM and its dual norm on the continuous dual $T_x'M$

d_F Length distance induced by a Banach–Finsler structure

$W^{r,p}(M,N)$ Manifold of Sobolev maps from M to N

$\mathcal{A}^r(\mathbf{P})$ Affine Sobolev space of connections on a principal bundle $\mathbf{P}$

$\mathcal{G}^{r+1}(\mathbf{P})$ Gauge group completed in Sobolev regularity

$\mathrm{Diff}^s(M)$ Sobolev completion of the diffeomorphism group

$H^\infty = \bigcap_{s \geq s_0} H^s$ Smooth core of a Hilbert scale

$\varprojlim H^s$ Projective limit of a Hilbert scale

$\mathrm{Met}^r(M)$ Open space of Riemannian metrics of Sobolev regularity r

$C^j_b(M, \mathbf{E})$ Sections of class C^j whose covariant derivatives up to order j are bounded

$C^{\infty,r}_b(M, N)$ Smooth maps whose covariant derivatives of df up to order $r-1$ are bounded

$\mathrm{Met}(I, B_k)(M)$ Complete metrics with positive injectivity radius and curvature bounded up to order k

Variational methods

I Variational functional or energy functional

$DI(u) = 0$ Critical point condition for the functional I

$J^{-1}(c)$ Level set at level c of the functional J

$\mathcal{N}$ Nehari manifold associated with a functional

$I \restriction_{\mathcal{N}}$ Restriction of the functional I to the Nehari manifold

$T_u\mathcal{N}$ Tangent space of the Nehari manifold at u

λ Lagrange multiplier, when it occurs in a variational constraint

K_c Set of critical points at level c

$I^{\leq a}$ Closed sublevel set $\{u \mid I(u) \leq a\}$

$I^{<a}$ Open sublevel set $\{u \mid I(u) < a\}$

$(PS)_c$ Palais–Smale condition at level c

Φ_t Time-t map of a deformation flow

Introduction **XXIII**

I Riemannian manifolds **1**

Introduction to Part I **3**

1 Fundamental notions of smooth manifolds **5**
1.1 From calculus to differential geometry . . . 5
1.1.1 Higher-order partial derivatives . . . 8
1.2 Smooth manifolds . . . 16
1.3 Smooth maps . . . 24
1.4 The tangent bundle . . . 27
1.5 Immersions, submersions, and embeddings . . . 39
1.6 Submanifolds . . . 43
1.7 Vector bundles and the cotangent bundle . . . 50
1.8 Integral curves and flows . . . 78
1.9 Lie groups and smooth actions . . . 93
1.10 Tensor fields and differential forms . . . 104

2 Riemannian manifolds **125**
2.1 Riemannian metrics . . . 126
2.2 Traces of tensors . . . 130
2.3 Fiberwise inner products of tensor fields . . . 131
2.4 Connections . . . 136
2.5 Hermitian bundles and conjugation of connections . . . 168
2.6 Principal bundles and principal connections . . . 171
2.6.1 Parallel transport and holonomy . . . 181
2.7 Covariant differentiation along curves and parallel transport . . . 186
2.7.1 Horizontal–vertical decomposition induced by a connection . . . 200
2.8 Geodesics . . . 204
2.8.1 The exponential map . . . 210
2.8.2 Geodesic normal coordinates . . . 213

2.9 The Riemannian distance function . . . 216
2.10 Curvature . . . 223
2.11 Riemannian submanifolds . . . 231
2.12 Tubular neighborhoods and Fermi coordinates . . . 234
2.12.1 Fermi coordinates . . . 237
2.13 Jacobi fields and comparison theory . . . 239
2.14 Integration on Riemannian manifolds . . . 248
2.15 The Riemann–Lebesgue measure . . . 260
2.16 Gradient, divergence, and the Laplace–Beltrami operator . . . 267
2.17 Clifford geometry and spin structures . . . 272
2.17.1 Clifford algebras . . . 272
2.17.2 The groups Pin(n) and Spin(n) . . . 273
2.17.3 Complex spinor modules . . . 276
2.17.4 The orthonormal frame bundle and spin structures . . . 277
2.17.5 The spin connection . . . 279
2.17.6 Clifford modules and connections . . . 279
2.17.7 Spin^c structures . . . 280

II Nonlinear analysis in Euclidean spaces 283

Introduction to Part II 285

3 Sobolev spaces on open subsets of $\mathbb{R}^n$ 287
3.1 Weak derivatives . . . 288
3.2 Sobolev spaces . . . 290
3.3 Sobolev embeddings . . . 294
3.3.1 Density and extension by zero . . . 306
3.4 The Rellich–Kondrashov theorem in Euclidean spaces . . . 311
3.4.1 Global embeddings and localization in $\mathbb{R}^n$ . . . 314
3.5 Sobolev embeddings into Hölder spaces . . . 315
3.6 Localized embeddings on the half-space . . . 325
3.6.1 Summary of domains and embeddings . . . 332
3.7 The trace theorem on the half-space . . . 332

4 Distributions and Fourier analysis 337
4.1 The space $\mathcal{D}(\Omega)$ . . . 339
4.2 Projective limits . . . 341
4.3 The topology of $\mathcal{D}(\Omega)$ . . . 348
4.4 LF spaces . . . 356
4.5 Distributions: the dual of $\mathcal{D}(\Omega)$ . . . 365
4.6 Order of a distribution . . . 370
4.7 Distributional derivatives . . . 376
4.8 Rapidly decreasing functions and the Schwartz class . . . 387
4.9 Tempered distributions . . . 389

4.10 Convolution and regularization . . . 391
4.11 The Fourier transform . . . 393
4.11.1 The transform on L^2 and on the L^p scale . . . 396
4.11.2 Fourier on tempered distributions . . . 398
4.12 Littlewood–Paley dyadic decomposition . . . 398

5 Interpolation spaces 401
5.1 Compatible pairs of Banach spaces . . . 401
5.2 The real method: the K-functional . . . 402
5.3 Interpolation of operators . . . 405
5.4 The J-method . . . 407
5.5 Reiteration . . . 409
5.6 Duality for real interpolation . . . 414
5.7 The complex method . . . 416
5.7.1 Translations, regularization, and boundary estimates . . . 423
5.7.2 Sums of spaces and Banach-valued functions . . . 426
5.7.3 Complex reiteration . . . 428
5.8 Lorentz spaces as interpolation spaces . . . 434

6 Intermediate regularity 439
6.1 Bessel potentials and the spaces $H^{s,p}(\mathbb{R}^n)$ . . . 440
6.1.1 The Euclidean Hilbert scale and localization . . . 442
6.1.2 Multiplication, regularization, and commutators . . . 444
6.2 Slobodeckij spaces . . . 449
6.2.1 The Slobodeckij interpolation identity . . . 452
6.3 Besov and Triebel–Lizorkin spaces . . . 455
6.3.1 Multiplier tools . . . 455
6.3.2 Fundamental identifications and interpolation . . . 463
6.4 Multipliers, changes of coordinates, and localization . . . 471
6.5 Open subsets, extension operators, and comparison of scales . . . 479
6.6 Sobolev embeddings of real order . . . 486
6.7 Fractional-order traces . . . 492

III Nonlinear analysis on Riemannian manifolds 499

Introduction to Part III 501

7 Sobolev spaces on Riemannian manifolds 503
7.1 Definition and basic properties . . . 506
7.2 Kato's inequality . . . 518
7.3 Sobolev embeddings on compact Riemannian manifolds . . . 525
7.4 The Rellich–Kondrashov theorem on compact Riemannian manifolds . . . 528

8 Partial differential operators on vector bundles 533
8.1 Motivation and basic properties . . . 533
8.2 Formal Hermitian adjoints . . . 571
8.3 Operators associated with Clifford connections . . . 591
8.3.1 Bochner and Lichnerowicz formulas . . . 593
8.3.2 Twisted operators and Spin^c . . . 595

9 Sobolev spaces on vector bundles: an intrinsic approach 597
9.1 Weak covariant derivatives and Sobolev spaces on vector bundles . . . 597
9.1.1 Fundamental properties: uniform convexity, reflexivity, and separability . . . 604
9.1.2 Compatibility with restrictions and local expressions for covariant derivatives on vector bundles . . . 619
9.1.3 The integration-by-parts formula for vector bundles and the formal adjoint . . . 622
9.1.4 Equivalence of norms: an application of the integration-by-parts formula in vector bundles 638
9.1.5 Local characterization of Sobolev spaces in vector bundles . . . 653
9.1.6 The Meyers–Serrin approximation theorem in vector bundles . . . 666
9.2 Sobolev embeddings and the Rellich–Kondrashov theorem for vector bundles . . . 671
9.2.1 Embeddings into spaces of Hölder sections . . . 675
9.2.2 Independence of Sobolev spaces in the compact case . . . 688
9.3 Interpolation: the Gagliardo–Nirenberg inequality . . . 690
9.4 Sobolev spaces on manifolds with boundary . . . 694
9.4.1 The trace operator . . . 704
9.4.2 Intrinsic Sobolev–Slobodeckij spaces and the exact trace . . . 707
9.4.3 Embeddings for sections on compact manifolds with boundary . . . 719
9.5 The weak Kato inequality . . . 728
9.6 The Poincaré inequality in the compact case . . . 736

10 Distributions on vector bundles 745
10.1 The space of test sections . . . 745
10.2 Distributions on vector bundles . . . 756
10.2.1 Partial differential operators and distributions . . . 762
10.2.2 Local properties . . . 774
10.2.3 External products and parameter-dependent sections . . . 786
10.2.4 Tensor products of test spaces . . . 793
10.2.5 The Schwartz kernel theorem . . . 799

11 Principal symbol and elliptic operators 803
11.1 The principal symbol . . . 803
11.1.1 Elementary symbol calculus . . . 805
11.2 Elliptic operators . . . 808
11.3 Elliptic estimates on vector bundles . . . 809
11.3.1 An interpolation inequality . . . 809
11.3.2 Systems with constant coefficients . . . 810
11.3.3 Freezing coefficients . . . 812

11.3.4 Globalization on a closed manifold . . . 815
11.4 Elliptic regularity . . . 817
11.4.1 Minimal and maximal realizations on a closed manifold . . . 821
11.5 Powers of the Bochner Laplacian . . . 823

12 Fractional Sobolev spaces on vector bundles and the heat kernel: an intrinsic approach 825
12.1 The connection Laplacian on $L^2(M,\mathbf{E})$ . . . 826
12.1.1 The realization determined by the energy form . . . 826
12.1.2 The spectral semigroup and the scalar semigroup . . . 832
12.1.3 The Kato–Simon inequality . . . 834
12.2 The covariant heat kernel . . . 837
12.2.1 Regularization and continuity of evaluations . . . 837
12.3 Extension of the semigroup to $L^p(M,\mathbf{E})$ . . . 843
12.3.1 The scalar semigroup on the L^p scale . . . 843
12.3.2 The covariant semigroup on $L^p(M,\mathbf{E})$ . . . 845
12.4 Bessel potentials and spaces of real order . . . 848
12.4.1 Bessel potentials . . . 848
12.4.2 The Bessel kernel . . . 850
12.4.3 Definition of the fractional scale . . . 853

Introduction

When we begin studying a differential equation on a manifold, something familiar happens: we choose a chart and, for a moment, the problem becomes one defined on an open subset of $\mathbb{R}^n$. There we can differentiate, integrate, and use many of the tools of Euclidean analysis. The difficulty arises when we want to leave that chart. We must then know which parts of the calculation depended on coordinates, which quantities have intrinsic meaning, and how to combine the estimates obtained locally to draw a conclusion about the entire manifold.

Global analysis studies precisely this passage from the local to the global. Coordinates do not disappear: they remain an indispensable computational tool. What matters is understanding which information survives a change of chart and how geometry modifies arguments we already know in $\mathbb{R}^n$. A connection allows us to differentiate sections of a bundle; a metric allows us to measure and integrate them; Sobolev spaces make it possible to work with solutions that are not smooth; spectral theory and heat relate local operators to global information; and variational methods turn many equations into energy problems on infinite-dimensional spaces.

This is the viewpoint that guides the book. Rather than presenting differential geometry, functional analysis, and partial differential equations separately, we want to see how these theories meet in the study of a concrete problem on a manifold. Throughout the text, we will therefore return to the same pattern: first formulate the object intrinsically, then express it in coordinates when a calculation is needed, and finally check which hypotheses allow us to pass from local estimates back to a global statement.

Much of this book grew out of teaching in the graduate program in Mathematical Sciences, in the courses *Nonlinear analysis on Riemannian manifolds I and II* and *Variational methods on Riemannian manifolds I and II*. These courses were led by Dr. María de los Ángeles Sandoval Romero, who taught the nonlinear analysis courses jointly with Carlos Daniel Velázquez Mendoza, M.Sc., and the variational courses jointly with Dr. Romulo Diaz Carlos.

In the classroom, many arguments can be completed with an explanation at the blackboard, an example, or a reference to something covered a few weeks earlier. Turning that material into a book required these connections to be put into writing. This is the source of our concern to state the hypotheses of each result carefully, recover the intermediate steps of proofs, and show explicitly where geometry enters an argument that might at first appear purely analytic.

Note to the reader. This manuscript is a work in progress and may still undergo minor corrections and editorial refinements. Comments, suggestions, and corrections are very welcome.

From local calculus to intrinsic geometry

The starting point is differential calculus. Newton and Leibniz developed, in different languages, tools for studying velocities, tangents, areas, and accumulated quantities. Over time, these ideas acquired increasingly precise formulations: first in one variable, then in several variables, and finally in more general spaces. The derivative ceased to be viewed merely as a computational rule and came to be understood as the linear approximation describing the first-order behavior of a nonlinear object.

Differential geometry then required an answer to a new question: what does differentiation mean when the space on which we work is curved? Gauss showed that the curvature of a surface can be recognized from measurements made within the surface itself, without reference to the ambient space. Riemann extended this idea to arbitrary dimensions and proposed describing geometry through a way of measuring lengths and angles infinitesimally. Later, Poincaré brought another difficulty to the forefront: knowing each small region of a space well is not necessarily enough to understand its global shape. The work of Gauss, Riemann, and Poincaré thus marks the passage from calculus on embedded figures to intrinsic geometry, and then to the study of truly global properties [65, 121, 118].

Figure 1. From infinitesimal calculus to global geometry. Newton and Leibniz established the fundamental languages of calculus; Gauss discovered the intrinsic nature of surface curvature; Riemann extended metric geometry to arbitrary dimensions; Poincaré made the global organization of spaces a central mathematical problem.

Gauss, Riemann, and the intrinsic viewpoint

In his *Disquisitiones generales circa superficies curvas* of 1828, Gauss studied the geometry of a surface through its first fundamental form and established that Gaussian curvature is intrinsic. Riemann's habilitation lecture of 1854, published posthumously in 1868, changed the scale of the problem: a metric could be considered on spaces of any dimension, and curvature became a property of the space itself. The tensor language and connections subsequently developed by Christoffel, Ricci, Levi–Civita, and Cartan gave this vision an operational form. In this book, that history reappears concretely: tangent spaces and tensors are constructed first; the metric, connection, geodesics, and curvature are then introduced; and finally these structures become coefficients, operators, and energies.

This historical development also explains the order we will follow. The covariant derivative, Laplacian, Sobolev norms, and principal symbol will be introduced, whenever possible, as intrinsic objects. Coordinates will appear when they are needed for calculations, comparison with a Euclidean model, or the proof of an estimate. We do not seek to avoid local calculations, but to use them without confusing the coordinate expression with the geometric object it represents.

The emergence of function spaces

Geometry is not the only difficulty. When the unknown in an equation is a function or a section, the set of possible solutions no longer lies in a finite-dimensional space. To study a minimizing sequence, we need to know in what sense it can converge; to discuss weak derivatives, we need a space that records both size and regularity; to apply variational methods, we need a structure in which continuity, compactness, and differentiation make sense. This was one of the fundamental changes in twentieth-century analysis. In 1906, Fréchet introduced a systematic theory of metric spaces and functional calculus [62], and in 1932 Banach organized a decisive portion of linear analysis around complete normed spaces [18]. Functions could then be studied as points of a space that, although infinite-dimensional, had an appropriate geometry and topology.

Sobolev showed that a function can have derivatives in a sense compatible with integration by parts even when it is not classically differentiable, and his embedding theorems related the number of integrable derivatives to the regularity of the function [136]. Shortly afterward, Laurent Schwartz developed distribution theory, which allows singular objects such as the Dirac delta to be treated rigorously and extends differentiation to a much broader class [131]. These ideas made it natural to begin with weak solutions, obtain estimates, and then ask whether the equation itself forces regularity to be recovered.

Sobolev and Schwartz: regularity without classical smoothness

The conceptual change lay not in abandoning derivatives but in recognizing them through their integral effects. In a Sobolev space, the derivative is identified by an integration-by-parts formula; in distribution theory, that same formula becomes the definition of differentiation. This perspective allows us to begin with data of low regularity, obtain a priori estimates, and then prove that the solution has more regularity than initially seemed available. The route we will follow retraces this development: weak derivatives, Sobolev spaces, distributions, Fourier analysis, interpolation, fractional regularity, and, later, their geometric versions.

What makes global analysis global

In this context, the adjective *global* does not simply mean that the manifold is large or cannot be covered by a single chart. It means that the answer may depend on how the entire space is organized. An elliptic equation is written locally, yet the dimension of its kernel may contain topological information; a Sobolev inequality is proved in charts, yet its constants may depend on volume, curvature, or behavior at infinity; a geodesic satisfies an ordinary differential equation, yet its extendibility for all time is a global property; Ricci flow is a parabolic equation for a metric, yet the study of its singularities ultimately reveals the topology of the manifold.

This relationship between analysis and topology became particularly clear through Hodge theory, Morse theory, and the study of elliptic operators. The Atiyah–Singer theorem subsequently gave that relationship a much more general form: the analytic index of an elliptic operator agrees with an index constructed from its symbol and the topology of the manifold [11]. Microlocal analysis, the pseudodifferential calculus, and K-theory arise naturally on the way to this statement. Instead of presenting them as separate topics, we will develop them as parts of a single chain of ideas.

Another way to obtain global information is to let the geometry evolve. In 1982, Hamilton introduced Ricci flow to deform a metric according to its Ricci curvature [75]. Shortly afterward, DeTurck identified the gauge that reveals a strictly parabolic system behind the diffeomorphism invariance [43]. Two decades later, Perelman intro-

duced monotone quantities, the noncollapsing principle, and new tools for studying singularities and completing the geometrization program in dimension three [114, 116, 115]. This example captures the spirit of geometric analysis: geometry suggests an equation, analysis makes it possible to control its solutions, and the behavior of those solutions ultimately provides information about the original space.

Atiyah–Singer: a bridge between two ways of counting

For a Fredholm operator, the index is the difference between the dimension of the solution space and the dimension of the obstruction space. At first sight, it is an analytic number: it is obtained by solving an equation. The Atiyah–Singer theorem asserts that this same integer can be calculated from topological data of the principal symbol. The result does not erase the distance between analysis and topology; it explains why they describe the same phenomenon from different ends. For this reason, the part devoted to index theory does not begin with the final formula: it first constructs the pseudodifferential calculus, Fredholm theory, the symbol class, Bott periodicity, and the Thom isomorphism.

A contemporary perspective

The preceding questions remain open in many directions and today constitute a broad part of global and geometric analysis. Elliptic and spectral theory study how geometry influences the kernel of an operator, its spectrum, and heat. On noncompact manifolds, bounded geometry allows local estimates to be recovered with constants independent of the point. In the presence of a boundary, traces, boundary terms, and the need for precise control of the normal direction arise. Spaces of maps, connections, and metrics lead naturally to infinite-dimensional geometry, while geometric flows use evolution, rescaling, and compactness to study curvature and singularities.

Recent problems directly related to the themes of the book include new forms of approximation by smooth objects in Sobolev spaces on manifolds [33]; the development of Sobolev, Besov, and Bessel potential scales on manifolds with boundary, bounded geometry, or singularities [6]; characterizations of traces that incorporate the connection and curvature [127]; and intrinsic formulations of integration by parts and Sobolev spaces on vector bundles [41]. These examples are different, but they share a common concern: determining precisely which geometric hypotheses allow a familiar analytic tool to be transferred to the global setting.

For this reason, throughout the book we will not treat settings requiring different arguments as interchangeable. Compactness can replace uniform control at infinity; a boundary introduces traces and boundary terms; the curvature of a connection reappears when derivatives are commuted; and a weak metric in infinite dimensions does not automatically possess the properties of a strong metric. Distinguishing these hypotheses is more than a matter of precision in statements: it is often exactly what makes it possible to understand why a proof works.

The approach to exposition

The book is written so that, whenever possible, the reader can follow the full development of a tool from the Euclidean case to its geometric version. First, the local result is formulated with the hypotheses it actually needs; we then study what happens under multiplication by cutoff functions, changes of coordinates, or passage from one trivialization to another; finally, the result is globalized. Vector bundles also bring bundle metrics and connections into play; noncompact geometry requires uniform control of constants; and in the presence of a boundary, adapted charts and Fermi coordinates allow the normal direction to be separated from the tangential directions.

For the same reason, many proofs are developed in greater detail than would be necessary in a text intended solely as a reference. When an argument is localized, the cutoffs, supports, and norms being compared are specified; when a partition of unity is used, the contribution of its terms is shown; and when a proof depends on an external result, the point at which it is used is identified. The aim is for the logical chain to be reconstructible from the text itself, so that phrases such as “the argument is local” or “this follows by a partition of unity” do not conceal the steps where the real substance lies.

The longer chapters can be read at different levels of depth. A first reading allows the reader to follow the motivation, definitions, and main results; a closer reading allows the proofs to be reconstructed and the roles of the metric, connection, compactness, and boundary to be identified. The examples and exercises then help verify that the constructions are more than formal. Rather than memorizing a list of theorems, the goal is to recognize a few ideas that recur throughout the book in different forms.

Organization of the book

The first part assembles the geometric language used throughout the book. It begins with smooth manifolds, maps, tangent spaces, submanifolds, vector bundles, flows, differential forms, and Lie groups and algebras. Riemannian metrics, principal and associated bundles, connections, parallel transport, geodesics, distance, curvature, and integration then follow. These tools also allow the construction of Clifford algebras, Spin and Spin^c structures, spinor bundles, and their connections. Dirac operators are introduced later, once a general theory of differential operators on bundles is available. The general references for this part are [94, 95, 109, 21].

The second part serves as a Euclidean laboratory. Integer-order Sobolev spaces are constructed from weak derivatives, distributions and Fourier analysis are developed, and interpolation is introduced. Bessel potentials and Slobodeckij, Besov, and Triebel–Lizorkin spaces then organize regularity of real order. This is the setting in which we prove the multiplication, localization, change-of-variables, embedding, compactness, and trace results needed for the passage to manifolds [1, 61, 97, 98, 20, 145, 146, 130].

With these tools available, the third part turns to analysis on manifolds and vector bundles. Sobolev spaces are defined through weak covariant derivatives, and differential operators and bundle-valued distributions are developed. The integration-by-parts formula, Kato and Poincaré inequalities, embeddings, compactness, and trace theorems appear here. The connection Laplacian and the heat semigroup then provide an intrinsic construction of spaces of fractional order. Finally, bounded geometry allows these tools to be retained on noncompact manifolds with uniform estimates, and traces on submanifolds and boundaries to be studied [14, 79, 78, 53, 109, 69, 72, 6].

The fourth part is devoted to index theory. The pseudodifferential calculus allows parametrices for elliptic operators to be constructed and their regularity to be studied; Fredholm theory turns this information into an analytic index; K-theory organizes symbol classes; and Bott periodicity together with the Thom isomorphism leads to the topological index. These constructions finally come together in the Atiyah–Singer theorem for closed manifolds and several of its fundamental geometric examples.

The fifth part concerns geometric evolution equations. We begin with a parabolic theory for quasilinear systems on closed manifolds and apply it to Ricci flow. Diffeomorphism invariance leads to DeTurck’s procedure; curvature evolution equations, maximum principles, a priori estimates, and rescalings prepare the study of singularities. The part concludes with Hamilton compactness and Perelman’s tools: monotone quantities, noncollapsing, κ-solutions, and surgery.

The sixth part changes scale and takes geometry into infinite dimensions. Fréchet calculus on Banach spaces leads to Banach manifolds, bundles, connections, flows, and Hilbert or Banach–Finsler structures. Spaces of maps,

metrics, and connections, gauge groups, and diffeomorphism groups then enter the picture, with fixed regularity carefully distinguished from ILH scales. The application chapters show how harmonic maps, Yang–Mills theory, and the Euler equations can be viewed as geometric problems on configuration spaces [28, 31, 91, 85, 46].

The seventh part brings together the variational methods we will use to prove the existence of solutions. Weak formulations and Nemytski operators allow energy functionals to be constructed; the direct method combines coercivity, reflexivity, and semicontinuity; the Palais–Smale condition and pseudogradients allow sublevel sets to be deformed; and regular constraints and the Nehari method allow the search for nontrivial critical points. The emphasis is on how these techniques adapt to the function space and the geometry of the problem, rather than on treating them as isolated procedures [138, 112, 45, 13, 87].

The appendices collect the tools of topology, mathematical analysis, linear algebra, and tensor notation consulted throughout the book. Their purpose is to let the main development remain continuous without concealing the auxiliary results that support the proofs.

Reading paths

Although the chapters are arranged for continuous reading, it is not necessary to work through the entire book before reaching a particular topic. For Sobolev spaces and variational problems on compact manifolds, a natural route passes through Chapters 1–9 and continues with Chapters 29–32. For trace theory and bounded geometry, it is useful to add Chapters 12–14. Index theory uses the Clifford geometry of the first part, the differential construction of Dirac operators in Chapter 8, and Chapters 11 and 15–19. Ricci flow requires Riemannian geometry and elliptic and Sobolev theory, and is developed in Chapters 20–22. Infinite-dimensional geometry can be studied starting in Chapter 23, although its applications frequently use the Sobolev spaces constructed earlier.

These paths continually intersect. Integration by parts reappears in the definition of weak derivatives, formal adjoints, and Euler–Lagrange equations; compactness underlies Rellich–Kondrashov, Fredholm theory, and Palais–Smale; a connection serves both to differentiate sections and to construct Laplacians, study heat, or describe configuration spaces; and the principal symbol begins as a local object and ends by relating regularity, parametrices, and the topological index. An important part of the book consists precisely in making these connections visible.

The book is intended for advanced undergraduate and graduate students, as well as readers approaching global analysis from geometry or differential equations. Basic knowledge of real analysis, topology, linear algebra, and multivariable calculus is assumed; when an additional tool is needed, it will be recalled in the text or a reference will be given to the appropriate appendix. The aim is that, as readers progress through these pages, they will be able to move naturally between three levels that recur throughout: the equation to be studied, the function space in which it is formulated, and the geometry of the space on which it is defined.

Part I

Riemannian manifolds

Introduction to Part I

Before studying equations, Sobolev spaces, or differential operators on a manifold, we must address a more elementary question: how can we do calculus on a space that generally has no single coordinate system? Locally, a manifold resembles an open subset of $\mathbb{R}^n$, so many constructions can be expressed in coordinates. Yet the geometric object is not the chart we choose to describe it. The first aim of this part is to learn how to pass from a local description to a formulation independent of that choice.

Chapter 1 constructs the smooth structure and the objects that arise from it: tangent and cotangent spaces, submanifolds, vector bundles, flows, differential forms, Lie groups, and smooth actions. Chapter 2 adds the Riemannian structure. Connections, parallel transport, geodesics, distance, curvature, Riemannian measure, and the basic differential operators then enter the picture. The part concludes by introducing Clifford algebras, the groups Spin and Spin^c, and spinor bundles. Dirac operators will be studied later, once the general theory of differential operators on bundles is available.

These constructions are linked by very concrete needs. Charts allow us to calculate, but the tangent space identifies the directions that exist independently of coordinates. A vector bundle brings together data that vary from point to point; a connection makes it possible to compare and differentiate them; the metric measures lengths, angles, and energies; curvature records the discrepancy that arises when transporting and differentiating in different directions. The intention in this part is for these ideas to emerge as natural responses to geometric problems, rather than as an isolated sequence of definitions.

A shared geometric tradition

Gauss showed that a surface has geometric properties that can be recognized without reference to the space in which it is drawn. Riemann extended this idea to arbitrary dimensions and made the metric the starting point of intrinsic geometry. In the following decades, Christoffel, Ricci, and Levi–Civita developed tensor calculus and the notion of a connection, while Cartan reorganized much of the theory using differential forms and moving frames. The modern language retains all these perspectives. We will therefore use coordinates, tensors, connections, and differential forms as the problem requires, without treating them as competing languages.

1

Fundamental notions of smooth manifolds

"One geometry cannot be more true than another; it can only be more convenient."
— Henri Poincaré, *Science and Hypothesis* (1902)

Differential geometry begins with a simple observation: a space may look almost Euclidean when viewed up close, yet have a global shape that no single coordinate system can describe. A sphere, a torus, or a surface with boundary admits local calculus, but its most important features emerge only when different regions are compared. The notion of a smooth manifold gives precise form to this interplay between the local and the global.

This first chapter develops the language that will accompany the reader throughout the book. We begin with derivatives in Euclidean spaces, move on to charts and changes of coordinates, and arrive at tangent spaces, vector bundles, submanifolds, flows, and differential forms. Each definition addresses a concrete geometric need and prepares an analytic tool for later use. The exposition follows primarily Lee [94, 95] and draws on Nicolaescu's approach [109], particularly where smooth geometry begins to provide the foundations for global analysis.

1.1 From calculus to differential geometry

Differential geometry extends a central idea of calculus: approximating a nonlinear object locally by linear data. Newton and Leibniz independently developed the foundations of differential and integral calculus; Leibniz's notation and Newton's dynamical interpretation continue to be reflected in the modern language of derivatives, curves, and fields.

The subsequent formalization of calculus led to the modern notions of limit, continuity, and differentiability. On a manifold, coordinates allow us to transfer a problem temporarily to an open subset of $\mathbb{R}^n$; compatibility between charts ensures that the resulting objects do not depend on this local choice. The derivative is then understood as more than a slope: it is the linear map that approximates a nonlinear map to first order.

Before introducing smooth manifolds, we recall this formulation of the derivative in Euclidean spaces. Fréchet's definition expresses linear approximation precisely and anticipates the version we will later use in Banach spaces.

Isaac Newton
(1642–1727)

Gottfried Wilhelm Leibniz
(1646–1716)

Figure 1.1. Newton and Leibniz developed the foundations of differential and integral calculus in different mathematical languages.

Definition 1.1.1. Let $U \subseteq \mathbb{R}^n$ be an open set and let $f\colon U \longrightarrow \mathbb{R}^m$ be a function. We say that f is Fréchet differentiable, or simply differentiable, at $x_0 \in U$ if there exists a linear map $L\colon \mathbb{R}^n \longrightarrow \mathbb{R}^m$ such that $\lim_{h\to 0} \dfrac{f(x_0+h)-f(x_0)-L(h)}{\|h\|} = 0$. We denote this linear map by df_{x_0} or by $Df(x_0)$. The map df_{x_0} is unique and is called the derivative of f at x_0. If f is differentiable at every point of U, we say that f is differentiable on U, or simply differentiable when the domain is understood.

In the preceding definition, it is essential that the domain of f be open. Since U is open, there exists $r > 0$ such that $B_{\text{euc}}(x_0, r) \subseteq U$. Therefore, if $h \in \mathbb{R}^n$ and $\|h\| < r$, then $x_0 + h \in U$, and the linear approximation to f can be tested in every direction in $\mathbb{R}^n$. This condition allows us to recover a unique linear map associated with f at the point x_0.

The situation changes when the domain is not open. In that case, the expression $f(x_0+h)$ makes sense only for those h for which x_0+h belongs to the domain of f. Thus the linear approximation detects the behavior of f only along directions contained in the domain. As a result, two distinct linear maps may give the same approximation on the set where the function is defined.

Example 1.1.2. Let $A = \{(x,0) \in \mathbb{R}^2 \mid x \in \mathbb{R}\}$ and let $f\colon A \longrightarrow \mathbb{R}$ be given by $f(x,0) = x$. Consider the point $0 = (0,0) \in A$. Let $L, \widetilde{L}\colon \mathbb{R}^2 \longrightarrow \mathbb{R}$ be the linear maps given by $L(x,y) = x$ and $\widetilde{L}(x,y) = x + y$.
If $h = (h_1, 0) \in A$, then $f(0+h) - f(0) - L(h) = h_1 - h_1 = 0$. Therefore,

$$\lim_{\substack{h\to 0 \\ h\in A}} \frac{f(0+h)-f(0)-L(h)}{\|h\|} = 0.$$

Similarly, if $h = (h_1, 0) \in A$, we have $f(0+h) - f(0) - \widetilde{L}(h) = h_1 - \widetilde{L}(h_1, 0) = h_1 - h_1 = 0$. Hence,

$$\lim_{\substack{h\to 0 \\ h\in A}} \frac{f(0+h)-f(0)-\widetilde{L}(h)}{\|h\|} = 0.$$

Thus the linear maps L and $\widetilde{L}$ satisfy the same approximation condition on A, although they are distinct as linear maps on $\mathbb{R}^2$. The reason is that the set A allows us to approach the origin only through vectors of the form $(h_1, 0)$. Consequently, the function does not detect the component transverse to the x-axis: L and $\widetilde{L}$ agree on A but differ in the transverse directions.

The preceding example explains why the usual definition of the derivative is formulated for open domains. In differential geometry, however, we need to consider functions defined on subsets that are not open in $\mathbb{R}^n$, as happens in the study of manifolds with boundary. In these cases, a natural way to define regularity is to require the existence of smooth local extensions.

Definition 1.1.3. (Differentiability by local extension) Let $A \subseteq \mathbb{R}^n$, let $x_0 \in A$, and let $f : A \longrightarrow \mathbb{R}^m$. We say that f is differentiable at x_0 by local extension if there exist an open set $U_{x_0} \subseteq \mathbb{R}^n$, with $x_0 \in U_{x_0}$, and a function $\widetilde{f} : U_{x_0} \longrightarrow \mathbb{R}^m$ differentiable at x_0, such that $\widetilde{f} \restriction_{U_{x_0} \cap A} = f \restriction_{U_{x_0} \cap A}$.
If the extension $\widetilde{f}$ can be chosen to be of class C^k in a neighborhood of x_0, we say that f is of class C^k at x_0 by local extension.

Remark 1.1.4. The preceding definition provides a notion of regularity for functions defined on subsets of $\mathbb{R}^n$, but it does not, by itself, define an intrinsic derivative of f at x_0 as a linear map $\mathbb{R}^n \to \mathbb{R}^m$. The reason is that the derivative may depend on the chosen local extension.
The preceding example illustrates this dependence. The function $f : A \longrightarrow \mathbb{R}$ admits at least the extensions $\widetilde{f_1}(x, y) = x$ and $\widetilde{f_2}(x, y) = x + y$. Both agree with f on A, but $d(\widetilde{f_1})_{(0,0)}(v_1, v_2) = v_1$, whereas $d(\widetilde{f_2})_{(0,0)}(v_1, v_2) = v_1 + v_2$. Thus the derivatives of the extensions do not agree. This shows that, for arbitrary subsets, the existence of smooth local extensions allows us to define regularity, but does not necessarily yield a well-defined derivative.

The derivative is interpreted as the *best linear approximation to the function f at x_0*: if a function $f : U \subseteq \mathbb{R}^n \longrightarrow \mathbb{R}$ is differentiable at $x_0 \in U$, then the graph of the function $H : \mathbb{R}^n \longrightarrow \mathbb{R}$ given by $H(x) = df_{x_0}(x - x_0) + f(x_0)$ is the tangent hyperplane to the graph of f at the point $(x_0, f(x_0))$.

Example 1.1.5. Let $f : \mathbb{R}^2 \longrightarrow \mathbb{R}$ be given by $f(x, y) = x^2 + xy + y^2$. We know that f is differentiable and that $df_{(x,y)}(u, v) = (2x + y)u + (x + 2y)v$. The tangent hyperplane to the graph of f at $(x, y, f(x, y))$ is given by $H(u, v) = df_{(x,y)}((u, v)-(x, y))+f(x, y) = (2x+y)(u-x)+(x+2y)(v-y)+x^2+xy+y^2 = 2xu+yu+xv+2yv-x^2-y^2-xy$, or, in Cartesian form, is the plane $w = 2xu + yu + xv + 2yv - x^2 - y^2 - xy$.

Surface $f(x, y) = x^2 + xy + y^2$ and its tangent plane at $(1, 2, 7)$

The notion of a tangent hyperplane illustrates especially well the power of the *derivative* to provide linear approximations to nonlinear objects, the idea underlying what is known as *nonlinear analysis*.

We can define the tangent hyperplane to a surface if we know a function describing the surface, either as the graph of the function or through a parametrization. However, the notion of a *surface* should not depend on a function describing it: the surface should be a well-defined mathematical object with fixed topological properties. As we will see later, the concept of a *differentiable manifold* resolves these difficulties.

Other approximations to a differentiable function are obtained using polynomial functions. These approximations need not be linear, but they approximate the function increasingly well, thanks to what is known as *Taylor's theorem*. The coefficients of the Taylor expansion are given by higher-order partial derivatives. These derivatives will also help us study the regularity of functions that need not be differentiable, using Sobolev spaces and the concept of a *weak derivative*. Their properties will be essential there, since several properties of weak derivatives are inherited from ordinary partial derivatives. We therefore review these derivatives and the notion of a ***multi-index*** for readers unfamiliar with this notation.

1.1.1 Higher-order partial derivatives

Before iterating partial derivatives, it is useful to recall the directional derivative. This notion connects Euclidean calculus with a construction that will later appear on manifolds: differentiating a field or a section in the direction of a vector by means of a connection.

Definition 1.1.6. (directional derivative) Let $U \subseteq \mathbb{R}^n$ be open, let $f : U \longrightarrow \mathbb{R}^m$ be a function, and let $x_0 \in U$ and $v \in \mathbb{R}^n$. We say that f is differentiable at x_0 in the direction of v if

$$\lim_{t\to 0} \frac{f(x_0 + tv) - f(x_0)}{t}$$

exists. This limit is called the ***directional derivative of*** f ***in the direction of*** v and is denoted by $D_v f(x_0)$. The directional derivative for $v = 0$ always exists and equals 0.
If f is differentiable at every point $x \in U$ in the direction of v, we simply say that f has a directional derivative in the direction of v or with respect to v.

These directional derivatives can be iterated to define *higher-order directional derivatives*.

Definition 1.1.7. Let $f : U \subseteq \mathbb{R}^n \longrightarrow \mathbb{R}^m$ and $x_0 \in U$. We define higher-order directional derivatives recursively.

(a) If $v_1, v_2 \in \mathbb{R}^n$ and there exists $r_1 > 0$ such that $B_{\text{euc}}(x_0, r_1) \subseteq U$ and $D_{v_1} f(x)$ exists for every $x \in B_{\text{euc}}(x_0, r_1)$, we say that f has a second directional derivative with respect to v_1, v_2 at x_0 if

$$\lim_{t\to 0} \frac{D_{v_1} f(x_0 + tv_2) - D_{v_1} f(x_0)}{t}$$

exists, and we denote this limit by $D_{v_2,v_1} f(x_0)$.

(b) If $v_1, \ldots, v_{k+1} \in \mathbb{R}^n$ and there exists $r_k > 0$ such that $B_{\text{euc}}(x_0, r_k) \subseteq U$ and $D_{v_k,\ldots,v_1} f(x)$ is defined and exists for every $x \in B_{\text{euc}}(x_0, r_k)$, we say that f has a $(k+1)$st directional derivative with respect to

$v_1,\dots,v_{k+1}$ at x_0 if

$$\lim_{t\to 0}\frac{D_{v_k,\dots,v_1}f(x_0+tv_{k+1})-D_{v_k,\dots,v_1}f(x_0)}{t}$$

exists, and we denote this limit by $D_{v_{k+1},\dots,v_1}f(x_0)$.

If, for $v_1,\dots,v_k$, $D_{v_k,\dots,v_1}f(x)$ exists for every $x\in U$, we say that f has a directional derivative with respect to $v_1,\dots,v_k$.

Although the notion of a directional derivative is pointwise, if a function has a directional derivative at every point of its domain in the same direction (or directions), this defines a function with the same domain and codomain as the original function.

Definition 1.1.8. Let $f\colon U\subseteq\mathbb{R}^n\longrightarrow\mathbb{R}^m$ and $v_1,\dots,v_k\in\mathbb{R}^n$. If $D_{v_k,\dots,v_1}f(x)$ exists for every $x\in U$, we denote by $D_{v_k,\dots,v_1}f$ the function assigning to each $x\in U$ the value $D_{v_k,\dots,v_1}f(x)$.

This allows us to define higher-order partial derivatives, which have various uses, including polynomial approximations to sufficiently regular functions.

Definition 1.1.9. Let $f\colon U\subseteq\mathbb{R}^n\longrightarrow\mathbb{R}^m$ and $x_0\in U$. Let $\{e_1,\dots,e_n\}$ be the standard basis of $\mathbb{R}^n$, and let $i_1,\dots,i_k\in\{1,\dots,n\}$. If $D_{e_{i_k}\dots e_{i_1}}f(x_0)$ exists, we define the kth partial derivative of f with respect to $x^{i_1},\dots,x^{i_k}$ at x_0, denoted by $\dfrac{\partial^k f}{\partial x_{i_k}\cdots\partial x_{i_1}}(x_0)$, by $\dfrac{\partial^k f}{\partial x_{i_k}\cdots\partial x_{i_1}}(x_0):=D_{e_{i_k}\dots e_{i_1}}f(x_0)$.

If $i_1=\cdots=i_k=i$, we simply denote it by $\dfrac{\partial^k f}{\partial x_i^k}(x_0)$ and call it the kth partial derivative of f with respect to x^i at x_0. The number k is called the ***order of the partial derivative***.

If $k=0$, we simply write $\dfrac{\partial^k f}{\partial x_i^k}(x_0)=f(x_0)$.

Multi-index notation provides a compact way to express the existence of all partial derivatives up to a given order.

Definition 1.1.10. An element $\alpha=(\alpha_1,\dots,\alpha_n)\in\mathbb{N}_0^n$ is called a **multi-index** of length n. Its order is $|\alpha|:=\alpha_1+\cdots+\alpha_n$. If $f\colon U\subseteq\mathbb{R}^n\longrightarrow\mathbb{R}^m$ and the indicated derivatives exist, we write

$$D^\alpha f:=\frac{\partial^{|\alpha|}f}{\partial x_1^{\alpha_1}\cdots\partial x_n^{\alpha_n}},$$

with differentiation understood componentwise when $m>1$, and set $D^0f:=f$. We denote by e_j the multi-index whose entries are all zero except the jth, which equals one. We also set

$$\alpha!:=\alpha_1!\cdots\alpha_n!,\qquad x^\alpha:=(x^1)^{\alpha_1}\cdots(x^n)^{\alpha_n},$$

and write $\beta\le\alpha$ when $\beta_j\le\alpha_j$ for every j.

The class of functions having continuous partial derivatives up to order k will be important in defining differentiable structures.

Definition 1.1.11. (functions of class C^k) Let $U \subseteq \mathbb{R}^n$ be an open set and let $f\colon U \longrightarrow \mathbb{R}^m$. We say that $f \in C^0(U,\mathbb{R}^m)$ if f is continuous. For $k \in \mathbb{N}$, we say that $f \in C^k(U,\mathbb{R}^m)$ if, for every $\alpha \in \mathbb{N}_0^n$ with $|\alpha| \leq k$, the partial derivative $D^\alpha f$ exists on U and is continuous on U. Finally, we say that $f \in C^\infty(U,\mathbb{R}^m)$ if $f \in C^k(U,\mathbb{R}^m)$ for every $k \in \mathbb{N}_0$.
If $x_0 \in U$ and $k \in \mathbb{N}_0 \cup \{\infty\}$, we say that f is of class C^k at x_0 if there is an open neighborhood $V \subseteq U$ of x_0 such that $f\restriction_V \in C^k(V,\mathbb{R}^m)$. Functions of class C^∞ are also called *smooth*.
We write

$$C^k(U,\mathbb{R}^m) := \{f\colon U \longrightarrow \mathbb{R}^m \mid f \text{ is of class } C^k\}.$$

If $m = 1$, we write $C^k(U) := C^k(U,\mathbb{R})$.

The following result, known as the *Clairaut–Schwarz theorem*, gives local conditions under which mixed second partial derivatives commute.

Theorem 1.1.12. (Clairaut–Schwarz) Let $f\colon U \subseteq \mathbb{R}^n \longrightarrow \mathbb{R}^m$ and $x_0 \in U$. Suppose that there exists $r > 0$ such that $B_{\text{euc}}(x_0,r) \subseteq U$. If $i,j \in \{1,\dots,n\}$ and the second partial derivatives $\dfrac{\partial^2 f}{\partial x_i \partial x_j}(x)$ and $\dfrac{\partial^2 f}{\partial x_j \partial x_i}(x)$ exist for every $x \in B_{\text{euc}}(x_0,r)$ and are continuous at x_0, then

$$\frac{\partial^2 f}{\partial x_i \partial x_j}(x_0) = \frac{\partial^2 f}{\partial x_j \partial x_i}(x_0).$$

Proof. It suffices to work componentwise, so we assume that $m = 1$. Let $h,k \neq 0$ be small enough that the rectangle with vertices

$$x_0, \qquad x_0 + he_i, \qquad x_0 + ke_j, \qquad x_0 + he_i + ke_j$$

is contained in $B_{\text{euc}}(x_0,r)$, and define

$$R(h,k) := f(x_0 + he_i + ke_j) - f(x_0 + he_i) - f(x_0 + ke_j) + f(x_0).$$

We apply the mean value theorem, first in the e_i direction to

$$t \longmapsto f(x_0 + te_i + ke_j) - f(x_0 + te_i),$$

and then in the e_j direction. There exist $\theta_{h,k}$ between 0 and h and $\eta_{h,k}$ between 0 and k such that

$$\frac{R(h,k)}{hk} = \partial_j \partial_i f(x_0 + \theta_{h,k} e_i + \eta_{h,k} e_j).$$

Reversing the order of the two applications gives $\widehat{\theta}_{h,k}$ between 0 and h and $\widehat{\eta}_{h,k}$ between 0 and k for which

$$\frac{R(h,k)}{hk} = \partial_i \partial_j f(x_0 + \widehat{\theta}_{h,k} e_i + \widehat{\eta}_{h,k} e_j).$$

As $(h,k) \to (0,0)$, all the intermediate points converge to x_0. Continuity of the two mixed derivatives at x_0 proves the desired equality. □

Corollary 1.1.13. Let $f: U \subseteq \mathbb{R}^n \longrightarrow \mathbb{R}^m$ be of class C^2 at $x_0 \in U$. Then, for any $i, j \in \{1, \ldots, n\}$,

$$\frac{\partial^2 f}{\partial x_i \partial x_j}(x_0) = \frac{\partial^2 f}{\partial x_j \partial x_i}(x_0).$$

Proof. Since f is of class C^2 at x_0, there is a ball centered at x_0 on which both mixed derivatives exist and are continuous. Apply Theorem 1.1.12. □

The preceding notation simplifies higher-order partial derivatives. We give a few examples of its use.

Example 1.1.14. (a) Let $f(x_1, x_2, x_3) = x_1^2 x_2^3 \sin(x_3)$. Consider the multi-index $\alpha = (2, 1, 1)$. Then

$$D^\alpha f = \frac{\partial^4 f}{\partial x_1^2 \partial x_2 \partial x_3}.$$

Differentiating successively, we obtain:

$$\frac{\partial f}{\partial x_3} = x_1^2 x_2^3 \cos(x_3), \quad \frac{\partial}{\partial x_2}\left(\frac{\partial f}{\partial x_3}\right) = 3x_1^2 x_2^2 \cos(x_3),$$

$$\frac{\partial}{\partial x_1}\left(3x_1^2 x_2^2 \cos(x_3)\right) = 6x_1 x_2^2 \cos(x_3), \quad \frac{\partial^2}{\partial x_1^2}\left(3x_1^2 x_2^2 \cos(x_3)\right) = 6x_2^2 \cos(x_3).$$

(b) If $f(x, y) = e^{xy}$ and we use the multi-index $\alpha = (1, 2)$, then

$$D^\alpha f = \frac{\partial^3 f}{\partial x_1 \partial x_2^2} = \frac{\partial^3 f}{\partial x \partial y^2}.$$

We compute:

$$\frac{\partial f}{\partial y} = x e^{xy}, \quad \frac{\partial^2 f}{\partial y^2} = x^2 e^{xy}, \quad \frac{\partial^3 f}{\partial x \partial y^2} = \frac{\partial}{\partial x}(x^2 e^{xy}) = (2x + x^2 y) e^{xy}.$$

(c) Let $f(x_1, x_2) = \ln(1 + x_1^2 + x_2^2)$ and let $\alpha = (1, 1)$. Then

$$D^\alpha f = \frac{\partial^2 f}{\partial x_1 \partial x_2}.$$

We compute:

$$\frac{\partial f}{\partial x_2} = \frac{2x_2}{1 + x_1^2 + x_2^2}, \quad \frac{\partial^2 f}{\partial x_1 \partial x_2} = \frac{\partial}{\partial x_1}\left(\frac{2x_2}{1 + x_1^2 + x_2^2}\right) = \frac{-4x_1 x_2}{(1 + x_1^2 + x_2^2)^2}.$$

(d) If we take the multi-index $\alpha = (0, \ldots, 0, k, 0, \ldots, 0)$ with a k in the ith position, then

$$D^\alpha f(x) = \frac{\partial^k f}{\partial x_i^k}(x),$$

which is simply the derivative of order k with respect to the variable x^i.

We use multi-index notation to present the most important properties of higher-order partial derivatives for sufficiently regular functions. Among the properties we will study is the familiar Leibniz rule for products. It

is useful first to recall the result for functions from $\mathbb{R}$ to $\mathbb{R}$. Its proof uses properties of binomial coefficients, in particular the following result:

Theorem 1.1.15. (Pascal's triangle) For all integers $n \geq 1$ and $1 \leq k \leq n$, the following identity between binomial coefficients holds:

$$\binom{n}{k} = \binom{n-1}{k-1} + \binom{n-1}{k}.$$

This identity reflects the construction of Pascal's triangle: each number is the sum of the two numbers directly above it.

Proof. If $1 \leq k \leq n-1$, then

$$\binom{n-1}{k-1} + \binom{n-1}{k} = \frac{k(n-1)! + (n-k)(n-1)!}{k!(n-k)!} = \frac{n!}{k!(n-k)!} = \binom{n}{k}.$$

For $k = n$, using the convention $\binom{n-1}{n} = 0$, the right-hand side is $\binom{n-1}{n-1} = 1 = \binom{n}{n}$. □

The Leibniz rule states the following:

Theorem 1.1.16. (generalized Leibniz formula) Let $n \in \mathbb{N}$ and $f, g \colon I \subseteq \mathbb{R} \longrightarrow \mathbb{R}$ be n-times differentiable functions. Then fg is n-times differentiable and

$$(fg)^{(n)} = \sum_{k=0}^{n} \binom{n}{k} f^{(k)} g^{(n-k)}.$$

Proof. We proceed by induction on n. The case $n = 1$ states that

$$(fg)' = fg' + f'g,$$

which is the usual product rule. Suppose that the assertion holds for a fixed $n \geq 1$, and now let f and g be $(n+1)$-times differentiable functions. The induction hypothesis gives

$$(fg)^{(n)} = \sum_{k=0}^{n} \binom{n}{k} f^{(k)} g^{(n-k)}.$$

Then

$$\begin{aligned}
(fg)^{(n+1)} &\overset{\text{induction hypothesis}}{=} \left[\sum_{k=0}^{n} \binom{n}{k} f^{(k)} g^{(n-k)} \right]' \\
&= \sum_{k=0}^{n} \binom{n}{k} f^{(k)} g^{(n+1-k)} + \sum_{k=0}^{n} \binom{n}{k} f^{(k+1)} g^{(n-k)} \\
&= \sum_{k=0}^{n} \binom{n}{k} f^{(k)} g^{(n+1-k)} + \sum_{k=1}^{n+1} \binom{n}{k-1} f^{(k)} g^{(n+1-k)}
\end{aligned}$$

$$= \binom{n}{0} f^{(0)} g^{(n+1)} + \sum_{k=1}^{n} \left[\binom{n}{k} + \binom{n}{k-1} \right] f^{(k)} g^{(n+1-k)} + \binom{n}{n} f^{(n+1)} g^{(0)}$$

$$\overset{\text{Theorem 1.1.15}}{=} \binom{n+1}{0} f^{(0)} g^{(n+1)} + \sum_{k=1}^{n} \binom{n+1}{k} f^{(k)} g^{(n+1-k)} + \binom{n+1}{n+1} f^{(n+1)} g^{(0)}$$

$$= \sum_{k=0}^{n+1} \binom{n+1}{k} f^{(k)} g^{(n+1-k)}.$$

Thus the assertion holds for $n+1$, and the principle of induction shows that it holds for every $n \in \mathbb{N}$. □

For functions of class $C^{|\alpha|}$, multi-index notation gives a formula similar to the preceding one. We conclude this section by presenting this formula together with other properties of higher-order derivatives.

Proposition 1.1.17. (Properties of partial derivatives in multi-index notation) Let $\alpha, \beta \in \mathbb{N}_0^n$, $f, g\colon U \subseteq \mathbb{R}^n \longrightarrow \mathbb{R}$ be functions of class $C^{|\alpha|}$, and let $h\colon U \subseteq \mathbb{R}^n \longrightarrow \mathbb{R}$ be a function of class $C^{|\alpha+\beta|}$, where $|\alpha+\beta| = |\alpha|+|\beta|$. Then the following properties hold:

(a) Linearity:
$$D^\alpha(\lambda f + \mu g) = \lambda D^\alpha f + \mu D^\alpha g, \quad \text{for any } \lambda, \mu \in \mathbb{R}.$$

(b) $D^\beta(D^\alpha h) = D^{\alpha+\beta} h = D^\alpha(D^\beta h)$.

(c) Product rule (Leibniz rule):
$$D^\alpha(fg) = \sum_{\beta \le \alpha} \binom{\alpha}{\beta} D^\beta f \cdot D^{\alpha-\beta} g,$$
where $\binom{\alpha}{\beta} = \prod_{i=1}^{n} \binom{\alpha_i}{\beta_i}$ is the binomial coefficient and $\beta \le \alpha$ if and only if $\beta_j \le \alpha_j$ for every $j \in \{1, \dots, n\}$.

Proof. (a) This follows immediately from the linearity of partial derivatives.

(b) Suppose that h is of class $C^{|\alpha|+|\beta|}$. Repeated application of Theorem 1.1.12 to lower-order derivatives allows us to interchange adjacent partial derivatives. Therefore,

$$D^\beta(D^\alpha h) = \frac{\partial^{|\beta|}}{\partial x_1^{\beta_1} \cdots \partial x_n^{\beta_n}} \left(\frac{\partial^{|\alpha|} h}{\partial x_1^{\alpha_1} \cdots \partial x_n^{\alpha_n}} \right) = \frac{\partial^{|\alpha|+|\beta|} h}{\partial x_1^{\beta_1} \cdots \partial x_n^{\beta_n} \partial x_1^{\alpha_1} \cdots \partial x_n^{\alpha_n}}$$

$$= \frac{\partial^{|\alpha+\beta|} h}{\partial x_1^{\alpha_1+\beta_1} \cdots \partial x_n^{\alpha_n+\beta_n}} = D^{\alpha+\beta} h.$$

which is what we wanted to prove. Interchanging α and β in the same calculation and applying the Clairaut–Schwarz theorem again gives $D^\alpha(D^\beta h) = D^{\alpha+\beta} h$.

(c) We proceed by induction on $|\alpha|$. For $|\alpha| = 0$, the sum contains only $\beta = 0$ and the identity is $fg = fg$. Suppose the formula has been proved for all multi-indices of order r, and let $|\alpha| = r+1$. Choose j with $\alpha_j > 0$ and set $\alpha' := \alpha - e_j$. By the induction hypothesis, the usual product rule, and the preceding

item,

$$D^\alpha(fg) = D^{e_j}\left(\sum_{\beta\le\alpha'}\binom{\alpha'}{\beta}D^\beta f\,D^{\alpha'-\beta}g\right)$$
$$= \sum_{\beta\le\alpha'}\binom{\alpha'}{\beta}\left(D^{\beta+e_j}f\,D^{\alpha'-\beta}g + D^\beta f\,D^{\alpha'-\beta+e_j}g\right).$$

In the first sum we set $\delta = \beta + e_j$ and in the second $\delta = \beta$. With the convention that a multi-index coefficient is zero when any component of the lower index is negative or exceeds the corresponding component of the upper index, the coefficient of $D^\delta f\,D^{\alpha-\delta}g$ is

$$\binom{\alpha'}{\delta - e_j} + \binom{\alpha'}{\delta}.$$

The factors corresponding to coordinates other than j agree, and in coordinate j Pascal's identity gives

$$\binom{\alpha_j - 1}{\delta_j - 1} + \binom{\alpha_j - 1}{\delta_j} = \binom{\alpha_j}{\delta_j}.$$

Therefore,

$$D^\alpha(fg) = \sum_{\delta\le\alpha}\binom{\alpha}{\delta}D^\delta f\,D^{\alpha-\delta}g,$$

which completes the induction.

□

Motivated by the multinomial theorem, we can state a version of the Leibniz rule for several factors:

Proposition 1.1.18. (Leibniz rule for several factors) Let $\alpha \in \mathbb{N}_0^n$ and let $m \in \mathbb{N}$ and $f_1, \dots, f_m \colon U \subseteq \mathbb{R}^n \longrightarrow \mathbb{R}$ be functions of class $C^{|\alpha|}$. Then

$$D^\alpha\Big(\prod_{r=1}^m f_r\Big) = \sum_{\substack{\beta_1,\dots,\beta_m\in\mathbb{N}_0^n\\ \beta_1+\cdots+\beta_m=\alpha}} \frac{\alpha!}{\beta_1!\cdots\beta_m!}\prod_{r=1}^m D^{\beta_r}f_r.$$

Proof. We proceed by induction on m. For $m = 2$, the formula is precisely the Leibniz rule in Proposition 1.1.17.

Suppose the assertion holds for m factors and consider $f_1, \dots, f_{m+1}$. Write $F := \prod_{r=1}^m f_r$, so that $\prod_{r=1}^{m+1} f_r = F f_{m+1}$.

Applying the Leibniz rule for two factors,

$$D^\alpha(F f_{m+1}) = \sum_{\gamma\le\alpha}\binom{\alpha}{\gamma}D^\gamma F\,D^{\alpha-\gamma}f_{m+1}.$$

By the induction hypothesis,

$$D^\gamma F = \sum_{\substack{\beta_1,\dots,\beta_m\in\mathbb{N}_0^n\\ \beta_1+\cdots+\beta_m=\gamma}} \frac{\gamma!}{\beta_1!\cdots\beta_m!}\prod_{r=1}^m D^{\beta_r}f_r.$$

Substituting and using $\binom{\alpha}{\gamma}\gamma! = \dfrac{\alpha!}{(\alpha-\gamma)!}$, we obtain

$$D^\alpha\left(\prod_{r=1}^{m+1} f_r\right) = \sum_{\gamma\le\alpha} \sum_{\substack{\beta_1,\dots,\beta_m\in\mathbb{N}_0^n \\ \beta_1+\cdots+\beta_m=\gamma}} \frac{\alpha!}{\beta_1!\cdots\beta_m!(\alpha-\gamma)!}\left(\prod_{r=1}^{m} D^{\beta_r} f_r\right) D^{\alpha-\gamma} f_{m+1}.$$

Now define

$$\beta_{m+1} := \alpha - \gamma.$$

Since $\gamma \le \alpha$, we have $\beta_{m+1} \in \mathbb{N}_0^n$ and, conversely, given any family $\beta_1,\dots,\beta_{m+1} \in \mathbb{N}_0^n$ such that

$$\beta_1 + \cdots + \beta_{m+1} = \alpha,$$

if we set

$$\gamma := \beta_1 + \cdots + \beta_m,$$

then $\gamma \le \alpha$ and $\beta_{m+1} = \alpha - \gamma$. This correspondence is a bijection between the pairs

$$(\gamma, \beta_1, \dots, \beta_m) \quad \text{with} \quad \beta_1 + \cdots + \beta_m = \gamma \le \alpha$$

and the families

$$(\beta_1, \dots, \beta_{m+1}) \quad \text{with} \quad \beta_1 + \cdots + \beta_{m+1} = \alpha.$$

Reindexing the sum by this bijection gives

$$D^\alpha\left(\prod_{r=1}^{m+1} f_r\right) = \sum_{\substack{\beta_1,\dots,\beta_{m+1}\in\mathbb{N}_0^n \\ \beta_1+\cdots+\beta_{m+1}=\alpha}} \frac{\alpha!}{\beta_1!\cdots\beta_{m+1}!}\prod_{r=1}^{m+1} D^{\beta_r} f_r,$$

which completes the induction.

□

The following multi-index form of the chain rule gives explicit control over the partial derivatives of a composition.

Theorem 1.1.19. (Faà di Bruno formula for multi-indices) Let $f\colon U \subseteq \mathbb{R}^n \longrightarrow \mathbb{R}^m$ and $g\colon V \subseteq \mathbb{R}^m \longrightarrow \mathbb{R}$, with $f(U) \subseteq V$, both be of class C^k. Write $f = (f_1,\dots,f_m)$. Then $g\circ f$ is of class C^k and, for $x_0 \in U$ and $\alpha \in \mathbb{N}_0^n$ with $1 \le |\alpha| \le k$,

$$D^\alpha(g\circ f)(x_0) = \sum_{\substack{\beta\in\mathbb{N}_0^m,\ 1\le|\beta|\le|\alpha| \\ \gamma=(\gamma_1,\dots,\gamma_{|\beta|}),\ \gamma_i\in\mathbb{N}_0^n,\ |\gamma_i|>0,\ \sum_{i=1}^{|\beta|}\gamma_i=\alpha \\ l=(l_1,\dots,l_{|\beta|}),\ l_i\in\{1,\dots,m\} \\ \#\{i\mid l_i=j\}=\beta_j,\ 1\le j\le m}} c_{\alpha,\beta,\gamma,l} D^\beta g(f(x_0)) \prod_{i=1}^{|\beta|} D^{\gamma_i} f_{l_i}(x_0).$$

The coefficients $c_{\alpha,\beta,\gamma,l}$ are nonnegative combinatorial constants depending only on the indicated indices.

Proof. We proceed by induction on $q := |\alpha|$. If $q = 1$, there exists $r \in \{1, \dots, n\}$ with $\alpha = e_r$, and the chain rule gives

$$D^{e_r}(g \circ f)(x_0) = \sum_{j=1}^{m} (D^{e_j} g)(f(x_0)) D^{e_r} f_j(x_0).$$

This is the formula in the statement with $\beta = e_j$, $\gamma = (e_r)$, $l = (j)$, and coefficient 1.
Suppose the assertion holds for multi-indices of length q, and let α' have length $q+1$. Choose r with $\alpha'_r > 0$ and set $\alpha = \alpha' - e_r$. Each term in the inductive formula has the form

$$c\,(D^{\beta} g)(f(x)) \prod_{a=1}^{|\beta|} D^{\gamma_a} f_{l_a}(x), \qquad \sum_{a=1}^{|\beta|} \gamma_a = \alpha.$$

Differentiating with respect to x^r, the derivative of the first factor yields

$$c \sum_{j=1}^{m} (D^{\beta + e_j} g)(f(x)) D^{e_r} f_j(x) \prod_{a=1}^{|\beta|} D^{\gamma_a} f_{l_a}(x).$$

This adds e_r to the family (γ_a), adds j to (l_a), and replaces β by $\beta + e_j$. If the derivative acts on the factor with index a, it yields

$$c\,(D^{\beta} g)(f(x)) D^{\gamma_a + e_r} f_{l_a}(x) \prod_{\substack{b=1 \\ b \neq a}}^{|\beta|} D^{\gamma_b} f_{l_b}(x).$$

Here γ_a is replaced by $\gamma_a + e_r$. In both cases, the new multi-indices sum to α', and all the restrictions in the statement are preserved. Like terms are collected; their coefficients are added and remain nonnegative combinatorial constants. This completes the induction. The same construction shows, order by order, that the resulting derivatives are continuous, so $g \circ f$ is of class C^k. □

1.2 Smooth manifolds

A smooth manifold formalizes the idea of a space that may be globally curved or topologically complicated, yet admits Euclidean coordinates around each point. The sphere and the torus are familiar examples: no single chart describes either one completely, but every sufficiently small region can be compared with an open subset of the plane.

The dimension of these spaces is intrinsic. Although the usual sphere is drawn inside $\mathbb{R}^3$, only two local coordinates are needed to move along it. Requiring a space to be locally homeomorphic to an open subset of $\mathbb{R}^n$ captures this topological observation; requiring smooth compatibility between charts then makes it possible to transport calculus. This concept is fundamental in nonlinear analysis, since many partial differential equations and variational problems are naturally formulated on spaces that are not open subsets of $\mathbb{R}^n$. For example:

- Models in mathematical physics whose domain is a curved surface or a space with variable curvature (waves on the sphere, diffusion on the torus).
- Problems in differential geometry involving the boundary of a manifold, such as trace theorems for Sobolev functions defined on the boundary.

Élie Cartan (1869–1951)

Figure 1.2. Élie Cartan was a central figure in the development of modern differential geometry. His work on differential forms, moving frames, connections, and curvature made decisive contributions to the intrinsic study of manifolds and established part of the language that now underlies Riemannian geometry and global analysis.

- Elliptic and parabolic equations on compact spaces with or without boundary, where the Riemannian metric directly influences the differential operators.

The notion of a smooth manifold allows us to extend differential calculus to these settings. Once manifolds are equipped with a Riemannian metric, we will have the tools to define gradients, divergences, Laplacians, and elliptic operators intrinsically. This will allow us to develop the study of Sobolev spaces on manifolds, state and prove trace theorems, and analyze partial differential equations in a general geometric setting.

We will present the modern definition of a *differentiable manifold*, first introducing several preliminary concepts.

Definition 1.2.1. Let M be a topological space. We say that M is a **topological manifold without boundary of dimension** n if:

(a) M is Hausdorff.

(b) M is second countable.

(c) For every $p \in M$, there exist an open set $U \subseteq M$ and a homeomorphism $\varphi\colon U \longrightarrow \varphi(U)$, where $\varphi(U) \subseteq \mathbb{R}^n$ is open (M is locally homeomorphic to $\mathbb{R}^n$), such that $p \in U$.

To become familiar with the property of *being locally homeomorphic to* $\mathbb{R}^n$, it is useful to consider the following picture:

Remark 1.2.2. To simplify notation, the open set U and the homeomorphism

$$\varphi\colon U \longrightarrow \varphi(U) \subseteq \mathbb{R}^n$$

are usually considered together as an ordered pair (U,φ), called a *coordinate chart*, or simply a *chart*.

The topological structure captures the locally Euclidean character of the space, but does not yet allow differentiation. To transport calculus between charts, we must require the changes of coordinates to be smooth. A compatible atlas thus assembles the local information into a coherent global structure.

Definition 1.2.3. Let M be a topological manifold without boundary of dimension n.

(a) We say that two charts (U,φ) and (V,ψ) are smoothly compatible if $U \cap V = \varnothing$ or if the transition map

$$\psi \circ \varphi^{-1}\colon \varphi(U \cap V) \longrightarrow \psi(U \cap V)$$

is a diffeomorphism of class C^∞ (henceforth called smooth).

(b) An atlas for M is a collection of charts $\mathcal{A}$ such that $\bigcup_{(U,\varphi)\in\mathcal{A}} U = M$.

(c) A smooth atlas is an atlas $\mathcal{A}$ such that any two charts in $\mathcal{A}$ are smoothly compatible.

(d) A smooth structure on M is a smooth atlas $\mathcal{A}$ maximal with respect to $\subseteq$ among the smooth atlases of M.

We can now define a *differentiable manifold (or smooth manifold)*:

Definition 1.2.4. A smooth manifold without boundary of dimension n is a topological manifold M of dimension n equipped with a smooth structure $\mathcal{A}$. We write $(M,\mathcal{A})$ when we wish to refer explicitly to the smooth structure.

Remark 1.2.5. We can also define manifolds without boundary of class C^k by requiring the transition maps

$$\psi \circ \varphi^{-1}\colon \varphi(U \cap V) \longrightarrow \psi(U \cap V)$$

to be diffeomorphisms of class C^k, that is, functions of class C^k whose inverses are of class C^k.

Topological manifolds (and therefore smooth manifolds) have several interesting topological properties:

Proposition 1.2.6. Let M be a topological manifold without boundary.

(a) M is locally path connected.

(b) M is connected if and only if it is path connected.

(c) The connected components of M coincide with its path components.

(d) M has countably many connected components, each of which is an open subset of M and a connected topological manifold.

Proof. Let $p \in M$ and let U be an open neighborhood of p. Choose a chart (V, φ) with $p \in V$. The open set $\varphi(U \cap V)$ contains an open Euclidean ball B centered at $\varphi(p)$. Then $\varphi^{-1}(B)$ is a neighborhood of p, is contained in U, and is path connected because B is convex. This proves (1).
Now fix $p \in M$ and let C_p be the set of points that can be joined to p by a path. By (1), C_p is open. The same argument at each point of $M \setminus C_p$ shows that its complement is also open. If M is connected, it follows that $C_p = M$. Since every path connected space is connected, this proves (2). Applying (2) to each connected component gives (3), and local path connectedness also shows that every component is open.
Finally, let $\mathcal{B}$ be a countable basis for M. Each connected component C is open and nonempty, and therefore contains some nonempty basis element $B_C \in \mathcal{B}$. Distinct components contain distinct basis elements, since they are disjoint; hence the family of components is countable. Restricting the charts of M makes each component a connected topological manifold. This proves (4). □

Manifolds are also locally compact:

Proposition 1.2.7. Every topological manifold with or without boundary is locally compact.

Proof. Let $p \in M$ and choose a chart $\varphi\colon U \to \varphi(U) \subseteq \mathbb{H}^n$ around p, where $\mathbb{H}^n = \mathbb{R}^n$ if M has no boundary. Since $\varphi(U)$ is open in $\mathbb{H}^n$, there exists $r > 0$ such that

$$\overline{B}_{\text{euc}}(\varphi(p), r) \cap \mathbb{H}^n \subseteq \varphi(U).$$

The preimage

$$K := \varphi^{-1}\left(\overline{B}_{\text{euc}}(\varphi(p), r) \cap \mathbb{H}^n\right)$$

is compact, since it is homeomorphic to a closed and bounded subset of $\mathbb{R}^n$, and it contains the relatively open neighborhood

$$\varphi^{-1}\left(B_{\text{euc}}(\varphi(p), r) \cap \mathbb{H}^n\right)$$

of p. □

Another covering property of manifolds is paracompactness, which will be very useful in geometric analysis:

Theorem 1.2.8. (Manifolds are paracompact) Let (M, τ_M) be a topological manifold with or without boundary. Given an open cover $\mathcal{U} \subseteq \tau_M$ of M and any basis $\mathcal{B}$ for τ_M, there exists a countable, locally finite open refinement of $\mathcal{U}$ consisting of elements of $\mathcal{B}$.

Proof. We first construct a compact exhaustion. Since M is locally compact and second countable, it has a countable basis $(V_j)_{j\geq 1}$ of precompact open sets. Set $K_0 := \varnothing$ and $K_1 := \overline{V}_1$. Once K_j has been constructed, each point of the compact set $K_j \cup \overline{V}_{j+1}$ has a precompact open neighborhood. A finite subcover of these neighborhoods has union W, and the union of their closures defines a compact set K_{j+1} satisfying

$$K_j \cup \overline{V}_{j+1} \subseteq W \subseteq \operatorname{Int} K_{j+1}.$$

Recursively, we obtain compact sets $(K_j)_{j\geq 1}$ such that

$$K_j \subseteq \operatorname{Int} K_{j+1}, \qquad V_1 \cup \cdots \cup V_j \subseteq K_j.$$

Since the sets V_j cover M, we have $M = \bigcup_{j\geq 1} K_j$.

Define

$$C_0 := K_1, \qquad W_0 := \operatorname{Int} K_2,$$

and, for $j \geq 1$,

$$C_j := K_{j+1} \setminus \operatorname{Int} K_j, \qquad W_j := \operatorname{Int} K_{j+2} \setminus K_{j-1}.$$

Each C_j is compact and contained in W_j. For $j \geq 0$ and $x \in C_j$, choose $U_x \in \mathcal{U}$ with $x \in U_x$ and, since $\mathcal{B}$ is a basis, an element $B_x \in \mathcal{B}$ such that

$$x \in B_x \subseteq U_x \cap W_j.$$

Compactness of C_j allows us to retain finitely many of these open sets. The union of the finite families obtained for $j = 0, 1, 2, \ldots$ is countable and refines $\mathcal{U}$.

We show that this family covers M. Given $x \in M$, there exists $j \geq 0$ such that $x \in \operatorname{Int} K_{j+1}$; choose the smallest such index. If $j = 0$, then $x \in C_0$. If $j \geq 1$, minimality implies $x \notin \operatorname{Int} K_j$, while $x \in K_{j+1}$, and therefore $x \in C_j$.

It remains to verify local finiteness. Let $x \in M$ and choose $N \geq 1$ with $x \in \operatorname{Int} K_N$. If $j \geq N+1$, then $K_N \subseteq K_{j-1}$ and

$$\operatorname{Int} K_N \cap W_j = \varnothing.$$

Thus the neighborhood $\operatorname{Int} K_N$ of x can intersect only elements arising from the indices $0, \ldots, N$, and for each of these we chose a finite family. The refinement is locally finite.

The proof uses only the fact that charts provide a basis of precompact open sets; it therefore applies unchanged to charts taking values in relatively open subsets of $\mathbb{H}^n$. □

Various coordinate systems can be defined on a smooth manifold. Among them is the notion of a *regular coordinate ball*, which generalizes the notion of a *ball* in Euclidean spaces to manifolds.

Definition 1.2.9. If M is a smooth manifold without boundary, we use the following terminology:

(a) $B \subseteq M$ is a coordinate ball centered at x (or at $\varphi^{-1}(x)$) if there exists a homeomorphism $\varphi\colon B \longrightarrow B_{\mathrm{euc}}(x, r)$, where

$$B_{\mathrm{euc}}(x, r) := \{y \in \mathbb{R}^n \mid \|y - x\| < r\},$$

for some $r > 0$ and $x \in \mathbb{R}^n$, such that (B, φ) is a smooth chart of M.

(b) $B \subseteq M$ is a regular coordinate ball (centered at x) if there exists a coordinate ball B' such that $\overline{B} \subseteq B'$ and there is a smooth coordinate map $\varphi\colon B' \longrightarrow \mathbb{R}^n$ such that, for some positive numbers $r' > r > 0$, we have $\varphi(B) = B_{\mathrm{euc}}(x, r)$, $\varphi(\overline{B}) = \overline{B}_{\mathrm{euc}}(x, r)$, and $\varphi(B') = B_{\mathrm{euc}}(x, r')$.

If M has boundary, we use the same terminology, replacing Euclidean balls by the relative balls $B_{\mathrm{euc}}(x, r) \cap \mathbb{H}^n$ in a boundary chart and taking closures in $\mathbb{H}^n$.

Remark 1.2.10. Every regular coordinate ball (B, φ) has the property that $\overline{B}$ is compact and φ extends to $\overline{B}$. We will call domains of this type ***compact regular coordinate balls***.

Regular coordinate balls are important because of their topological properties. Moreover, every smooth manifold admits a countable atlas of regular coordinate balls, as the following proposition shows:

Figure 1.3. A precompact regular coordinate ball whose coordinate map extends to the boundary.

Proposition 1.2.11. Every smooth manifold with or without boundary has a countable basis of regular coordinate balls, and therefore admits a countable, locally finite open cover by regular coordinate balls.

Proof. By second countability, we extract a countable subcover from the cover by chart domains. Within each coordinate image, we take Euclidean balls, or half-balls in a boundary chart, with rational centers and radii, whose closures lie in slightly larger balls in the same coordinate domain. Their preimages form a countable family of regular coordinate balls and constitute a basis for M. Applying Theorem 1.2.8 to this basis and to the cover $\{M\}$ gives a countable, locally finite subfamily covering M. □

Finally, to complete the definitions in this section, we specify the appropriate model for a manifold with boundary:

$$\mathbb{H}^n := \mathbb{R}^{n-1} \times [0,\infty), \qquad \operatorname{Int} \mathbb{H}^n = \mathbb{R}^{n-1} \times (0,\infty), \qquad \partial \mathbb{H}^n = \mathbb{R}^{n-1} \times \{0\}.$$

All open subsets of $\mathbb{H}^n$ are understood in the relative topology. A function defined on one of them is smooth if, in a neighborhood of each point, it is the restriction of a smooth function defined on an open subset of $\mathbb{R}^n$.

Definition 1.2.12. Let M be a topological space.

(a) We say that M is a **topological manifold with boundary of dimension** n if it is Hausdorff and second countable, and each point has an open neighborhood homeomorphic to a relatively open subset of $\mathbb{H}^n$.

(b) A chart for M is a pair (U,φ), where $U \subseteq M$ is open and $\varphi\colon U \longrightarrow \varphi(U) \subseteq \mathbb{H}^n$ is a homeomorphism onto a relatively open subset.

(c) A chart (U,φ) is an **interior chart** if $\varphi(U) \subseteq \operatorname{Int} \mathbb{H}^n$; in that case, its image is an open subset of $\mathbb{R}^n$. It is a **boundary chart** if $\varphi(U) \cap \partial \mathbb{H}^n \neq \varnothing$. The domain of a boundary chart may contain both interior and boundary points.

(d) An atlas for M is a collection of charts $\mathcal{A}$ such that $\bigcup_{(U,\varphi)\in\mathcal{A}} U = M$.

Compatibility and maximality for charts of a manifold with boundary are defined as follows:

Definition 1.2.13. Let M be a topological manifold with boundary of dimension n.

(a) We say that two charts (U,φ) and (V,ψ) are smoothly compatible if $U\cap V=\varnothing$ or if the transition map

$$\psi\circ\varphi^{-1}\colon \varphi(U\cap V)\longrightarrow \psi(U\cap V)$$

is a diffeomorphism of class C^∞.

(b) A smooth atlas is an atlas $\mathcal{A}$ such that any two charts in $\mathcal{A}$ are smoothly compatible.

(c) A smooth structure on M is a smooth atlas $\mathcal{A}$ maximal with respect to $\subseteq$ among the smooth atlases of M.

Definition 1.2.14. A smooth manifold with boundary of dimension n is a topological manifold with boundary of dimension n equipped with a smooth structure.

Theorem 1.2.15. (Smooth invariance of the boundary) Let (U,φ) and (V,ψ) be smoothly compatible charts of a manifold with boundary, and let $p\in U\cap V$. Then

$$\varphi(p)\in\partial\mathbb{H}^n \quad\Longleftrightarrow\quad \psi(p)\in\partial\mathbb{H}^n.$$

Consequently, the notions of interior point and boundary point obtained by examining the image of a point do not depend on the chart.

The proof follows the strategy of Lee [94].

Proof. Suppose, by contradiction, that $x:=\varphi(p)$ is interior and that $y:=\psi(p)$ belongs to $\partial\mathbb{H}^n$. Restricting the charts, we may take a Euclidean ball B around x, contained in $\varphi(U\cap V)\cap\operatorname{Int}\mathbb{H}^n$. The change of coordinates

$$F:=\psi\circ\varphi^{-1}\colon B\longrightarrow\mathbb{H}^n$$

is smooth, and its inverse admits a smooth extension near y to an open subset of $\mathbb{R}^n$. The identity $F^{-1}\circ F=\mathrm{Id}$ on B and the chain rule show that dF_x has a left inverse; since its domain and codomain have dimension n, dF_x is invertible. The inverse function theorem implies that $F(B)$ contains a Euclidean neighborhood of y. This is impossible because $F(B)\subseteq\mathbb{H}^n$ and no Euclidean neighborhood of a point of $\partial\mathbb{H}^n$ is contained in $\mathbb{H}^n$. Interchanging the charts rules out the opposite possibility. □

Definition 1.2.16. Let M be a smooth manifold with boundary. A point $p\in M$ is an **interior point** if $\varphi(p)\in\operatorname{Int}\mathbb{H}^n$ in one —and, by the preceding theorem, in every— chart containing it. It is a **boundary point** if $\varphi(p)\in\partial\mathbb{H}^n$. We denote the corresponding sets by $\operatorname{Int}M$ and ∂M.
A boundary chart is **centered at** $p\in\partial M$ if, after a translation in the first $n-1$ coordinates, $\varphi(p)=0$. This condition concerns the image of the distinguished point; it does not mean that the entire chart domain

consists of boundary points.

Remark 1.2.17. (Convention for finite-dimensional manifolds) Throughout the finite-dimensional treatment, the term manifold includes the Hausdorff and second countability assumptions in the preceding definitions; we will not repeat them in every statement.

Remark 1.2.18. The following properties hold:

(a) The boundary ∂M and the interior $\operatorname{Int} M$ are disjoint and their union is M. Moreover, $\operatorname{Int} M$ is open and ∂M is closed.

(b) A smooth manifold may be regarded as the special case of a smooth manifold with empty boundary, or one in which every point of M is an interior point.

The abstract definition is especially useful when a space is constructed by gluing local models. The following lemma collects the conditions under which a family of coordinates uniquely determines the topology and smooth structure of the resulting set.

Lemma 1.2.19. (Smooth chart lemma) Let M be a set, and suppose we have a collection $\{U_\alpha\}_{\alpha\in A}$ of subsets of M and maps $\varphi_\alpha\colon U_\alpha \longrightarrow \mathbb{R}^n$ (or $\varphi_\alpha\colon U_\alpha \longrightarrow \mathbb{H}^n$) such that:

(a) For each $\alpha \in A$, φ_α is a bijection between U_α and an open subset $\varphi_\alpha(U_\alpha) \subseteq \mathbb{R}^n$ (or a relatively open subset $\varphi_\alpha(U_\alpha) \subseteq \mathbb{H}^n$).

(b) For each $\alpha, \beta \in A$, the sets $\varphi_\alpha(U_\alpha \cap U_\beta)$ and $\varphi_\beta(U_\alpha \cap U_\beta)$ are open in $\mathbb{R}^n$ (or relatively open in $\mathbb{H}^n$).

(c) If $U_\alpha \cap U_\beta \neq \varnothing$, the map $\varphi_\beta \circ \varphi_\alpha^{-1}\colon \varphi_\alpha(U_\alpha \cap U_\beta) \longrightarrow \varphi_\beta(U_\alpha \cap U_\beta)$ is smooth.

(d) There exists a countable $N \subseteq A$ such that $M = \bigcup_{\alpha\in N} U_\alpha$.

(e) If $p, q \in M$ and $p \neq q$, then either there exists $\alpha \in A$ such that $p, q \in U_\alpha$, or there exist $\alpha, \beta \in A$ such that $U_\alpha \cap U_\beta = \varnothing$ with $p \in U_\alpha$ and $q \in U_\beta$.

Then M has a unique topology and a unique smooth structure such that M is a smooth manifold (with boundary) and $(U_\alpha, \varphi_\alpha)$ is a smooth chart for every $\alpha \in A$.

Proof. We write $\mathbb{E}^n$ for the appropriate model space, $\mathbb{R}^n$ or $\mathbb{H}^n$, always using the relative topology in the latter case. Consider the family

$$\mathcal{C} := \left\{ \varphi_\alpha^{-1}(V) \,\middle|\, \alpha \in A,\ V \subseteq \varphi_\alpha(U_\alpha) \text{ open} \right\}.$$

This family covers M. If p belongs to $\varphi_\alpha^{-1}(V)\cap\varphi_\beta^{-1}(W)$, then

$$\varphi_\alpha^{-1}(V)\cap\varphi_\beta^{-1}(W)=\varphi_\alpha^{-1}\left(V\cap(\varphi_\beta\circ\varphi_\alpha^{-1})^{-1}(W)\right).$$

The set in parentheses is open in $\varphi_\alpha(U_\alpha)$: we first restrict to the open set $\varphi_\alpha(U_\alpha\cap U_\beta)$ and then use continuity of the change of coordinates. Therefore, $\mathcal{C}$ is a basis for a topology τ on M.
By construction, each U_α is open and φ_α is a homeomorphism from U_α onto its image. We show that (M,τ) is Hausdorff. If two distinct points p,q belong to the same U_α, we separate their images in the Hausdorff space $\mathbb{E}^n$ and take preimages. If we do not use a common chart, the last assumption provides disjoint domains U_α and U_β containing p and q, respectively. In both cases we obtain disjoint open neighborhoods.
Let $N\subseteq A$ be countable, as in the fourth assumption. Each $\varphi_\alpha(U_\alpha)$, with $\alpha\in N$, has a countable basis; the preimages of all these bases form a countable family. This is a basis for M, since the sets U_α, $\alpha\in N$, cover the space. Thus (M,τ) is second countable and locally Euclidean, or locally modeled on $\mathbb{H}^n$.
For $U_\alpha\cap U_\beta\neq\varnothing$, the third assumption, together with the same assumption with α and β interchanged, shows that $\varphi_\beta\circ\varphi_\alpha^{-1}$ is a diffeomorphism between the corresponding open sets. The given charts therefore form a smooth atlas. The maximal atlas containing it defines a smooth structure on M. In the case of $\mathbb{H}^n$, the same construction yields boundary charts, and all local extensions involved in the notion of smoothness are taken on open subsets of $\mathbb{R}^n$; thus the argument also covers manifolds with boundary.
Finally, any other topology making all the maps φ_α homeomorphisms onto their images would necessarily have $\mathcal{C}$ as a basis, and would therefore coincide with τ. A smooth structure for which the given charts were smooth would have the same maximal atlas, since a chart belongs to this atlas if and only if it is smoothly compatible with every chart φ_α. This proves both uniqueness assertions. □

1.3 Smooth maps

A smooth structure allows us not only to discuss functions on a manifold, but also to compare manifolds through maps that respect calculus. The condition is checked in coordinates, but its validity must be independent of the chosen charts.

Given charts around a point and its image, the map temporarily becomes a function between Euclidean open sets. We require this coordinate representation to be smooth. Compatibility of the atlases ensures that the definition does not depend on the pair of charts used.

Definition 1.3.1. Let M and N be smooth manifolds with or without boundary, and let $F\colon M\longrightarrow N$ be a function. We say that F is a smooth map if, for every $p\in M$, there exist coordinate charts (U,φ) and (V,ψ) containing p and $F(p)$, respectively, such that $F(U)\subseteq V$ and the map $\psi\circ F\circ\varphi^{-1}$ is a smooth function from $\varphi(U)$ to $\psi(V)$.
We say that the map is of class C^k if $\psi\circ F\circ\varphi^{-1}$ is of class C^k.

Definition 1.3.2. If M and N are smooth manifolds with or without boundary and $k\in\mathbb{N}\cup\{\infty\}$, we write $C^k(M,N):=\{f:M\longrightarrow N\mid f \text{ is of class } C^k\}$. If $N=\mathbb{R}$, we simply write $C^k(M):=C^k(M,\mathbb{R})$.

Remark 1.3.3. The function $\psi\circ F\circ\varphi^{-1}$ is called the *coordinate representation of* F and is sometimes denoted by $\hat{F}:=\psi\circ F\circ\varphi^{-1}$.

A partition of unity turns local constructions into global objects while retaining control over supports. It will be our basic tool for gluing functions, metrics, sections, and estimates defined in different charts.

Definition 1.3.4. Let M be a topological space and let $\mathscr{U} = \{U_\alpha \mid \alpha \in J\}$ be an open cover of M. A partition of unity subordinate to $\mathscr{U}$ is a family of continuous functions $(\psi_\alpha)_{\alpha\in J}$, $\psi_\alpha : M \longrightarrow \mathbb{R}$, such that:

(a) $0 \le \psi_\alpha(x) \le 1$ for every $\alpha \in J$ and every $x \in M$.

(b) $\operatorname{supp}(\psi_\alpha) \subseteq U_\alpha$ for each $\alpha \in J$.

(c) The family $(\operatorname{supp}(\psi_\alpha))_{\alpha\in J}$ is locally finite.

(d) $\sum_{\alpha\in J} \psi_\alpha(x) = 1$ for each $x \in M$.

We have the following well-known result.

Theorem 1.3.5. (Existence of partitions of unity) Suppose that M is a smooth manifold with or without boundary and that $\mathscr{U} = (U_\alpha)_{\alpha\in J}$ is an open cover of M. Then there exists a partition of unity consisting of smooth functions and subordinate to $\mathscr{U}$.

Proof. We apply the construction in Theorem 1.2.8, choosing, in each of the compact sets occurring in its proof, two concentric regular coordinate balls

$$B_i \Subset B_i' \Subset U_{a(i)}, \qquad a(i) \in J,$$

so that the inner balls $(B_i)_{i\ge1}$ cover M and the family of outer balls $(B_i')_{i\ge1}$ is locally finite. To do this, for each point of the corresponding compact set we choose a ball whose closure is contained in another ball in the same coordinate domain, and then take a finite subcover. Since the outer balls remain within the open sets W_j used in that proof, local finiteness is preserved.
Recall the elementary construction of a cutoff function. Let

$$\vartheta(t) := \begin{cases} e^{-\frac{1}{t}}, & t > 0, \\ 0, & t \le 0. \end{cases}$$

All its derivatives at the origin vanish, so ϑ is smooth. If $0 < r < R_0 < R$, the function

$$\chi_{r,R_0}(x) := \frac{\vartheta(R_0^2 - \|x\|^2)}{\vartheta(R_0^2 - \|x\|^2) + \vartheta(\|x\|^2 - r^2)}$$

is smooth, equals one on $\overline{B}_{\text{euc}}(0,r)$, and has support contained in $\overline{B}_{\text{euc}}(0,R_0) \subset B_{\text{euc}}(0,R)$. The denominator never vanishes. After translating the center in coordinates, restricting this function to $\mathbb{H}^n$ gives the same construction for a relative ball in a boundary chart.
Transporting these functions through the charts and extending them by zero, we obtain $f_i \in C^\infty(M)$ such that

$$0 \le f_i \le 1, \qquad f_i = 1 \text{ on } \overline{B}_i, \qquad \operatorname{supp} f_i \subseteq B_i'.$$

The extension is smooth because the support of the coordinate expression is contained in the interior of B_i'. The family of supports is locally finite, so

$$f := \sum_{i=1}^{\infty} f_i$$

is a smooth function. Since the sets B_i cover M, we have $f > 0$. Hence $g_i := \frac{f_i}{f}$ is smooth, the family $(\operatorname{supp} g_i)$ is locally finite, and $\sum_{i=1}^{\infty} g_i = 1$.
For $\alpha \in J$, define

$$\psi_\alpha := \sum_{\substack{i \in \mathbb{N} \\ a(i) = \alpha}} g_i,$$

interpreting the sum as zero if there are no corresponding indices. All these sums are locally finite. Moreover, the union of the supports appearing in each ψ_α is closed by local finiteness and is contained in U_α; consequently, $\operatorname{supp} \psi_\alpha \subseteq U_\alpha$. It is immediate that $0 \le \psi_\alpha \le 1$ and that $\sum_{\alpha \in J} \psi_\alpha = 1$. We have constructed the subordinate partition. Restricting the Euclidean cutoff functions directly proves the case with boundary. □

The existence of partitions of unity has the following important consequence:

Proposition 1.3.6. (Existence of bump functions) Let M be a smooth manifold with or without boundary. For any closed set $A \subseteq M$ and any open set $U \subseteq M$ such that $A \subseteq U$, there exists a smooth function $\psi \colon M \longrightarrow \mathbb{R}$ such that $0 \le \psi \le 1$, $\psi \equiv 1$ on A, and $\operatorname{supp}(\psi) \subseteq U$.

Proof. Apply Theorem 1.3.5 to the cover $\{U, M \setminus A\}$. Let (ψ_0, ψ_1) be a subordinate partition, with $\operatorname{supp} \psi_0 \subseteq U$ and $\operatorname{supp} \psi_1 \subseteq M \setminus A$. On A we have $\psi_1 = 0$ and, since $\psi_0 + \psi_1 = 1$, we have $\psi_0 = 1$. Therefore, $\psi := \psi_0$ has all the required properties. □

This result allows us to extend smooth functions defined in a neighborhood of a given point to all of M as follows:

Theorem 1.3.7. (Extension of smooth functions) Let M be a smooth manifold with or without boundary and let $U \subseteq M$ be open. If $p \in U$ and $f \in C^\infty(U)$, then there exist an open set $W \subseteq M$ such that $p \in W \subseteq \overline{W} \subseteq U$ and a smooth function $\tilde{f} \colon M \longrightarrow \mathbb{R}$ such that $\tilde{f} \restriction_W = f$.

Proof. Let $U \subseteq M$ be open, and let $p \in U$ and $f \in C^\infty(U)$. Since M is a regular topological space, there exists an open set $W \subseteq M$ such that $p \in W \subseteq \overline{W} \subseteq U$. By Proposition 1.3.6, there exists a smooth function $\psi\colon M \longrightarrow \mathbb{R}$ such that $0 \leq \psi \leq 1$, $\psi \equiv 1$ on $\overline{W}$, and $\operatorname{supp}(\psi) \subseteq U$. Define

$$\tilde{f}\colon M \longrightarrow \mathbb{R}, \qquad \tilde{f}(q) = \begin{cases} \psi f(q) & \text{if } q \in U \\ 0 & \text{if } q \notin U \end{cases}.$$

Then $\tilde{f}$ is smooth because $\operatorname{supp}(\psi) \subseteq U$ and $\tilde{f}\restriction_W = f$. □

1.4 The tangent bundle

Approximating a nonlinear object by linear data is one of the central ideas of analysis. In Example 1.1.5, we saw that the graph of a differentiable function is approximated near each point by its tangent plane. On an abstract manifold, we need to preserve this intuition without relying on an ambient space.

In multivariable calculus, many manifolds can be described locally as the image of a *parametrization*

$$\psi\colon \widetilde{U} \subset \mathbb{R}^k \longrightarrow \mathbb{R}^n,$$

where $\widetilde{U} \subseteq \mathbb{R}^k$ is open, $k \leq n$, and $d\psi_x$ has rank k for each $x \in \widetilde{U}$. For example, the sphere, cylinder, and torus admit descriptions of this kind in small neighborhoods of each point.

Fix $x_0 \in \widetilde{U}$ and let $p = \psi(x_0)$. The Fréchet derivative of ψ at x_0,

$$\mathrm{d}\psi_{x_0}\colon \mathbb{R}^k \longrightarrow \mathbb{R}^n,$$

is a linear map that describes how the coordinates of $\mathbb{R}^n$ change when we vary the coordinates of $\widetilde{U}$ slightly around x_0. The image of $\mathrm{d}\psi_{x_0}$ is a vector subspace of $\mathbb{R}^n$ of dimension k that "best approximates" $\psi(\widetilde{U})$ near p. The following example illustrates this:

Example 1.4.1. Consider the parametrization $\psi\colon \mathbb{R}^2 \longrightarrow \mathbb{R}^3$ given by

$$\psi(x, y) = (\cos x,\ \sin x,\ y).$$

This function describes a cylinder of radius 1 in $\mathbb{R}^3$. Fix $x_0 = (0, 0)$, so that $p = (1, 0, 0)$. The Fréchet derivative at $(0, 0)$ is

$$\mathrm{d}\psi_{(0,0)}(h_1, h_2) = (-\sin 0 \cdot h_1,\ \cos 0 \cdot h_1,\ h_2) = (0,\ h_1,\ h_2).$$

The space

$$\operatorname{Im}(\mathrm{d}\psi_{(0,0)}) := \{(0, y, z) \mid y, z \in \mathbb{R}\}$$

is a vector subspace of $\mathbb{R}^3$ of dimension 2. Translating it by the vector $(1, 0, 0)$ gives the tangent plane to the cylinder at the point $(1, 0, 0)$, given by $\Pi := \{(1, y, z) \in \mathbb{R}^3 \mid y, z \in \mathbb{R}\}$, as illustrated below:

This subspace has basis

$$\beta = \left\{ \frac{\partial \psi}{\partial x}(x_0), \frac{\partial \psi}{\partial y}(x_0) \right\} = \{(0,1,0),(0,0,1)\}.$$

Under these assumptions, we refer to $\mathrm{Im}(d\psi_{x_0})$ as the tangent space to $\psi(\widetilde{U})$ at $p = \psi(x_0)$.
The local tool that makes this description precise is the following theorem from differential calculus.

Theorem 1.4.2. (Rank theorem) Let $f\colon \widetilde{U} \subseteq \mathbb{R}^k \longrightarrow \mathbb{R}^n$ be a function of class C^1, and let $x_0 \in \widetilde{U}$. Suppose there exists $r > 0$, with $B_{\mathrm{euc}}(x_0, r) \subseteq \widetilde{U}$, such that df_x has constant rank m for every $x \in B_{\mathrm{euc}}(x_0, r)$. Then there exist open sets $\widetilde{V}_1, \widetilde{V}_2 \subseteq \mathbb{R}^k$ and $V_1, V_2 \subseteq \mathbb{R}^n$, with $x_0 \in \widetilde{V}_1$, $0 \in \widetilde{V}_2$, $f(x_0) \in V_1$, and $0 \in V_2$, and diffeomorphisms of class C^1

$$\Phi\colon \widetilde{V}_2 \longrightarrow \widetilde{V}_1, \qquad \Psi\colon V_2 \longrightarrow V_1,$$

such that

$$\Psi^{-1} \circ f \circ \Phi(x_1, \ldots, x_k) = (x_1, \ldots, x_m, 0, \ldots, 0).$$

In particular, near x_0, the map f can be expressed in suitable coordinates on the domain and codomain as projection onto the first m coordinates followed by the natural inclusion into $\mathbb{R}^n$.

Proof. We apply Lemma 1.5.5, whose proof follows directly from contractions and does not use the rank theorem. After permuting coordinates in the domain and codomain, we may assume that the minor formed by the first m rows and columns of df_{x_0} is invertible. Write $f = (f^1, \ldots, f^n)$ and define

$$H(x) := (f^1(x), \ldots, f^m(x), x^{m+1}, \ldots, x^k).$$

The differential dH_{x_0} is invertible. By Lemma 1.5.5, after restricting the domain, $\widehat{H}(x) := H(x) - H(x_0)$ is a diffeomorphism onto a neighborhood of 0. Let $\Phi = \widehat{H}^{-1}$. In the new coordinates,

$$f \circ \Phi(y) = \big(y^1 + f^1(x_0), \ldots, y^m + f^m(x_0), h^{m+1}(y), \ldots, h^n(y)\big).$$

The first m rows of its Jacobian matrix contain the block $(I_m\ 0)$. Since the total rank is m, necessarily

$$\frac{\partial h^a}{\partial y^b} = 0, \qquad a = m+1,\dots,n, \quad b = m+1,\dots,k.$$

Restrict the neighborhood to a box. Integrating these derivatives along segments parallel to the last $k-m$ axes shows that each h^a depends only on $y^1,\dots,y^m$.
Let $\widehat{h}^a$ be the resulting functions and define, near $f(x_0)$,

$$K(z) := \big(z^1 - f^1(x_0),\dots,z^m - f^m(x_0), z^{m+1} - \widehat{h}^{m+1}(z^1 - f^1(x_0),\dots,z^m - f^m(x_0)),\dots,z^n - \widehat{h}^n(z^1 - f^1(x_0),\dots,z^m - f^m(x_0))\big).$$

This map is a diffeomorphism: its inverse is obtained by adding $f^a(x_0)$ in the first m coordinates and, in the remaining coordinates, the functions $\widehat{h}^a$ evaluated at those first normalized coordinates. More precisely,

$$K^{-1}(w) = \big(w^1 + f^1(x_0),\dots,w^m + f^m(x_0), w^{m+1} + \widehat{h}^{m+1}(w^1,\dots,w^m),\dots,w^n + \widehat{h}^n(w^1,\dots,w^m)\big).$$

By construction,

$$K \circ f \circ \Phi(y) = (y^1,\dots,y^m,0,\dots,0).$$

Taking $\Psi = K^{-1}$ and restricting the open sets so that all the compositions are defined gives the statement. □

Proposition 1.4.3. (Local description by curves) Let $\psi\colon \widetilde{U} \subseteq \mathbb{R}^k \to \mathbb{R}^n$ be of class C^1, let $x_0 \in \widetilde{U}$, and assume only that $d\psi_{x_0}$ has rank k. Then there exists an open neighborhood $V \subseteq \widetilde{U}$ of x_0 such that $\psi \restriction_V\colon V \to \mathbb{R}^n$ is an embedding of class C^1. If $p = \psi(x_0)$, every such neighborhood satisfies

$$\operatorname{Im}(d\psi_{x_0}) = \left\{ \gamma'(0) \;\middle|\; \begin{array}{l} \gamma\colon (-\varepsilon,\varepsilon) \to \mathbb{R}^n \text{ is of class } C^1, \quad \gamma(0) = p, \\ \gamma((-\varepsilon,\varepsilon)) \subseteq \psi(V) \text{ for some } \varepsilon > 0 \end{array} \right\}.$$

Proof. Since $d\psi_{x_0}$ has rank k, some minor of order k of its Jacobian matrix is nonzero. By continuity, this minor remains nonzero in a neighborhood of x_0, where the rank is therefore constantly k. Theorem 1.4.2, followed by a restriction of the neighborhood, gives open sets $V \ni x_0$ and $W \ni p$ and coordinates in which

$$\psi \restriction_V (x^1,\dots,x^k) = (x^1,\dots,x^k,0,\dots,0).$$

Thus $\psi \restriction_V$ is an injective immersion and a homeomorphism onto $\psi(V)$ with the subspace topology; that is, it is an embedding of class C^1.
Let $v = d\psi_{x_0}(w)$. If $w = 0$, the constant curve represents v. If $w \neq 0$, choose $\varepsilon > 0$ so that $x_0 + tw \in V$ whenever $|t| < \varepsilon$, and set $\gamma(t) = \psi(x_0 + tw)$. Then $\gamma'(0) = v$.
Conversely, if γ is a curve as in the statement, the inverse C^1 of the local embedding allows us to define

$$\delta = (\psi \restriction_V)^{-1} \circ \gamma.$$

The chain rule gives $\gamma'(0) = d\psi_{x_0}(\delta'(0))$, and hence $\gamma'(0) \in \operatorname{Im}(d\psi_{x_0})$. □

Remark 1.4.4. (Why the assertion is local) We cannot replace $\psi(V)$ by the entire image $\psi(\widetilde{U})$. An immersion may have self-intersections: a curve passing through $p = \psi(x_0)$ along another branch may have a velocity that does not belong to $\operatorname{Im}(d\psi_{x_0})$. The choice of V separates the branch determined by x_0.

In what follows, we return to considering manifolds in $\mathbb{R}^n$; taking $k \le n$ and considering it to have dimension k served to illustrate what happens when the manifold lies in a possibly larger ambient space.

The preceding motivation leads to an intrinsic definition that works unchanged at interior and boundary points alike.

Definition 1.4.5. Let M be a smooth manifold with or without boundary and let $p \in M$. A **derivation at** p is a linear map $v\colon C^\infty(M) \longrightarrow \mathbb{R}$ such that

$$v(fg) = f(p)v(g) + g(p)v(f)$$

for any $f, g \in C^\infty(M)$. The set of all derivations at p is denoted by T_pM and is called the **tangent space to** M **at** p. Its elements are the tangent vectors at p.

Remark 1.4.6. With addition and scalar multiplication defined pointwise, T_pM is a real vector space. If $v \in T_pM$, then $v(1) = 0$ and therefore $v(c) = 0$ for every constant function c.

At interior points, we recover the geometric description using two-sided curves.

Definition 1.4.7. (Tangent space defined by curves) Let M be a smooth manifold with or without boundary and let $p \in \operatorname{Int} M$. Consider smooth curves $\gamma\colon (-\varepsilon, \varepsilon) \longrightarrow M$ with $\gamma(0) = p$. Two such curves are equivalent if, for some interior chart φ around p, we have $(\varphi \circ \gamma_1)'(0) = (\varphi \circ \gamma_2)'(0)$. The chain rule shows that this condition is independent of the chart. We denote the class of γ by $[\gamma]$.

Lemma 1.4.8. (Locality of derivations) Let M be a smooth manifold with or without boundary, let $p \in M$, and let $v \in T_pM$. If $f, g \in C^\infty(M)$ agree in a neighborhood of p, then $v(f) = v(g)$. Consequently, v can be evaluated unambiguously on the germ of a smooth function defined only near p.

Proof. Set $h = f - g$ and choose an open set W containing p on which $h = 0$. By Proposition 1.3.6, there exists $\chi \in C^\infty(M)$ with $\chi(p) = 1$ and $\operatorname{supp}\chi \subseteq W$. Since $\chi h = 0$ and $h(p) = 0$, the Leibniz rule gives

$$0 = v(\chi h) = \chi(p)v(h) + h(p)v(\chi) = v(h).$$

Therefore, $v(f) = v(g)$. If a function is defined only near p, Theorem 1.3.7 provides a global extension agreeing with it on a smaller neighborhood; the equality just proved shows that the value is independent of the extension. □

The identification between curves and derivations uses the following two formulas from Euclidean calculus.

Theorem 1.4.9. (Taylor's theorem with multi-indices) Let $f \in C^{k+1}(U)$ and $a \in U$. We define the Taylor

polynomial of f of order k centered at $a \in U$ by

$$P_{k,a,f}(x) := \sum_{|\alpha| \le k} \frac{1}{\alpha!} D^\alpha f(a)(x-a)^\alpha,$$

where $\frac{1}{\alpha!} := \frac{1}{\alpha_1!} \cdots \frac{1}{\alpha_n!}$. Define $R_{k,a,f}(x) = f(x) - P_{k,a,f}(x)$ and call it the remainder of order k of f at a. Then:

(a) If $x \in U$ is such that $[a,x] \subseteq U$, there exists $\xi \in [a,x]$ such that

$$R_{k,a,f}(x) = \sum_{|\alpha|=k+1} \frac{1}{\alpha!} D^\alpha f(\xi)(x-a)^\alpha.$$

(b) If $x \in U$ is such that $[a,x] \subseteq U$, then

$$R_{k,a,f}(x) = \sum_{|\alpha|=k+1} \frac{k+1}{\alpha!} (x-a)^\alpha \int_0^1 (1-t)^k D^\alpha f(a+t(x-a))\,dt.$$

(c) We have

$$\lim_{x \to a} \frac{f(x) - P_{k,a,f}(x)}{\|x-a\|^k} = \lim_{x \to a} \frac{R_{k,a,f}(x)}{\|x-a\|^k} = 0$$

and $P_{k,a,f}(x)$ is the unique polynomial of degree at most k with this property.

Proof. Fix $x \in U$ with $[a,x] \subseteq U$, set $h = x - a$, and define $\gamma(t) := f(a+th)$. Induction on j, together with the chain rule, the Clairaut–Schwarz theorem, and the multinomial formula, gives

$$\gamma^{(j)}(t) = \sum_{|\alpha|=j} \frac{j!}{\alpha!} D^\alpha f(a+th) h^\alpha, \qquad 0 \le j \le k+1. \tag{1.1}$$

Indeed, if the equality holds for j, differentiation gives

$$\sum_{|\alpha|=j} \sum_{r=1}^{n} \frac{j!}{\alpha!} D^{\alpha+e_r} f(a+th) h^{\alpha+e_r}.$$

For a multi-index β of length $j+1$, the coefficient of the corresponding term is

$$\sum_{r:\beta_r>0} \frac{j!}{(\beta-e_r)!} = \frac{j!}{\beta!} \sum_{r=1}^{n} \beta_r = \frac{(j+1)!}{\beta!},$$

which completes the induction.

The one-dimensional Taylor formula with integral remainder, obtained by successive applications of the fundamental theorem of calculus, states that

$$\gamma(1) = \sum_{j=0}^{k} \frac{\gamma^{(j)}(0)}{j!} + \frac{1}{k!} \int_0^1 (1-t)^k \gamma^{(k+1)}(t)\,dt.$$

Substituting (1.1), the finite sum is $P_{k,a,f}(x)$, and the last term is

$$\sum_{|\alpha|=k+1} \frac{k+1}{\alpha!} h^\alpha \int_0^1 (1-t)^k D^\alpha f(a+th)\,dt.$$

This proves (2). The mean value theorem for integrals gives $\theta \in [0,1]$ such that the one-dimensional remainder is $\gamma^{(k+1)}(\theta)/(k+1)!$. Using (1.1) again and taking $\xi = a+\theta h$ gives (1).
The derivatives of order $k+1$ are bounded on a closed ball centered at a and contained in U. For x near a, the integral formula implies

$$|R_{k,a,f}(x)| \le C\|x-a\|^{k+1},$$

and proves the limit in (3). If Q is another polynomial of degree at most k with this property, then

$$\frac{(Q-P_{k,a,f})(x)}{\|x-a\|^k} \longrightarrow 0.$$

If $S := Q - P_{k,a,f} \neq 0$, let S_j be its first nonzero homogeneous part, of degree $j \le k$, and choose v with $S_j(v) \neq 0$. Then

$$\frac{S(a+tv)}{\|tv\|^k} = \frac{t^j S_j(v) + O(t^{j+1})}{t^k \|v\|^k}$$

does not tend to zero as $t \to 0^+$: it is unbounded if $j < k$, and tends to $S_k(v)/\|v\|^k \neq 0$ if $j = k$. This contradiction proves uniqueness. □

Lemma 1.4.10. (Finite-dimensional Hadamard lemma with integral remainder) Let $U \subseteq \mathbb{R}^n$ be open, let $x_0, x \in U$, and suppose that $x_0 + t(x-x_0) \in U$ for every $t \in [0,1]$. If $F\colon U \longrightarrow \mathbb{R}^N$ is of class C^1, then

$$F(x) - F(x_0) = \int_0^1 DF\big(x_0 + t(x-x_0)\big)[x-x_0],dt. \tag{1.2}$$

In particular,

$$F(x) - F(x_0) = \sum_{j=1}^n (x^j - x_0^j) F_j(x,x_0), \qquad F_j(x,x_0) := \int_0^1 \frac{\partial F}{\partial x^j}\big(x_0 + t(x-x_0)\big),dt. \tag{1.3}$$

If F is of class C^2, $F(x_0) = 0$, and $DF(x_0) = 0$, then

$$F(x) = \sum_{j,k=1}^n (x^j - x_0^j)(x^k - x_0^k) \int_0^1 (1-t) \frac{\partial^2 F}{\partial x^j \partial x^k}\big(x_0 + t(x-x_0)\big),dt. \tag{1.4}$$

The same formulas hold for a family $F(z,x)$ depending smoothly on a finite-dimensional parameter z: the functions defined by the integrals above are jointly smooth in (z,x,x_0) as long as the segments under consideration remain in the domain.

Proof. Define $g(t) := F(x_0 + t(x-x_0))$. The chain rule gives

$$g'(t) = DF\big(x_0 + t(x-x_0)\big)[x-x_0].$$

The fundamental theorem of calculus, applied componentwise in $\mathbb{R}^N$, proves $F(x)-F(x_0)=g(1)-g(0)=\int_0^1 g'(t)\,dt$ and, upon expressing the differential in the standard basis, yields (1.3).
Now suppose that $F(x_0)=0$ and $DF(x_0)=0$. For each $t\in[0,1]$, applying the preceding formula to DF on the subsegment joining x_0 to $x_0+t(x-x_0)$ gives

$$DF\big(x_0+t(x-x_0)\big)[x-x_0]=t\int_0^1 D^2F\big(x_0+st(x-x_0)\big)[x-x_0,x-x_0]\,ds.$$

Substitute this identity into (1.2). The change of variable $\tau=st$ and Fubini's theorem on the triangle $0\le\tau\le t\le 1$ yield

$$F(x)=\int_0^1 (1-\tau)D^2F\big(x_0+\tau(x-x_0)\big)[x-x_0,x-x_0]\,d\tau,$$

which is precisely (1.4) after expanding the bilinear form in coordinates. The assertion with parameters follows by differentiating under the integral over the compact interval $[0,1]$. □

Proposition 1.4.11. (Equivalence between curves and derivations) Let M be a smooth manifold with or without boundary and let $p\in \operatorname{Int} M$. The map

$$\{\text{classes of two-sided curves at } p\}\longrightarrow T_pM,\qquad [\gamma]\longmapsto v_{[\gamma]},$$

where

$$v_{[\gamma]}(f):=\frac{d}{dt}(f\circ\gamma)(t)\Big|_{t=0},\qquad f\in C^\infty(M),$$

is a canonical bijection.

Proof. If $[\gamma_1]=[\gamma_2]$, choose an interior chart $\varphi\colon U\to\mathbb{R}^n$ around p. For $F=f\circ\varphi^{-1}$, the chain rule gives

$$\frac{d}{dt}(f\circ\gamma_i)(t)\Big|_{t=0}=DF(\varphi(p))[(\varphi\circ\gamma_i)'(0)],\qquad i=1,2.$$

The coordinate velocities agree, so $v_{[\gamma]}$ is well defined. Linearity and the product rule show that

$$v_{[\gamma]}(\lambda f+\mu g)=\lambda v_{[\gamma]}(f)+\mu v_{[\gamma]}(g),\qquad v_{[\gamma]}(fg)=f(p)v_{[\gamma]}(g)+g(p)v_{[\gamma]}(f).$$

Therefore, $v_{[\gamma]}\in T_pM$.
Write $\varphi=(x^1,\dots,x^n)$. By Lemma 1.4.8, the coordinate functions can be evaluated as germs, and

$$(\varphi\circ\gamma)'(0)=\big(v_{[\gamma]}(x^1),\dots,v_{[\gamma]}(x^n)\big).$$

Thus $v_{[\gamma_1]}=v_{[\gamma_2]}$ implies $[\gamma_1]=[\gamma_2]$, and the map is injective.
For surjectivity, let $v\in T_pM$ and set $x_0=\varphi(p)$ and

$$w^i:=v(x^i),\qquad w=(w^1,\dots,w^n).$$

Since p is interior, for sufficiently small $|t|$ the curve

$$\gamma(t) := \varphi^{-1}(x_0 + tw),$$

is defined, and $(\varphi \circ \gamma)'(0) = w$. Let $f \in C^\infty(M)$ and write $F = f \circ \varphi^{-1}$. Apply Taylor's theorem with integral remainder at the point x_0:

$$R_{1,x_0,F}(x) = \sum_{|\alpha|=2} \frac{2}{\alpha!}(x - x_0)^\alpha \int_0^1 (1-t) D^\alpha F\big(x_0 + t(x - x_0)\big)\, dt,$$

and therefore

$$F(x) = F(x_0) + \sum_{i=1}^n \frac{\partial F}{\partial x_i}(x_0)(x_i - x_i^{(0)}) + R_{1,x_0,F}(x).$$

Taking $x = \varphi(q)$ for q near p, we obtain:

$$f(q) = f(p) + \sum_{i=1}^n \frac{\partial F}{\partial x_i}(x_0)\big(x^i(q) - x^i(p)\big) + \underbrace{R_{1,x_0,F}\big(\varphi(q)\big)}_{=:\, r(q)}.$$

We can rewrite this as

$$r(q) = \sum_{|\alpha|=2} \big(\varphi(q) - \varphi(p)\big)^\alpha h_\alpha(q), \qquad h_\alpha(q) := \frac{2}{\alpha!} \int_0^1 (1-t) D^\alpha F\big(\varphi(p) + t(\varphi(q) - \varphi(p))\big)\, dt,$$

where each h_α is smooth and well defined near p.
The vector v annihilates the remainder term r. For each multi-index α with $|\alpha| = 2$, let

$$m_\alpha(q) := \big(\varphi(q) - \varphi(p)\big)^\alpha = \prod_{i=1}^n \big(x^i(q) - x^i(p)\big)^{\alpha_i}.$$

Then $m_\alpha(p) = 0$, and m_α can be viewed as a product of at least two factors vanishing at p, since $|\alpha| = 2$ forces either two of the α_j to be 1 or one to be 2. By repeated application of the Leibniz rule,

$$v\big(m_\alpha\big) = 0 \quad \text{and} \quad v\big(m_\alpha h_\alpha\big) = m_\alpha(p) v(h_\alpha) + h_\alpha(p) v(m_\alpha) = 0.$$

Summing over $|\alpha| = 2$, we conclude that $v(r) = 0$. Applying v to the decomposition of f gives

$$v(f) = \sum_{i=1}^n \frac{\partial F}{\partial x^i}(x_0) v\big(x^i\big).$$

On the other hand,

$$v_{[\gamma]}(f) = \frac{d}{dt}(f \circ \gamma)(t)\Big|_{t=0} = \frac{d}{dt} F(x_0 + tw)\Big|_{t=0} = \sum_{i=1}^n w^i \frac{\partial F}{\partial x^i}(x_0),$$

and since $w^i = v(x^i)$, we have $v(f) = v_{[\gamma]}(f)$ for every $f \in C^\infty(M)$. Thus $v = v_{[\gamma]}$, and every derivation arises

from an equivalence class of curves. We conclude that the map

$$\{\text{classes of two-sided curves at } p\} \longrightarrow T_pM, \qquad [\gamma] \longmapsto v_{[\gamma]},$$

is bijective when $p \in \operatorname{Int} M$. □

At a boundary point this equivalence no longer holds for two-sided curves contained in M. We will return to this distinction after describing the coordinate basis of T_pM.

There are other equivalent descriptions of the tangent space. One uses *germs of smooth functions*, which reflect the local nature of differentiation.

Definition 1.4.12. Let M be a smooth manifold with or without boundary and let $p \in M$. Define an equivalence relation on $C^\infty(M)$ by

$$f \sim g \iff \text{there exists a neighborhood } U \text{ of } p \text{ such that } f\restriction_U = g\restriction_U.$$

We denote the equivalence class of f by $[f]$ and call it the *germ of f at p*. The set of all such classes is denoted by $C^\infty_p(M)$ and is called the *ring of germs of smooth functions at p*.

Proposition 1.4.13. (Derivations of the ring of germs) Let M be a smooth manifold with or without boundary and let $p \in M$. There is a canonical linear isomorphism

$$T_pM \longrightarrow \operatorname{Der}\big(C^\infty_p(M), \mathbb{R}\big), \qquad v \longmapsto \big([f] \longmapsto v(f)\big).$$

Its inverse sends a derivation D of germs to the derivation $v_D(f) := D([f])$ of $C^\infty(M)$.

Proof. Addition and multiplication of germs are defined by $[f]+[g] = [f+g]$ and $[f][g] = [fg]$; these operations are independent of representatives because equality of germs is preserved by addition and multiplication of functions. Moreover, $f(p)$ depends only on $[f]$. Therefore, the rule

$$D([f][g]) = f(p)D([g]) + g(p)D([f])$$

is well defined.
If $v \in T_pM$, Lemma 1.4.8 shows that $\widetilde{v}([f]) := v(f)$ is independent of the representative. Linearity and the Leibniz rule for $\widetilde{v}$ follow from those for v. Conversely, if $D \in \operatorname{Der}(C^\infty_p(M), \mathbb{R})$, then $v_D(f) := D([f])$ is linear and

$$v_D(fg) = D([f][g]) = f(p)v_D(g) + g(p)v_D(f),$$

so $v_D \in T_pM$. Finally, $v_{\widetilde{v}}(f) = \widetilde{v}([f]) = v(f)$ and $\widetilde{v_D}([f]) = v_D(f) = D([f])$. The two constructions are inverse to each other and require no choices. □

With the tangent space defined, we can now introduce the tangent map, or differential, of a smooth function.

Definition 1.4.14. Let M and N be smooth manifolds with or without boundary, and let $F\colon M \longrightarrow N$ be a

smooth map. For each $p \in M$, define the map

$$dF_p \colon T_pM \longrightarrow T_{F(p)}N$$

called the **tangent map or differential of** F **at** p, by

$$dF_p(v)(f) := v(f \circ F), \qquad v \in T_pM, \quad f \in C^\infty(N).$$

Indeed, $dF_p(v)$ is linear and, for $f, g \in C^\infty(N)$,

$$dF_p(v)(fg) = f(F(p))dF_p(v)(g) + g(F(p))dF_p(v)(f),$$

so it belongs to $T_{F(p)}N$.

The tangent map, or differential, has the following properties:

Proposition 1.4.15. Let M, N, and P be smooth manifolds with or without boundary, and let $F \colon M \longrightarrow N$ and $G \colon N \longrightarrow P$ be smooth maps. Let $p \in M$.

(a) $dF_p \colon T_pM \longrightarrow T_{F(p)}N$ is linear.

(b) $d(G \circ F)_p = dG_{F(p)} \circ dF_p \colon T_pM \longrightarrow T_{G(F(p))}P$.

(c) $d(\mathrm{Id}_M)_p = \mathrm{Id}_{T_pM}$.

(d) If F is a diffeomorphism, then $dF_p \colon T_pM \longrightarrow T_{F(p)}N$ is an isomorphism and

$$(dF_p)^{-1} = d(F^{-1})_{F(p)}.$$

Proof. Linearity follows directly from the linearity of each derivation. If $v \in T_pM$ and $h \in C^\infty(P)$, then

$$d(G \circ F)_p(v)(h) = v(h \circ G \circ F) = dF_p(v)(h \circ G) = dG_{F(p)}(dF_p(v))(h),$$

which proves the chain rule. The formula for the identity is the immediate case $h \circ \mathrm{Id}_M = h$. If F is a diffeomorphism, apply the chain rule to $F^{-1} \circ F = \mathrm{Id}_M$ and to $F \circ F^{-1} = \mathrm{Id}_N$; thus $d(F^{-1})_{F(p)}$ is the inverse of dF_p. □

Since T_pM is a vector space, a basis is useful for describing it. In the Euclidean case, $T_p\mathbb{R}^n$ is isomorphic to $\mathbb{R}^n$ for every $p \in \mathbb{R}^n$, and tangent vectors may be viewed as directional derivatives at p in the direction of $v \in T_p\mathbb{R}^n$. This leads to the following proposition:

Proposition 1.4.16. Let M be a smooth manifold with or without boundary of dimension n, and let $p \in M$. Then T_pM is a vector space of dimension n, and for each smooth chart (U, φ) such that $p \in U$, with $\varphi = (x^1, \ldots, x^n)$, the vectors

$$\partial_i|_p(f) := \frac{\partial \widetilde{F}}{\partial x^i}(\varphi(p)), \qquad F = f \circ \varphi^{-1},$$

form a basis for T_pM. Here $\widetilde{F} = F$ in an interior chart; in a boundary chart, $\widetilde{F}$ is any smooth extension of F

to a Euclidean neighborhood of $\varphi(p)$.

Proof. In a boundary chart, the definition of a smooth function provides the extension $\widetilde{F}$. If two extensions agree on the relatively open set $\varphi(U) \subseteq \mathbb{H}^n$, their partial derivatives agree at interior points and, by continuity, also at boundary points. Thus the formula is independent of the extension. Euclidean linearity and the Leibniz rule show that each $\partial_i|_p$ is a derivation at p.
Let $v \in T_pM$ and write $x_0 = \varphi(p)$. Restrict the chart, if necessary, so that segments starting at x_0 remain in its image. Hadamard's lemma 1.4.10, applied to a Euclidean extension when $p \in \partial M$, gives smooth functions F_i such that, near x_0,

$$F(x) - F(x_0) = \sum_{i=1}^{n} (x^i - x_0^i) F_i(x), \qquad F_i(x_0) = \frac{\partial \widetilde{F}}{\partial x^i}(x_0).$$

Lemma 1.4.8 allows us to apply v to this identity of germs. Since each $x^i - x_0^i$ vanishes at p, we obtain

$$v(f) = \sum_{i=1}^{n} v(x^i) \frac{\partial \widetilde{F}}{\partial x^i}(x_0) = \left(\sum_{i=1}^{n} v(x^i)\, \partial_i|_p \right)(f).$$

Thus the coordinate vectors span T_pM. If $\sum_{i=1}^{n} a^i\, \partial_i|_p = 0$, evaluation on the germ of x^j gives $a^j = 0$. They are therefore linearly independent and form a basis; in particular, $\dim T_pM = n$.
If $(y^1, \dots, y^n)$ is another coordinate system around p, the expansion just proved, applied to $v = \partial_i|_p$, gives the change-of-basis formula

$$\partial_i|_p = \sum_{j=1}^{n} \frac{\partial y^j}{\partial x^i}(p)\, \partial_j\Big|_p. \tag{1.5}$$

□

Remark 1.4.17. (Two-sided curves at the boundary) Suppose that $p \in \partial M$ and take a boundary chart with $\mathbb{H}^n = \{x^n \geq 0\}$ and $x^n(p) = 0$. If $\gamma\colon (-\varepsilon, \varepsilon) \to M$ is smooth and $\gamma(0) = p$, the function $t \mapsto x^n(\gamma(t))$ is nonnegative and attains a minimum at 0; therefore, $(x^n \circ \gamma)'(0) = 0$. The velocities of two-sided curves contained in M range over precisely the coordinate subspace

$$\operatorname{span}\left\{ \partial_1|_p, \dots, \partial_{n-1}|_p \right\},$$

which will later be identified with $T_p\partial M$, rather than all of T_pM. The reverse inclusion follows by using the coordinate curves $t \mapsto x_0 + t(w^1, \dots, w^{n-1}, 0)$.
With this convention, a vector $v = v^i\, \partial_i|_p$ points inward if $v^n > 0$, outward if $v^n < 0$, and is tangent to the boundary if $v^n = 0$. The sign is independent of the chart: for two normal boundary coordinates x^n and y^n, Hadamard's lemma gives $y^n = a x^n$ in a relative neighborhood of p, with $a(p) > 0$. For this reason, the primary definition of T_pM at a boundary point is the definition by derivations, rather than the description by two-sided curves.

This notation is suggestive because it essentially transfers the concept of a partial derivative from the Euclidean setting to manifolds. The following definition makes this precise:

Definition 1.4.18. Let M be a smooth manifold with or without boundary, let (U,φ) be a smooth chart of M, with $\varphi = (x^1,\dots,x^n)$, and let $f : U \longrightarrow \mathbb{R}$ be a smooth function. Given a multi-index $\alpha = (\alpha_1,\dots,\alpha_n) \in \mathbb{N}_0^n$, we define:

(a) For each $p \in U$, the partial derivative of f associated with α at p by $\partial^\alpha f(p) := \partial^\alpha (f \circ \varphi^{-1})(\varphi(p))$.

(b) The partial derivative function of f associated with α on U by $\partial^\alpha f : U \longrightarrow \mathbb{R}$, given by $p \mapsto \partial^\alpha f(p)$.

The tangent bundle, which gives this section its name, is defined as follows:

Definition 1.4.19. Let M be a smooth manifold with or without boundary. Define the **tangent bundle of** M by

$$TM := \coprod_{p\in M} T_pM$$

Elements of TM have the form (p,v) with $p \in M$, $v \in T_pM$. The following notations are commonly used for an element of TM: (p,v), v_p, and v, the last when we do not wish to emphasize the base point. By Proposition 1.4.16, every element of T_pM can be written in the form (using Einstein notation)

$$v_p = v^i \partial_i \Big|_p ,$$

which gives another way to express elements of TM.

The tangent bundle can be equipped with a smooth manifold structure, with or without boundary according to the type of manifold we start with. The following proposition describes the construction:

Proposition 1.4.20. If M is a smooth n-manifold with or without boundary, the tangent bundle TM has a natural topology and smooth structure making it a smooth $2n$-manifold with or without boundary. With respect to this smooth structure, the projection $\pi : TM \longrightarrow M$ is smooth. The coordinate charts for this smooth structure are given as follows:

(a) If (U,φ) is an interior chart of M, then $\widetilde{\varphi} : \pi^{-1}(U) \longrightarrow \mathbb{R}^{2n}$, given by

$$\widetilde{\varphi}\left(p, v^i \partial_i \Big|_p\right) = (x^1(p),\dots,x^n(p),v^1,\dots,v^n)$$

makes $(\pi^{-1}(U),\widetilde{\varphi})$ an interior chart of TM.

(b) If (U,φ) is a boundary chart of M, then $\widetilde{\varphi} : \pi^{-1}(U) \longrightarrow \mathbb{H}^{2n}$, given by

$$\widetilde{\varphi}\left(p, v^i \partial_i \Big|_p\right) = (v^1,\dots,v^n,x^1(p),\dots,x^n(p))$$

makes $(\pi^{-1}(U),\widetilde{\varphi})$ a boundary chart of TM.

Proof. For each chart (U,φ), the map $\widetilde{\varphi}$ is a bijection onto $\varphi(U)\times\mathbb{R}^n$ in the interior case and onto $\mathbb{R}^n \times \varphi(U)$ in the boundary case; the latter set is open in $\mathbb{H}^{2n}$ under the convention in the statement. If (V,ψ) is another chart, write $y = \psi \circ \varphi^{-1}(x)$. The change-of-basis formula (1.5) shows that, on the overlap, the components

of a vector satisfy

$$w^j = \sum_{i=1}^{n} \frac{\partial y^j}{\partial x^i}(x) v^i.$$

Thus, apart from explicitly interchanging the order of the two blocks in a boundary chart, the change of coordinates on TM is

$$(x, v) \longmapsto \big(y(x), Dy(x)v\big).$$

It is smooth, and its inverse is obtained by replacing y by $x(y)$. An overlap between an interior chart and a boundary chart contains no points of ∂M, so the same formula is interpreted on Euclidean open sets.
The smooth chart lemma proved above, applied to this family, provides a unique Hausdorff, second countable topology and the stated smooth structure on TM. In these coordinates, the projection is $(x, v) \mapsto x$ (with the corresponding interchange of blocks at the boundary), so it is smooth. If M has no boundary, all charts are interior charts; if it has boundary, the boundary charts described above determine the boundary of TM. This also completes the uniqueness of the structure for which the charts in the statement are smooth. □

1.5 Immersions, submersions, and embeddings

As in the Euclidean case, the differential of a function between manifolds, which plays the role of the usual derivative, describes the best linear approximation to a smooth map near each point. Thus many local properties of a map can be studied through the linear properties of its differential. This motivates the following definition.

Definition 1.5.1. Let M and N be smooth manifolds with or without boundary, and let $F\colon M \longrightarrow N$ be a smooth map. We define the rank of F at a point $p \in M$ as the rank of the linear map

$$dF_p\colon T_pM \longrightarrow T_{F(p)}N.$$

Equivalently, the rank of F at p is the dimension of the image of dF_p. In coordinates, this number equals the rank of the Jacobian matrix of a coordinate representation of F. If F has the same rank at every point of its domain, we say that F has constant rank.

The notions of immersion and submersion generalize, respectively, injectivity and surjectivity of linear maps to the smooth setting.

Definition 1.5.2. Let M and N be smooth manifolds without boundary, and let $F\colon M \longrightarrow N$ be a smooth map. We say that:

(a) F is an immersion if dF_p is injective for every $p \in M$;

(b) F is a submersion if dF_p is surjective for every $p \in M$.

Being an immersion or a submersion is a local property. If the differential of a map is injective or surjective at a point, the same property holds throughout some open neighborhood of that point.

Proposition 1.5.3. Let M and N be smooth manifolds without boundary, let $F\colon M \longrightarrow N$ be a smooth map, and let $p \in M$.

(a) If dF_p is injective, there exists an open neighborhood U of p such that $F\restriction_U$ is an immersion.

(b) If dF_p is surjective, there exists an open neighborhood U of p such that $F\restriction_U$ is a submersion.

Proof. In charts around p and $F(p)$, the differential is represented by the Jacobian matrix. If dF_p is injective and $m = \dim M$, some minor of order m has nonzero determinant. By continuity, this minor remains nonsingular in a neighborhood of p; there the rank is m, so the differential is injective. If dF_p is surjective and $n = \dim N$, the same argument applies to a minor of order n, and the differential is surjective in a neighborhood of p. □

We now give some examples of immersions and submersions.

Example 1.5.4. (a) If $M_1,\dots,M_k$ are smooth manifolds without boundary, each projection $\pi_i\colon M_1 \times \cdots \times M_k \longrightarrow M_i$ is a submersion. For each $(p_1,\dots,p_k) \in M_1 \times \cdots \times M_k$, its differential satisfies $d(\pi_i)_{(p_1,\dots,p_k)}(v_1,\dots,v_k) = v_i$. Indeed, given $w \in T_{p_i}M_i$, the vector $(0,\dots,0,w,0,\dots,0)$ in the tangent space to the product is sent to w; therefore, the differential is surjective.

(b) The map $F\colon \mathbb{R}^m \longrightarrow \mathbb{R}^n$, given by $F(x^1,\dots,x^m) = (x^1,\dots,x^m,0,\dots,0)$, with $m \le n$, is an immersion. Its differential is the natural linear inclusion $\mathbb{R}^m \hookrightarrow \mathbb{R}^n$, which is injective.

(c) The map $G\colon \mathbb{R}^3 \longrightarrow \mathbb{R}^2$, given by $G(x,y,z) = (x,y)$, is a submersion, since $dG_{(x,y,z)}(a,b,c) = (a,b)$ for every $(x,y,z) \in \mathbb{R}^3$, and this linear map is surjective.

(d) The map $\gamma\colon \mathbb{R} \longrightarrow \mathbb{R}^2$, given by $\gamma(t) = (\cos t, \sin t)$, is an immersion, since $\gamma'(t) = (-\sin t, \cos t) \neq 0$ for every $t \in \mathbb{R}$.

(e) The map $H\colon \mathbb{R}^2 \longrightarrow \mathbb{R}$, given by $H(x,y) = x^2 + y^2$, is not a submersion on all of $\mathbb{R}^2$, since $dH_{(0,0)} = 0$. It is, however, a submersion on $\mathbb{R}^2 \setminus \{(0,0)\}$.

(f) Consider the map $K\colon \mathbb{R}^2 \longrightarrow \mathbb{R}^2$, given by $K(x,y) = (x^2 - y^2, 2xy)$. Identifying $\mathbb{R}^2$ with $\mathbb{C}$, this map corresponds to $z \mapsto z^2$. A direct calculation shows that $DK(x,y) = \begin{pmatrix} 2x & -2y \\ 2y & 2x \end{pmatrix}$, whose determinant is $4(x^2+y^2)$. Thus K is both an immersion and a submersion at every point other than the origin, but has neither property at $(0,0)$.

The most important theorems of multivariable differential calculus also hold for smooth manifolds and will be useful throughout the book. We present them next.

Lemma 1.5.5. (Euclidean inverse function theorem) Let $\Omega \subseteq \mathbb{R}^n$ be open, let $f \in C^1(\Omega, \mathbb{R}^n)$, and let $a \in \Omega$. If $Df(a)$ is invertible, there exist connected open sets $U \subseteq \Omega$ and $V \subseteq \mathbb{R}^n$, with $a \in U$ and $f(a) \in V$, such that $f\restriction_U\colon U \longrightarrow V$ is a diffeomorphism of class C^1. If f is of class C^r, with $2 \le r \le \infty$, its inverse is also of class C^r.

Proof. Set $A := Df(a)$ and $c := \|A^{-1}\|_{\mathrm{op}}$. By continuity of Df, there exists $r > 0$ such that $\overline{B}(a,r) \subseteq \Omega$ and

$$\|I - A^{-1}Df(x)\|_{\mathrm{op}} \le \frac{1}{2}, \qquad x \in \overline{B}(a,r). \tag{1.6}$$

Let $\delta := \frac{r}{2c}$ and fix $y \in B(f(a),\delta)$. Define

$$T_y(x) := x - A^{-1}(f(x) - y), \qquad x \in \overline{B}(a,r).$$

The fundamental theorem of calculus applied to the segment joining x and z, followed by (1.6), gives

$$\|T_y(x) - T_y(z)\| \le \frac{1}{2}\|x - z\|, \qquad x, z \in \overline{B}(a,r).$$

Moreover,

$$\|T_y(x) - a\| \le \|T_y(x) - T_y(a)\| + \|A^{-1}(y - f(a))\| < \frac{r}{2} + \frac{r}{2} = r.$$

Thus T_y maps the closed ball into itself and is a contraction.
If $x_0 \in \overline{B}(a,r)$ and $x_{k+1} := T_y(x_k)$, then

$$\|x_{k+1} - x_k\| \le 2^{-k}\|x_1 - x_0\|.$$

Summing these bounds shows that (x_k) is Cauchy. The closed ball is complete, so $x_k \to x$, and continuity of T_y gives $T_y(x) = x$. If x' is another fixed point, then $\|x - x'\| \le \frac{1}{2}\|x - x'\|$, whence $x = x'$. Denote this unique fixed point by $g(y)$. The equation $T_y(g(y)) = g(y)$ is equivalent to $f(g(y)) = y$.
If $y, z \in B(f(a),\delta)$, the contraction inequality gives

$$\begin{aligned}\|g(y) - g(z)\| &\le \|T_y(g(y)) - T_y(g(z))\| + \|T_y(g(z)) - T_z(g(z))\| \\ &\le \frac{1}{2}\|g(y) - g(z)\| + c\|y - z\|.\end{aligned}$$

Thus

$$\|g(y) - g(z)\| \le 2c\|y - z\|, \tag{1.7}$$

and g is continuous.
Let $V := B(f(a),\delta)$ and set $U := f^{-1}(V) \cap B(a,r)$. Each $y \in V$ has exactly one preimage in $\overline{B}(a,r)$, and the preceding strict estimate shows that this preimage belongs to $B(a,r)$. Hence $f\restriction_U$ is a bijection onto V, with inverse g. The set U is open and connected, since $U = g(V)$ and V is connected.
It remains to prove regularity of the inverse. From (1.6), we obtain $A^{-1}Df(x) = I - R_x$ with $\|R_x\| \le \frac{1}{2}$. The geometric series $\displaystyle\sum_{k=0}^{\infty} R_x^k$ converges in operator norm and is the inverse of $I - R_x$; thus $Df(x)$ is invertible for $x \in U$. Fix $y \in V$, $x := g(y)$, and write $h := g(y+k) - g(y)$ when $y + k \in V$. Differentiability of f at x gives

$$k = Df(x)h + r_x(h), \qquad \frac{\|r_x(h)\|}{\|h\|} \longrightarrow 0 \quad (h \to 0).$$

By (1.7), $\|h\| \le 2c\|k\|$. Consequently,

$$\frac{\|g(y+k)-g(y)-Df(x)^{-1}k\|}{\|k\|} \le 2c\|Df(x)^{-1}\|_{\mathrm{op}}\frac{\|r_x(h)\|}{\|h\|} \longrightarrow 0.$$

Thus $Dg(y) = Df(g(y))^{-1}$. Continuity of Df, of g, and of inversion on the set of invertible matrices shows that Dg is continuous. If f is of class C^r for some $r \ge 2$, the preceding formula and smoothness of the inversion map on $\mathrm{GL}(n,\mathbb{R})$ allow induction on j: if $g \in C^j$ and $1 \le j < r$, then $Df \in C^{r-1}$ implies $Df \circ g \in C^j$; hence $Dg \in C^j$ and $g \in C^{j+1}$. Starting from $g \in C^1$, the formula successively yields $g \in C^2, \dots, C^r$. For $r = \infty$, apply the argument at every finite order. This completes the proof. □

Theorem 1.5.6. (inverse function theorem) Let M and N be smooth manifolds without boundary, and let $F\colon M \longrightarrow N$ be a smooth map. If $p \in M$ is such that dF_p is invertible, there exist connected open neighborhoods U_0 of p and V_0 of $F(p)$ such that $F\restriction_{U_0}\colon U_0 \longrightarrow V_0$ is a diffeomorphism.

Proof. Since dF_p is a bijection, we have $\dim(M) = \dim(N)$. Consider smooth charts (U,φ) and (V,ψ) centered at p and $F(p)$, respectively, with $F(U) \subseteq V$. Then $\widetilde{F} := \psi \circ F \circ \varphi^{-1}$ maps the open set $\widetilde{U} := \varphi(U) \subseteq \mathbb{R}^n$ into the open set $\widetilde{V} := \psi(V) \subseteq \mathbb{R}^n$.
Since φ and ψ are diffeomorphisms, the differential

$$d\widetilde{F}_{\varphi(p)} = d\psi_{F(p)} \circ dF_p \circ d(\varphi^{-1})_{\varphi(p)}$$

is an isomorphism. Lemma 1.5.5, applied to $\widetilde{F}$, gives connected open sets $\widetilde{U}_0 \subseteq \widetilde{U}$ and $\widetilde{V}_0 \subseteq \widetilde{V}$, with $\varphi(p) \in \widetilde{U}_0$ and $\widetilde{F}(\varphi(p)) \in \widetilde{V}_0$, such that $\widetilde{F}\restriction_{\widetilde{U}_0}\colon \widetilde{U}_0 \longrightarrow \widetilde{V}_0$ is a diffeomorphism.
Defining $U_0 := \varphi^{-1}(\widetilde{U}_0)$ and $V_0 := \psi^{-1}(\widetilde{V}_0)$, we obtain connected open neighborhoods of p and $F(p)$, respectively, such that $F\restriction_{U_0}\colon U_0 \longrightarrow V_0$ is a diffeomorphism. □

Remark 1.5.7. The preceding statement requires the manifolds to have no boundary. If boundary is allowed, the result may fail. For example, the inclusion $\iota\colon \mathbb{H}^n \hookrightarrow \mathbb{R}^n$ has invertible differential at every point but is not a local diffeomorphism at points of $\partial\mathbb{H}^n$.

This motivates the concept of a local diffeomorphism:

Definition 1.5.8. Let M and N be manifolds with or without boundary. A function $F\colon M \longrightarrow N$ is called a local diffeomorphism if every $p \in M$ has an open neighborhood U such that $F(U)$ is open in N and $F\restriction_U\colon U \longrightarrow F(U)$ is a diffeomorphism.

Local diffeomorphisms have the following useful property.

Proposition 1.5.9. Let M and N be smooth manifolds without boundary, and let $F\colon M \longrightarrow N$ be a function.

(a) F is a local diffeomorphism if and only if it is both a smooth immersion and a smooth submersion.

(b) If $\dim(M) = \dim(N)$ and F is a smooth immersion or a smooth submersion, then it is a local diffeomorphism.

Proof. If F is a local diffeomorphism, it has a smooth inverse around each $p \in M$. The chain rule shows that dF_p and $d(F^{-1})_{F(p)}$ are inverse to each other; thus F is an immersion and a submersion.
Conversely, if F is an immersion and a submersion, each dF_p is an isomorphism. Theorem 1.5.6 provides neighborhoods on which F is a diffeomorphism, so F is a local diffeomorphism. This proves (1). When the dimensions are equal, every injective linear map between the tangent spaces is surjective, and conversely; (2) follows from (1). □

The rank theorem (Theorem 1.4.2) has an analogue for smooth manifolds, bearing the same name.

Theorem 1.5.10. (Rank theorem) Let M and N be smooth manifolds without boundary of dimensions m and n, respectively, and let $F\colon M \longrightarrow N$ be a smooth map of constant rank r. Then, for every $p \in M$, there exist smooth charts (U,φ) of M centered at p and (V,ψ) of N centered at $F(p)$ such that $F(U) \subseteq V$ and the coordinate representation $\widetilde{F} := \psi \circ F \circ \varphi^{-1}$ has the form $\widetilde{F}(x^1,\dots,x^m) = (x^1,\dots,x^r,0,\dots,0)$.
In particular, if F is an immersion, then $r = m$ and $\widetilde{F}(x^1,\dots,x^m) = (x^1,\dots,x^m,0,\dots,0)$. Likewise, if F is a submersion, then $r = n$ and $\widetilde{F}(x^1,\dots,x^m) = (x^1,\dots,x^n)$.

Proof. Fix $p \in M$. Take smooth charts (U_0,φ_0) of M around p and (V_0,ψ_0) of N around $F(p)$, with $F(U_0) \subseteq V_0$. Consider the coordinate representation $f := \psi_0 \circ F \circ \varphi_0^{-1}\colon \varphi_0(U_0) \subseteq \mathbb{R}^m \longrightarrow \mathbb{R}^n$. Since F has constant rank r, the derivative of f also has constant rank r. Moreover, since F is smooth, f is of class C^∞. Applying the smooth version of Theorem 1.4.2 gives open sets $\widetilde{W}_1, \widetilde{W}_2 \subseteq \mathbb{R}^m$ and $W_1, W_2 \subseteq \mathbb{R}^n$, together with smooth diffeomorphisms $\Phi\colon \widetilde{W}_2 \longrightarrow \widetilde{W}_1$ and $\Psi\colon W_2 \longrightarrow W_1$, such that

$$\Psi^{-1} \circ f \circ \Phi(x^1,\dots,x^m) = (x^1,\dots,x^r,0,\dots,0).$$

Define $U := \varphi_0^{-1}(\widetilde{W}_1)$ and $V := \psi_0^{-1}(W_1)$. Restricting U if necessary, we may assume that $F(U) \subseteq V$. Now take the charts $\varphi := \Phi^{-1} \circ \varphi_0 \restriction_U$ and $\psi := \Psi^{-1} \circ \psi_0 \restriction_V$. Then (U,φ) is a smooth chart of M centered at p, and (V,ψ) is a smooth chart of N centered at $F(p)$. In these charts,

$$\psi \circ F \circ \varphi^{-1} = \Psi^{-1} \circ \psi_0 \circ F \circ \varphi_0^{-1} \circ \Phi = \Psi^{-1} \circ f \circ \Phi.$$

Therefore, $\widetilde{F}(x^1,\dots,x^m) = (x^1,\dots,x^r,0,\dots,0)$.
If F is an immersion, then $r = m$, and the preceding expression becomes $\widetilde{F}(x^1,\dots,x^m) = (x^1,\dots,x^m,0,\dots,0)$.
If F is a submersion, then $r = n$, and the expression reduces to $\widetilde{F}(x^1,\dots,x^m) = (x^1,\dots,x^n)$. □

1.6 Submanifolds

A submanifold allows us to treat a subset as a smooth space in its own right. The definition must reconcile two features: the induced topology and injectivity of the differential. The following figures motivate this condition before we formulate it precisely.

Definition 1.6.1. (Embeddings and submanifolds) Let M be a smooth manifold without boundary.

(a) A smooth map $F\colon N \to M$ is a **smooth embedding** if it is an injective immersion and a homeomorphism from N onto $F(N)$ with the topology induced by M.

Figure 1.4. Tangent space to a submanifold.

(b) A subset $S \subseteq M$, equipped with a smooth manifold structure, is an **immersed submanifold** if the inclusion $\iota\colon S \hookrightarrow M$ is an immersion.

(c) It is an **embedded submanifold** if ι is a smooth embedding. It is **properly embedded** if, in addition, ι is proper.

For an immersed submanifold, the topology on S may be finer than the subspace topology; for an embedded submanifold, the two coincide.

Definition 1.6.2. (Slice chart) Let M be a smooth manifold without boundary, and let $S \subseteq M$ and $p \in S$. A chart (U, φ) of M is **adapted to** S **at** p, or is a **slice chart**, if $p \in U$, $\varphi(p) = 0$, and, for some k,

$$\varphi(U \cap S) = \varphi(U) \cap \left(\mathbb{R}^k \times \{0\}^{n-k}\right).$$

The last equality includes the local topology of the subset, not merely an equality of tangent spaces.

Theorem 1.6.3. (Local slice criterion) A subset S of a smooth n-manifold without boundary admits an embedded submanifold structure of dimension k if and only if each $p \in S$ has a slice chart of dimension k. When it exists, this smooth structure is unique.

Proof. If slice charts exist, the maps

$$\varphi_S := \mathrm{pr}_{\mathbb{R}^k} \circ \varphi \restriction_{U \cap S}$$

are homeomorphisms onto open subsets of $\mathbb{R}^k$. Their changes of coordinates are restrictions of the smooth changes of charts on M, and hence are smooth. Since S carries the subspace topology, it is Hausdorff and second countable. The smooth chart lemma gives it the structure of a k-manifold, and in these coordinates the inclusion is $x \mapsto (x, 0)$; it is therefore an embedding.
Conversely, if $\iota\colon S \hookrightarrow M$ is an embedding, Theorem 1.5.10 applied to ι gives this normal form in a neighborhood of each point. Being a homeomorphism onto its image allows us to shrink the neighborhood in M until no other parts of S occur there. This gives the slice equality. Finally, any structure making S an

embedded submanifold has these same restricted charts, which proves uniqueness. □

Proposition 1.6.4. (Tangent space of an embedded submanifold) Let M be a smooth manifold without boundary, let $S \subseteq M$ be an embedded submanifold without boundary of dimension k, and let $\iota\colon S \hookrightarrow M$ be the inclusion. Then $d\iota_p$ is injective and gives the identification

$$T_pS \cong d\iota_p(T_pS) \subseteq T_pM.$$

In a slice chart $(x^1,\dots,x^n)$,

$$d\iota_p(T_pS) = \operatorname{span}\left\{\partial_1|_p,\dots,\partial_k|_p\right\}.$$

Proof. In slice coordinates, ι is the linear inclusion $\mathbb{R}^k \hookrightarrow \mathbb{R}^n$. Its differential has the same form, proving both injectivity and the formula. □

Proposition 1.6.5. (Smooth graphs) Let M and N be smooth manifolds without boundary. If $U \subseteq M$ is open and $f : U \to N$ is smooth, then

$$\Gamma_f := \{(p, f(p)) \mid p \in U\} \subseteq M \times N$$

is an embedded submanifold diffeomorphic to U. At the point $(p, f(p))$,

$$T_{(p,f(p))}\Gamma_f = \{(v, df_p v) \mid v \in T_pM\}.$$

Proof. The map $F\colon U \to M\times N$, $F(p) = (p, f(p))$, is injective, and $dF_p(v) = (v, df_p v)$ is injective. The restriction of the first projection to Γ_f is the continuous inverse of F, so F is an embedding. The tangent-space formula follows from the preceding proposition. □

Definition 1.6.6. Let $F\colon M \to N$ be a smooth map between manifolds without boundary, and let $q \in N$. We say that q is a **regular value** of F if dF_p is surjective for each $p \in F^{-1}(q)$. If the preimage is empty, the condition is considered satisfied.

Theorem 1.6.7. (Regular preimage theorem) Let M^m and N^n be smooth manifolds without boundary, and let $F\colon M \to N$ be smooth. If q is a regular value, then $F^{-1}(q)$ is either empty or a properly embedded submanifold of dimension $m-n$, and

$$T_pF^{-1}(q) = \ker dF_p, \qquad p \in F^{-1}(q).$$

Proof. At each point of the level set, Theorem 1.5.10 gives coordinates in which $F(x^1,\dots,x^m) = (x^1,\dots,x^n)$. The level set is then the slice $x^1 = \cdots = x^n = 0$, and the preceding local criterion gives it its embedded structure. The same coordinate expression identifies its tangent space with the kernel of dF_p. Since $\{q\}$ is closed, the level set is a closed subset of M; the inclusion of a closed subset is proper over every compact set. □

Definition 1.6.8. (Submanifold with boundary) A smooth manifold S with boundary contained in a smooth manifold M is an **embedded submanifold with boundary** if the inclusion $S \hookrightarrow M$ is a smooth embedding. If M has no boundary, a **half-slice chart** of dimension k for S is a chart of M in which

$$S \cap U \longleftrightarrow \varphi(U) \cap \left(\mathbb{H}^k \times \{0\}^{n-k}\right),$$

where $\mathbb{H}^k = \mathbb{R}^{k-1} \times [0, \infty)$.

Theorem 1.6.9. (Local criterion with boundary) Let M be a smooth manifold without boundary and let $S \subseteq M$. Then S is an embedded submanifold with boundary of dimension k if and only if each interior point of S has a slice chart and each point of ∂S has a half-slice chart. This characterization uniquely determines the smooth structure of S.

Proof. First suppose the indicated charts exist. In a slice chart, define

$$\varphi_S := \mathrm{pr}_{\mathbb{R}^k} \circ \varphi \restriction_{U \cap S},$$

and in a half-slice chart use the same formula, with image in $\mathbb{H}^k$. These maps are homeomorphisms onto open subsets of $\mathbb{R}^k$ or relatively open subsets of $\mathbb{H}^k$. If two of them overlap, the change of coordinates is obtained by restricting a change of charts on M to $\mathbb{R}^k \times \{0\}^{n-k}$. More precisely, if F is the ambient change of coordinates, the change on S is represented by

$$u \longmapsto \mathrm{pr}_{\mathbb{R}^k} F(u, 0).$$

This expression extends smoothly to an open subset of $\mathbb{R}^k$, as does its inverse. Thus the restricted charts form a smooth atlas with boundary on S. In these charts, the inclusion has the expression $u \mapsto (u, 0)$, so it is an immersion. Since S carries the subspace topology, the inclusion is also a homeomorphism onto its image and is therefore an embedding.

Conversely, suppose the inclusion $\iota\colon S \hookrightarrow M$ is an embedding. At an interior point, Theorem 1.5.10 applies, as in Theorem 1.6.3. Now let $p \in \partial S$. Choose a boundary chart

$$\theta\colon W \longrightarrow O \cap \mathbb{H}^k$$

of S, centered at p, where $O \subseteq \mathbb{R}^k$ is open, and a chart ψ of M centered at p. After shrinking W and the domain of ψ, the coordinate map

$$f := \psi \circ \iota \circ \theta^{-1}$$

admits a smooth extension $\widehat{f}\colon \widehat{O} \to \mathbb{R}^n$ to an open set $\widehat{O} \subseteq \mathbb{R}^k$ containing the origin. Since $d\iota_p$ is injective, $D\widehat{f}(0)$ has rank k. Some minor of order k remains nonsingular in a neighborhood of 0; hence $\widehat{f}$ has constant rank k there. The Euclidean rank theorem gives local diffeomorphisms α and β, with $\alpha(0) = 0$, such that

$$(\beta \circ \widehat{f} \circ \alpha^{-1})(u) = (u, 0)$$

for u in a neighborhood of 0 in $\mathbb{R}^k$.

It remains to straighten the image under α of the half-space constituting the original domain. In a neigh-

borhood of 0, define

$$r(u) := \big(\alpha^{-1}(u)\big)^k.$$

Since α is a diffeomorphism, $dr_0 \neq 0$. Choose linear forms $\ell^1, \dots, \ell^{k-1}$ such that $\ell^1, \dots, \ell^{k-1}, dr_0$ form a basis for $(\mathbb{R}^k)^*$, and define

$$\eta(u) := (\ell^1(u), \dots, \ell^{k-1}(u), r(u)).$$

The differential of η at 0 is invertible. By the inverse function theorem, there are open neighborhoods A_η and B_η of the origin such that

$$\eta \colon A_\eta \longrightarrow B_\eta$$

is a diffeomorphism. Shrink the domains of α and β so that the image of α is contained in A_η. Then

$$\eta\big(\alpha(O \cap \mathbb{H}^k)\big) = \eta(\alpha(O)) \cap \mathbb{H}^k$$

locally, since the last component of $\eta \circ \alpha$ is the last coordinate of the original domain. After also restricting the normal variables, choose a neighborhood C of the origin in $\mathbb{R}^{n-k}$ and define the diffeomorphism

$$\widetilde{\eta} \colon A_\eta \times C \longrightarrow B_\eta \times C, \qquad \widetilde{\eta}(u, z) := (\eta(u), z).$$

Set $\alpha_1 := \eta \circ \alpha$ and $\beta_1 := \widetilde{\eta} \circ \beta$, after the corresponding restriction of the domain of β. Then

$$\begin{aligned}(\beta_1 \circ \widehat{f} \circ \alpha_1^{-1})(u) &= \widetilde{\eta}\big(\beta \circ \widehat{f} \circ \alpha^{-1}(\eta^{-1}(u))\big) \\ &= \widetilde{\eta}(\eta^{-1}(u), 0) = (u, 0).\end{aligned}$$

Thus the ambient chart $\beta_1 \circ \psi$ sends the local image of S to $\mathbb{H}^k \times \{0\}^{n-k}$. Since W is open in S and S has the topology induced by M, there exists an ambient open set whose intersection with S is contained in W. Restricting the chart once more excludes the points of S outside the local image and gives a half-slice chart centered at p.

The construction also proves uniqueness. In any smooth structure with boundary for which the inclusion is an embedding, charts obtained by restricting slice charts and half-slice charts are smooth. Conversely, these charts generate the smooth structure because they cover S. Thus every structure with the stated property has the same maximal atlas. □

Theorem 1.6.10. (The boundary as a submanifold) If M is a smooth manifold with boundary of dimension n, then ∂M has a unique smooth manifold structure without boundary of dimension $n-1$ for which the inclusion $\iota_\partial \colon \partial M \hookrightarrow M$ is a proper embedding. In a boundary chart $(x^1, \dots, x^n)$,

$$d(\iota_\partial)_p(T_p \partial M) = \operatorname{span}\left\{ \partial_1|_p, \dots, \partial_{n-1}|_p \right\}.$$

Proof. For each boundary chart (U, φ), the map

$$\varphi_\partial := \operatorname{pr}_{\mathbb{R}^{n-1}} \circ \varphi \restriction_{U \cap \partial M}$$

is a homeomorphism onto an open subset of $\mathbb{R}^{n-1}$. Smooth invariance of the boundary ensures that the changes of coordinates preserve $x^n = 0$; their restrictions, and those of their inverses, are smooth. These

charts give ∂M the asserted structure. In these charts, the inclusion is $(x',0) \mapsto (x',0)$, proving the tangent-space assertion and uniqueness. The inclusion is an embedding because we use the subspace topology. Finally, ∂M is closed in M, so its intersection with any compact set is compact and the inclusion is proper. □

Theorem 1.6.11. (Regular preimage in a manifold with boundary) Let M^m be a smooth manifold with boundary, let N^n be a manifold without boundary, and let $F\colon M \to N$ be smooth. If $q \in N$ is a regular value of both F and $F\restriction_{\partial M}$, then $F^{-1}(q)$ is a properly embedded submanifold with boundary of dimension $m-n$, and

$$\partial\big(F^{-1}(q)\big) = F^{-1}(q) \cap \partial M, \qquad T_p F^{-1}(q) = \ker dF_p.$$

Proof. At interior points, Theorem 1.6.7 applies. Let $p \in F^{-1}(q) \cap \partial M$. Take boundary coordinates $(y^1,\dots,y^{m-1},t)$ centered at p, with $t \geq 0$, and coordinates on N centered at q. Denote the coordinate representation of F by f. Surjectivity of

$$d(F\restriction_{\partial M})_p\colon T_p\partial M \longrightarrow T_qN$$

implies that, after reordering the tangential variables, the matrix $\partial(f^1,\dots,f^n)/\partial(y^1,\dots,y^n)$ is invertible at the origin. Consider

$$\Psi(y,t) := \big(f(y,t), y^{n+1},\dots,y^{m-1},t\big).$$

Its Jacobian at the origin is invertible. Extend f smoothly to negative values of t and apply the inverse function theorem to the extension of Ψ. Since the last component of Ψ is t, the resulting restriction is a diffeomorphism between relative neighborhoods in the half-space and preserves its boundary. In the new coordinates $z = \Psi(y,t)$, we have

$$f(z) = (z^1,\dots,z^n).$$

Consequently, the level set $f^{-1}(0)$ is described by $z^1 = \cdots = z^n = 0$ and $z^m \geq 0$; it is a half-slice of dimension $m-n$, whose boundary corresponds exactly to $t = 0$.
Together with the slices obtained at interior points, Theorem 1.6.9 gives $F^{-1}(q)$ the structure of an embedded submanifold with boundary. In the preceding coordinates, the tangent space to the level set is the kernel of the linear projection representing dF_p, whence $T_pF^{-1}(q) = \ker dF_p$. Finally, $F^{-1}(q)$ is closed because $\{q\}$ is closed; thus the preimage of a compact set under the inclusion is a closed subset of a compact set, and is therefore compact. The inclusion is proper. □

The double replaces a manifold with boundary by a manifold without boundary containing two copies of the original manifold. This construction is useful, for example, for extending smooth objects across the boundary and locally applying results formulated for manifolds without boundary.

Theorem 1.6.12. (Collar and smooth double) Let M be a smooth manifold with boundary.

(a) There exist $\varepsilon > 0$ and a smooth embedding

$$c\colon \partial M \times [0,\varepsilon) \longrightarrow M, \qquad c(x,0) = x,$$

whose image is a neighborhood of ∂M in M.

(b) If M_+ and M_- are two copies of M, the quotient

$$DM := (M_+ \sqcup M_-)/\big(x_+ \sim x_- \text{ for } x \in \partial M\big)$$

admits a smooth manifold structure without boundary. The inclusions of both copies are smooth embeddings with boundary, and their boundaries have the same image, an embedded hypersurface of DM.

The diffeomorphism type of DM does not depend on the chosen collar.

Proof. Part (a) is the collar theorem [94, Theorem 9.25]. For part (b), apply the smooth manifold gluing theorem to the two copies of M and the identity diffeomorphism of ∂M; see [94, Theorem 9.29 and Example 9.32]. These results construct the smooth structure on the quotient, prove the assertions about the inclusions, and show that two choices of collar produce diffeomorphic doubles. □

Corollary 1.6.13. (Smooth extension to the double) Let M be a smooth manifold with boundary and let DM be its double. Every smooth function and every smooth tensor field on one copy of M admit a smooth extension to DM. If $\mathbf{g}$ is a Riemannian metric on M, a symmetric tensor extension $\widetilde{\mathbf{g}}$ can be chosen that is Riemannian on an open neighborhood of that copy.

Proof. Identify M with the copy $M_+ \subset DM$ and let $\mathbf{T}$ be a smooth tensor field on M_+. By the definition of smoothness up to the boundary, for every $p \in M_+$ there exist an open set $V_p \subset DM$ containing p and a smooth tensor field $\widetilde{\mathbf{T}}_p$ on V_p whose restriction to $V_p \cap M_+$ agrees with $\mathbf{T}$. At interior points, we simply take $V_p \subset \mathrm{Int}(M_+)$; at boundary points, we extend the local components of $\mathbf{T}$ to negative values of the normal coordinate in a chart of the double.
The family

$$\{V_p : p \in M_+\} \cup \{DM \setminus M_+\}$$

is an open cover of DM. Let $(\chi_p)_{p\in M_+} \cup \{\chi_0\}$ be a smooth, locally finite partition of unity subordinate to this cover. Each product $\chi_p \widetilde{\mathbf{T}}_p$, extended by zero outside V_p, is a smooth tensor field on DM. By local finiteness, the sum

$$\widetilde{\mathbf{T}} := \sum_{p\in M_+} \chi_p \widetilde{\mathbf{T}}_p$$

is well defined and smooth. If $x \in M_+$, then $\chi_0(x) = 0$, and each $\widetilde{\mathbf{T}}_p(x)$ occurring in the sum agrees with $\mathbf{T}(x)$; consequently,

$$\widetilde{\mathbf{T}}(x) = \left(\sum_{p\in M_+} \chi_p(x)\right) \mathbf{T}(x) = \mathbf{T}(x).$$

The same argument, with tensors of type $(0,0)$, treats functions.
If $\mathbf{T} = \mathbf{g}$, replace the resulting extension by its symmetric part. The extension still agrees with $\mathbf{g}$ on M_+. Since the set of positive definite symmetric bilinear forms is open in each fiber and the extension is continuous, the set of points of DM where $\widetilde{\mathbf{g}}$ is positive definite is an open set containing M_+. Therefore, $\widetilde{\mathbf{g}}$ is a Riemannian metric on an open neighborhood of that copy. □

1.7 Vector bundles and the cotangent bundle

The tangent bundle suggests a more general construction. Over each point of a manifold we may place a vector space, provided these fibers can be identified locally in a smooth manner and the identifications are linear on each fiber. This leads to vector bundles, the natural setting for fields, differential forms, tensors, spinors, and the geometric unknowns that will appear later.

Definition 1.7.1. Let M be a topological space. A **real vector bundle of rank k over M** is a topological space $\mathbf{E}$ together with a continuous surjective function $\pi\colon \mathbf{E} \longrightarrow M$ such that:

(a) For each $p \in M$, the fiber $\mathbf{E}_p = \pi^{-1}(p)$ over p is equipped with the structure of a real vector space of dimension k.

(b) For each $p \in M$, there exist a neighborhood U of p in M and a homeomorphism $\Phi\colon \pi^{-1}(U) \longrightarrow U \times \mathbb{R}^k$ such that $\pi_U \circ \Phi = \pi$, where $\pi_U\colon U \times \mathbb{R}^k \longrightarrow U$ is the projection, and for each $q \in U$, the restriction of Φ to $\mathbf{E}_q$ is an isomorphism from $\mathbf{E}_q$ to $\{q\} \times \mathbb{R}^k \cong \mathbb{R}^k$. ($\Phi$ is called a **local trivialization of $\mathbf{E}$ over U.**)

Definition 1.7.2. Let M and $\mathbf{E}$ be smooth manifolds with or without boundary such that $\pi\colon \mathbf{E} \longrightarrow M$ is a continuous surjective map making $\mathbf{E}$ a real vector bundle of rank k over M. We say that $\mathbf{E}$ is a **smooth vector bundle of rank k over M** if

(a) π is a smooth map.

(b) For each $p \in M$, there exist a neighborhood U of p and a local trivialization $\Phi\colon \pi^{-1}(U) \longrightarrow U \times \mathbb{R}^k$ of $\mathbf{E}$ over U such that Φ is a diffeomorphism. This map is called a **smooth local trivialization of $\mathbf{E}$ over U**.

Definition 1.7.3. (Smooth complex vector bundle) Let M be a smooth manifold with or without boundary. A *smooth complex vector bundle of rank r* over M is a smooth map $\pi\colon \mathbf{E} \to M$ admitting, around each point of M, a smooth trivialization

$$\Phi\colon \pi^{-1}(U) \longrightarrow U \times \mathbb{C}^r$$

whose restriction to each fiber is complex linear. In particular, the total space is regarded as a smooth real manifold, and the transition functions take values in $GL(r, \mathbb{C})$.

Remark 1.7.4. When no ambiguity arises, we omit the projection when referring to a vector bundle, and may even omit the base space M. Thus, if $\pi\colon \mathbf{E} \longrightarrow M$ is a vector bundle, we write $\mathbf{E} \longrightarrow M$ or $(\mathbf{E}, M)$ or simply $\mathbf{E}$.

The simplest example of a vector bundle is what is known as the *trivial bundle of rank k over M*.

Example 1.7.5. If M is a smooth manifold with or without boundary, the bundle $\underline{\mathbb{R}}^k_M = M \times \mathbb{R}^k$ is a smooth vector bundle of rank k over M. It is called the ***trivial bundle of rank k over M***.

The vector bundle in this example is trivial in the sense that it admits a global trivialization (a local trivialization with $U = M$).

Figure 1.5. Local trivialization of a vector bundle.

The tangent bundle provides another example of a vector bundle.

Proposition 1.7.6. Let M be a smooth manifold with or without boundary of dimension n. Its tangent bundle TM is a smooth vector bundle of rank n over M.

Proof. Given a coordinate chart (U,φ) of M such that $\varphi = (x^1,\dots,x^n)$ and $p \in U$, define the map $\Phi\colon \pi^{-1}(U) \longrightarrow U \times \mathbb{R}^n$ by

$$\Phi\left(p, v^i \partial_i\Big|_p\right) = (p,(v^1,\dots,v^n)).$$

The map Φ is linear on the fibers of π and satisfies $\pi_U \circ \Phi = \pi$. If (U,φ) is an interior chart, the tangent-bundle chart in Proposition 1.4.20 satisfies

$$\widetilde{\varphi} = (\varphi \times \mathrm{Id}_{\mathbb{R}^n}) \circ \Phi.$$

If it is a boundary chart, the tangent-bundle chart places the vector coordinates first, followed by those of the base point. Therefore,

$$\widetilde{\varphi} = S \circ (\varphi \times \mathrm{Id}_{\mathbb{R}^n}) \circ \Phi, \qquad S(x,v) = (v,x).$$

The interchange S is a linear isomorphism of $\mathbb{R}^{2n}$ and sends $\varphi(U) \times \mathbb{R}^n$ diffeomorphically onto $\mathbb{R}^n \times \varphi(U)$, a relatively open subset of $\mathbb{H}^{2n}$. In both cases, Φ is a composition of diffeomorphisms, and hence is a smooth

local trivialization. □

Every nontrivial vector bundle requires more than one local trivialization. The following lemma shows that the composition of two smooth local trivializations has a simple form where they overlap.

Lemma 1.7.7. Let M be a smooth manifold with or without boundary and let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle of rank k. Suppose $\Phi\colon \pi^{-1}(U) \longrightarrow U \times \mathbb{R}^k$ and $\Psi\colon \pi^{-1}(V) \longrightarrow V \times \mathbb{R}^k$ are smooth local trivializations of $\mathbf{E}$ with $U \cap V \neq \varnothing$. Then there exists a smooth map $\tau\colon U \cap V \longrightarrow GL(k,\mathbb{R})$ such that

$$\Phi \circ \Psi^{-1}\colon (U \cap V) \times \mathbb{R}^k \longrightarrow (U \cap V) \times \mathbb{R}^k$$

has the form

$$(\Phi \circ \Psi^{-1})(p,v) = (p, \tau(p)v),$$

where $\tau(p)v$ denotes the usual action of the matrix $\tau(p)$ in $k \times k$ on $v \in \mathbb{R}^k$.

Proof. The following diagram commutes:

$$\begin{array}{ccccc} (U \cap V) \times \mathbb{R}^k & \xleftarrow{\Psi} & \pi^{-1}(U \cap V) & \xrightarrow{\Phi} & (U \cap V) \times \mathbb{R}^k \\ & {\scriptstyle \pi_1} \searrow & \downarrow {\scriptstyle \pi} & \swarrow {\scriptstyle \pi_1} & \\ & & U \cap V & & \end{array}$$

where the maps at the top are interpreted as the restrictions of Ψ and Φ to $\pi^{-1}(U \cap V)$. Commutativity of the diagram tells us that

$$\pi_1 \circ (\Phi \circ \Psi^{-1}) = \pi_1,$$

where π_1 is projection onto the first coordinate.
This implies that there exists a map $\sigma\colon (U \cap V) \times \mathbb{R}^k \longrightarrow \mathbb{R}^k$ such that

$$(\Phi \circ \Psi^{-1})(p,v) = (p, \sigma(p,v)).$$

By construction, σ is the second coordinate function of $\Phi \circ \Psi^{-1}$; that is,

$$\sigma = \pi_2 \circ (\Phi \circ \Psi^{-1}),$$

where π_2 is projection onto the second coordinate.
For each $p \in U \cap V$, the map $v \mapsto \sigma(p,v)$ from $\mathbb{R}^k$ to itself is linear and invertible, since Φ and Ψ are local trivializations; hence $\Phi \circ \Psi^{-1}$ is a fiberwise diffeomorphism preserving the first coordinate. In particular, there is a unique matrix $\tau(p) \in GL(k,\mathbb{R})$ such that

$$\sigma(p,v) = \tau(p)v \qquad \text{for every } v \in \mathbb{R}^k.$$

We now show that $p \mapsto \tau(p)$ is smooth.
Fix the standard basis $(e_1,\dots,e_k)$ of $\mathbb{R}^k$. Since $v \mapsto \sigma(p,v)$ is linear, it is determined by its values on the basis

vectors, and we define $\tau(p)$ as the matrix with these values as columns:

$$\tau(p)e_j = \sigma(p, e_j) \qquad \text{for } j \in \{1, \dots, k\}.$$

The map

$$p \longmapsto \sigma(p, e_j) = \pi_2\big((\Phi \circ \Psi^{-1})(p, e_j)\big)$$

is a composition of smooth functions (since (p, e_j) is constant in the second coordinate and $\Phi \circ \Psi^{-1}$ is smooth), and is therefore a smooth map from $U \cap V$ to $\mathbb{R}^k$ for each $j \in \{1, \dots, k\}$.
Denoting projection onto the ith coordinate by $\mathrm{pr}_i \colon \mathbb{R}^k \longrightarrow \mathbb{R}$, the entries of the matrix $\tau(p) = (\tau_{ij}(p))$ are given by

$$\tau_{ij}(p) = \mathrm{pr}_i\big(\sigma(p, e_j)\big), \qquad i, j \in \{1, \dots, k\}.$$

Each function τ_{ij} is smooth on p, so $p \mapsto \tau(p)$ is a smooth map.
Consequently,

$$(\Phi \circ \Psi^{-1})(p, v) = (p, \tau(p)v)$$

with $\tau \colon U \cap V \longrightarrow GL(k, \mathbb{R})$ a smooth function, as desired. □

The following result allows us to construct smooth vector bundles.

Lemma 1.7.8. (Smooth vector bundle lemma) Let $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, let M be a smooth manifold with or without boundary, and for each $p \in M$ let $\mathbf{E}_p$ be a vector space of fixed dimension r over $\mathbb{K}$. Set $\mathbf{E} = \coprod_{p \in M} \mathbf{E}_p$ and let $\pi \colon \mathbf{E} \longrightarrow M$ be the map sending each element of $\mathbf{E}_p$ to p. Suppose we are given:

(a) An open cover $\{U_\alpha\}_{\alpha \in A}$ of M.

(b) For each $\alpha \in A$, a fiber-preserving bijection

$$\Phi_\alpha \colon \pi^{-1}(U_\alpha) \longrightarrow U_\alpha \times \mathbb{K}^r$$

whose restriction to $\mathbf{E}_p$ is a $\mathbb{K}$-linear isomorphism from $\mathbf{E}_p$ onto $\{p\} \times \mathbb{K}^r$.

(c) For $U_\alpha \cap U_\beta \neq \varnothing$, a smooth map $g_{\alpha\beta} \colon U_\alpha \cap U_\beta \longrightarrow GL(r, \mathbb{K})$ such that

$$(\Phi_\alpha \circ \Phi_\beta^{-1})(p, z) = (p, g_{\alpha\beta}(p)z).$$

Then $\mathbf{E}$ has a unique topology and a unique real smooth structure making it a smooth manifold with or without boundary, for which π is smooth and the maps Φ_α are smooth, $\mathbb{K}$-linear local trivializations. Addition $\mathbf{E} \times_M \mathbf{E} \to \mathbf{E}$ and scalar multiplication $\mathbb{K} \times \mathbf{E} \to \mathbf{E}$ are smooth. In particular, $\mathbf{E} \to M$ is a smooth real vector bundle if $\mathbb{K} = \mathbb{R}$ and a smooth complex vector bundle if $\mathbb{K} = \mathbb{C}$.

Proof. Let $d = \dim_{\mathbb{R}} \mathbb{K}$. For each α and each chart (V, φ) of M with $V \subseteq U_\alpha$, define

$$\widetilde{\varphi}_{\alpha, V} := (\varphi \times \mathrm{Id}_{\mathbb{K}^r}) \circ \Phi_\alpha \colon \pi^{-1}(V) \longrightarrow \varphi(V) \times \mathbb{K}^r.$$

Identify $\mathbb{K}^r$ with $\mathbb{R}^{dr}$. If (V, φ) is an interior chart, its image is open in $\mathbb{R}^{n+dr}$; if it is a boundary chart, reordering the coordinates identifies $\varphi(V) \times \mathbb{R}^{dr}$ with a relatively open subset of $\mathbb{H}^{n+dr}$.

Consider two charts (V,φ) and (W,ψ) subordinate, respectively, to U_α and U_β. On the intersection, the change of coordinates from the second chart to the first is

$$(y,z) \longmapsto \left(\varphi\circ\psi^{-1}(y), g_{\alpha\beta}(\psi^{-1}(y))z\right).$$

It is smooth as a real map, and its inverse is obtained by interchanging α,β; indeed, the given bijections imply $g_{\beta\alpha} = g_{\alpha\beta}^{-1}$. The images of the intersections are open because they have the form $\varphi(V\cap W)\times\mathbb{K}^r$.
This family of charts on the total space has a countable subfamily covering $\mathbf{E}$: simply choose a countable subcover of the domains V on the base, since M is second countable. Two points of $\mathbf{E}$ lying in the same fiber belong to a common chart $\pi^{-1}(V)$. If their base points are distinct, first choose disjoint coordinate domains in M, restricted to their respective sets U_α, and then take their preimages. This verifies the second countability and separation assumptions of Lemma 1.2.19. The lemma provides a Hausdorff, second countable topology and a smooth structure on $\mathbf{E}$ for which the maps $\widetilde{\varphi}_{\alpha,V}$ are charts.
Each Φ_α is a diffeomorphism: after restriction to $\pi^{-1}(V)$, with $V\subseteq U_\alpha$, its expression in the newly constructed charts and the product chart of $V\times\mathbb{K}^r$ is the identity. In the same coordinates, π is $(x,z)\mapsto x$, and hence is smooth. Fiberwise addition and scalar multiplication have the expressions

$$(x,z,w)\longmapsto(x,z+w), \qquad (\lambda,x,z)\longmapsto(x,\lambda z),$$

which are smooth as real maps and $\mathbb{K}$-linear in the fiber variables.
If another topology and smooth structure had the properties in the statement, all the maps Φ_α would be diffeomorphisms. Consequently, the sets $\Phi_\alpha^{-1}(O)$, with O open in $U_\alpha\times\mathbb{K}^r$, would necessarily form a basis for the same topology, and the charts $\widetilde{\varphi}_{\alpha,V}$ would belong to the same smooth structure. This proves uniqueness.
In the case with boundary, the construction also shows that $\partial\mathbf{E} = \pi^{-1}(\partial M)$.
In the complex case, the same construction is carried out on the underlying real manifold and preserves the complex linearity of the transition maps. □

This lemma produces nontrivial vector bundles, as the following example shows:

Example 1.7.9. (Möbius bundle) Define on $\mathbb{R}^2$ the relation

$$(x,y)\sim(x',y') \Longleftrightarrow (x',y') = (x+n,(-1)^n y), \quad n\in\mathbb{Z}.$$

Let $\mathbf{E} = \mathbb{R}^2/\sim$ and let $q\colon\mathbb{R}^2\longrightarrow\mathbf{E}$ be the quotient projection. Geometrically, $\mathbf{E}$ is obtained from $[0,1]\times\mathbb{R}$ by identifying $(0,y)$ with $(1,-y)$; the subset $q([0,1]\times[-r,r])$ is the compact Möbius strip of width $2r$.
Let $\pi_1(x,y) = x$ and $\varepsilon(x) = e^{2\pi i x}$. If U is a proper open arc of $\mathbb{S}^1$ admitting a continuous branch of the argument, each component $\widetilde{U}$ of $\varepsilon^{-1}(U)$ is an open interval and $\varepsilon\restriction_{\widetilde{U}}\colon\widetilde{U}\to U$ is a diffeomorphism; its inverse is obtained by dividing that branch of the argument by 2π. Since $\varepsilon(x+n) = \varepsilon(x)$, the map $\varepsilon\circ\pi_1$ is constant on the equivalence classes of $\sim$. Therefore,

$$\pi\colon\mathbf{E}\longrightarrow\mathbb{S}^1, \qquad \pi([(x,y)]) = \varepsilon(x),$$

is well defined and satisfies $\pi\circ q = \varepsilon\circ\pi_1$. This is summarized by the diagram:

$$\begin{array}{ccc} \mathbb{R}^2 & \xrightarrow{q} & \mathbf{E} = \mathbb{R}^2/\sim \\ {\scriptstyle \pi_1}\downarrow & & \downarrow{\scriptstyle \pi} \\ \mathbb{R} & \xrightarrow{\varepsilon} & \mathbb{S}^1 \end{array}$$

Let $p \in \mathbb{S}^1$ and choose $x_0 \in \mathbb{R}$ such that $\varepsilon(x_0) = p$. First characterize the real numbers x with $\varepsilon(x) = p$. Since $\varepsilon(x) = e^{2\pi i x}$, the equality $\varepsilon(x) = \varepsilon(x_0)$ is equivalent to $e^{2\pi i(x-x_0)} = 1$. The real solutions of $e^{2\pi i t} = 1$ are precisely the integers $t \in \mathbb{Z}$, so $\varepsilon(x) = \varepsilon(x_0)$ if and only if $x - x_0 \in \mathbb{Z}$, that is, if and only if $x = x_0 + n$ for some $n \in \mathbb{Z}$. Consequently,

$$\pi^{-1}(p) = \{[(x,y)] \in \mathbf{E} \mid \varepsilon(x) = p\} = \{[(x_0+n, y)] \mid n \in \mathbb{Z},\ y \in \mathbb{R}\}.$$

We can rewrite this fiber by recalling the definition of $\sim$. We know that $(x_0+n, y) \sim (x_0, (-1)^n y)$ for any $n \in \mathbb{Z}$ and $y \in \mathbb{R}$. This allows us to conclude that

$$\pi^{-1}(p) = \{[(x_0, (-1)^n y)] \mid n \in \mathbb{Z}, y \in \mathbb{R}\},$$

which can be rewritten as $\pi^{-1}(p) = \{[(x_0, t)] \mid t \in \mathbb{R}\}$.
Define $j_p \colon \pi^{-1}(p) \longrightarrow \mathbb{R}$ by $j_p([(x_0,t)]) = t$.
We show that this does not depend on the chosen t: if $(x_0,t) \sim (x_0,t')$, there exists $n \in \mathbb{Z}$ such that $(x_0,t') = (x_0+n, (-1)^n t)$, which gives $n = 0$ and therefore $t = t'$.
The function j_p is injective because $j_p([(x_0,t)]) = j_p([(x_0,s)])$ implies $t = s$, and surjective because $a = j_p([(x_0,a)])$ for every $a \in \mathbb{R}$. Equip $\pi^{-1}(p)$ with the vector space structure given by

$$[(x_0,t)] + [(x_0,s)] := [(x_0, t+s)]$$

and

$$\lambda[(x_0,t)] = [(x_0, \lambda t)].$$

These operations are well defined by the uniqueness of the representative of the form (x_0,t) proved above. With these operations, j_p preserves addition and scalar multiplication, and is therefore a linear isomorphism. If another lift $x_0' = x_0 + m$ is chosen, with $m \in \mathbb{Z}$, then

$$[(x_0,t)] = [(x_0', (-1)^m t)].$$

The corresponding isomorphism j_p' satisfies $j_p' = (-1)^m j_p$. Since multiplication by $(-1)^m$ is a linear isomorphism of $\mathbb{R}$, the operations of addition and scalar multiplication transported to the fiber are unchanged. Its vector space structure is therefore independent of the chosen lift.
Take the cover

$$U_\pm = \mathbb{S}^1 \setminus \{(\pm 1, 0)\}.$$

Fix components

$$\widetilde{U}_- = (-\frac{1}{2}, \frac{1}{2}) \subset \varepsilon^{-1}(U_-), \qquad \widetilde{U}_+ = (0,1) \subset \varepsilon^{-1}(U_+),$$

so that $\varepsilon|_{\widetilde{U}_\pm} \colon \widetilde{U}_\pm \longrightarrow U_\pm$ are homeomorphisms. Define the trivializations

$$\Phi_\pm \colon \pi^{-1}(U_\pm) \longrightarrow U_\pm \times \mathbb{R}, \quad [(x,y)] \mapsto (\varepsilon(x), y), \ \ x \in \widetilde{U}_\pm,$$

Both satisfy $\pi = \pi_1 \circ \Phi_\pm$. For $p \in U_\pm$, let $x_\pm \in \widetilde{U}_\pm$ be the unique point with $\varepsilon(x_\pm) = p$. If $x_0 \in \mathbb{R}$ is any other lift of p, there exists $m \in \mathbb{Z}$ such that $x_0 = x_\pm + m$, and then

$$\Phi_\pm([(x_0, t)]) = \Phi_\pm([(x_\pm, (-1)^m t)]) = (p, (-1)^m t).$$

In particular, using the representative with $x_0 = x_\pm$, the second component is t. With any other lift, it changes only by the linear isomorphism $t \mapsto (-1)^m t$. Thus the restriction of $\Phi_\pm$ to each fiber is a vector space isomorphism.

We next compute the transition maps. Let $(p, v) \in (U_+ \cap U_-) \times \mathbb{R}$. To invert Φ_-, choose the representative

$$\Phi_-^{-1}(p, v) = [(x_-, v)] \quad \text{where} \quad x_- = (\varepsilon|_{\widetilde{U}_-})^{-1}(p) \in (-\frac{1}{2}, \frac{1}{2}) \setminus \{0\}.$$

To then apply Φ_+, express the same class using a representative whose first component lies in $\widetilde{U}_+ = (0, 1)$:

$$x_+ = \begin{cases} x_- + 1, & \text{if } x_- \in (-\frac{1}{2}, 0), \\ x_-, & \text{if } x_- \in (0, \frac{1}{2}), \end{cases} \qquad [(x_-, v)] = \begin{cases} [(x_+, -v)], & \text{if } x_- \in (-\frac{1}{2}, 0), \\ [(x_+, v)], & \text{if } x_- \in (0, \frac{1}{2}), \end{cases}$$

since $(x_-, v) \sim (x_- + 1, -v)$ by the equivalence relation. Consequently,

$$(\Phi_+ \circ \Phi_-^{-1})(p, v) = \begin{cases} (p, -v), & \text{if } x_- \in (-\frac{1}{2}, 0), \\ (p, v), & \text{if } x_- \in (0, \frac{1}{2}). \end{cases}$$

This can be written as

$$(\Phi_+ \circ \Phi_-^{-1})(p, v) = (p, \tau_{+-}(p)v), \qquad \tau_{+-} \colon U_+ \cap U_- \longrightarrow GL(1, \mathbb{R}),$$

where $\tau_{+-}(p) = -1$ on the component corresponding to $x_- \in (-\frac{1}{2}, 0)$ and $\tau_{+-}(p) = 1$ on the component corresponding to $x_- \in (0, \frac{1}{2})$. The image of τ_{+-} is the subset $\{+1, -1\} \subset GL(1, \mathbb{R})$, and τ_{+-} is smooth because it is constant on each connected component of $U_+ \cap U_-$.

These trivializations and transition maps satisfy the assumptions of Lemma 1.7.8. Therefore, $(\mathbf{E}, \pi, \mathbb{S}^1)$ is a smooth vector bundle of rank 1. To verify that it is nontrivial, suppose it admits a nowhere vanishing continuous section. Lifting it through q represents the section by a continuous function $a \colon \mathbb{R} \to \mathbb{R}$ satisfying

$$a(x + 1) = -a(x),$$

because of the relation $(x, y) \sim (x + 1, -y)$. If $a(0) > 0$, then $a(1) < 0$, and if $a(0) < 0$, then $a(1) > 0$; in both cases, the intermediate value theorem gives $x \in [0, 1]$ with $a(x) = 0$. The case $a(0) = 0$ is immediate. Thus every continuous section vanishes somewhere. A trivial rank-one bundle has the nowhere vanishing global section $p \mapsto (p, 1)$; therefore, $\mathbf{E}$ is nontrivial.

Figure 1.6. The Möbius bundle and $[0,1]\times\mathbb{R}$ as a fundamental domain representing it.

Operations on vector spaces also produce new bundles, as follows.

Definition 1.7.10. Given a smooth manifold M with or without boundary and smooth vector bundles $\pi'\colon \mathbf{E}' \longrightarrow M$ and $\pi''\colon \mathbf{E}'' \longrightarrow M$ of ranks k' and k'', respectively, define the **Whitney sum of $\mathbf{E}'$ and $\mathbf{E}''$** by $\mathbf{E}' \oplus_W \mathbf{E}'' := \coprod_{p\in M} (\mathbf{E}'_p \oplus \mathbf{E}''_p)$, with projection $\pi\colon \mathbf{E}'\oplus\mathbf{E}'' \longrightarrow M$ given by $\pi(p,(v',v'')) = p$ for each $p \in M$.

Proposition 1.7.11. Let M be a smooth manifold with or without boundary. The Whitney sum of two smooth vector bundles over M of ranks k' and k'' is a smooth vector bundle over M of rank $k'+k''$.

Proof. For each $p \in M$, consider an open neighborhood U of p over which there exist local trivializations (U,Φ') of $\mathbf{E}'$ and (U,Φ'') of $\mathbf{E}''$, and define $\Phi\colon \pi^{-1}(U) \longrightarrow U\times\mathbb{R}^{k'+k''}$ by $\Phi(v',v'') = (\pi'(v'),(\pi_{\mathbb{R}^{k'}}\circ\Phi'(v'),\pi_{\mathbb{R}^{k''}}\circ\Phi''(v'')))$.
Suppose we are given another pair of local trivializations $(\widetilde{U},\widetilde{\Phi}')$ and $(\widetilde{U},\widetilde{\Phi}'')$. Let $\tau'\colon (U\cap\widetilde{U}) \longrightarrow GL(k',\mathbb{R})$ and $\tau''\colon (U\cap\widetilde{U}) \longrightarrow GL(k'',\mathbb{R})$ be their respective transition functions. Then the transition function for $\mathbf{E}'\oplus_W\mathbf{E}''$ is given by:

$$(\widetilde{\Phi}\circ\Phi^{-1})(p,(v',v'')) = (p,\tau(p)(v',v'')),$$

where $\tau(p) = \begin{bmatrix} \tau'(p) & 0 \\ 0 & \tau''(p) \end{bmatrix}$, is smooth. Thus Lemma 1.7.8 ensures that $\mathbf{E}'\oplus\mathbf{E}''$ is a vector bundle of rank $k'+k''$ over M. □

We now introduce *local and global sections* and *local and global frames*. These will allow us to describe fully the vector bundles commonly used on a smooth manifold M. They will also make it easier to define vector fields and tensor fields.

Definition 1.7.12. Let $\pi\colon \mathbf{E} \longrightarrow M$ be a vector bundle. A **local section of $\mathbf{E}$** is a continuous map $\sigma\colon U \longrightarrow \mathbf{E}$ defined on an open set $U \subseteq M$ such that $\pi\circ\sigma = \mathrm{Id}_U$. If $U = M$, we also call σ a **global section of $\mathbf{E}$**.

Definition 1.7.13. Let M be a smooth manifold with or without boundary and let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle. A **smooth (local or global) section of $\mathbf{E}$** is a (local or global) section that is a smooth map from its domain to $\mathbf{E}$.

Remark 1.7.14. For some purposes, we need to consider functions that satisfy the conditions for a section except for continuity. A function satisfying all the conditions for a section other than continuity will be called a ***rough (local or global) section of*** $\mathbf{E}$.

Figure 1.7. Local section of a vector bundle.

Since we will consider sections of various degrees of regularity, it is useful to have notation that simplifies specifying the differentiability class of a section.

Definition 1.7.15. Let M be a smooth manifold with or without boundary and let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle. Let $k \in \mathbb{N}_0 \cup \{\infty\}$. Define

$$\Gamma^k(\mathbf{E}) := \{\sigma\colon M \longrightarrow \mathbf{E} \mid \sigma \text{ is a section of class } C^k\}.$$

We will sometimes need to work with compactly supported sections, so we also define the support of a section. If $\sigma\colon M \longrightarrow \mathbf{E}$ is a section (possibly rough), write

$$\operatorname{supp}(\sigma) := \overline{\{p \in M \mid \sigma(p) \neq 0_p\}}$$

and also define

$$\Gamma_c^k(\mathbf{E}) := \{\sigma \in \Gamma^k(\mathbf{E}) \mid \sigma \text{ has compact support}\}.$$

If $k = \infty$, we simply write

$$\Gamma(\mathbf{E}) := \Gamma^\infty(\mathbf{E}) \qquad \text{and} \qquad \Gamma_c(\mathbf{E}) := \Gamma_c^\infty(\mathbf{E}).$$

When we need to specify the manifold on which sections are being considered, for example when working with several bundles over different smooth manifolds, we write $\Gamma^k(M,\mathbf{E})$, $\Gamma(M,\mathbf{E})$, $\Gamma_c^k(M,\mathbf{E})$, and $\Gamma_c(M,\mathbf{E})$ with the same meanings as above.

We now define local and global frames. Among other uses, these will give an important criterion for determining when a section is smooth.

Definition 1.7.16. Let $\pi\colon \mathbf{E} \longrightarrow M$ be a vector bundle, let $U \subseteq M$ be an open subset, and let $(\sigma_1,\dots,\sigma_k)$ be a k-tuple of local sections of $\mathbf{E}$ over U. We say that $(\sigma_1,\dots,\sigma_k)$ is a **local frame for E over U** if $\{\sigma_1(p),\dots,\sigma_k(p)\}$ is a basis for $\mathbf{E}_p$ for each $p \in U$. If $U = M$, the local frame $(\sigma_1,\dots,\sigma_k)$ is called a **global frame for E over** U. To simplify notation, we write $(\sigma_i)_{i=1}^k := (\sigma_1,\dots,\sigma_k)$ or simply $(\sigma_i) := (\sigma_1,\dots,\sigma_k)$ when the index set is clear.

Definition 1.7.17. Let M be a smooth manifold with or without boundary. If $\pi\colon \mathbf{E} \longrightarrow M$ is a smooth vector bundle, we say that a local frame $(\sigma_i)_{i=1}^k$ defined on an open subset U of M is a **smooth local frame** if σ_i is a smooth section for every $i \in \{1,\dots,k\}$.

Smooth local frames and smooth local trivializations of a smooth vector bundle are related as follows:

Proposition 1.7.18. Let M be a smooth manifold with or without boundary. If $\pi\colon \mathbf{E} \longrightarrow M$ is a smooth vector bundle of rank k, then:

(a) Every smooth local trivialization $\Phi\colon \pi^{-1}(U) \longrightarrow U \times \mathbb{R}^k$ induces a smooth local frame given by $\sigma_i = \Phi^{-1}(p,\mathbf{e}_i)$ for each $p \in U$.

(b) Every smooth local frame (σ_i) defined on an open set $U \subseteq M$ induces a smooth local trivialization.

Proof. (a) If $\Phi\colon \pi^{-1}(U) \longrightarrow U \times \mathbb{R}^k$ is a smooth local trivialization of $\mathbf{E}$, we can construct a smooth local frame for $\mathbf{E}$ over U. For each $i \in \{1,\dots,k\}$, define maps $\sigma_1,\dots,\sigma_k\colon U \longrightarrow \mathbf{E}$ by $\sigma_i(p) = \Phi^{-1}(p,\mathbf{e}_i) = \Phi^{-1} \circ \widetilde{\mathbf{e}_i}(p)$, where $\widetilde{\mathbf{e}_i}\colon M \longrightarrow M \times \mathbb{R}^k$, $\widetilde{\mathbf{e}_i}(p) = (p,\mathbf{e}_i)$, and $\{\mathbf{e}_i\}_{i=1}^k$ is the standard basis of $\mathbb{R}^k$. The family $(\widetilde{\mathbf{e}_i})_{i=1}^k$ forms a smooth global frame for the bundle $\pi_1\colon M \times \mathbb{R}^k \longrightarrow M$, where π_1 is projection onto the first coordinate.

Then σ_i is smooth because Φ is a diffeomorphism; moreover, $\pi_1 \circ \Phi = \pi$, so

$$\pi \circ \sigma_i(p) = \pi \circ \Phi^{-1}(p,\mathbf{e}_i) = \pi_1(p,\mathbf{e}_i) = p,$$

which says that σ_i is a section. To see that $(\sigma_i(p))$ forms a basis for $\mathbf{E}_p$, note that Φ restricts to an isomorphism from $\mathbf{E}_p$ to $\{p\}\times\mathbb{R}^k$ and that $\Phi(\sigma_i(p)) = (p,\mathbf{e}_i)$; hence Φ sends $(\sigma_i(p))$ to the standard basis for $\{p\} \times \mathbb{R}^k$. Therefore, (σ_i) is a smooth local frame for $\mathbf{E}$, called **the smooth local frame associated with the smooth local trivialization** Φ.

(b) Suppose $(\sigma_i)_{i=1}^k$ is a smooth local frame for $\mathbf{E}$ defined on an open set $U \subseteq M$. Define $\Psi\colon U \times \mathbb{R}^k \longrightarrow \pi^{-1}(U)$ by

$$\Psi(p,(v^1,\dots,v^k)) = v^i \sigma_i(p).$$

Since $\{\sigma_i(p) \mid i \in \{1,\dots,k\}\}$ forms a basis for $\mathbf{E}_p$ for each $p \in U$, Ψ is bijective. Moreover, $\sigma_i = \Psi \circ \widetilde{\mathbf{e}}_i$. If we prove that Ψ is a diffeomorphism, then Ψ^{-1} will be a smooth local trivialization whose associated smooth local frame is $(\sigma_i)_{i=1}^k$. Since Ψ is bijective, it suffices to show that it is a local diffeomorphism. Let $q \in U$. By the definition of a smooth vector bundle, there exist an open set $V_0 \subseteq M$ with $q \in V_0$ and a smooth local trivialization $\Phi\colon \pi^{-1}(V_0) \longrightarrow V_0 \times \mathbb{R}^k$. Replacing V_0 by $V := V_0 \cap U$ and restricting Φ gives a smooth local trivialization over an open set $V \subseteq U$ containing q. Since Φ is a diffeomorphism, it suffices to prove that

$$(\Phi \circ \Psi)\restriction_{V\times\mathbb{R}^k}\colon V \times \mathbb{R}^k \longrightarrow V \times \mathbb{R}^k$$

is a diffeomorphism.

For each $i \in \{1,\dots,k\}$, the map $(\Phi \circ \sigma_i)\restriction_V\colon V \longrightarrow V \times \mathbb{R}^k$ is smooth. Thus there exist smooth functions $\sigma_i^1,\dots,\sigma_i^k\colon V \longrightarrow \mathbb{R}$ such that $(\Phi \circ \sigma_i)(p) = (p,(\sigma_i^1(p),\dots,\sigma_i^k(p)))$ for every $p \in V$. Consequently,

$$(\Phi \circ \Psi)(p,(v^1,\dots,v^k)) = (p,(v^i\sigma_i^1(p),\dots,v^i\sigma_i^k(p))),$$

so $(\Phi \circ \Psi)\restriction_{V\times\mathbb{R}^k}$ is smooth.

For each $p \in V$, the matrix $(\sigma_i^j(p))$ is invertible because $\{\sigma_i(p) \mid i \in \{1,\dots,k\}\}$ is a basis for $\mathbf{E}_p$. Denote its inverse matrix by $(\tau_i^j(p))$. Since inversion on $GL(k,\mathbb{R})$ is smooth, the functions τ_i^j are smooth and

$$(\Phi \circ \Psi)^{-1}(p,(w^1,\dots,w^k)) = (p,(w^i\tau_i^1(p),\dots,w^i\tau_i^k(p))).$$

Therefore, $(\Phi \circ \Psi)^{-1}$ is smooth. This proves that Ψ is a local diffeomorphism around q, and since $q \in U$ was arbitrary, the proof is complete.

□

Remark 1.7.19. In particular, Proposition 1.7.18 tells us that there always exists an open cover $(U_\alpha)_{\alpha\in J}$ by domains of smooth local frames.

We obtain the following corollary:

Corollary 1.7.20. Let M be a smooth manifold with or without boundary, let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle of rank k, let (V,φ) be a smooth chart on M with coordinate functions $\varphi = (x^1,\dots,x^n)$, and suppose we have a smooth local frame $(\sigma_i)_{i=1}^k$ for $\mathbf{E}$ over V. Define $\widetilde{\varphi}\colon \pi^{-1}(V) \longrightarrow \varphi(V) \times \mathbb{R}^k$ by

$$\widetilde{\varphi}(v^i\sigma_i) = (x^1(p),\dots,x^n(p),v^1,\dots,v^k).$$

Then $(\pi^{-1}(V),\widetilde{\varphi})$ is a smooth coordinate chart of $\mathbf{E}$.

Proof. The frame determines the smooth trivialization

$$\Psi\colon V\times\mathbb{R}^k \longrightarrow \pi^{-1}(V), \qquad \Psi(p,v)=\sum_{i=1}^{k} v^i \boldsymbol{\sigma}_i(p),$$

by Proposition 1.7.18. The function in the statement is $\widetilde{\varphi}=(\varphi\times \mathrm{Id}_{\mathbb{R}^k})\circ\Psi^{-1}$; it is therefore a diffeomorphism onto $\varphi(V)\times\mathbb{R}^k$. □

We now have a smoothness criterion for rough local sections.

Proposition 1.7.21. Let M be a smooth manifold with or without boundary, let $\pi\colon \mathbf{E}\longrightarrow M$ be a smooth vector bundle, and let $\boldsymbol{\tau}\colon M\longrightarrow \mathbf{E}$ be a rough section. If $(\boldsymbol{\sigma}_i)$ is a smooth local frame for $\mathbf{E}$ defined on an open set $U\subseteq M$, then $\boldsymbol{\tau}$ is smooth on U if and only if its component functions with respect to $(\boldsymbol{\sigma}_i)$ are smooth.

Proof. Let Ψ be the trivialization associated with the frame. If $\boldsymbol{\tau}=\sum_{i=1}^{k}\tau^i\boldsymbol{\sigma}_i$, then

$$(\Psi^{-1}\circ\boldsymbol{\tau})(p)=\big(p,(\tau^1(p),\dots,\tau^k(p))\big).$$

Since Ψ and Ψ^{-1} are smooth, $\boldsymbol{\tau}$ is smooth if and only if all its component functions τ^i are smooth. □

Multiplication by smooth functions makes the space of sections of a vector bundle a $C^\infty(M)$-module. This algebraic structure expresses the fact that the coefficients of a section can vary smoothly over the base.

Proposition 1.7.22. Let $\pi\colon \mathbf{E}\longrightarrow M$ be a smooth vector bundle over a smooth manifold M with or without boundary. Define an action of $C^\infty(M)$ on $\Gamma(\mathbf{E})$ by

$$(f\boldsymbol{\sigma})(p) \;:=\; f(p)\boldsymbol{\sigma}(p), \qquad f\in C^\infty(M),\ \boldsymbol{\sigma}\in\Gamma(\mathbf{E}),\ p\in M.$$

Then $\Gamma(\mathbf{E})$, with the usual addition of functions and this action, is a $C^\infty(M)$-module.

Proof. Let $(U_\alpha)_{\alpha\in J}$ be an open cover of M such that, for each $\alpha\in J$, there exists a smooth local frame $(\boldsymbol{\sigma}_{\alpha,i})_{i=1}^{k}$ of $\mathbf{E}$ defined on U_α. If $\boldsymbol{\sigma}\in\Gamma(\mathbf{E})$, on each U_α we can write

$$\boldsymbol{\sigma}\restriction_{U_\alpha}=\sum_{i=1}^{k} a_\alpha^i\boldsymbol{\sigma}_{\alpha,i}, \qquad a_\alpha^i\in C^\infty(U_\alpha),$$

where k is the rank of $\mathbf{E}$. For $f\in C^\infty(M)$, we have

$$(f\boldsymbol{\sigma})\restriction_{U_\alpha}=\sum_{i=1}^{k}\big(f\restriction_{U_\alpha}\cdot a_\alpha^i\big)\boldsymbol{\sigma}_{\alpha,i}.$$

By Proposition 1.7.21, $f\boldsymbol{\sigma}$ is smooth on U_α because $f\restriction_{U_\alpha}\cdot a_\alpha^i$ is smooth for every i. Since this holds for every $\alpha\in J$, we conclude that $f\boldsymbol{\sigma}\in\Gamma(\mathbf{E})$.

The module identities are

$$(f+g)\sigma = f\sigma + g\sigma, \qquad f(\sigma+\tau) = f\sigma + f\tau, \qquad (fg)\sigma = f(g\sigma), \qquad 1\cdot\sigma = \sigma,$$

To verify them, evaluate each side at a point $p \in M$ and use the vector space identities in the fiber $\mathbf{E}_p$. For example,

$$((fg)\sigma)(p) = f(p)g(p)\sigma(p) = \big(f(g\sigma)\big)(p).$$

The other three equalities follow in the same way. Therefore, $\Gamma(\mathbf{E})$ is a $C^\infty(M)$-module. □

The natural notion of a map between two vector bundles should cover a map between their base spaces and be linear on each fiber. This leads to the following definition.

Definition 1.7.23. If $\pi\colon \mathbf{E} \longrightarrow M$ and $\pi'\colon \mathbf{E}' \longrightarrow M'$ are vector bundles over the same field $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, a continuous function $F\colon \mathbf{E} \longrightarrow \mathbf{E}'$ is called a ***bundle homomorphism*** if there exists a function $f\colon M \longrightarrow M'$ such that $\pi' \circ F = f \circ \pi$, that is, such that the following diagram commutes

$$\begin{array}{ccc} \mathbf{E} & \xrightarrow{F} & \mathbf{E}' \\ \downarrow{\scriptstyle \pi} & & \downarrow{\scriptstyle \pi'} \\ M & \xrightarrow[f]{} & M' \end{array}$$

with the property that, for every $p \in M$, $F\restriction_{\mathbf{E}_p}\colon \mathbf{E}_p \longrightarrow \mathbf{E}'_{f(p)}$ is $\mathbb{K}$-linear. We express the relation between F and f by saying that F ***covers*** f.
If $\mathbf{E}$, $\mathbf{E}'$, and F are smooth, we say that F is a ***smooth bundle homomorphism***. When both bundles have the same base and the covered map is the identity, we write

$$\underline{\mathrm{Hom}}(\mathbf{E}, \mathbf{E}') := \{F\colon \mathbf{E} \longrightarrow \mathbf{E}' \mid F \text{ is a smooth bundle homomorphism over } M\}.$$

We have not required f to be continuous; this follows from continuity of F, which also determines it uniquely.

Proposition 1.7.24. Let $\pi\colon \mathbf{E} \longrightarrow M$ and $\pi'\colon \mathbf{E}' \longrightarrow M'$ be vector bundles, and let $F\colon \mathbf{E} \longrightarrow \mathbf{E}'$ be a bundle homomorphism covering $f\colon M \longrightarrow M'$. Then f is continuous and uniquely determined by F. If, in addition, M and M' are smooth manifolds with or without boundary, the bundles are smooth, and F is smooth, then f is also smooth.

Proof. We have $f = \pi' \circ F \circ \zeta$, where $\zeta\colon M \longrightarrow \mathbf{E}$ is such that $\zeta(p) = 0_{\mathbf{E}_p} \in \mathbf{E}_p$ for each $p \in M$. To verify this, note that $(\pi' \circ F \circ \zeta)(p) = \pi'(F(0_{\mathbf{E}_p})) = \pi'(0_{\mathbf{E}_{f(p)}}) = f(p)$. Thus f is continuous, and if the bundles and F are smooth, then π' and ζ are smooth, so f is smooth.
Moreover, f is uniquely determined by F, since every f making the diagram commute must equal that composition. □

Definition 1.7.25. If $F\colon \mathbf{E} \longrightarrow \mathbf{E}'$ is a bijective bundle homomorphism whose inverse is a bundle homomorphism, we say that F is a *bundle isomorphism*. If F is a diffeomorphism, we say that F is a *smooth bundle isomorphism*.

The next exercise shows that, over the same base, bijectivity of a smooth homomorphism suffices for its inverse

to be smooth.

Exercise 1.7.26. Let M be a smooth manifold with or without boundary. Prove that if $\mathbf{E}$ and $\mathbf{E}'$ are smooth vector bundles over M and $F \in \underline{\mathrm{Hom}}(\mathbf{E}, \mathbf{E}')$ is bijective, then it is a smooth bundle isomorphism.

Remark 1.7.27. If $\mathbf{E}, \mathbf{E}' \longrightarrow M$ are smooth vector bundles over a smooth manifold M with or without boundary and $F \in \underline{\mathrm{Hom}}(\mathbf{E}, \mathbf{E}')$, then composition with F induces a map

$$\widetilde{F} \colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{E}')$$

as follows:

$$\widetilde{F}(\sigma)(p) = (F \circ \sigma)(p) = F(\sigma(p)).$$

We have $\widetilde{F}(\sigma) \in \Gamma(\mathbf{E}')$, since it is smooth as a composition of smooth functions. If the bundles are defined over $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, linearity of F on each fiber implies that $\widetilde{F}$ is $\mathbb{K}$-linear on sections. Moreover, for $f \in C^\infty(M)$,

$$\widetilde{F}(f\sigma)(p) = F_p\big(f(p)\sigma(p)\big) = f(p)F_p\big(\sigma(p)\big) = \big(f\widetilde{F}(\sigma)\big)(p),$$

so $\widetilde{F}$ is $C^\infty(M)$-linear; that is, $\widetilde{F} \in \mathrm{Hom}_{C^\infty(M)}(\Gamma(\mathbf{E}), \Gamma(\mathbf{E}'))$.

The preceding remark tells us that every bundle homomorphism induces a homomorphism between the modules of smooth sections. The converse will also hold: every module homomorphism between the sections of the bundles induces a bundle homomorphism. To prove this, we first need a lemma.

Lemma 1.7.28. (Section with prescribed value in a fiber) Let M be a smooth manifold with or without boundary, let $\pi \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle, let $p \in M$, and let $v \in \mathbf{E}_p$. Then there exists a smooth global section $\sigma \in \Gamma(\mathbf{E})$ with $\sigma(p) = v$. Moreover, if U is a neighborhood of p over which $\mathbf{E}$ admits a local trivialization, we can choose σ with $\operatorname{supp}\sigma \subset U$.

Proof. Let (U, Φ) be a local trivialization of $\mathbf{E}$ on an open neighborhood of p, with

$$\Phi \colon \pi^{-1}(U) \longrightarrow U \times \mathbb{R}^k.$$

Write $\Phi(v) = (p, u_0)$ with $u_0 \in \mathbb{R}^k$. By Proposition 1.3.6, we can choose a bump function $\chi \in C^\infty(M)$ with $\chi(p) = 1$ and $\operatorname{supp}\chi \subset U$. Define

$$\sigma(q) = \begin{cases} \Phi^{-1}\big(q, \chi(q)u_0\big), & q \in U, \\ 0_q, & q \notin U, \end{cases}$$

where 0_q denotes the zero vector in the fiber $\mathbf{E}_q$. On U, the composition $q \mapsto \chi(q)u_0$ is smooth and, since Φ^{-1} is smooth, $\sigma \restriction_U$ is smooth. If $q \notin \overline{U}$, then σ agrees with the zero section, which is smooth.
To justify gluing at the boundary, we use the condition $\operatorname{supp}\chi \subset U$. By definition, $M \setminus \operatorname{supp}\chi$ is open and contains ∂U, so for each $q_0 \in \partial U$ there exists an open neighborhood $V_{q_0} \subset M$ such that $V_{q_0} \cap \operatorname{supp}\chi = \varnothing$, and in particular $\chi \restriction_{V_{q_0}} = 0$. Consequently, for $q \in V_{q_0} \cap U$ we have

$$\sigma(q) = \Phi^{-1}\big(q, \chi(q)u_0\big) = \Phi^{-1}(q, 0_{\mathbb{R}^k}) = 0_q,$$

and for $q \in V_{q_0} \setminus U$ we also have $\sigma(q) = 0_q$ by definition. In other words, on an open neighborhood of each point of ∂U, both expressions for σ agree exactly with the zero section. Therefore, σ is smooth on M.
By construction, $\sigma(p) = \Phi^{-1}(p, u_0) = v$. Moreover, if $q \in U$ and $\chi(q) = 0$, then $\sigma(q) = 0_q$, and if $q \notin U$, we also have $\sigma(q) = 0_q$, so $\operatorname{supp}\sigma \subset \operatorname{supp}\chi \subset U$. □

Lemma 1.7.29. (Characterization of bundle homomorphisms) Let M be a smooth manifold with or without boundary, and let $\pi\colon \mathbf{E} \longrightarrow M$ and $\pi'\colon \mathbf{E}' \longrightarrow M$ be smooth vector bundles. A map

$$\mathcal{F}\colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{E}')$$

is $C^\infty(M)$-linear if and only if there exists a *unique* smooth bundle homomorphism $F\colon \mathbf{E} \longrightarrow \mathbf{E}'$ over M such that

$$\mathcal{F}(\sigma) = F \circ \sigma, \qquad \forall \sigma \in \Gamma(\mathbf{E}).$$

Proof. If $F\colon \mathbf{E} \to \mathbf{E}'$ is a smooth homomorphism over M, then $\sigma \mapsto F \circ \sigma$ is $C^\infty(M)$-linear by linearity of each F_p.
Conversely, let $\mathcal{F}\colon \Gamma(\mathbf{E}) \to \Gamma(\mathbf{E}')$ be a $C^\infty(M)$-linear map. For $p \in M$ and $v \in \mathbf{E}_p$, choose $\sigma \in \Gamma(\mathbf{E})$ with $\sigma(p) = v$, whose existence is guaranteed by Lemma 1.7.28, and define

$$F_p(v) := \mathcal{F}(\sigma)(p).$$

We show that the value is independent of σ. It suffices to consider a section τ with $\tau(p) = 0$ and verify that $\mathcal{F}(\tau)(p) = 0$. Take a local frame $(\mathbf{e}_1, \dots, \mathbf{e}_r)$ of $\mathbf{E}$ on an open set U containing p, and a bump function χ supported in U and equal to one in a neighborhood of p. On U, write $\tau = \sum_{i=1}^{r} a^i \mathbf{e}_i$, where $a^i(p) = 0$. Also choose a bump function ρ supported in U and equal to one on $\operatorname{supp}\chi$. Extend $\widetilde{a}^i := \chi a^i$ and $\widetilde{\mathbf{e}}_i := \rho \mathbf{e}_i$ by zero. These are, respectively, smooth global functions and sections, $\widetilde{a}^i(p) = 0$, and $\chi\tau = \sum_{i=1}^{r} \widetilde{a}^i \widetilde{\mathbf{e}}_i$. $C^\infty(M)$-linearity gives

$$\mathcal{F}(\chi\tau)(p) = \sum_{i=1}^{r} \widetilde{a}^i(p)\mathcal{F}(\widetilde{\mathbf{e}}_i)(p) = 0.$$

The section $(1-\chi)\tau$ vanishes in a neighborhood of p. If η is a bump function with $\eta(p) = 1$ and support contained in that neighborhood, then

$$\mathcal{F}((1-\chi)\tau)(p) = \eta(p)\mathcal{F}((1-\chi)\tau)(p) = \mathcal{F}(\eta(1-\chi)\tau)(p) = 0.$$

Thus $\mathcal{F}(\tau)(p) = 0$, and F_p is well defined. Linearity of F_p follows by choosing sections with prescribed values and using linearity of $\mathcal{F}$.
Define $F\colon \mathbf{E} \to \mathbf{E}'$ by $F(v) = F_{\pi(v)}(v)$. To prove smoothness, let $(\mathbf{e}_1, \dots, \mathbf{e}_r)$ and $(\mathbf{e}'_1, \dots, \mathbf{e}'_s)$ be local frames defined on an open set U around p. Choose an open set V such that $p \in V$ and $\overline{V} \subseteq U$, and a bump function $\rho \in C^\infty(M)$ with $\rho = 1$ in a neighborhood of $\overline{V}$ and $\operatorname{supp}\rho \subseteq U$. For each i, define

$$\widetilde{\mathbf{e}}_i(q) = \begin{cases} \rho(q)\mathbf{e}_i(q), & q \in U, \\ 0_q, & q \notin U. \end{cases}$$

The support condition on ρ shows, as in Lemma 1.7.28, that $\widetilde{\mathbf{e}}_i$ is a smooth global section; moreover, it agrees with $\mathbf{e}_i$ on V. There exist smooth functions A_i^a such that

$$\mathcal{F}(\widetilde{\mathbf{e}}_i) = \sum_{a=1}^{s} A_i^a \mathbf{e}'_a$$

on V. If $q \in V$ and $v = \sum_{i=1}^{r} z^i \mathbf{e}_i(q)$, the independence just proved gives

$$F_q(v) = \sum_{a=1}^{s} \sum_{i=1}^{r} A_i^a(q) z^i \mathbf{e}'_a(q).$$

In trivializations, the total map thus has the expression $(q, z) \mapsto (q, A(q)z)$, which is smooth. By construction, it covers the identity, is linear on each fiber, and satisfies $F \circ \sigma = \mathcal{F}(\sigma)$ for every $\sigma \in \Gamma(\mathbf{E})$.
If G is another homomorphism with the same action on sections, given $p \in M$ and $v \in \mathbf{E}_p$, choose $\sigma(p) = v$ and obtain $F_p(v) = (F \circ \sigma)(p) = (G \circ \sigma)(p) = G_p(v)$. Therefore, $F = G$. □

The spaces of linear maps between the fibers themselves form a vector bundle. The following proposition makes this construction precise.

Proposition 1.7.30. Let M be a smooth manifold with or without boundary, and let $\mathbf{E} \to M$ and $\mathbf{E}' \to M$ be smooth vector bundles of ranks k and l. Define

$$\operatorname{Hom}(\mathbf{E}, \mathbf{E}') := \coprod_{p \in M} \operatorname{Hom}(\mathbf{E}_p, \mathbf{E}'_p), \qquad \pi_{\operatorname{Hom}} \colon \operatorname{Hom}(\mathbf{E}, \mathbf{E}') \longrightarrow M, \quad (p, T_p) \mapsto p,$$

with $T_p \in \operatorname{Hom}(\mathbf{E}_p, \mathbf{E}'_p)$. Then $\operatorname{Hom}(\mathbf{E}, \mathbf{E}')$ admits a unique topology and a unique smooth structure making it a smooth vector bundle of rank kl over M for which the matrix trivializations induced by smooth local frames of $\mathbf{E}$ and $\mathbf{E}'$ are smooth.

Proof. Let $(U_\alpha)_{\alpha \in J}$ be an open cover of M such that, for every $\alpha \in J$, there exist smooth local frames

$$(\sigma_{\alpha,i})_{i=1}^{k} \text{ of } \mathbf{E} \text{ on } U_\alpha, \qquad (\sigma'_{\alpha,j})_{j=1}^{l} \text{ of } \mathbf{E}' \text{ on } U_\alpha.$$

The associated trivializations

$$\Phi_\alpha^{\mathbf{E}} \colon \pi_{\mathbf{E}}^{-1}(U_\alpha) \longrightarrow U_\alpha \times \mathbb{R}^k, \qquad \Phi_\alpha^{\mathbf{E}'} \colon \pi_{\mathbf{E}'}^{-1}(U_\alpha) \longrightarrow U_\alpha \times \mathbb{R}^l$$

are characterized by

$$\Phi_\alpha^{\mathbf{E}}\big(\sigma_{\alpha,i}(p)\big) = (p, e_i), \qquad \Phi_\alpha^{\mathbf{E}'}\big(\sigma'_{\alpha,j}(p)\big) = (p, e'_j),$$

where $(e_i)_{i=1}^{k}$ and $(e'_j)_{j=1}^{l}$ are the standard bases of $\mathbb{R}^k$ and $\mathbb{R}^l$.
Given $p \in U_\alpha$ and $T_p \in \operatorname{Hom}(\mathbf{E}_p, \mathbf{E}'_p)$, write its matrix in the local frames as

$$T_\alpha(p) = \big(T_\alpha(p)_i^j\big)_{j,i} \in M_{l \times k}(\mathbb{R}),$$

defined by

$$T_p(\sigma_{\alpha,i}(p)) = \sum_{j=1}^{l} T_\alpha(p)_i^j \sigma'_{\alpha,j}(p).$$

In particular, the linear map $T_\alpha(p)\colon \mathbb{R}^k \longrightarrow \mathbb{R}^l$ satisfies

$$T_\alpha(p)(e_i) = \sum_{j=1}^{l} T_\alpha(p)_i^j e'_j.$$

Then define the local trivialization of $\mathrm{Hom}(\mathbf{E}, \mathbf{E}')$ by

$$\Phi_\alpha^{\mathrm{Hom}}(T_p) := (p, T_\alpha(p)).$$

This function is bijective, with inverse given by

$$(p,S) \longmapsto \left(u = \sum_{i=1}^{k} u^i \sigma_{\alpha,i}(p) \mapsto \sum_{j=1}^{l}\sum_{i=1}^{k} S_i^j u^i \sigma'_{\alpha,j}(p) \right), \qquad S \in M_{l\times k}(\mathbb{R}).$$

Here S is an arbitrary matrix in $M_{l\times k}(\mathbb{R})$. If $S = T_\alpha(p)$, the reconstructed map agrees exactly with T_p; and if we start from an arbitrary S and then apply $\Phi_\alpha^{\mathrm{Hom}}$, we recover (p,S). This shows that the two functions are indeed inverse to each other.
In particular, for each $p \in U_\alpha$, the restriction

$$\Phi_\alpha^{\mathrm{Hom}} \restriction_{\mathrm{Hom}(\mathbf{E}_p, \mathbf{E}'_p)}\colon \mathrm{Hom}(\mathbf{E}_p, \mathbf{E}'_p) \longrightarrow \{p\} \times M_{l\times k}(\mathbb{R})$$

is a linear isomorphism of real vector spaces.
If $U_\alpha \cap U_\beta \neq \varnothing$, Lemma 1.7.7 says that the changes of trivialization of $\mathbf{E}$ and $\mathbf{E}'$ are described by smooth functions

$$\tau_{\alpha\beta}^{\mathbf{E}}\colon U_\alpha \cap U_\beta \longrightarrow GL(k,\mathbb{R}), \qquad \tau_{\alpha\beta}^{\mathbf{E}'}\colon U_\alpha \cap U_\beta \longrightarrow GL(l,\mathbb{R}),$$

which, by Proposition 1.7.18, are characterized by

$$\sigma_{\beta,i} = \sum_{m=1}^{k} (\tau_{\alpha\beta}^{\mathbf{E}})_i^m \sigma_{\alpha,m}, \qquad \sigma'_{\beta,j} = \sum_{n=1}^{l} (\tau_{\alpha\beta}^{\mathbf{E}'})_j^n \sigma'_{\alpha,n}.$$

With this notation, if the matrix of T_p in U_β is $T_\beta(p)$, its matrix in U_α is

$$T_\alpha(p) = \tau_{\alpha\beta}^{\mathbf{E}'}(p) T_\beta(p) \big(\tau_{\alpha\beta}^{\mathbf{E}}(p)\big)^{-1}.$$

Consequently, the change of trivialization of $\mathrm{Hom}(\mathbf{E}, \mathbf{E}')$ is described by the function

$$\tau_{\alpha\beta}^{\mathrm{Hom}}\colon U_\alpha \cap U_\beta \longrightarrow GL(kl,\mathbb{R}),$$

defined at each $p \in U_\alpha \cap U_\beta$ by

$$\tau_{\alpha\beta}^{\mathrm{Hom}}(p)(S) = \tau_{\alpha\beta}^{\mathbf{E}'}(p) S (\tau_{\alpha\beta}^{\mathbf{E}}(p))^{-1}, \qquad S \in M_{l\times k}(\mathbb{R}).$$

Indeed,

$$(\Phi_\alpha^{\mathrm{Hom}} \circ (\Phi_\beta^{\mathrm{Hom}})^{-1})(p,S) = \Phi_\alpha^{\mathrm{Hom}}\left(u = \sum_{i=1}^{k} u^i \sigma_{\beta,i}(p) \;\mapsto\; \sum_{j=1}^{l}\sum_{i=1}^{k} S_i^j u^i \sigma'_{\beta,j}(p)\right) = (p, T_\alpha(p))$$

$$= (p, \tau_{\alpha\beta}^{\mathbf{E}'}(p) S \left(\tau_{\alpha\beta}^{\mathbf{E}}(p)\right)^{-1}).$$

For each p, the map $S \mapsto \tau_{\alpha\beta}^{\mathrm{Hom}}(p)(S)$ is linear. Moreover, it depends smoothly on p, since matrix multiplication and inversion are smooth and the functions $\tau_{\alpha\beta}^{\mathbf{E}}$ and $\tau_{\alpha\beta}^{\mathbf{E}'}$ are smooth.
Consequently, the transition functions of $\mathrm{Hom}(\mathbf{E},\mathbf{E}')$ are smooth and linear on each fiber. Lemma 1.7.8 provides the unique topology and smooth structure making this space a smooth vector bundle of rank kl over M for which the maps $\Phi_\alpha^{\mathrm{Hom}}$ are smooth local trivializations. The same transition calculation applies to any other pair of smooth local frames of the original bundles. Their matrix trivializations are therefore smooth for this structure, and the asserted uniqueness follows from uniqueness for the family already constructed. □

We use the notation $\mathrm{End}(\mathbf{E}) := \mathrm{Hom}(\mathbf{E},\mathbf{E})$.
The concepts introduced above are related as follows:

Proposition 1.7.31. Let M be a smooth manifold with or without boundary, and let $\pi\colon \mathbf{E} \longrightarrow M$ and $\pi'\colon \mathbf{E}' \longrightarrow M$ be smooth vector bundles. Then we have the following natural identifications:

(a) Each smooth bundle homomorphism $F\colon \mathbf{E} \longrightarrow \mathbf{E}'$ over M determines a smooth section $p \longmapsto \big(F_p\colon \mathbf{E}_p \longrightarrow \mathbf{E}'_p\big)$ of the bundle $\mathrm{Hom}(\mathbf{E},\mathbf{E}')$. Conversely, every section $\mathbf{A} \in \Gamma(\mathrm{Hom}(\mathbf{E},\mathbf{E}'))$ defines a bundle homomorphism $F\colon \mathbf{E} \longrightarrow \mathbf{E}'$ by $F(v) = \mathbf{A}(\pi(v))(v)$ for every $v \in \mathbf{E}$. This gives a natural bijection

$$\underline{\mathrm{Hom}}(\mathbf{E},\mathbf{E}') \cong \Gamma\big(\mathrm{Hom}(\mathbf{E},\mathbf{E}')\big),$$

where $\underline{\mathrm{Hom}}(\mathbf{E},\mathbf{E}')$ denotes the set of bundle homomorphisms over M.

(b) Every section $\mathbf{A} \in \Gamma(\mathrm{Hom}(\mathbf{E},\mathbf{E}'))$ induces a map $\mathcal{F}_{\mathbf{A}}\colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{E}')$ given by $\big(\mathcal{F}_{\mathbf{A}}(\sigma)\big)(p) = \mathbf{A}(p)(\sigma(p))$ for $\sigma \in \Gamma(\mathbf{E})$. This map is $C^\infty(M)$-linear. Conversely, if $\mathcal{F}\colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{E}')$ is $C^\infty(M)$-linear, there exists a unique section $\mathbf{A} \in \Gamma(\mathrm{Hom}(\mathbf{E},\mathbf{E}'))$ such that $\mathcal{F} = \mathcal{F}_{\mathbf{A}}$. This gives a natural isomorphism of $C^\infty(M)$-modules

$$\Gamma\big(\mathrm{Hom}(\mathbf{E},\mathbf{E}')\big) \cong \mathrm{Hom}_{C^\infty(M)}\big(\Gamma(\mathbf{E}),\Gamma(\mathbf{E}')\big).$$

(c) Composing the two correspondences above gives a natural identification

$$\underline{\mathrm{Hom}}(\mathbf{E},\mathbf{E}') \cong \mathrm{Hom}_{C^\infty(M)}\big(\Gamma(\mathbf{E}),\Gamma(\mathbf{E}')\big),$$

compatible with composition of bundle homomorphisms and composition of $C^\infty(M)$-linear maps.

Proof. (a) Let $F\colon \mathbf{E} \longrightarrow \mathbf{E}'$ be a bundle homomorphism over M, that is, a smooth map such that $\pi' \circ F = \pi$. For each $p \in M$, the restriction $F_p\colon \mathbf{E}_p \longrightarrow \mathbf{E}'_p$ is linear. Define a section $\mathbf{A}_F \in \Gamma(\mathrm{Hom}(\mathbf{E},\mathbf{E}'))$ by $\mathbf{A}_F(p) := F_p$. To see that $\mathbf{A}_F$ is smooth, it suffices to work in local trivializations.
On an open set U_α with smooth local frames $(\sigma_{\alpha,i})_{i=1}^k$ of $\mathbf{E}$ and $(\sigma'_{\alpha,j})_{j=1}^l$ of $\mathbf{E}'$, every vector $v \in \mathbf{E}_p$ can be

written as $v = \sum_{i=1}^{k} u^i \sigma_{\alpha,i}(p)$. Denote by $T_\alpha(p) = \big(T_\alpha(p)_i^j\big) \in M_{l\times k}(\mathbb{R})$ the *matrix* of F_p with respect to these frames; that is,

$$F_p\big(\sigma_{\alpha,i}(p)\big) = \sum_{j=1}^{l} T_\alpha(p)_i^j \sigma'_{\alpha,j}(p) \quad \text{for each } i \in \{1,\dots,k\}.$$

Then, for $v \in \mathbf{E}_p$,

$$F_p(v) = \sum_{i=1}^{k} u^i F_p\big(\sigma_{\alpha,i}(p)\big) = \sum_{i=1}^{k} u^i \sum_{j=1}^{l} T_\alpha(p)_i^j \sigma'_{\alpha,j}(p).$$

Since F is smooth, the associated matrix $T_\alpha(p)$ depends smoothly on p, and by Lemma 1.7.21, $\mathbf{A}_F$ is a smooth section of $\operatorname{Hom}(\mathbf{E},\mathbf{E}')$.

Conversely, let $\mathbf{A} \in \Gamma(\operatorname{Hom}(\mathbf{E},\mathbf{E}'))$. For each $p \in M$ and $v \in \mathbf{E}_p$, define $F_{\mathbf{A}}(v) := \mathbf{A}(p)(v)$. Then $F_{\mathbf{A}}\colon \mathbf{E} \longrightarrow \mathbf{E}'$ is a smooth map, linear on each fiber, and moreover $\pi'(F_{\mathbf{A}}(v)) = p = \pi(v)$, so $F_{\mathbf{A}}$ is a smooth bundle homomorphism over M.

If we start with F and construct $\mathbf{A}_F$, then $F_{\mathbf{A}_F}(v) = \mathbf{A}_F(p)(v) = F_p(v) = F(v)$ for every $v \in \mathbf{E}_p$, so $F_{\mathbf{A}_F} = F$.

In the other direction, if we start with $\mathbf{A}$ and construct $F_{\mathbf{A}}$, for each $p \in M$ we have $\mathbf{A}_{F_{\mathbf{A}}}(p) = (F_{\mathbf{A}})_p\colon \mathbf{E}_p \longrightarrow \mathbf{E}'_p$ and $(F_{\mathbf{A}})_p(v) = F_{\mathbf{A}}(v) = \mathbf{A}(p)(v)$ for every $v \in \mathbf{E}_p$. Since $\mathbf{A}_{F_{\mathbf{A}}}(p)$ and $\mathbf{A}(p)$ agree on every vector in $\mathbf{E}_p$, we conclude that $\mathbf{A}_{F_{\mathbf{A}}}(p) = \mathbf{A}(p)$ for every $p \in M$, and hence $\mathbf{A}_{F_{\mathbf{A}}} = \mathbf{A}$.

We conclude that the correspondences $F \mapsto \mathbf{A}_F$ and $\mathbf{A} \mapsto F_{\mathbf{A}}$ are inverse to each other, proving the bijection

$$\underline{\operatorname{Hom}}(\mathbf{E},\mathbf{E}') \cong \Gamma\big(\operatorname{Hom}(\mathbf{E},\mathbf{E}')\big).$$

(b) Define

$$\Theta\colon \Gamma(\operatorname{Hom}(\mathbf{E},\mathbf{E}')) \longrightarrow \operatorname{Hom}_{C^\infty(M)}\big(\Gamma(\mathbf{E}),\Gamma(\mathbf{E}')\big), \qquad \Theta(\mathbf{A})(\sigma)(p) := \mathbf{A}(p)\big(\sigma(p)\big).$$

By Remark 1.7.27, $\Theta(\mathbf{A})$ is $C^\infty(M)$-linear.

We show that Θ is $C^\infty(M)$-linear in $\mathbf{A}$. Let $f \in C^\infty(M)$ and $\mathbf{A},\mathbf{B} \in \Gamma(\operatorname{Hom}(\mathbf{E},\mathbf{E}'))$. We have

$$\Theta(f\mathbf{A}+\mathbf{B})(\sigma)(p) = (f\mathbf{A}+\mathbf{B})(p)(\sigma(p)) = (f(p)\mathbf{A}(p)+\mathbf{B}(p))(\sigma(p))$$

$$= f(p)\mathbf{A}(p)(\sigma(p)) + \mathbf{B}(p)(\sigma(p)) = (f\Theta(\mathbf{A}))(\sigma)(p) + \Theta(\mathbf{B})(\sigma)(p),$$

and therefore $\Theta(f\mathbf{A}+\mathbf{B}) = f\Theta(\mathbf{A}) + \Theta(\mathbf{B})$.

For surjectivity, let $\mathcal{F}\colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{E}')$ be a $C^\infty(M)$-linear map. By Lemma 1.7.29, there exists a unique bundle homomorphism $F\colon \mathbf{E} \longrightarrow \mathbf{E}'$ such that $\mathcal{F}(\sigma) = F \circ \sigma$ for every $\sigma \in \Gamma(\mathbf{E})$. By (a), F corresponds to a section $\mathbf{A}_F \in \Gamma(\operatorname{Hom}(\mathbf{E},\mathbf{E}'))$ and, by definition, $\Theta(\mathbf{A}_F) = \mathcal{F}$.

For injectivity, suppose that $\Theta(\mathbf{A}_1) = \Theta(\mathbf{A}_2)$. Then, for every section $\sigma \in \Gamma(\mathbf{E})$ and every $p \in M$, we have $\mathbf{A}_1(p)\big(\sigma(p)\big) = \mathbf{A}_2(p)\big(\sigma(p)\big)$. Now let $v \in \mathbf{E}_p$. By Lemma 1.7.28, there exists a section $\sigma \in \Gamma(\mathbf{E})$ with $\sigma(p) = v$. Substituting into the preceding equality gives $\mathbf{A}_1(p)(v) = \mathbf{A}_2(p)(v)$. Since this holds for every $v \in \mathbf{E}_p$ and every $p \in M$, it follows that $\mathbf{A}_1 = \mathbf{A}_2$.

Thus Θ is an isomorphism of $C^\infty(M)$-modules.

(c) The identification in part (c) is obtained by composing those in (a) and (b). Compatibility with composition is justified as follows. Let $F\colon \mathbf{E} \longrightarrow \mathbf{E}'$ and $G\colon \mathbf{E}' \longrightarrow \mathbf{E}''$ be smooth bundle homomorphisms over M. Their composition $G \circ F\colon \mathbf{E} \longrightarrow \mathbf{E}''$ is also a bundle homomorphism, and the associated section

is $\mathbf{A}_{G\circ F}(p) = (G\circ F)_p = G_p \circ F_p$ for $p \in M$.
On the other hand, the operator induced by $\mathbf{A}_{G\circ F}$ satisfies

$$\Theta(\mathbf{A}_{G\circ F})(\sigma)(p) = \mathbf{A}_{G\circ F}(p)(\sigma(p)) = (G_p \circ F_p)(\sigma(p)).$$

Writing $\tau = F\circ\sigma \in \Gamma(\mathbf{E}')$, we have $\Theta(\mathbf{A}_{G\circ F})(\sigma)(p) = G_p(\tau(p)) = \Theta(\mathbf{A}_G)(\tau)(p) = \Theta(\mathbf{A}_G)(F\circ\sigma)(p)$. Since $F\circ\sigma = \Theta(\mathbf{A}_F)(\sigma)$, it follows that

$$\Theta(\mathbf{A}_{G\circ F})(\sigma) = \Theta(\mathbf{A}_G)(\Theta(\mathbf{A}_F)(\sigma)) = (\Theta(\mathbf{A}_G)\circ\Theta(\mathbf{A}_F))(\sigma).$$

Therefore, $\Theta(\mathbf{A}_{G\circ F}) = \Theta(\mathbf{A}_G)\circ\Theta(\mathbf{A}_F)$, proving that the correspondence is compatible with composition of bundle homomorphisms.
Moreover, since (b) showed that Θ is an isomorphism of $C^\infty(M)$-modules, the identification is also compatible with the action of smooth functions; that is, $\Theta(\mathbf{A})(f\sigma) = f\cdot\Theta(\mathbf{A})(\sigma)$ for $f \in C^\infty(M)$ and $\sigma \in \Gamma(\mathbf{E})$.
Consequently,

$$\underline{\mathrm{Hom}}(\mathbf{E},\mathbf{E}') \cong \mathrm{Hom}_{C^\infty(M)}\big(\Gamma(\mathbf{E}),\Gamma(\mathbf{E}')\big)$$

is a natural identification, compatible with both composition and the $C^\infty(M)$-module structure. □

The dual bundle is the special case of the homomorphism bundle in which the target bundle is the trivial rank-one bundle.

Definition 1.7.32. (Dual bundle) Let M be a smooth manifold with or without boundary, and let $\mathbf{E}\to M$ be a smooth real vector bundle. Its *dual bundle* is

$$\mathbf{E}^* := \mathrm{Hom}(\mathbf{E},\underline{\mathbb{R}}_M).$$

In particular, $(\mathbf{E}^*)_p = \mathrm{Hom}_{\mathbb{R}}(\mathbf{E}_p,\mathbb{R})$ for every $p\in M$.

Remark 1.7.33. (Dual frames and transition matrices) Let $\mathbf{E}\to M$ be a smooth vector bundle of rank k, and let $(\sigma_1,\dots,\sigma_k)$ be a smooth local frame of $\mathbf{E}$ defined on an open set $U\subseteq M$. The *dual local frame* $(\sigma^1,\dots,\sigma^k)$ of $\mathbf{E}^*$ on U is characterized by the condition

$$\sigma^i(\sigma_j) = \delta^i_j, \qquad 1\le i,j\le k.$$

If $(\tau_1,\dots,\tau_k)$ is another smooth local frame of $\mathbf{E}$ on U, there exist smooth functions $A^j_i : U\longrightarrow\mathbb{R}$ such that

$$\tau_i = \sum_{j=1}^{k} A^j_i\sigma_j, \qquad i\in\{1,\dots,k\}.$$

Thus the transition matrix between frames of $\mathbf{E}$ is $A = (A^j_i)\in GL(k,\mathbb{R})$.
The dual frame $(\tau^1,\dots,\tau^k)$ on $\mathbf{E}^*$ must satisfy

$$\tau^i(\tau_j) = \delta^i_j,$$

which implies, in index notation,

$$\boldsymbol{\tau}^i = \sum_{j=1}^{k} (A^{-1})^i_j \boldsymbol{\sigma}^j.$$

In matrix form, if $[\boldsymbol{\tau}] = A[\boldsymbol{\sigma}]$ denotes the relation between frames of $\mathbf{E}$, the dual frames satisfy

$$[\boldsymbol{\tau}^T] = [\boldsymbol{\sigma}^T]A^{-1},$$

so the transition matrix of $\mathbf{E}^*$ is

$$B = (A^{-1})^T.$$

Thus the transition matrices of the dual bundle $\mathbf{E}^*$ are the *inverse transposes* of the transition matrices of $\mathbf{E}$.

Conjugate spaces and bundles. In the complex case, we need to distinguish the ordinary dual from conjugation. We first specify these constructions without imposing an identification between a vector space and its dual.

Definition 1.7.34. (Conjugate vector space) Let V be a complex vector space. Its *conjugate space* $\overline{V}$ is the same abelian group as V, with elements denoted by $\overline{v}$ and scalar multiplication

$$\lambda \cdot \overline{v} := \overline{\overline{\lambda}\, v}. \tag{1.8}$$

The ordinary complex dual V^* continues to mean $\mathrm{Hom}_{\mathbb{C}}(V, \mathbb{C})$.

Proposition 1.7.35. (Functorial properties of conjugation) The preceding structure makes $\overline{V}$ a complex vector space, and the map

$$c_V \colon V \longrightarrow \overline{V}, \qquad c_V(v) = \overline{v},$$

is additive and antilinear. The map

$$j_V \colon \overline{\overline{V}} \longrightarrow V, \qquad j_V(\overline{\overline{v}}) = v,$$

is a canonical complex-linear isomorphism.
If $A \colon V \to W$ is complex linear, there exists a complex-linear map

$$\overline{A} \colon \overline{V} \longrightarrow \overline{W}, \qquad \overline{A}(\overline{v}) = \overline{Av}.$$

We have

$$\overline{B \circ A} = \overline{B} \circ \overline{A}, \qquad \overline{\mathrm{id}_V} = \mathrm{id}_{\overline{V}}, \qquad \overline{A^{-1}} = (\overline{A})^{-1}$$

when A is invertible, and $j_W \circ \overline{\overline{A}} = A \circ j_V$.

Proof. Addition is that of the underlying abelian group; that is, $\overline{v} + \overline{w} = \overline{v + w}$. For $\lambda, \mu \in \mathbb{C}$ and $v, w \in V$, the definition gives

$$\begin{aligned}
\lambda \cdot (\overline{v} + \overline{w}) &= \overline{\overline{\lambda}(v + w)} = \lambda \cdot \overline{v} + \lambda \cdot \overline{w}, \\
(\lambda + \mu) \cdot \overline{v} &= \overline{(\overline{\lambda} + \overline{\mu})v} = \lambda \cdot \overline{v} + \mu \cdot \overline{v}, \\
\lambda \cdot (\mu \cdot \overline{v}) &= \overline{\overline{\lambda}\,\overline{\mu}\, v} = (\lambda\mu) \cdot \overline{v},
\end{aligned}$$

$$1 \cdot \overline{v} = \overline{v}.$$

Together with the additive group axioms, these are all the vector space identities. Moreover, $c_V(v+w) = c_V(v) + c_V(w)$ and $c_V(\lambda v) = \overline{\lambda v} = \overline{\lambda} \cdot \overline{v}$, so c_V is additive and antilinear. Under double conjugation,

$$j_V\big(\lambda \cdot \overline{\overline{v}}\big) = j_V\big(\overline{\overline{\lambda} \cdot_{\overline{V}} \overline{v}}\big) = j_V(\overline{\overline{\lambda v}}) = \lambda v,$$

which proves linearity of j_V; its inverse is $v \mapsto \overline{\overline{v}}$.
For $\overline{A}$, if $\lambda \in \mathbb{C}$, then

$$\overline{A}(\lambda \overline{v}) = \overline{A(\overline{\lambda} v)} = \overline{\overline{\lambda} A v} = \lambda \overline{A v}.$$

The remaining identities are checked on elements $\overline{v}$, and hence hold as identities of maps. □

Proposition 1.7.36. (Duality and conjugation) There is a natural complex-linear isomorphism

$$\kappa_V : \overline{V^*} \longrightarrow (\overline{V})^*, \qquad \kappa_V(\overline{\ell})(\overline{v}) := \overline{\ell(v)}. \tag{1.9}$$

In particular, V^*, $\overline{V}$, $\overline{V^*}$, and $(\overline{V})^*$ are distinct objects; only $\overline{V^*} \cong (\overline{V})^*$ are canonically identified by (1.9).

Proof. For $\mu \in \mathbb{C}$,

$$\kappa_V(\overline{\ell})(\mu \overline{v}) = \overline{\ell(\overline{\mu} v)} = \mu \, \overline{\ell(v)},$$

so $\kappa_V(\overline{\ell}) \in (\overline{V})^*$. Likewise,

$$\kappa_V(\lambda \overline{\ell})(\overline{v}) = \kappa_V(\overline{\overline{\lambda} \ell})(\overline{v}) = \lambda \, \overline{\ell(v)},$$

so κ_V is complex linear. The formula

$$\ell(v) := \overline{L(\overline{v})}, \qquad L \in (\overline{V})^*,$$

defines a complex-linear functional, since $\overline{\lambda v} = \overline{\lambda} \cdot \overline{v}$ in $\overline{V}$, and is the two-sided inverse of (1.9). Finally, if $A : V \to W$ is complex linear and $A^* \ell = \ell \circ A$, then

$$\kappa_V \circ \overline{A^*} = (\overline{A})^* \circ \kappa_W,$$

as one checks by evaluating both sides at $\overline{v}$; this proves the asserted naturality. □

For complex bundles, homomorphisms are complex linear on each fiber, in accordance with Definition 1.7.23. The construction of $\mathrm{Hom}(\mathbf{E}, \mathbf{F})$ in Proposition 1.7.30 applies unchanged, replacing $\mathbb{R}$ by $\mathbb{C}$ and requiring complex linearity. Likewise, for a complex bundle we set

$$\mathbf{E}^* := \mathrm{Hom}_{\mathbb{C}}(\mathbf{E}, \underline{\mathbb{C}}_M).$$

Definition 1.7.37. (Conjugate bundle) Let M be a smooth manifold with or without boundary and let $\pi : \mathbf{E} \to M$ be a smooth complex vector bundle. The *conjugate bundle* $\overline{\mathbf{E}} \to M$ has the same total space, underlying smooth real manifold, projection, and fiberwise addition as $\mathbf{E}$. We write $\overline{v}$ when an element

$v \in \mathbf{E}$ is regarded as an element of $\overline{\mathbf{E}}$, and define scalar multiplication by

$$\lambda \cdot_{\overline{\mathbf{E}}} \overline{v} := \overline{\overline{\lambda}\, v}, \qquad \lambda \in \mathbb{C}. \tag{1.10}$$

Proposition 1.7.38. (Construction and naturality of the conjugate bundle) Let M be a smooth manifold with or without boundary and let $\mathbf{E} \longrightarrow M$ be a smooth complex vector bundle. Each fiber $\overline{\mathbf{E}}_p$ is the conjugate vector space of $\mathbf{E}_p$, and the projection $\overline{\mathbf{E}} \to M$ is smooth. If

$$\Phi_\alpha : \mathbf{E}|_{U_\alpha} \longrightarrow U_\alpha \times \mathbb{C}^r, \qquad \Phi_\alpha(v) = (p, z),$$

is a smooth complex trivialization of $\mathbf{E}$, then

$$\overline{\Phi}_\alpha : \overline{\mathbf{E}}|_{U_\alpha} \longrightarrow U_\alpha \times \mathbb{C}^r, \qquad \overline{\Phi}_\alpha(\overline{v}) := (p, \overline{z}),$$

is a smooth complex trivialization of $\overline{\mathbf{E}}$. If the transition functions of $\mathbf{E}$ are given by

$$(\Phi_\beta \circ \Phi_\alpha^{-1})(p, z) = (p, g_{\beta\alpha}(p) z),$$

the transition functions computed for $\overline{\mathbf{E}}$ are $\overline{g_{\beta\alpha}}$. Consequently,

$$\overline{g_{\gamma\beta}}\,\overline{g_{\beta\alpha}} = \overline{g_{\gamma\alpha}}, \qquad \overline{g_{\alpha\beta}} = (\overline{g_{\beta\alpha}})^{-1}.$$

The construction is independent of the chosen trivializations, since it is defined on the same total space by the intrinsic operation (1.10) on each fiber. The assignment on sections

$$\Gamma(\mathbf{E}) \longrightarrow \Gamma(\overline{\mathbf{E}}), \qquad \mathbf{u} \longmapsto \overline{\mathbf{u}}, \qquad \overline{\mathbf{u}}(x) := \overline{\mathbf{u}(x)},$$

is an additive, antilinear bijection compatible with restrictions.
If $A : \mathbf{E} \to \mathbf{F}$ is a homomorphism of complex bundles, then

$$\overline{A} : \overline{\mathbf{E}} \longrightarrow \overline{\mathbf{F}}, \qquad \overline{A}(\overline{v}) = \overline{A(v)},$$

is a smooth homomorphism of complex bundles. Conjugation preserves identities, compositions, and inverses, and there is a natural identification $j_{\mathbf{E}} : \overline{\overline{\mathbf{E}}} \xrightarrow{\cong} \mathbf{E}$. Finally,

$$\kappa_{\mathbf{E}} : \overline{\mathbf{E}^*} \longrightarrow (\overline{\mathbf{E}})^*, \qquad \kappa_{\mathbf{E}}(\overline{\ell})(\overline{v}) = \overline{\ell(v)},$$

is a smooth complex-linear bundle isomorphism.

Proof. Proposition 1.7.35, applied fiberwise, proves the complex vector space axioms on $\overline{\mathbf{E}}_p$. The underlying real manifold and the projection are unchanged; therefore, $\overline{\mathbf{E}} \to M$ remains a smooth map.
Let $\Phi_\alpha(v) = (p, z)$. Since conjugation $z \mapsto \overline{z}$ is a real-linear isomorphism of $\mathbb{C}^r$, the map $\overline{\Phi}_\alpha$ is a real diffeomorphism. If $\lambda \in \mathbb{C}$, then

$$\overline{\Phi}_\alpha(\lambda \cdot_{\overline{\mathbf{E}}} \overline{v}) = \overline{\Phi}_\alpha(\overline{\overline{\lambda} v}) = (p, \lambda \overline{z}),$$

so it is complex linear on each fiber. Thus these functions are smooth complex trivializations of the struc-

ture already defined.
To compute their transition maps, start with a vector whose coordinate is w in the conjugate trivialization $\overline{\Phi}_\alpha$. The same element, regarded as an element of $\mathbf{E}$, has coordinate $\overline{w}$; hence

$$(\overline{\Phi}_\beta \circ \overline{\Phi}_\alpha^{-1})(p,w) = \big(p, \overline{g_{\beta\alpha}(p)\overline{w}}\big) = \big(p, \overline{g_{\beta\alpha}(p)}w\big).$$

The two identities in the statement now follow by conjugating the elementary identities already satisfied by the transition functions of $\mathbf{E}$. These were not used to construct $\overline{\mathbf{E}}$: they are consequences of the intrinsic construction. Since the total space, the projection, and scalar multiplication (1.10) are all independent of any chart, independence of the trivializations is immediate.
If u_α are the local components of $\mathbf{u}$, then $u_\beta = g_{\beta\alpha}u_\alpha$. Therefore, $\overline{u_\beta} = \overline{g_{\beta\alpha}}\,\overline{u_\alpha}$, which are exactly the transformation rules for a section of $\overline{\mathbf{E}}$. The reverse argument uses conjugation once more. The scalar multiplication rule on $\overline{\mathbf{E}}$ proves $\overline{f\mathbf{u}} = \overline{f}\,\overline{\mathbf{u}}$ for $f \in C^\infty(M,\mathbb{C})$; compatibility with restrictions is pointwise.
In local frames, if A has matrix $A_\alpha(x)$, then $\overline{A}$ has matrix $\overline{A_\alpha(x)}$; the change-of-frame rules show that these matrices glue, and smoothness is immediate. Complex linearity of $\overline{A}$ is checked using (1.10). The functorial properties and the formula $j_{\mathbf{E}}(\overline{v}) = v$ are verified fiberwise by Proposition 1.7.35; in conjugate trivializations, $j_{\mathbf{E}}$ has the identity matrix and is smooth. The last assertion is the bundle version of (1.9); its local formula and that of its inverse have constant matrices, so both maps are smooth. □

Corollary 1.7.39. (Transition functions of dual and homomorphism bundles) Let M be a smooth manifold with or without boundary, and let $\mathbf{E},\mathbf{F} \longrightarrow M$ be smooth complex vector bundles. With the preceding convention, the transition functions of $\mathbf{E}^*$ are $(g_{\beta\alpha}^{-1})^T$, those of $\overline{\mathbf{E}}$ are $\overline{g_{\beta\alpha}}$, and those of $\mathrm{Hom}(\mathbf{E},\mathbf{F})$ act on a matrix A by

$$A \longmapsto h_{\beta\alpha}Ag_{\beta\alpha}^{-1}.$$

Conjugating them gives precisely the transition functions of the corresponding conjugate bundles. These formulas do not identify $\mathbf{E}$ with $\mathbf{E}^*$.

Proof. The first formula follows by requiring the evaluation $\mathbf{E}^*\otimes\mathbf{E} \to \underline{\mathbb{C}}$ to be independent of the frame. The second is the definition, and the third follows from $A_\beta(g_{\beta\alpha}v) = h_{\beta\alpha}A_\alpha(v)$. Conjugating each equality gives the last assertion. □

Certain sections of the tangent bundle TM receive a special name because of their importance in the study of smooth manifolds. These sections are called vector fields:

Definition 1.7.40. Let M be a smooth manifold with or without boundary. A **vector field on** M is a section $\mathbf{X}\colon M \longrightarrow TM$ of the map $\pi\colon TM \longrightarrow M$. We usually write $\mathbf{X}(p)$ as $\mathbf{X}_p$ for each $p \in M$.

Note 1.7.41. The set of smooth vector fields defined on a smooth manifold M with or without boundary is usually denoted by $\mathfrak{X}(M)$.

By Proposition 1.4.16, every vector field $\mathbf{X}\colon M \longrightarrow TM$ can be written in terms of a smooth chart (U,φ) with $\varphi = (x^1,\ldots,x^n)$ as $\mathbf{X} = X^i\partial_i$, where, for each $i \in \{1,\ldots,n\}$, $\partial_i\colon U \longrightarrow TU$ is the vector field defined on U by $\partial_i(p) := \partial_i\Big|_p$ for each $p \in U$. The functions X^i are called the ***component functions of*** $\mathbf{X}$ ***on*** U.
We have the following criterion for smoothness of a vector field:

Proposition 1.7.42. Let M be a smooth manifold with or without boundary and let $\mathbf{X}\colon M \longrightarrow TM$ be a rough vector field. If $(U,(x^i))$ is any smooth coordinate chart on M, then $\mathbf{X}\restriction_U$ is smooth if and only if its component functions with respect to this chart are smooth.

Proof. In the coordinate trivialization of $TM\restriction_U$, the section $\mathbf{X}\restriction_U$ is represented precisely by the map $p \mapsto (X^1(p),\dots,X^n(p))$. Proposition 1.7.21 states that the section is smooth if and only if this map is smooth, which is equivalent to smoothness of each of its component functions. □

The preceding proposition tells us that the coordinate vector fields ∂_i are smooth vector fields on U.

An essential property of vector fields is that they define operators on spaces of smooth real-valued functions. If $\mathbf{X} \in \mathfrak{X}(M)$, $U \subseteq M$ is open, and $f \in C^\infty(U)$, we obtain a new function $\mathbf{X}(f)\colon U \longrightarrow \mathbb{R}$ defined by

$$(\mathbf{X}(f))(p) = \mathbf{X}_p(f).$$

This terminology gives another smoothness criterion for vector fields.

Proposition 1.7.43. Let M be a smooth manifold with or without boundary, and let $\mathbf{X}\colon M \longrightarrow TM$ be a rough vector field. The following are equivalent:

(a) $\mathbf{X}$ is smooth.

(b) For each $f \in C^\infty(M)$, the function $\mathbf{X}(f)$ is smooth on M.

(c) For every open subset $U \subseteq M$ and every $f \in C^\infty(U)$, the function $(\mathbf{X}\restriction_U)(f)$ is smooth on U.

Proof. If $\mathbf{X} = X^i\partial_i$ is smooth in a chart U, then for $f \in C^\infty(U)$ we have

$$(\mathbf{X}\restriction_U)(f) = \sum_{i=1}^{n} X^i \frac{\partial f}{\partial x^i} \in C^\infty(U).$$

This proves $(a) \Rightarrow (c)$, and $(c) \Rightarrow (b)$ follows by taking $U = M$.

Suppose (b) holds. Fix $p \in M$, a chart (U,x) around p, and an open set W with $p \in W \Subset U$. Let $\chi \in C^\infty(M)$ equal 1 on $\overline{W}$ and have support contained in U. The function defined by χx^i on U and by zero outside U is smooth on M. On W,

$$\mathbf{X}(\chi x^i) = \mathbf{X}(x^i) = X^i.$$

Assumption (b) shows that each component X^i is smooth near p. Since p was arbitrary, Proposition 1.7.42 proves $(b) \Rightarrow (a)$. □

Finally, we introduce the notions of a cotangent vector, cotangent space, and cotangent bundle of a smooth manifold M with or without boundary. We have the following definitions:

Definition 1.7.44. Let M be a smooth manifold with or without boundary. For each $p \in M$, define the **cotangent space to** M **at** p, denoted by T_p^*M, as the dual space of T_pM,

$$T_p^*M := (T_pM)^*.$$

Remark 1.7.45. For each $p \in M$, if (U, φ) is a coordinate chart on an open subset $U \subseteq M$ with $p \in U$, the basis $\left(\partial_i\Big|_p\right)$ gives a dual basis for T_p^*M. Denote this basis by $(\lambda^i|_p)$. Now recall the differential of a function and that, if $f \in C^\infty(M)$, then $T_{f(p)}\mathbb{R} \cong \mathbb{R}$. We may therefore regard $df_p(v) \in \mathbb{R}$ for each $v \in T_pM$ and each $p \in M$. Then $df_p \in T_p^*M$ for each $f \in C^\infty(M)$. We know that $df_p = A_i(p)\lambda^i|_p$ for some function $A_i \colon U \longrightarrow \mathbb{R}$. By the definition of the differential and the fact that $(\lambda^i|_p)$ is the dual basis of $\partial_i\Big|_p$,

$$A_i(p) = df_p\left(\partial_i\Big|_p\right) = \partial_i\Big|_p(f) = \frac{\partial f}{\partial x^i}(p)$$

so

$$df_p = \frac{\partial f}{\partial x^i}(p)\lambda^i|_p$$

In particular, taking $x^j \in C^\infty(U)$, for each $p \in U$ we have $\mathbf{d}x^j_p \in T_p^*(M)$, so

$$\mathbf{d}x^j|_p = \frac{\partial x^j}{\partial x^i}(p)\lambda^i|_p = \delta_i^j\lambda^i|_p = \lambda^j|_p$$

Thus the dual basis of $T_p^*(M)$ is in fact $(\mathbf{d}x^i|_p)$. The assignment $p \mapsto \mathbf{d}x^i|_p$ defines a covector field (for now, a rough one) on U called a ***coordinate covector field***.

We define the cotangent bundle:

Definition 1.7.46. If M is a smooth manifold with or without boundary, define the **cotangent bundle of** M by

$$T^*M := \coprod_{p\in M} T_p^*M.$$

Of course, for the cotangent bundle we can define an analogue of vector fields on the tangent bundle.

Definition 1.7.47. Let M be a smooth manifold with or without boundary. A local or global section of T^*M is called a **covector field**. A **rough covector field** is a local or global section that need not be continuous, and a **smooth covector field** is a smooth local or global section.

The smooth structure is obtained by dualizing the changes of basis in the tangent bundle.

Proposition 1.7.48. Let M be a smooth manifold with or without boundary of dimension n. With the standard projection $\pi \colon T^*M \longrightarrow M$ such that $\pi(\omega_p) = p$ if $\omega_p \in T_p^*M$, and with the vector space structure on each fiber of π inherited from that of T_pM, the cotangent bundle T^*M has a unique topology and a unique smooth structure making it a smooth vector bundle of rank n over M for which the coordinate covector fields are smooth local sections. Moreover, if $U \subseteq M$ is the domain of a smooth chart with coordinates $\varphi = (x^1, \ldots, x^n)$, the map

$$\widetilde{\varphi}(\xi_i\mathbf{d}x^i|_p) = (x^1(p), \ldots, x^n(p), \xi_1, \ldots, \xi_n)$$

is a smooth coordinate chart for T^*M.

Proof. For a chart (U,x), with $x=(x^1,\dots,x^n)$, define the trivialization

$$\Phi_x\colon \pi^{-1}(U)\longrightarrow U\times\mathbb{R}^n,\qquad \Phi_x\left(\sum_{i=1}^n \xi_i\,\mathbf{d}x^i|_p\right)=(p,(\xi_1,\dots,\xi_n)).$$

It is a fiber-preserving bijection and is linear on each fiber. Let (U,x) and (V,y) be two charts, and set

$$J(p):=D(y\circ x^{-1})(x(p)).$$

The change-of-basis formula (1.5) says that the components of a vector satisfy $v_y=Jv_x$. The identity $\omega(v)=\xi_x^Tv_x=\xi_y^Tv_y$ for every v then implies

$$\xi_y=(J^{-1})^T\xi_x.$$

Consequently, the change of trivialization of the cotangent bundle is

$$(\Phi_y\circ\Phi_x^{-1})(p,\xi)=\big(p,(J(p)^{-1})^T\xi\big).$$

The map $p\mapsto(J(p)^{-1})^T$ is smooth and takes values in $GL(n,\mathbb{R})$. Lemma 1.7.8 gives a unique topology and a unique smooth structure for which the maps Φ_x are local trivializations. In a chart of the total space, the projection is $(x,\xi)\mapsto x$ and the fields $\mathbf{d}x^i$ have constant components; hence the projection and the coordinate covector fields are smooth. The same calculation works on relatively open subsets of $\mathbb{H}^n$ and covers the boundary case. □

We have the following smoothness criterion for a covector field:

Proposition 1.7.49. Let M be a smooth manifold with or without boundary and let $\omega\colon M\longrightarrow T^*M$ be a rough covector field. The following statements are equivalent:

(a) ω is smooth.

(b) In every coordinate chart, the component functions of ω are smooth.

(c) Every point of M lies in some coordinate chart in which ω has smooth component functions.

(d) For every smooth vector field $\mathbf{X}\in\mathfrak{X}(M)$, the function $\omega(\mathbf{X})$ is smooth on M.

(e) For every open subset $U\subseteq M$ and every smooth vector field $\mathbf{X}$ on U, the function $\omega(\mathbf{X})\colon U\longrightarrow\mathbb{R}$ is smooth on U.

Proof. In a chart (U,x), write $\omega=\omega_i\,\mathbf{d}x^i$. The component criterion in Proposition 1.7.21 proves the equivalence of (a), (b), and (c).
If (a) holds and $\mathbf{X}=X^i\partial_i$ is smooth on U, then $\omega(\mathbf{X})=\omega_iX^i$ is smooth. Therefore, $(a)\Rightarrow(e)\Rightarrow(d)$.
Suppose (d) holds. For a chart (U,x), a point $p\in U$, and an open set W with $p\in W\Subset U$, choose $\chi\in C^\infty(M)$ equal to 1 on $\overline{W}$ and supported in U. The field defined by $\chi\partial_i$ on U and by zero outside U is smooth on M. On W,

$$\omega(\chi\partial_i)=\omega_i.$$

Assumption (d) shows that the components are smooth near every point, proving (c). □

This has the following consequence:

Corollary 1.7.50. Let M be a smooth manifold with or without boundary. The differential of every function $f \in C^\infty(M)$ is a smooth covector field.

Proof. In coordinates,

$$df = \sum_{i=1}^{n} \frac{\partial f}{\partial x^i}\, \mathbf{d}x^i.$$

Its components are smooth, so the preceding proposition applies. □

Finally, before concluding this section, we introduce the concept of a smooth vector subbundle:

Definition 1.7.51. If $\pi_{\mathbf{E}} \colon \mathbf{E} \longrightarrow M$ is a vector bundle, a **vector subbundle of E** is a vector bundle $\pi_{\mathbf{D}} \colon \mathbf{D} \longrightarrow M$, where $\mathbf{D} \subseteq \mathbf{E}$ carries the subspace topology and $\pi_{\mathbf{D}}$ is the restriction of $\pi_{\mathbf{E}}$ to $\mathbf{D}$, such that, for each $p \in M$, $\mathbf{D}_p = \mathbf{D} \cap \mathbf{E}_p$ is a vector subspace of $\mathbf{E}_p$ and all the fibers $\mathbf{D}_p$ have the same dimension. If M is a smooth manifold with or without boundary and $\mathbf{E} \longrightarrow M$ is a smooth vector bundle, a **smooth vector subbundle of E** is a smooth vector bundle that is a vector subbundle of $\mathbf{E}$ and an embedded submanifold of $\mathbf{E}$.

Figure 1.8. Smooth vector subbundle.

Lemma 1.7.52. (Smooth local frame criterion for subbundles) Let M be a smooth manifold with or without boundary, and let $\pi \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle. Suppose that, for each $p \in M$, we are given a vector subspace of fixed finite dimension m, $\mathbf{D}_p \subseteq \mathbf{E}_p$. Then $\mathbf{D} = \bigcup_{p \in M} \mathbf{D}_p \subseteq \mathbf{E}$ is a smooth vector subbundle of $\mathbf{E}$ if and only if every point of M has a neighborhood U on which there exist smooth local sections $\sigma_1, \ldots, \sigma_m \colon U \longrightarrow \mathbf{E}$ such that $\sigma_1(q), \ldots, \sigma_m(q)$ form a basis for $\mathbf{D}_q$ for each $q \in U$.

Proof. If $\mathbf{D}$ is a smooth vector subbundle, a local trivialization of $\mathbf{D}$ gives a smooth local frame $\sigma_1,\dots,\sigma_m$. The smooth inclusion $\mathbf{D} \hookrightarrow \mathbf{E}$ allows us to regard its elements as smooth sections of $\mathbf{E}$, and their values form a basis for $\mathbf{D}_q$.

Conversely, suppose such sections exist around $p \in M$. Choose a local frame $\boldsymbol{e}_1,\dots,\boldsymbol{e}_r$ of $\mathbf{E}$. In the fiber over p, extend $\sigma_1(p),\dots,\sigma_m(p)$ to a basis for $\mathbf{E}_p$ using some of the vectors $\boldsymbol{e}_j(p)$. The determinant of the matrix of these vectors in the frame $(\boldsymbol{e}_j)$ is nonzero at p; by continuity, it remains nonzero after shrinking the neighborhood. We thus obtain a local frame of $\mathbf{E}$

$$\sigma_1,\dots,\sigma_m,\tau_{m+1},\dots,\tau_r.$$

In the trivialization determined by this frame,

$$\mathbf{D}\restriction_U \longleftrightarrow U \times (\mathbb{R}^m \times \{0\}) \subseteq U \times \mathbb{R}^r.$$

Therefore, $\mathbf{D}\restriction_U \to U$ is a smooth vector bundle of rank m, and its total space is an embedded submanifold of $\mathbf{E}\restriction_U$. On intersections, changes of frame between the first m sections take values in $GL(m,\mathbb{R})$ and are smooth, so these local structures glue. Thus $\mathbf{D}$ is a smooth vector subbundle of $\mathbf{E}$. □

1.8 Integral curves and flows

A vector field can be read as a law of motion: at each point, it prescribes a velocity. The trajectories obeying this law are its integral curves. Local existence and uniqueness for ordinary differential equations allow us to assemble them into a family of diffeomorphisms between open subsets of the manifold, called a flow.

The existence time may depend on the initial point, so a flow need not be defined for every $t \in \mathbb{R}$ or on the entire manifold. When it is, it determines a smooth action of $\mathbb{R}$ on M.

The next definition specifies this relation between velocity and vector field.

Definition 1.8.1. Let M be a smooth manifold without boundary and let $\mathbf{X} \in \mathfrak{X}(M)$. We say that a smooth curve $\gamma\colon I \longrightarrow M$ is an integral curve of $\mathbf{X}$ if, for every $t \in I$,

$$\gamma'(t) = \mathbf{X}(\gamma(t)).$$

If $0 \in I$, we call $\gamma(0)$ the *initial point of* γ.

Example 1.8.2. (a) Consider $\mathbb{R}^2$ with standard coordinates (x,y), and let $\mathbf{X} = \dfrac{\partial}{\partial x}$. The integral curves of $\mathbf{X}$ are precisely the lines parallel to the x-axis, parametrized as

$$\gamma(t) = (a+t, b).$$

In particular, there is a unique integral curve starting at each point of the plane, and the images of distinct integral curves either coincide or are disjoint.

(b) Let $\mathbf{W} = x\dfrac{\partial}{\partial y} - y\dfrac{\partial}{\partial x}$ on $\mathbb{R}^2$. If $\gamma\colon \mathbb{R} \longrightarrow \mathbb{R}^2$ is a smooth curve given by $\gamma(t) = (x(t), y(t))$, the condition

$\gamma'(t) = \mathbf{W}(\gamma(t))$ becomes

$$x'(t)\frac{\partial}{\partial x}\bigg|_{\gamma(t)} + y'(t)\frac{\partial}{\partial y}\bigg|_{\gamma(t)} = x(t)\frac{\partial}{\partial y}\bigg|_{\gamma(t)} - y(t)\frac{\partial}{\partial x}\bigg|_{\gamma(t)}.$$

Equating components gives the system of ordinary differential equations

$$\begin{cases} x'(t) = -y(t), \\ y'(t) = x(t). \end{cases}$$

Its solutions are

$$x(t) = a\cos(t) - b\sin(t), \qquad y(t) = a\sin(t) + b\cos(t), \qquad a, b \in \mathbb{R}.$$

Thus the integral curves are given by

$$\gamma(t) = (a\cos(t) - b\sin(t),\, a\sin(t) + b\cos(t)).$$

When $a = b = 0$, we obtain the constant solution $\gamma(t) \equiv 0$; otherwise, the trajectories are circles centered at the origin, traversed counterclockwise. Since $\gamma(0) = (a, b)$, there is a unique integral curve starting at each point of $\mathbb{R}^2$, and the images of integral curves either coincide or are disjoint.

(a) Integral curves of $X = \frac{\partial}{\partial x}$

(b) Integral curves of $W = x\frac{\partial}{\partial y} - y\frac{\partial}{\partial x}$

As the examples illustrate, finding integral curves "reduces" to solving a system of ordinary differential equations in a chart. Suppose that $\mathbf{X} \in \mathfrak{X}(M)$ and that $\gamma\colon I \longrightarrow M$ is a curve.

Let (U, φ) be a chart such that $\gamma(I) \subset U$, and write $\varphi \circ \gamma = \widetilde{\gamma} = (x^1(t), \ldots, x^n(t))$. Also write the vector field $\mathbf{X}$ in coordinates as $\mathbf{X} = X^i\partial_i$.

The condition that γ be an integral curve of $\mathbf{X}$, namely $\gamma'(t) = \mathbf{X}(\gamma(t))$, becomes in coordinates

$$\dot{x}^i(t)\partial_i\Big|_{\gamma(t)} = X^i(x(t))\partial_i\Big|_{\gamma(t)}.$$

Equating components gives the system of ordinary differential equations

$$\begin{aligned} \dot{x}^1(t) &= X^1(x^1(t),\dots,x^n(t)),\\ &\vdots\\ \dot{x}^n(t) &= X^n(x^1(t),\dots,x^n(t)). \end{aligned}$$

This shows that finding integral curves is equivalent, in coordinates, to solving an autonomous system of ordinary differential equations. The terminology comes precisely from this observation: finding integral curves corresponds to "integrating" the system.

The following result on ordinary differential equations will be fundamental for the subsequent development.

Theorem 1.8.3. (Fundamental theorem for autonomous systems) Let $U \subseteq \mathbb{R}^n$ be open and let $V \in C^\infty(U,\mathbb{R}^n)$. For $(t_0,x_0) \in \mathbb{R}\times U$, consider the initial value problem

$$\begin{cases} \dot{y}^i(t) = V^i(y^1(t),\dots,y^n(t)), \quad i \in \{1,\dots,n\},\\ y(t_0) = x_0. \end{cases} \tag{1.11}$$

Then the following assertions hold:

(a) (Local existence) For each $(t_0,x_0) \in \mathbb{R}\times U$, there exist an open interval $J_0 \subseteq \mathbb{R}$ with $t_0 \in J_0$ and an open set $U_0 \subseteq U$ with $x_0 \in U_0$ such that, for each $x \in U_0$, problem (1.11) with initial condition $y(t_0) = x$ admits a solution $y\colon J_0 \longrightarrow U$ of class C^1.

(b) (Uniqueness) If y_1 and y_2 are two solutions of (1.11) defined on intervals containing t_0 and having the same initial condition, they agree on the intersection of their domains.

(c) (Smooth dependence) If J_0 and U_0 are as in (a), the map

$$\theta\colon J_0\times U_0 \longrightarrow U, \qquad \theta(t,x) = y(t),$$

where y is the unique solution of (1.11) with $y(t_0) = x$, is of class C^∞.

Proof. Apply Theorem B.13.1 with $E = \mathbb{R}^n$ and $F(t,y) = V(y)$. Since V is of class C^1, it is locally Lipschitz; the theorem gives a unique local solution. Proposition B.13.2 extends uniqueness to every common interval. Theorem B.13.5, applied without additional parameters, states that the natural domain

$$\mathcal{E} := \{(t,a) \in \mathbb{R}\times U : t \text{ belongs to the maximal interval of the solution with } y(t_0) = a\}$$

is open and that $(t,a) \mapsto y(t;t_0,a)$ is smooth. Since $(t_0,x_0) \in \mathcal{E}$, there exist an interval $J_0 \ni t_0$ and an open set $U_0 \ni x_0$ with $J_0\times U_0 \subseteq \mathcal{E}$. This gives the uniform choice in (a), uniqueness in (b), and smooth dependence in (c). □

We now establish existence of integral curves.

Proposition 1.8.4. Let M be a smooth manifold without boundary and let $\mathbf{X} \in \mathfrak{X}(M)$. For each $p \in M$, there exist $\varepsilon > 0$ and a smooth curve $\gamma\colon (-\varepsilon, \varepsilon) \longrightarrow M$ such that γ is an integral curve of $\mathbf{X}$ starting at p.

Proof. Let $p \in M$. Take a smooth chart (U, φ) such that $p \in U$, and write $\varphi = (x^1, \dots, x^n)$. Since $\mathbf{X} \in \mathfrak{X}(M)$, on U it can be written as $\mathbf{X} = X^i \partial_i$, where each $X^i\colon \varphi(U) \longrightarrow \mathbb{R}$ is smooth.
Consider the map $V\colon \varphi(U) \longrightarrow \mathbb{R}^n$ given by $V(x) = \big(X^1(x), \dots, X^n(x)\big)$, which is smooth. Let $x_0 := \varphi(p) \in \varphi(U)$. By Theorem 1.8.3, applied to the system $\dot{y}^i(t) = V^i(y^1(t), \dots, y^n(t))$, $i \in \{1, \dots, n\}$, with initial condition $y(0) = x_0$, there exist $\varepsilon > 0$ and a smooth curve $y\colon (-\varepsilon, \varepsilon) \longrightarrow \varphi(U)$ such that

$$\dot{y}^i(t) = X^i(y^1(t), \dots, y^n(t)), \quad i \in \{1, \dots, n\}, \qquad y(0) = x_0.$$

Define $\gamma\colon (-\varepsilon, \varepsilon) \longrightarrow M$ by $\gamma(t) := \varphi^{-1}(y(t))$. Then γ is smooth and $\gamma(0) = p$.
To verify that γ is an integral curve of $\mathbf{X}$, note that $\varphi \circ \gamma = y = (y^1, \dots, y^n)$, so

$$\gamma'(t) = \dot{y}^i(t)\partial_i\Big|_{\gamma(t)} = X^i(y(t))\partial_i\Big|_{\gamma(t)} = \mathbf{X}(\gamma(t)).$$

Consequently, γ is an integral curve of $\mathbf{X}$ starting at p. □

We now examine how affine reparametrizations affect integral curves:

Lemma 1.8.5. (rescaling) Let M be a smooth manifold without boundary, let $\mathbf{X} \in \mathfrak{X}(M)$, let $I \subseteq \mathbb{R}$ be an interval, and let $\gamma\colon I \longrightarrow M$ be an integral curve of $\mathbf{X}$. For any $a \in \mathbb{R}$, the curve $\widetilde{\gamma}\colon \widetilde{I} \longrightarrow M$ defined by $\widetilde{\gamma}(t) = \gamma(at)$ is an integral curve of $a\mathbf{X}$, where $\widetilde{I} = \{t \in \mathbb{R} \mid at \in I\}$.

Proof. Let $t_0 \in \widetilde{I}$ and let f be a smooth function defined on a neighborhood of $\widetilde{\gamma}(t_0)$. Then

$$\widetilde{\gamma}'(t_0)f = \frac{d}{dt}\Big|_{t=t_0} (f \circ \widetilde{\gamma})(t) = \frac{d}{dt}\Big|_{t=t_0} (f \circ \gamma)(at) = a\frac{d}{dt}\Big|_{t=at_0} (f \circ \gamma)(t).$$

Since γ is an integral curve of $\mathbf{X}$, we have

$$\frac{d}{dt}\Big|_{t=at_0} (f \circ \gamma)(t) = \mathbf{X}_{\gamma(at_0)}f = \mathbf{X}_{\widetilde{\gamma}(t_0)}f.$$

Therefore,

$$\widetilde{\gamma}'(t_0)f = a\mathbf{X}_{\widetilde{\gamma}(t_0)}f,$$

proving that $\widetilde{\gamma}$ is an integral curve of $a\mathbf{X}$. □

Lemma 1.8.6. (translation) Let M be a smooth manifold without boundary, let $\mathbf{X} \in \mathfrak{X}(M)$, let $I \subseteq \mathbb{R}$ be an interval, and let $\gamma\colon I \longrightarrow M$ be an integral curve of $\mathbf{X}$. For any $b \in \mathbb{R}$, the curve $\widetilde{\gamma}\colon \widetilde{I} \longrightarrow M$ given by $\widetilde{\gamma}(t) = \gamma(t + b)$ is an integral curve of $\mathbf{X}$, where $\widetilde{I} = \{t \in \mathbb{R} \mid t + b \in I\}$.

Proof. Let $t_0 \in \widetilde{I}$ and let f be a smooth function defined on a neighborhood of $\widetilde{\gamma}(t_0)$. Then

$$\widetilde{\gamma}'(t_0)f = \frac{d}{dt}\bigg|_{t=t_0} (f \circ \widetilde{\gamma})(t) = \frac{d}{dt}\bigg|_{t=t_0} (f \circ \gamma)(t+b) = \frac{d}{dt}\bigg|_{t=t_0+b} (f \circ \gamma)(t).$$

Since γ is an integral curve of $\mathbf{X}$, we have

$$\frac{d}{dt}\bigg|_{t=t_0+b} (f \circ \gamma)(t) = \mathbf{X}_{\gamma(t_0+b)}f = \mathbf{X}_{\widetilde{\gamma}(t_0)}f.$$

Therefore,

$$\widetilde{\gamma}'(t_0)f = \mathbf{X}_{\widetilde{\gamma}(t_0)}f,$$

proving that $\widetilde{\gamma}$ is an integral curve of $\mathbf{X}$. □

Smooth functions allow us to relate vector fields through the notion of F-related fields, which we introduce next.

Definition 1.8.7. Let M and N be smooth manifolds without boundary, let $F\colon M \longrightarrow N$ be a smooth map, and let $\mathbf{X} \in \mathfrak{X}(M)$ and $\mathbf{Y} \in \mathfrak{X}(N)$. We say that $\mathbf{X}$ and $\mathbf{Y}$ are *F-related* if

$$dF_p(\mathbf{X}_p) = \mathbf{Y}_{F(p)} \quad \text{for every } p \in M.$$

Proposition 1.8.8. Let M and N be smooth manifolds without boundary and let $F\colon M \longrightarrow N$ be a smooth map. Then $\mathbf{X} \in \mathfrak{X}(M)$ and $\mathbf{Y} \in \mathfrak{X}(N)$ are F-related if and only if, for every integral curve γ of $\mathbf{X}$, the curve $F \circ \gamma$ is an integral curve of $\mathbf{Y}$.

Proof. First suppose that $\mathbf{X}$ and $\mathbf{Y}$ are F-related, and let $\gamma\colon I \longrightarrow M$ be an integral curve of $\mathbf{X}$. Define $\sigma := F \circ \gamma$. Then

$$\sigma'(t) = (F \circ \gamma)'(t) = dF_{\gamma(t)}(\gamma'(t)) = dF_{\gamma(t)}(\mathbf{X}_{\gamma(t)}) = \mathbf{Y}_{F(\gamma(t))} = \mathbf{Y}_{\sigma(t)},$$

so σ is an integral curve of $\mathbf{Y}$.

Conversely, suppose F sends integral curves of $\mathbf{X}$ to integral curves of $\mathbf{Y}$. Let $p \in M$ and let $\gamma\colon (-\varepsilon, \varepsilon) \longrightarrow M$ be an integral curve of $\mathbf{X}$ with $\gamma(0) = p$. Then $F \circ \gamma$ is an integral curve of $\mathbf{Y}$ with $(F \circ \gamma)(0) = F(p)$, and therefore

$$\mathbf{Y}_{F(p)} = (F \circ \gamma)'(0) = dF_p(\gamma'(0)) = dF_p(\mathbf{X}_p).$$

This shows that $\mathbf{X}$ and $\mathbf{Y}$ are F-related. □

We now study the notion of a *flow*. To do so, we focus on the family of integral curves associated with a vector field.

Let M be a smooth manifold without boundary and let $\mathbf{X} \in \mathfrak{X}(M)$. Suppose that, for each $p \in M$, $\mathbf{X}$ has a unique integral curve defined for every $t \in \mathbb{R}$ and starting at p, which we denote by $\theta^{(p)}\colon \mathbb{R} \longrightarrow M$.

For each $t \in \mathbb{R}$, define a map $\theta_t\colon M \longrightarrow M$ by $\theta_t(p) := \theta^{(p)}(t)$. Intuitively, each θ_t moves points of M along their integral curves for time t.

The translation lemma implies that $t \mapsto \theta^{(p)}(t+s)$ is an integral curve of $\mathbf{X}$ starting at $q = \theta^{(p)}(s)$. Uniqueness

Figure 1.9. F-related vector fields.

of integral curves gives $\theta^{(q)}(t) = \theta^{(p)}(t+s)$. In terms of the maps θ_t, this becomes

$$\theta_t \circ \theta_s = \theta_{t+s}.$$

Moreover, $\theta_0(p) = \theta^{(p)}(0) = p$, so the map $\theta\colon \mathbb{R}\times M \longrightarrow M$, given by $\theta(t,p) = \theta_t(p)$, defines an action of the additive group $\mathbb{R}$ on M.

With this in mind, we give the following definition.

Definition 1.8.9. Let M be a smooth manifold without boundary. A ***global flow on*** M is a continuous action of the additive group $\mathbb{R}$ on M, that is, a map $\theta\colon \mathbb{R}\times M \longrightarrow M$ such that, for any $s,t\in\mathbb{R}$ and $p\in M$,

$$\theta(t,\theta(s,p)) = \theta(t+s,p), \qquad \theta(0,p) = p.$$

If θ is smooth, we say that θ is a ***smooth global flow on*** M.
Given a global flow θ on M, define:

(a) For each $t\in\mathbb{R}$, the map $\theta_t\colon M\longrightarrow M$ given by $\theta_t(p) = \theta(t,p)$. Then $\theta_t\circ\theta_s = \theta_{t+s}$ and $\theta_0 = \mathrm{Id}_M$, so each θ_t is a homeomorphism; if θ is smooth, θ_t is a diffeomorphism.

(b) For each $p\in M$, the curve $\theta^{(p)}\colon \mathbb{R}\longrightarrow M$ given by $\theta^{(p)}(t) = \theta(t,p)$. The image of this curve is called the orbit of p.

The following proposition shows that every smooth global flow arises from the integral curves of a smooth vector field.

Definition 1.8.10. Let M be a smooth manifold without boundary and let $\theta\colon \mathbb{R}\times M\longrightarrow M$ be a smooth global flow. For each $p\in M$, define a tangent vector $\mathbf{X}_p\in T_pM$ by

$$\mathbf{X}_p = (\theta^{(p)})'(0).$$

The assignment $p \mapsto \mathbf{X}_p$ is a rough vector field on M, called the ***infinitesimal generator of*** θ.

Proposition 1.8.11. Let M be a smooth manifold without boundary and let $\theta\colon \mathbb{R}\times M \longrightarrow M$ be a smooth global flow. The infinitesimal generator $\mathbf{X}$ of θ is a smooth vector field on M, and each $\theta^{(p)}$ is an integral curve of $\mathbf{X}$.

Proof. To see that $\mathbf{X}$ is smooth, Proposition 1.7.43 says it suffices to show that $\mathbf{X}f$ is smooth for every $f \in C^\infty(U)$, with $U \subseteq M$ an arbitrary open set. We have

$$\mathbf{X}f(p) = \mathbf{X}_p f = (\theta^{(p)})'(0)f = \frac{d}{dt}\bigg|_{t=0} f(\theta^{(p)}(t)) = \frac{\partial}{\partial t}\bigg|_{(0,p)} f(\theta(t,p)).$$

Since $f(\theta(t,p))$ is a smooth function of (t,p) by composition, its partial derivative with respect to t is also smooth. Thus $\mathbf{X}f(p)$ depends smoothly on p, so $\mathbf{X}$ is smooth. Finally, to see that the curve is an integral curve of $\mathbf{X}$, we must prove that $(\theta^{(p)})'(t) = \mathbf{X}_{\theta^{(p)}(t)}$ for every $p \in M$ and every $t \in \mathbb{R}$. Let $t_0 \in \mathbb{R}$ be arbitrary and let $q = \theta^{(p)}(t_0) = \theta_{t_0}(p)$. The group laws satisfied by θ give, for every $t \in \mathbb{R}$,

$$\theta^{(q)}(t) = \theta_t(q) = \theta_t(\theta_{t_0}(p)) = \theta_{t+t_0}(p) = \theta^{(p)}(t+t_0).$$

Therefore, for any $f \in C^\infty(U)$ where $q \in U$,

$$\mathbf{X}_q f = (\theta^{(q)})'(0)f = \frac{d}{dt}\bigg|_{t=0} f(\theta^{(q)}(t)) = \frac{d}{dt}\bigg|_{t=0} f(\theta^{(p)}(t+t_0)) = (\theta^{(p)})'(t_0)f.$$

□

We have seen that every smooth global flow gives rise to a smooth vector field whose integral curves are exactly the curves defined by the flow. Conversely, we would like to say that every smooth vector field is the infinitesimal generator of a smooth global flow. This is not always true, however, since some smooth vector fields have integral curves that are not defined for every $t \in \mathbb{R}$, as the following example shows:

Example 1.8.12. Let $M = \mathbb{R}^2$ and consider the vector field

$$\mathbf{X}(x,y) = x^2 \frac{\partial}{\partial x}.$$

The integral curve starting at $(1,0)$ is given by

$$\gamma(t) = \left(\frac{1}{1-t}, 0\right),$$

which solves the differential equation $x' = x^2$ with initial condition $x(0) = 1$.
Note that $\gamma(t)$ cannot be extended beyond $t = 1$, since $\dfrac{1}{1-t} \to +\infty$ as $t \to 1^-$. Thus the integral curve is not defined for every $t \in \mathbb{R}$, and consequently $\mathbf{X}$ does not generate a global flow.

For this reason, we need to restrict the domains on which flows are defined while retaining their characteristic properties.

Definition 1.8.13. Let M be a smooth manifold without boundary. A flow domain for M is an open subset $\mathcal{D} \subseteq \mathbb{R} \times M$ such that, for each $p \in M$, the set

$$\mathcal{D}^{(p)} = \{t \in \mathbb{R} \mid (t,p) \in \mathcal{D}\}$$

is an open interval containing 0. A ***flow*** on M is a continuous function $\theta\colon \mathcal{D} \longrightarrow M$, where $\mathcal{D} \subseteq \mathbb{R} \times M$ is a flow domain, satisfying the following group laws:

(a) For every $p \in M$, $\theta(0,p) = p$.

(b) For every $s \in \mathcal{D}^{(p)}$ and every $t \in \mathcal{D}^{(\theta(s,p))}$ such that $s + t \in \mathcal{D}^{(p)}$, $\theta(t, \theta(s,p)) = \theta(t+s,p)$.

We sometimes call θ a ***local flow*** to distinguish it from global flows. If θ is a flow, define $\theta_t(p) = \theta^{(p)}(t) = \theta(t,p)$ if $(t,p) \in \mathcal{D}$. For $t \in \mathbb{R}$, define

$$M_t := \{p \in M \mid (t,p) \in \mathcal{D}\},$$

so that $p \in M_t \iff t \in \mathcal{D}^{(p)} \iff (t,p) \in \mathcal{D}$. If θ is smooth, the infinitesimal generator of θ is defined by $\mathbf{X}_p := (\theta^{(p)})'(0)$.

Proposition 1.8.14. Let M be a smooth manifold without boundary. If $\theta\colon \mathcal{D} \longrightarrow M$ is a smooth flow, the infinitesimal generator $\mathbf{X}$ of θ is a smooth vector field, and each curve $\theta^{(p)}$ is an integral curve of $\mathbf{X}$.

Proof. Since $\mathcal{D}$ is open and contains $\{0\} \times M$, the map

$$p \longmapsto \mathbf{X}_p := d\theta_{(0,p)}(1,0)$$

is a smooth section of TM: in a chart of M, its components are the partial derivatives with respect to time of the components of θ, evaluated at $(0,p)$. This proves smoothness of $\mathbf{X}$.
Fix $p \in M$ and $t_0 \in \mathcal{D}^{(p)}$. Since $\mathcal{D}^{(\theta(t_0,p))}$ is an open interval containing zero, for s sufficiently close to zero the flow law gives

$$\theta\big(s, \theta(t_0,p)\big) = \theta(t_0 + s, p).$$

Differentiating with respect to s at $s = 0$, we obtain

$$\mathbf{X}_{\theta(t_0,p)} = \frac{d}{ds}\bigg|_{s=0} \theta(t_0 + s, p) = \frac{d}{dt}\theta^{(p)}(t_0).$$

Since t_0 was arbitrary, $\theta^{(p)}$ satisfies the integral-curve equation throughout its domain $\mathcal{D}^{(p)}$. □

Existence and uniqueness of the flow induced by a vector field is the most important result in flow theory. It will be useful later when we consider certain flows in the study of Sobolev spaces.

Theorem 1.8.15. (fundamental theorem of flows) Let M be a smooth manifold without boundary and let $\mathbf{X} \in \mathfrak{X}(M)$. Then there exists a unique maximal smooth flow $\theta\colon \mathcal{D} \longrightarrow M$ whose infinitesimal generator is $\mathbf{X}$ and which has the following properties:

(a) For each $p \in M$, the curve $\theta^{(p)}\colon \mathcal{D}^{(p)} \longrightarrow M$ is the unique maximal integral curve of $\mathbf{X}$ starting at p.

(b) If $s \in \mathcal{D}^{(p)}$, then $\mathcal{D}^{(\theta(s,p))}$ is the interval $\mathcal{D}^{(p)} - s = \{t - s \mid t \in \mathcal{D}^{(p)}\}$.

(c) For each $t \in \mathbb{R}$, the set M_t is open in M, and $\theta_t \colon M_t \longrightarrow M_{-t}$ is a diffeomorphism with inverse θ_{-t}.

Proof. For each $p \in M$, local existence and uniqueness in charts allow us to join all integral curves starting at p. This gives a unique maximal integral curve

$$\gamma_p \colon I_p \longrightarrow M, \qquad 0 \in I_p, \qquad \gamma_p(0) = p.$$

Define

$$\mathcal{D} := \{(t,p) \in \mathbb{R} \times M : t \in I_p\}, \qquad \theta(t,p) := \gamma_p(t).$$

Fix $(t_1, p_1) \in \mathcal{D}$. The image of the compact portion of I_{p_1} between 0 and t_1 is covered by finitely many chart domains. In each chart, Theorem 1.8.3 provides a common existence interval and smooth dependence on the initial data. Divide the interval between 0 and t_1 into finitely many subintervals subordinate to those domains. On the first, the final value depends smoothly on the initial point; this value serves as the initial data for the second, and so on. Composing finitely many of these solution maps gives an open set $U_1 \ni p_1$ and an interval $J_1 \ni t_1$ with

$$J_1 \times U_1 \subseteq \mathcal{D}$$

such that θ is smooth on $J_1 \times U_1$. Therefore, $\mathcal{D}$ is open and θ is smooth.
Let $s \in I_p$ and $q = \gamma_p(s)$. The curves

$$t \longmapsto \gamma_p(t+s), \qquad t \longmapsto \gamma_q(t)$$

are integral curves of $\mathbf{X}$ and take the value q at $t = 0$. By uniqueness, they agree on their common domain. Maximality in both directions implies

$$I_q = I_p - s, \qquad \gamma_q(t) = \gamma_p(t+s), \quad t \in I_p - s.$$

This proves (2), the flow laws, and $\theta^{(p)} = \gamma_p$, which is (1). Moreover,

$$\left.\frac{d}{dt}\right|_{t=0} \theta(t,p) = \gamma_p'(0) = \mathbf{X}_p,$$

so the generator is $\mathbf{X}$.
Since $\mathcal{D}$ is open, each $M_t = \{p : (t,p) \in \mathcal{D}\}$ is open. If $p \in M_t$ and $q = \theta_t(p)$, then $I_q = I_p - t$, so $q \in M_{-t}$, and the flow law gives $\theta_{-t}(q) = p$. The reverse argument starts with $q \in M_{-t}$. Thus $\theta_t \colon M_t \to M_{-t}$ is a diffeomorphism with inverse θ_{-t}, proving (3).
Any other smooth flow with generator $\mathbf{X}$ has integral curves of $\mathbf{X}$ as its orbits. If it is maximal, each orbit agrees with γ_p; hence both the domain and the flow agree. This proves uniqueness. □

The flow whose existence is guaranteed by Theorem 1.8.15 is called the *flow generated by* $\mathbf{X}$. The term *infinitesimal generator* is justified by the fact that the vector field $\mathbf{X}$ describes the instantaneous variation of the flow, in the sense that

$$\mathbf{X}(p) = \left.\frac{d}{dt}\theta(t,p)\right|_{t=0}.$$

In a smooth chart, this means that, at each point, the vector $\mathbf{X}(p)$ determines the tangent direction of the integral curve through p, and the flow is obtained by integrating these directions over time. Flows are natural with respect

Figure 1.10. Argument showing that $\mathcal{D}$ is open.

to smooth functions in the following sense:

Proposition 1.8.16. Let M and N be smooth manifolds without boundary, let $F\colon M \longrightarrow N$ be a smooth map, and let $\mathbf{X} \in \mathfrak{X}(M)$ and $\mathbf{Y} \in \mathfrak{X}(N)$. Let θ be the flow of $\mathbf{X}$ and η the flow of $\mathbf{Y}$. If $\mathbf{X}$ and $\mathbf{Y}$ are F-related, then, for each $t \in \mathbb{R}$, $F(M_t) \subseteq N_t$ and $\eta_t \circ F = F \circ \theta_t$ on M_t:

$$\begin{array}{ccc} M_t & \xrightarrow{\theta_t} & M_{-t} \\ {\scriptstyle F}\downarrow & & \downarrow{\scriptstyle F} \\ N_t & \xrightarrow{\eta_t} & N_{-t} \end{array}$$

Proof. By Proposition 1.8.8, for any $p \in M$, the curve $F \circ \theta^{(p)}$ is an integral curve of $\mathbf{Y}$ starting at $F(\theta^{(p)}(0)) = F(p)$. By uniqueness of integral curves, the maximal integral curve $\eta^{(F(p))}$ must be defined at least on $\mathcal{D}^{(p)}$, and $F \circ \theta^{(p)} = \eta^{(F(p))}$ on that interval. This means that

$$p \in M_t \Rightarrow t \in \mathcal{D}^{(p)} \Rightarrow t \in \mathcal{D}^{(F(p))} \Rightarrow F(p) \in N_t,$$

equivalently $F(M_t) \subseteq N_t$, and

$$F(\theta^{(p)}(t)) = \eta^{(F(p))}(t), \qquad \forall t \in \mathcal{D}^{(p)},$$

equivalently $\eta_t(F(p)) = F(\theta_t(p))$ for every $p \in M_t$. □

This gives the following corollary:

Corollary 1.8.17. (Invariance of flows under diffeomorphisms) Let M and N be smooth manifolds without boundary, let $F\colon M \longrightarrow N$ be a diffeomorphism, and let $\mathbf{X} \in \mathfrak{X}(M)$ have flow θ. Then the vector field $F_*\mathbf{X} \in \mathfrak{X}(N)$ defined by

$$(F_*\mathbf{X})(q) = dF_{F^{-1}(q)}\big(\mathbf{X}(F^{-1}(q))\big)$$

has flow given by

$$\eta_t = F \circ \theta_t \circ F^{-1},$$

with domain $N_t = F(M_t)$ for each $t \in \mathbb{R}$.

Proof. Set $\mathbf{Y} := F_*\mathbf{X}$. By the definition of the pushforward field,

$$dF_p(\mathbf{X}(p)) = \mathbf{Y}(F(p)), \qquad p \in M,$$

so $\mathbf{X}$ and $\mathbf{Y}$ are F-related. Proposition 1.8.16 applied to F gives

$$F(M_t) \subseteq N_t, \qquad \eta_t \circ F = F \circ \theta_t \quad \text{on } M_t.$$

Apply the same proposition to F^{-1}, observing that $(F^{-1})_*\mathbf{Y} = \mathbf{X}$. This gives

$$F^{-1}(N_t) \subseteq M_t.$$

Applying F to this inclusion yields $N_t \subseteq F(M_t)$; therefore,

$$N_t = F(M_t).$$

Finally, composing $\eta_t \circ F = F \circ \theta_t$ on the right with F^{-1} gives

$$\eta_t = F \circ \theta_t \circ F^{-1} \quad \text{on } N_t.$$

□

We record another important property of integral curves:

Lemma 1.8.18. (escape) Let M be a smooth manifold without boundary and let $\mathbf{X} \in \mathfrak{X}(M)$. If $\gamma\colon J \longrightarrow M$ is a maximal integral curve of $\mathbf{X}$ and its right endpoint $b := \sup J$ is finite, then, for every $t_0 \in J$, the tail $\gamma([t_0, b))$ is not contained in any compact subset of M. The assertion for the left endpoint follows by reversing the parameter: if $a := \inf J > -\infty$, no tail $\gamma((a, t_0])$ is contained in a compact set.

Proof. Suppose that $\gamma([t_0, b)) \subseteq K$ with K compact. For a sequence $t_j \to b^-$, compactness gives a subsequence, not relabeled, such that $\gamma(t_j) \to p \in K$. The local existence theorem and dependence on the initial data provide a neighborhood U of p and a common $\varepsilon > 0$ for all initial data in U. For sufficiently large j, $\gamma(t_j) \in U$ and $b - t_j < \frac{\varepsilon}{2}$. The local solution starting at $\gamma(t_j)$ at time t_j agrees by uniqueness with γ on their common domain and extends it to $t_j + \varepsilon > b$, contradicting maximality. For the left endpoint, apply the same argument to the field $-\mathbf{X}$ and the time-reversed curve. □

We give some local estimates for partial derivatives of a flow, which will be useful later when studying Sobolev

spaces on manifolds of bounded geometry.

Lemma 1.8.19. (Grönwall's inequality) Let $u\colon [0,T] \longrightarrow [0,\infty)$ be a continuous function, let $a \geq 0$, and let $b\colon [0,T] \longrightarrow [0,\infty)$ be a continuous function. Suppose that

$$u(t) \leq a + \int_0^t b(\tau)\, u(\tau)\, d\tau, \qquad \forall t \in [0,T].$$

Then

$$u(t) \leq a \exp\left(\int_0^t b(\tau)\, d\tau\right), \qquad \forall t \in [0,T].$$

Proof. Define

$$v(t) := a + \int_0^t b(\tau) u(\tau)\, d\tau.$$

Then $u \leq v$, $v(0) = a$, and

$$v'(t) = b(t)u(t) \leq b(t)v(t).$$

If $a > 0$, we have $v(t) > 0$, so

$$\frac{d}{dt} \log v(t) \leq b(t).$$

Integrating between 0 and t,

$$v(t) \leq a \exp\left(\int_0^t b(\tau)\, d\tau\right),$$

and the same bound holds for u. If $a = 0$, apply the preceding argument, for each $\varepsilon > 0$, to

$$v_\varepsilon(t) := \varepsilon + \int_0^t b(\tau) u(\tau)\, d\tau.$$

This gives

$$u(t) \leq v_\varepsilon(t) \leq \varepsilon \exp\left(\int_0^t b(\tau)\, d\tau\right).$$

Letting $\varepsilon \to 0^+$ yields $u(t) = 0$, which is the assertion in this case. □

Lemma 1.8.20. Let M be a smooth manifold without boundary of dimension n, and let $\mathbf{X} \in \mathfrak{X}(M)$ be a smooth vector field. Let

$$\Phi\colon D \subseteq \mathbb{R} \times M \longrightarrow M$$

be the flow of $\mathbf{X}$.
Let (U, φ) be a chart of M such that $\overline{U}$ is compact. Suppose that $p \in U$, that $t \geq 0$, and that

$$(\tau, p) \in D \quad \text{and} \quad \Phi(\tau, p) \in U, \qquad \tau \in [0,t].$$

Then, for each multi-index $\alpha \in \mathbb{N}_0^n$ with $|\alpha| \geq 1$, there exists a continuous function

$$\mathrm{Expr}_\alpha\colon [0,\infty) \times [0,\infty) \longrightarrow [0,\infty),$$

nondecreasing in each variable and depending only on α and n, such that

$$\left\|\partial_x^\alpha(\varphi\circ\Phi(t,\cdot)\circ\varphi^{-1})(\varphi(p))\right\| \le \operatorname{Expr}_\alpha\left(\sup_{\substack{\tau\in[0,t],\ \beta\in\mathbb{N}_0^n\\ 1\le|\beta|\le|\alpha|}}\left\|\partial_x^\beta(\varphi_*\mathbf{X})(\varphi(\Phi(\tau,p)))\right\|, t\right).$$

The vector norms are Euclidean. Moreover, if $|\alpha|=1$, we may take

$$\operatorname{Expr}_\alpha(M,t) = e^{\sqrt{n}Mt},$$

while for $|\alpha|\ge 2$ we can choose $\operatorname{Expr}_\alpha$ recursively.

Proof. Define

$$V := \varphi(U)\subseteq\mathbb{R}^n$$

and consider the vector field in coordinates

$$\widetilde{X} := \varphi_*\mathbf{X}\in\mathfrak{X}(V).$$

Since $\mathbf{X}$ is smooth and φ is a diffeomorphism onto its image, the field $\widetilde{X}$ is smooth.
Also define

$$\widetilde{D} := \left\{(\tau,x)\in\mathbb{R}\times V \;\middle|\; (\tau,\varphi^{-1}(x))\in D \text{ and } \Phi(\tau,\varphi^{-1}(x))\in U\right\}$$

and

$$\widetilde{\Phi}\colon \widetilde{D}\longrightarrow V, \qquad \widetilde{\Phi}(\tau,x) := \varphi\big(\Phi(\tau,\varphi^{-1}(x))\big).$$

The function $\widetilde{\Phi}$ is smooth. We will show that, for each $x\in V$, the curve

$$\tau\longmapsto\widetilde{\Phi}(\tau,x)$$

satisfies the differential equation associated with $\widetilde{X}$.
Fix $x\in V$ and write $q := \varphi^{-1}(x)$. Then

$$\frac{\partial}{\partial\tau}\widetilde{\Phi}(\tau,x) = d\varphi_{\Phi(\tau,q)}\left(\frac{\partial}{\partial\tau}\Phi(\tau,q)\right).$$

Since Φ is the flow of $\mathbf{X}$,

$$\frac{\partial}{\partial\tau}\Phi(\tau,q) = \mathbf{X}_{\Phi(\tau,q)}.$$

Therefore,

$$\frac{\partial}{\partial\tau}\widetilde{\Phi}(\tau,x) = d\varphi_{\Phi(\tau,q)}(\mathbf{X}_{\Phi(\tau,q)}) = \widetilde{X}(\widetilde{\Phi}(\tau,x)).$$

Moreover,

$$\widetilde{\Phi}(0,x) = x.$$

Thus $\tau\mapsto\widetilde{\Phi}(\tau,x)$ solves

$$z'(\tau) = \widetilde{X}(z(\tau)), \qquad z(0)=x.$$

Take

$$x_0 := \varphi(p), \qquad Z(\tau) := \widetilde{\Phi}(\tau, x_0).$$

Then

$$Z'(\tau) = \widetilde{X}(Z(\tau)), \qquad Z(0) = x_0,$$

and integration gives

$$Z(t) = x_0 + \int_0^t \widetilde{X}(Z(\tau))\, d\tau.$$

We proceed by induction on $|\alpha|$.

Case $|\alpha| = 1$**.** Define

$$Y_k(t) := \partial_{x_{0,k}} \widetilde{\Phi}(t, x_0).$$

Differentiating the integral equation,

$$Y_k(t) = e_k + \int_0^t d\widetilde{X}_{Z(\tau)}(Y_k(\tau))\, d\tau,$$

and therefore

$$Y_k'(t) = d\widetilde{X}_{Z(t)}(Y_k(t)), \qquad Y_k(0) = e_k.$$

Let

$$M_1(t) := \sup_{\substack{\tau\in[0,t]\\ j\in\{1,\dots,n\}}} \|\partial_j \widetilde{X}(Z(\tau))\|.$$

For $z \in V$ and $v = (v_1, \dots, v_n) \in \mathbb{R}^n$, we have

$$\|d\widetilde{X}_z(v)\| \le \max_{1\le j\le n} \|\partial_j \widetilde{X}(z)\| \sum_{j=1}^n |v_j| \le \sqrt{n} \max_{1\le j\le n} \|\partial_j \widetilde{X}(z)\| \|v\|.$$

Thus the operator norm of $d\widetilde{X}_{Z(\tau)}$ is at most $\sqrt{n} M_1(t)$ for $0 \le \tau \le t$. Fixing t,

$$\|Y_k(s)\| \le 1 + \int_0^s \sqrt{n} M_1(t) \|Y_k(\tau)\|\, d\tau, \qquad 0 \le s \le t.$$

Applying Lemma 1.8.19 and evaluating at $s = t$,

$$\|Y_k(t)\| \le e^{\sqrt{n} M_1(t) t}.$$

Inductive step. Suppose $|\alpha| = m \ge 2$ and that the result holds for every multi-index of strictly smaller order. Apply $\partial_{x_0}^\alpha$ to

$$\frac{\partial}{\partial t} \widetilde{\Phi}(t, x_0) = \widetilde{X}(\widetilde{\Phi}(t, x_0)).$$

Commuting derivatives,

$$\frac{\partial}{\partial t} \left(\partial_{x_0}^\alpha \widetilde{\Phi}(t, x_0) \right) = \partial_{x_0}^\alpha (\widetilde{X}(\widetilde{\Phi}(t, x_0))).$$

Applying the Faà di Bruno formula (Theorem 1.1.19), we obtain

$$\partial_{x_0}^{\alpha}(\widetilde{X}(\widetilde{\Phi}(t,x_0))) = \sum_{\substack{\beta\in\mathbb{N}_0^n \\ 1\le|\beta|\le|\alpha|}} \sum_{\substack{\gamma=(\gamma_1,\dots,\gamma_{|\beta|}) \\ |\gamma_i|>0,\ \sum_{i=1}^{|\beta|}\gamma_i=\alpha}} \sum_{l\in\{1,\dots,n\}^{|\beta|}} c_{\alpha,\beta,\gamma,l}\,\partial_x^{\beta}\widetilde{X}(Z(t))\prod_{i=1}^{|\beta|}\partial_{x_0}^{\gamma_i}\widetilde{\Phi}_{l_i}(t,x_0).$$

If $|\beta|=1$, then $\gamma=(\gamma_1)$ has only one component and $\gamma_1=\alpha$, giving

$$d\widetilde{X}_{Z(t)}(\partial_{x_0}^{\alpha}\widetilde{\Phi}(t,x_0)).$$

We therefore define explicitly

$$G_{\alpha}(t) := \sum_{\substack{\beta\in\mathbb{N}_0^n \\ 2\le|\beta|\le|\alpha|}} \sum_{\substack{\gamma=(\gamma_1,\dots,\gamma_{|\beta|}) \\ |\gamma_i|>0,\ \sum_{i=1}^{|\beta|}\gamma_i=\alpha}} \sum_{l\in\{1,\dots,n\}^{|\beta|}} c_{\alpha,\beta,\gamma,l}\,\partial_x^{\beta}\widetilde{X}(Z(t))\prod_{i=1}^{|\beta|}\partial_{x_0}^{\gamma_i}\widetilde{\Phi}_{l_i}(t,x_0).$$

Thus

$$\frac{\partial}{\partial t}(\partial_{x_0}^{\alpha}\widetilde{\Phi}) = d\widetilde{X}_{Z(t)}(\partial_{x_0}^{\alpha}\widetilde{\Phi}) + G_{\alpha}(t), \qquad \partial_{x_0}^{\alpha}\widetilde{\Phi}(0,x_0)=0.$$

Define

$$M_{\alpha}(t) := \sup_{\substack{\tau\in[0,t],\ \beta\in\mathbb{N}_0^n \\ 1\le|\beta|\le|\alpha|}} \|\partial_x^{\beta}\widetilde{X}(Z(\tau))\|.$$

By the induction hypothesis,

$$\|\partial_{x_0}^{\gamma}\widetilde{\Phi}(\tau,x_0)\| \le \mathrm{Expr}_{\gamma}(M_{\alpha}(t),t).$$

Taking norms in G_{α} and using these bounds shows that there exists a polynomial P_{α} with nonnegative coefficients such that

$$\|G_{\alpha}(\tau)\| \le P_{\alpha}\big(M_{\alpha}(t),\mathrm{Expr}_{\gamma^{(1)}}(M_{\alpha}(t),t),\dots\big).$$

Define

$$B_{\alpha}(M,t) := P_{\alpha}\big(M,\mathrm{Expr}_{\gamma^{(1)}}(M,t),\dots\big).$$

Let

$$u(s) := \|\partial_{x_0}^{\alpha}\widetilde{\Phi}(s,x_0)\|.$$

The norm comparison in the first-order case gives $\|d\widetilde{X}_{Z(\tau)}\|_{\mathrm{op}} \le \sqrt{n}\,M_{\alpha}(t)$ for $0\le\tau\le t$. Integrating the equation for $\partial_{x_0}^{\alpha}\widetilde{\Phi}$, whose initial value is zero, gives

$$u(s) \le tB_{\alpha}(M_{\alpha}(t),t) + \int_0^s \sqrt{n}\,M_{\alpha}(t)u(\tau)\,d\tau, \qquad 0\le s\le t.$$

Applying Lemma 1.8.19,

$$u(s) \le tB_{\alpha}(M_{\alpha}(t),t)e^{\sqrt{n}M_{\alpha}(t)s}.$$

Evaluating at $s = t$,

$$\|\partial_{x_0}^{\alpha}\widetilde{\Phi}(t,x_0)\| \le tB_{\alpha}(M_{\alpha}(t),t)e^{\sqrt{n}M_{\alpha}(t)t}.$$

Define

$$\mathrm{Expr}_{\alpha}(M,t) := tB_{\alpha}(M,t)e^{\sqrt{n}Mt}.$$

Finally, the function Expr_{α} is nondecreasing in each variable. By the induction hypothesis, the functions Expr_{γ} have this property; since P_{α} has nonnegative coefficients, B_{α} is nondecreasing in each variable; and the function $(M,t) \mapsto te^{\sqrt{n}Mt}$ is nondecreasing in $[0,\infty)\times[0,\infty)$. The assertion follows.
Finally,

$$\partial_x^{\alpha}(\varphi \circ \Phi(t,\cdot)\circ\varphi^{-1})(\varphi(p)) = \partial_{x_0}^{\alpha}\widetilde{\Phi}(t,x_0),$$

and

$$\partial_x^{\beta}\widetilde{X}(Z(\tau)) = \partial_x^{\beta}(\varphi_*\mathbf{X})(\varphi(\Phi(\tau,p))),$$

which completes the proof. □

1.9 Lie groups and smooth actions

Many geometric symmetries depend on continuous parameters. Translations of $\mathbb{R}^n$, rotations of the circle, and changes of frame can be composed and inverted, but they can also be differentiated with respect to those parameters. Lie groups bring these two structures together: the group law expresses composition of symmetries, while the smooth structure allows us to study how they vary.

Basic examples include $(\mathbb{R}^n,+)$, the circle S^1, $\mathrm{GL}(n,\mathbb{R})$, and its orthogonal subgroups; in the complex case, unitary groups arise in the same way. Isometry groups provide further examples when the necessary geometric structure is available. Near the identity, the tangent space T_eG and its bracket form the Lie algebra of G. This infinitesimal linearization allows us to study curves of symmetries through equations in a vector space.

The relation between the group and its algebra will appear in flows and one-parameter subgroups. Smooth actions will later lead to homogeneous spaces and principal bundles; in infinite dimensions, analogous ideas will arise in gauge groups and diffeomorphism groups.

In this section, we specify the Lie group conventions used later. If G is a group and $g \in G$, we write

$$L_g(h) := gh, \qquad R_{\mathbf{g}}(h) := hg, \qquad C_g(h) := ghg^{-1}.$$

For the standard finite-dimensional theory and a comparison of conventions, see [94, Chs. 7 and 20]. We will explicitly indicate external results whose proofs are not reproduced.

Definition 1.9.1. (Lie group) A *finite-dimensional real Lie group* is a smooth manifold G without boundary, equipped with a group structure for which the maps

$$\mu\colon G\times G \longrightarrow G, \qquad \mu(g,h)=gh, \qquad \iota\colon G\longrightarrow G, \qquad \iota(g)=g^{-1},$$

are smooth. Denote the identity element of G by e. A *Lie group homomorphism* is a group homomorphism that is also smooth.

Proposition 1.9.2. Let G and H be finite-dimensional real Lie groups whose underlying smooth manifolds have no boundary. For every $g \in G$, the maps L_g, $R_{\mathbf{g}}$, and C_g are diffeomorphisms, and

$$L_g^{-1} = L_{g^{-1}}, \qquad R_{\mathbf{g}}^{-1} = R_{g^{-1}}, \qquad C_g^{-1} = C_{g^{-1}}.$$

Moreover,

$$C_{gh} = C_g \circ C_h.$$

If $\Phi\colon G \to H$ is a Lie group homomorphism, then

$$\Phi \circ L_g = L_{\Phi(g)} \circ \Phi, \qquad \Phi \circ R_{\mathbf{g}} = R_{\Phi(g)} \circ \Phi, \qquad \Phi \circ C_g = C_{\Phi(g)} \circ \Phi.$$

Proof. All identities follow directly from the group laws. Smoothness of the maps and their inverses follows from smoothness of multiplication and inversion. □

Proposition 1.9.3. (Classical matrix groups) The groups

$$\mathrm{GL}(n,\mathbb{R}), \quad \mathrm{GL}(n,\mathbb{C}), \quad \mathrm{O}(n), \quad \mathrm{SO}(n), \quad \mathrm{U}(n)$$

are finite-dimensional real Lie groups with the smooth structures induced by their inclusions into matrix spaces. In particular, $\mathrm{U}(1) = \{z \in \mathbb{C} : |z| = 1\}$ is the circle viewed as a Lie group.

Proof. The set $\mathrm{GL}(n,\mathbb{K}) = \{A : \det A \neq 0\}$, for $\mathbb{K} = \mathbb{R}, \mathbb{C}$, is open in the real vector space of matrices. Multiplication is polynomial, and the formula $A^{-1} = \mathrm{adj}(A)/\det A$ proves that inversion is smooth.
For the orthogonal group, consider

$$F\colon M_n(\mathbb{R}) \longrightarrow \mathrm{Sym}_n(\mathbb{R}), \qquad F(A) = A^{\mathsf{T}}A.$$

If $A \in F^{-1}(I)$, then

$$dF_A(H) = A^{\mathsf{T}}H + H^{\mathsf{T}}A.$$

This differential is surjective: given a symmetric matrix S, simply take $H = AS/2$. By the regular value theorem, $\mathrm{O}(n) = F^{-1}(I)$ is a submanifold. The group operations are restrictions of smooth maps. Since the determinant takes only the values ± 1 on $\mathrm{O}(n)$, the subset $\mathrm{SO}(n) = \{A \in \mathrm{O}(n) : \det A = 1\}$ is open and closed in $\mathrm{O}(n)$, and is therefore also a Lie group.
The same argument, regarding complex spaces as real spaces and using

$$F_{\mathbb{C}}(A) = A^*A, \qquad d(F_{\mathbb{C}})_A(H) = A^*H + H^*A,$$

shows that $\mathrm{U}(n) = F_{\mathbb{C}}^{-1}(I)$ is a submanifold: for a Hermitian matrix S, the choice $H = AS/2$ proves surjectivity. The case $n = 1$ gives precisely the unit circle. □

Before defining the Lie algebra, we recall our convention for the bracket of vector fields.

Proposition 1.9.4. (Bracket of vector fields) Let M and N be smooth manifolds with or without boundary, and let $\mathbf{X}, \mathbf{Y} \in \mathfrak{X}(M)$. There is a unique smooth vector field $[\mathbf{X}, \mathbf{Y}]$ characterized by

$$[\mathbf{X}, \mathbf{Y}](f) = \mathbf{X}(\mathbf{Y}f) - \mathbf{Y}(\mathbf{X}f), \qquad f \in C^\infty(M). \tag{1.12}$$

The bracket is bilinear and antisymmetric and satisfies the Jacobi identity. If $F\colon M \to N$ is smooth, $\mathbf{X}_1, \mathbf{X}_2 \in \mathfrak{X}(M)$ and $\mathbf{Y}_1, \mathbf{Y}_2 \in \mathfrak{X}(N)$, and $\mathbf{X}_i$ is F-related to $\mathbf{Y}_i$ for $i = 1, 2$, then $[\mathbf{X}_1, \mathbf{X}_2]$ is F-related to $[\mathbf{Y}_1, \mathbf{Y}_2]$. In particular, if F is a diffeomorphism,

$$F_*[\mathbf{X}, \mathbf{Y}] = [F_*\mathbf{X}, F_*\mathbf{Y}].$$

Proof. For $f, g \in C^\infty(M)$, the Leibniz rule gives

$$\big(\mathbf{XY} - \mathbf{YX}\big)(fg) = f\big(\mathbf{XY} - \mathbf{YX}\big)g + g\big(\mathbf{XY} - \mathbf{YX}\big)f.$$

Thus, at each point p, the operator $f \mapsto (\mathbf{XY} - \mathbf{YX})f(p)$ is a derivation and therefore a tangent vector at T_pM. In coordinates, if $\mathbf{X} = X^i\partial_i$ and $\mathbf{Y} = Y^j\partial_j$, then

$$[\mathbf{X}, \mathbf{Y}] = \left(X^i\partial_i Y^j - Y^i\partial_i X^j\right)\partial_j,$$

so the resulting field is smooth. Antisymmetry and the Jacobi identity are the corresponding identities for commutators of linear operators.
If $\mathbf{X}_i$ is F-related to $\mathbf{Y}_i$, then, for $f \in C^\infty(N)$,

$$\mathbf{X}_i(f \circ F) = (\mathbf{Y}_i f) \circ F.$$

Applying this equality twice gives

$$[\mathbf{X}_1, \mathbf{X}_2](f \circ F) = \big([\mathbf{Y}_1, \mathbf{Y}_2]f\big) \circ F,$$

which is precisely the required relation. □

Definition 1.9.5. (Invariant fields and the Lie algebra) Let G be a finite-dimensional real Lie group whose underlying smooth manifold has no boundary. A field $\mathbf{X} \in \mathfrak{X}(G)$ is *left invariant* if

$$(L_g)_*\mathbf{X} = \mathbf{X} \qquad \text{for every } g \in G.$$

For $\xi \in T_eG$, define

$$\xi^L_g := (dL_g)_e\xi.$$

The vector space

$$\mathfrak{g} := T_eG$$

is called the *Lie algebra of* G. Its bracket is defined by

$$[\xi, \eta]_{\mathfrak{g}} := [\xi^L, \eta^L]_e. \tag{1.13}$$

We omit the subscript $\mathfrak{g}$ when there is no risk of confusion.

Proposition 1.9.6. Let G be a finite-dimensional real Lie group whose underlying smooth manifold has no boundary. The assignment

$$\mathfrak{g} \longrightarrow \{\mathbf{X} \in \mathfrak{X}(G) \mid \mathbf{X} \text{ is left invariant}\}, \qquad \xi \longmapsto \xi^L,$$

is a linear isomorphism with inverse $\mathbf{X} \mapsto \mathbf{X}_e$. Moreover,

$$[\xi^L, \eta^L] = [\xi, \eta]^L.$$

Therefore, (1.13) makes $\mathfrak{g}$ a Lie algebra.

Proof. Smoothness of ξ^L follows from smoothness of $(g, \xi) \mapsto (dL_g)_e \xi$. The identity $L_g \circ L_h = L_{gh}$ implies

$$(dL_g)_h(\xi^L_h) = (dL_g)_h (dL_h)_e \xi = (dL_{gh})_e \xi = \xi^L_{gh},$$

so ξ^L is left invariant. Conversely, if $\mathbf{X}$ is left invariant, then

$$\mathbf{X}_g = (dL_g)_e \mathbf{X}_e,$$

so $\mathbf{X} = (\mathbf{X}_e)^L$. Naturality of the bracket under L_g shows that the bracket of two left invariant fields is again left invariant. Evaluation at e gives $[\xi^L, \eta^L] = [\xi, \eta]^L$. The Lie algebra identities are then inherited from the bracket of vector fields. □

Proposition 1.9.7. (Lie algebras of the classical matrix groups) With the matrix bracket $[A, B] = AB - BA$, we have the identifications

$$\mathfrak{gl}(n, \mathbb{R}) = M_n(\mathbb{R}), \qquad \mathfrak{gl}(n, \mathbb{C}) = M_n(\mathbb{C})$$

as real Lie algebras, and

$$\mathfrak{o}(n) = \mathfrak{so}(n) = \{A \in M_n(\mathbb{R}) : A^{\mathsf{T}} + A = 0\}, \qquad \mathfrak{u}(n) = \{A \in M_n(\mathbb{C}) : A^* + A = 0\}.$$

In particular, $\mathfrak{u}(1) = i\mathbb{R}$.

Proof. The tangent space at the identity of a general linear group is the entire ambient space. If $A(t)$ is a curve in $\mathrm{O}(n)$ with $A(0) = I$, differentiating $A(t)^{\mathsf{T}} A(t) = I$ gives $A'(0)^{\mathsf{T}} + A'(0) = 0$. Conversely, each skew-symmetric matrix belongs to the kernel of dF_I, which is the tangent space to the regular level set. Since $\mathrm{SO}(n)$ is open in $\mathrm{O}(n)$, both groups have the same tangent space at the identity. The identity $A(t)^* A(t) = I$ similarly gives the description of $\mathfrak{u}(n)$.

Finally, for a matrix A, the left invariant field is $\mathbf{X}_A(g) = gA$. A calculation in the matrix space gives $[\mathbf{X}_A, \mathbf{X}_B](g) = g(AB - BA)$, so the bracket defined in (1.13) agrees with the commutator. □

Proposition 1.9.8. (Differential of a homomorphism) Let G and H be finite-dimensional real Lie groups whose underlying smooth manifolds have no boundary, and let $\Phi \colon G \to H$ be a Lie group homomorphism.

Then

$$d\Phi_e \colon \mathfrak{g} \longrightarrow \mathfrak{h}$$

is a Lie algebra homomorphism:

$$d\Phi_e[\xi, \eta] = [d\Phi_e \xi, d\Phi_e \eta].$$

Proof. The identity $\Phi \circ L_g = L_{\Phi(g)} \circ \Phi$ implies

$$d\Phi_g(\xi^L_g) = (dL_{\Phi(g)})_e (d\Phi_e \xi) = (\boldsymbol{d\Phi_e \xi})^L_{\Phi(g)}.$$

Thus ξ^L and $(\boldsymbol{d\Phi_e \xi})^L$ are Φ-related. Proposition 1.9.4 shows that their brackets are also related. Evaluating at e gives the formula. □

Lemma 1.9.9. (Bracket and flow) Let M be a smooth manifold without boundary, let $\mathbf{X} \in \mathfrak{X}(M)$, and let Φ_t be its local flow. For every $\mathbf{Y} \in \mathfrak{X}(M)$,

$$[\mathbf{X}, \mathbf{Y}] = \left. \frac{d}{dt} \right|_{t=0} (\Phi_{-t})_* \mathbf{Y}, \tag{1.14}$$

on any open set where both sides are defined.

Proof. As operators on functions,

$$\big((\Phi_{-t})_* \mathbf{Y}\big) f = \Phi_t^* \big(\mathbf{Y}(\Phi_{-t}^* f)\big).$$

The derivative at $t = 0$ of the operator Φ_t^* is $\mathbf{X}$, while the derivative of Φ_{-t}^* is $-\mathbf{X}$. By the product rule,

$$\left. \frac{d}{dt} \right|_0 \Phi_t^* \mathbf{Y} \Phi_{-t}^* = \mathbf{X}\mathbf{Y} - \mathbf{Y}\mathbf{X} = [\mathbf{X}, \mathbf{Y}].$$

□

Theorem 1.9.10. (Exponential map of a Lie group) Let G be a finite-dimensional real Lie group whose underlying smooth manifold has no boundary. For each $\xi \in \mathfrak{g}$, the field ξ^L is complete. If $\gamma_\xi \colon \mathbb{R} \to G$ is its integral curve with $\gamma_\xi(0) = e$, then

$$\gamma_\xi(t + s) = \gamma_\xi(t) \gamma_\xi(s).$$

The map

$$\exp_G \colon \mathfrak{g} \longrightarrow G, \qquad \exp_G(\xi) := \gamma_\xi(1),$$

is smooth and satisfies

$$\exp_G(t\xi) = \gamma_\xi(t), \qquad \exp_G((t + s)\xi) = \exp_G(t\xi) \exp_G(s\xi). \tag{1.15}$$

Moreover,

$$(d \exp_G)_0 = \mathrm{Id}_{\mathfrak{g}};$$

consequently, $\exp_G$ restricts to a diffeomorphism between an open neighborhood of $0 \in \mathfrak{g}$ and an open neighborhood of $e \in G$.

Proof. Let $\gamma_\xi : I \to G$ be the maximal integral curve of ξ^L starting at e. If $s \in I$, the curves

$$t \longmapsto \gamma_\xi(s+t), \qquad t \longmapsto \gamma_\xi(s)\gamma_\xi(t)$$

are integral curves of ξ^L and take the same value at $t = 0$. By uniqueness, they agree wherever both are defined.
The interval I contains some $(-\varepsilon, \varepsilon)$. If $b := \sup I < \infty$, choose $s \in I$ with $b - s < \varepsilon$. The formula

$$\widetilde{\gamma}(s+t) := \gamma_\xi(s)\gamma_\xi(t), \qquad |t| < \varepsilon,$$

agrees with γ_ξ on the overlap and extends the curve beyond b, contradicting maximality. The same argument at the left endpoint shows that $I = \mathbb{R}$. The group identity already obtained therefore holds for every $s, t \in \mathbb{R}$.
The rescaling lemma for integral curves gives

$$\gamma_{t\xi}(1) = \gamma_\xi(t),$$

which proves (1.15). To prove smoothness with respect to ξ, consider the smooth field on $G \times \mathfrak{g}$

$$\boldsymbol{\mathcal{X}}_{(g,\xi)} := \big((dL_g)_e \xi, 0\big).$$

Each integral curve of $\boldsymbol{\mathcal{X}}$ keeps its second component fixed, and its first component is an integral curve of a left invariant field; by what we have proved, $\boldsymbol{\mathcal{X}}$ is complete. The fundamental theorem of flows implies that its global flow depends smoothly on the initial point. Evaluating it at time 1 and at (e, ξ) shows that $\xi \mapsto \exp_G(\xi)$ is smooth.
Finally,

$$(d\exp_G)_0(\xi) = \left.\frac{d}{dt}\right|_0 \exp_G(t\xi) = \gamma'_\xi(0) = \xi.$$

Theorem 1.5.6 gives the local assertion. □

Corollary 1.9.11. (One-parameter subgroups) Let G be a finite-dimensional real Lie group whose underlying smooth manifold has no boundary. For each $\xi \in \mathfrak{g}$, the map

$$t \longmapsto \exp_G(t\xi)$$

is a smooth homomorphism $(\mathbb{R}, +) \to G$. Conversely, if $\alpha : (\mathbb{R}, +) \to G$ is a smooth homomorphism and $\xi = \alpha'(0)$, then

$$\alpha(t) = \exp_G(t\xi) \qquad \text{for every } t \in \mathbb{R}.$$

Proof. The first assertion is (1.15). For the converse,

$$\alpha(t+s) = \alpha(t)\alpha(s)$$

implies, on differentiating with respect to s at 0,

$$\alpha'(t) = (dL_{\alpha(t)})_e \xi = \xi^L_{\alpha(t)}.$$

Thus α and $t \mapsto \exp_G(t\xi)$ are integral curves of ξ^L with the same initial data, and uniqueness proves the equality. □

Definition 1.9.12. (Adjoint and infinitesimal representations) Let G be a finite-dimensional real Lie group whose underlying smooth manifold has no boundary. Define

$$\mathrm{Ad}_g := (dC_g)_e \in GL(\mathfrak{g}), \qquad \mathrm{Ad}\colon G \longrightarrow GL(\mathfrak{g}),$$

and

$$\mathrm{ad}_\xi \eta := \left.\frac{d}{dt}\right|_0 \mathrm{Ad}_{\exp_G(t\xi)}\eta.$$

Proposition 1.9.13. (Naturality and equivariance of the exponential map) Let G and H be finite-dimensional real Lie groups whose underlying smooth manifolds have no boundary. If $\Phi\colon G \to H$ is a Lie group homomorphism, then

$$\Phi(\exp_G \xi) = \exp_H(d\Phi_e \xi), \qquad \xi \in \mathfrak{g}.$$

In particular, for $g \in G$,

$$\exp_G(\mathrm{Ad}_g \xi) = g \exp_G(\xi) g^{-1}. \tag{1.16}$$

Proof. The two maps

$$t \longmapsto \Phi(\exp_G(t\xi)), \qquad t \longmapsto \exp_H(t\, d\Phi_e \xi)$$

are one-parameter subgroups of H with initial velocity $d\Phi_e\xi$. Uniqueness in Corollary 1.9.11 shows that they agree; evaluate at $t = 1$. For $\Phi = C_g$, its differential at e is Ad_g, giving (1.16). □

Proposition 1.9.14. (Identities for Ad and ad) Let G be a finite-dimensional real Lie group whose underlying smooth manifold has no boundary. The following identities hold:

$$\mathrm{Ad}_{gh} = \mathrm{Ad}_g \mathrm{Ad}_h, \tag{1.17}$$

$$\mathrm{Ad}_g[\xi,\eta] = [\mathrm{Ad}_g \xi, \mathrm{Ad}_g \eta], \tag{1.18}$$

$$\mathrm{ad}_\xi \eta = [\xi,\eta], \tag{1.19}$$

$$\mathrm{Ad}_{\exp_G(t\xi)} = \exp\big(t\,\mathrm{ad}_\xi\big), \tag{1.20}$$

$$\mathrm{Ad}_g \mathrm{ad}_\xi \mathrm{Ad}_{g^{-1}} = \mathrm{ad}_{\mathrm{Ad}_g \xi}, \tag{1.21}$$

$$\mathrm{ad}_{[\xi,\eta]} = [\mathrm{ad}_\xi, \mathrm{ad}_\eta]. \tag{1.22}$$

Proof. The identity $C_{gh} = C_g \circ C_h$ implies (1.17). Since C_g is a Lie group automorphism, Proposition 1.9.8 gives (1.18).

The flow of ξ^L is

$$\Phi_t = R_{\exp_G(t\xi)},$$

since the curve starting at g is $g\exp_G(t\xi)$. A direct verification gives

$$(R_h)_*\eta^L = (\mathbf{Ad}_{h^{-1}}\,\eta)^L.$$

By Lemma 1.9.9,

$$[\xi^L, \eta^L] = \frac{d}{dt}\Big|_0 (R_{\exp_G(-t\xi)})_*\eta^L = \left(\frac{\boldsymbol{d}}{\boldsymbol{dt}}\Big|_{\mathbf{0}} \mathbf{Ad}_{\mathbf{exp}_G(t\xi)}\,\eta\right)^L.$$

Evaluating at e gives (1.19).
By (1.17), the map $B(t) := \mathrm{Ad}_{\exp_G(t\xi)}$ satisfies

$$B(t+s) = B(t)B(s), \qquad B(0) = I.$$

Differentiating with respect to s at 0 gives $B'(t) = B(t)\,\mathrm{ad}_\xi$, whose unique solution is (1.20). Identity (1.21) follows by differentiating

$$\mathrm{Ad}_g \mathrm{Ad}_{\exp(t\xi)} \mathrm{Ad}_{g^{-1}} = \mathrm{Ad}_{\exp(t\,\mathrm{Ad}_g\,\xi)}.$$

Finally, (1.22) is the Jacobi identity written as an identity of endomorphisms. □

Theorem 1.9.15. (Closed subgroup theorem) Let G be a finite-dimensional real Lie group whose underlying smooth manifold has no boundary, and let $H \subseteq G$ be a subgroup closed in the topology of G. Then H has a unique smooth structure making it an embedded Lie subgroup of G. Its Lie algebra, identified with a subspace of $\mathfrak{g}$, is

$$\mathfrak{h} = \{\xi \in \mathfrak{g} \mid \exp_G(t\xi) \in H \text{ for every } t \in \mathbb{R}\}. \tag{1.23}$$

Existence and the characterization of the Lie algebra are [94, Theorem 20.12 and Proposition 20.9, pp. 521–523].

Proof. The existence assertion is the cited closed subgroup theorem. The structure is unique because an embedded Lie subgroup structure must be the submanifold structure induced by slice charts. Once it is constructed, (1.23) is the characterization given by the cited exponential characterization: the curves $t \mapsto \exp_G(t\xi)$ contained in H are precisely the one-parameter subgroups whose initial velocity belongs to T_eH. □

Proposition 1.9.16. (Centralizers) Let G be a finite-dimensional real Lie group whose underlying smooth manifold has no boundary. For any subset $S \subseteq G$, its centralizer

$$Z_G(S) := \{g \in G \mid gs = sg \text{ for every } s \in S\}$$

is a closed subgroup, and hence an embedded Lie subgroup. If G is compact, $Z_G(S)$ is compact. Its Lie algebra is

$$\mathrm{Lie}(Z_G(S)) = \{\xi \in \mathfrak{g} \mid \mathrm{Ad}_s\,\xi = \xi \text{ for every } s \in S\}. \tag{1.24}$$

If $S = H$ is a connected Lie subgroup with algebra $\mathfrak{h}$, this expression is equivalent to

$$\operatorname{Lie}(Z_G(H)) = \{\xi \in \mathfrak{g} \mid [\xi, \eta] = 0 \text{ for every } \eta \in \mathfrak{h}\}.$$

Proof. The centralizer is a subgroup by the group laws, and

$$Z_G(S) = \bigcap_{s \in S} \{g \in G \mid C_g(s) = s\}.$$

Each set on the right is closed, since $g \mapsto C_g(s)$ is continuous and $\{s\}$ is closed. Theorem 1.9.15 gives it its embedded structure; if G is compact, the closed subset $Z_G(S)$ is also compact.
By (1.23), a vector ξ belongs to its algebra if and only if $\exp_G(t\xi)$ commutes with every $s \in S$ for every t. Using (1.16), this condition becomes

$$\exp_G(t \operatorname{Ad}_s \xi) = \exp_G(t\xi) \quad (s \in S,\ t \in \mathbb{R}).$$

Differentiating at $t = 0$ gives $\operatorname{Ad}_s \xi = \xi$; the converse follows from the same equivariance formula. This proves (1.24).
If H is connected, it is generated by any neighborhood of the identity, and such a neighborhood can be covered by exponentials. By $\operatorname{Ad}_{\exp(t\eta)} = \exp(t \operatorname{ad}_\eta)$, a vector is fixed by every H if and only if $\operatorname{ad}_\eta \xi = [\eta, \xi] = 0$ for every $\eta \in \mathfrak{h}$. □

Definition 1.9.17. (Smooth actions and positive fundamental fields) Let G be a finite-dimensional real Lie group whose underlying smooth manifold has no boundary, and let M be a smooth manifold with or without boundary. A *smooth left action* of G on M is a smooth map

$$a \colon G \times M \longrightarrow M, \qquad (g, x) \longmapsto g \cdot x,$$

such that

$$e \cdot x = x, \qquad (gh) \cdot x = g \cdot (h \cdot x).$$

A *smooth right action* is a smooth map

$$r \colon M \times G \longrightarrow M, \qquad (x, g) \longmapsto x \cdot g,$$

such that

$$x \cdot e = x, \qquad (x \cdot g) \cdot h = x \cdot (gh).$$

We always use the *positive fundamental field*. For a left action, define

$$\xi_M(x) := \left.\frac{d}{dt}\right|_0 \exp_G(t\xi) \cdot x,$$

and for a right action, define

$$\xi_M(x) := \left.\frac{d}{dt}\right|_0 x \cdot \exp_G(t\xi).$$

Proposition 1.9.18. (Signs and transformation of fundamental fields) Let G be a finite-dimensional real Lie group whose underlying smooth manifold has no boundary, let M be a smooth manifold with or without boundary, consider a smooth left or right action of G on M, and let $\xi, \eta \in \mathfrak{g}$.

(a) For a left action, the flow of ξ_M is

$$\Phi_t(x) = \exp_G(t\xi) \cdot x,$$

and

$$[\xi_M, \eta_M] = -[\xi, \eta]_M, \tag{1.25}$$
$$(a_g)_* \xi_M = (\mathbf{Ad}_g\, \xi)_M, \qquad a_g(x) := g \cdot x. \tag{1.26}$$

(b) For a right action, the flow of ξ_M is

$$\Psi_t(x) = x \cdot \exp_G(t\xi),$$

and

$$[\xi_M, \eta_M] = [\xi, \eta]_M, \tag{1.27}$$
$$(r_g)_* \xi_M = (\mathbf{Ad}_{g^{-1}}\, \xi)_M, \qquad r_g(x) := x \cdot g. \tag{1.28}$$

Proof. The flow formulas follow immediately from the action law and the group law for $t \mapsto \exp_G(t\xi)$. For a left action,

$$g \exp(t\xi) \cdot x = \exp(t \operatorname{Ad}_g \xi) \cdot (g \cdot x),$$

and differentiating at $t = 0$ gives (1.26). Applying this identity with $g = \exp(-t\xi)$ and using Lemma 1.9.9,

$$[\xi_M, \eta_M] = \left.\frac{d}{dt}\right|_0 (a_{\exp(-t\xi)})_* \eta_M = \left.\frac{d}{dt}\right|_0 (\mathbf{Ad}_{\mathbf{exp}(-t\xi)}\, \eta)_M = -[\xi, \eta]_M.$$

For a right action,

$$(x \cdot \exp(t\xi)) \cdot g = (x \cdot g) \cdot \exp(t \operatorname{Ad}_{g^{-1}} \xi),$$

which proves (1.28). Applying it to $g = \exp(-t\xi)$,

$$[\xi_M, \eta_M] = \left.\frac{d}{dt}\right|_0 (r_{\exp(-t\xi)})_* \eta_M = \left.\frac{d}{dt}\right|_0 (\mathbf{Ad}_{\mathbf{exp}(t\xi)}\, \eta)_M = [\xi, \eta]_M.$$

□

Definition 1.9.19. (Orbit, stabilizer, and orbit map) Let G be a finite-dimensional real Lie group whose underlying smooth manifold has no boundary, let M be a smooth manifold with or without boundary, and consider a smooth left or right action of G on M. For a left action and $x \in M$, define

$$\mathcal{O}_x := G \cdot x, \qquad G_x := \{g \in G \mid g \cdot x = x\}, \qquad \vartheta_x \colon G \to M, \qquad \vartheta_x(g) = g \cdot x.$$

For a right action, use $\mathcal{O}_x = x \cdot G$, $G_x = \{g \mid x \cdot g = x\}$, and $\vartheta_x(g) = x \cdot g$. An action is *free* if all its stabilizers are trivial, and *transitive* if it has a single orbit.

Proposition 1.9.20. (Elementary properties of orbits) Let G be a finite-dimensional real Lie group whose underlying smooth manifold has no boundary, let M be a smooth manifold with or without boundary, and consider a smooth left or right action of G on M. The orbit map is smooth, G_x is a closed embedded Lie subgroup of G, and

$$(d\vartheta_x)_e\xi = \xi_M(x). \tag{1.29}$$

For a left action, $G_{g\cdot x} = gG_xg^{-1}$; for a right action, $G_{x\cdot g} = g^{-1}G_xg$. In particular, freeness and the dimension of the kernel of $(d\vartheta_x)_e$ are constant along each orbit.

Proof. Smoothness follows from that of the action with x fixed. The action laws show that G_x contains e and is closed under products and inverses. Moreover, $G_x = \vartheta_x^{-1}(\{x\})$ is closed because manifolds are Hausdorff; Theorem 1.9.15 gives it its embedded Lie subgroup structure. The identity (1.29) is exactly the definition of the fundamental field. Finally,

$$h\cdot(g\cdot x) = g\cdot x \iff g^{-1}hg\cdot x = x$$

proves the formula for a left action; the right-action formula follows from $(x\cdot g)\cdot h = x\cdot g$ by multiplying on the right by g^{-1}. The transformation of the kernels also follows from Proposition 1.9.18. □

Theorem 1.9.21. (Haar measure on compact groups) Let G be a compact finite-dimensional real Lie group whose underlying smooth manifold has no boundary. There exists a unique regular probability measure μ_G on G invariant under left and right translations:

$$(L_g)_*\mu_G = \mu_G = (R_g)_*\mu_G \qquad (g\in G).$$

For the construction of the normalized Haar volume form on a compact Lie group, see [94, Proposition 16.10]. Existence and uniqueness of Haar measure is the external result used here; right invariance follows by applying uniqueness of the left invariant probability measure to each right translation.

Proposition 1.9.22. (Averaging an inner product) Let G be a compact finite-dimensional real Lie group whose underlying smooth manifold has no boundary, and let $\rho\colon G\to GL(V)$ be a smooth representation on a finite-dimensional real vector space. Then V admits a G-invariant inner product.

Proof. Start with any inner product $\langle\cdot,\cdot\rangle_0$ and define

$$\langle v,w\rangle_G := \int_G \langle\rho(g)v,\rho(g)w\rangle_0\, d\mu_G(g).$$

The resulting form is bilinear, symmetric, and positive definite. For $h\in G$, right invariance of μ_G and $\rho(gh)=\rho(g)\rho(h)$ give

$$\langle\rho(h)v,\rho(h)w\rangle_G = \int_G \langle\rho(gh)v,\rho(gh)w\rangle_0\, d\mu_G(g) = \langle v,w\rangle_G.$$

□

Corollary 1.9.23. (Ad-invariant inner product) Let G be a compact finite-dimensional real Lie group whose underlying smooth manifold has no boundary. Its Lie algebra $\mathfrak{g}$ admits an inner product $\langle\cdot,\cdot\rangle_{\mathfrak{g}}$ such that

$$\langle \mathrm{Ad}_g\,\xi, \mathrm{Ad}_g\,\eta\rangle_{\mathfrak{g}} = \langle \xi,\eta\rangle_{\mathfrak{g}} \qquad (g\in G).$$

Proof. Apply Proposition 1.9.22 to the representation $\rho = \mathrm{Ad}$. □

1.10 Tensor fields and differential forms

Tangent and cotangent spaces allow us to construct tensors pointwise. Assembling them over M gives tensor bundles, whose sections describe metrics, differential forms, curvature, and many other geometric fields. This final section of the chapter first recalls the necessary multilinear algebra and then organizes it smoothly over the manifold.

Definition 1.10.1. If $V_1,\dots,V_k$ and W are vector spaces, a function $F\colon V_1\times\cdots\times V_k\longrightarrow W$ is called **multilinear** if it is linear in each argument when the others are fixed. The space of multilinear functions is denoted by $L(V_1,\dots,V_k;W)$.

Definition 1.10.2. If $V_1,\dots,V_k$ and $W_1,\dots,W_l$ are vector spaces, and $\omega\in L(V_1,\dots,V_k;\mathbb{R})$ and $\eta\in L(W_1,\dots,W_l;\mathbb{R})$, define a function $\omega\otimes\eta\colon V_1\times\cdots\times V_k\times W_1\times\cdots\times W_l\longrightarrow\mathbb{R}$, called the **tensor product of ω and η**, by

$$\omega\otimes\eta(v_1,\dots,v_k,w_1,\dots,w_l)=\omega(v_1,\dots,v_k)\eta(w_1,\dots,w_l).$$

The space of multilinear functions is a vector space, and if the underlying vector spaces are finite dimensional, it is also finite dimensional:

Proposition 1.10.3. Let $V_1,\dots,V_k$ and W be real vector spaces. Then $L(V_1,\dots,V_k;W)$ is a real vector space under the operations

$$(F+G)(v_1,\dots,v_k)=F(v_1,\dots,v_k)+G(v_1,\dots,v_k),$$

$$(aF)(v_1,\dots,v_k)=a(F(v_1,\dots,v_k))$$

for each $F,G\in L(V_1,\dots,V_k;W)$ and each $a\in\mathbb{R}$.

Proof. Fixing all variables except the jth, the functions $F+G$ and aF are, respectively, a sum and a scalar multiple of linear maps $V_j\to W$; hence they are again linear in that variable. Since this holds for each j, both functions are multilinear. The vector space identities are checked pointwise and reduce to the corresponding identities in W. The zero function is the identity element, and the additive inverse of F is the function $-F$. □

Proposition 1.10.4. Let $V_1,\dots,V_k$ be vector spaces of dimensions $n_1,\dots,n_k$, respectively. For each $j\in\{1,\dots,k\},$ let $\{\mathbf{E}_1^{(j)},\dots,\mathbf{E}_{n_j}^{(j)}\}$ be a basis for V_j and let $\{\varepsilon^1_{(j)},\dots,\varepsilon^{n_j}_{(j)}\}$ be the corresponding dual basis for V_j^*. Then

$$\mathscr{B}=\{\varepsilon^{i_1}_{(1)}\otimes\cdots\otimes\varepsilon^{i_k}_{(k)}\mid 1\le i_1\le n_1,\dots,1\le i_k\le n_k\}$$

is a basis for $L(V_1,\dots,V_k;\mathbb{R})$, so this vector space has dimension $n_1\cdots n_k$.

Proof. Let $F\in L(V_1,\dots,V_k;\mathbb{R})$ and write

$$v_j=\sum_{i_j=1}^{n_j} v_j^{i_j}\mathbf{E}_{i_j}^{(j)}\qquad (1\le j\le k).$$

Successive application of linearity in each argument gives

$$F(v_1,\dots,v_k)=\sum_{i_1=1}^{n_1}\cdots\sum_{i_k=1}^{n_k}F(\mathbf{E}_{i_1}^{(1)},\dots,\mathbf{E}_{i_k}^{(k)})v_1^{i_1}\cdots v_k^{i_k}.$$

Since $v_j^{i_j}=\varepsilon_{(j)}^{i_j}(v_j)$, this equality expresses F as a linear combination of the elements of $\mathscr{B}$. To prove independence, suppose a combination with coefficients $c_{i_1\dots i_k}$ is zero. Evaluating it at $(\mathbf{E}_{r_1}^{(1)},\dots,\mathbf{E}_{r_k}^{(k)})$, the identities $\varepsilon_{(j)}^{i_j}(\mathbf{E}_{r_j}^{(j)})=\delta_{r_j}^{i_j}$ give $c_{r_1\dots r_k}=0$. All coefficients vanish, so $\mathscr{B}$ is a basis, and its cardinality is $n_1\cdots n_k$. □

Finally, the preceding definition of the tensor product of two multilinear functions allows us to define the tensor product of vector spaces as a vector space satisfying the following *universal property*:

Definition 1.10.5. (Universal property of the tensor product) Let $V_1,\dots,V_k$ be vector spaces. The **tensor product** $V_1\otimes\cdots\otimes V_k$ is a vector space equipped with a canonical multilinear map $\pi\colon V_1\times\cdots\times V_k\to V_1\otimes\cdots\otimes V_k$ having the following property: if $F\colon V_1\times\cdots\times V_k\longrightarrow X$ is any multilinear function taking values in a vector space X, there exists a unique linear function $\widetilde{F}\colon V_1\otimes\cdots\otimes V_k\longrightarrow X$ such that the following diagram commutes:

$$\begin{array}{ccc} V_1\times\cdots\times V_k & \xrightarrow{F} & X \\ \downarrow{\scriptstyle\pi} & \nearrow{\scriptstyle \exists!\widetilde{F}} & \\ V_1\otimes\cdots\otimes V_k & & \end{array}$$

Remark 1.10.6. (Existence and uniqueness of the tensor product) Let $\mathbb{R}^{(V_1\times\cdots\times V_k)}$ be the free vector space generated by the symbols $[v_1,\dots,v_k]$. Take the quotient by the subspace generated, for each argument, by the relations

$$[v_1,\dots,av_j+bw_j,\dots,v_k]-a[v_1,\dots,v_j,\dots,v_k]-b[v_1,\dots,w_j,\dots,v_k].$$

The class of $[v_1,\dots,v_k]$ defines the map π, and the quotient relations ensure that it is multilinear. If F is multilinear, the assignment $[v_1,\dots,v_k]\mapsto F(v_1,\dots,v_k)$ vanishes on the subspace of relations and therefore induces a unique linear map $\widetilde{F}$. This proves existence. If two pairs (T,π_T) and (S,π_S) satisfy the universal property, it yields unique linear maps $T\to S$ and $S\to T$ preserving simple tensors; their compositions are the identity by the same uniqueness. Thus the tensor product is unique up to a unique isomorphism compatible with the canonical maps.

The following proposition relates the space of multilinear functions to the tensor product of vector spaces:

Proposition 1.10.7. Let $V_1,\dots,V_k$ be finite-dimensional real vector spaces. Then there is a canonical isomorphism

$$V_1^*\otimes\cdots\otimes V_k^* \cong L(V_1,\dots,V_k;\mathbb{R}).$$

Proof. The map

$$(\lambda_1,\dots,\lambda_k)\longmapsto\big[(v_1,\dots,v_k)\longmapsto\lambda_1(v_1)\cdots\lambda_k(v_k)\big]$$

is multilinear in $\lambda_1,\dots,\lambda_k$. The universal property therefore induces a canonical linear map

$$\Phi\colon V_1^*\otimes\cdots\otimes V_k^*\longrightarrow L(V_1,\dots,V_k;\mathbb{R}).$$

In the dual bases of the preceding proposition, Φ sends the tensor $\varepsilon^{i_1}_{(1)}\otimes\cdots\otimes\varepsilon^{i_k}_{(k)}$ to the element of the basis $\mathscr{B}$ with the same indices. Thus Φ sends a basis to a basis and is an isomorphism. The construction is independent of the bases, since Φ was defined solely by evaluation. □

We define tensors on a given vector space as follows:

Definition 1.10.8. Let V be a finite-dimensional vector space. Define the vector space of mixed tensors of type (k,l), k times contravariant and l times covariant, on V by

$$T^{(k,l)}(V) := \underbrace{V\otimes\cdots\otimes V}_{k\text{ times}}\otimes\underbrace{V^*\otimes\cdots\otimes V^*}_{l\text{ times}}.$$

We are ready to define tensor bundles on a smooth manifold:

Definition 1.10.9. Let M be a smooth manifold with or without boundary. Define the **bundle of mixed tensors of type** (k,l) by

$$T^{(k,l)}(TM) := \bigsqcup_{p\in M} T^{(k,l)}(T_pM).$$

Remark 1.10.10. We have the following identifications:

(a) $T^{(0,0)}(TM) = M\times\mathbb{R}$.

(b) $T^{(0,1)}(TM) = T^*M$.

(c) $T^{(1,0)}(TM) = TM$.

We can equip tensor bundles with a smooth structure as follows:

Proposition 1.10.11. Let M be a smooth manifold with or without boundary and let $\dim M = n$. Then, for every pair of integers $k,l\geq 0$, the tensor bundle

$$T^{(k,l)}(TM)\longrightarrow M$$

admits a unique topology and a unique smooth structure making it a vector bundle of rank n^{k+l} over M for which the component trivializations induced by smooth charts of M are smooth.

Proof. We apply Lemma 1.7.8, first constructing the maps that will serve as local trivializations.
If $p \in U$ and (U, φ) is a smooth chart of M such that $p \in U$, every $A_p \in T^{(k,l)}(T_pM)$ can be written uniquely as

$$A_p = A^{i_1 \dots i_k}_{j_1 \dots j_l} \partial_{i_1}\Big|_p \otimes \cdots \otimes \partial_{i_k}\Big|_p \otimes \mathbf{d}x^{j_1}|_p \otimes \cdots \otimes \mathbf{d}x^{j_l}|_p,$$

where $\varphi = (x^1, \dots, x^n)$ and each $A^{i_1 \dots i_k}_{j_1 \dots j_l} \in \mathbb{R}$ is a component of A_p with respect to the tensor frame induced by the chart. When A_p varies as a section $\mathbf{A}$ over U, these components become functions $A^{i_1 \dots i_k}_{j_1 \dots j_l} \colon U \to \mathbb{R}$.
Define $\pi \colon T^{(k,l)}(TM) \longrightarrow M$ by $\pi(A_p) = p$.
Take an open cover $\{U_\alpha\}_{\alpha \in J}$ by smooth coordinate chart domains for M. For each $\alpha \in J$, define $\Phi_\alpha \colon \pi^{-1}(U_\alpha) \longrightarrow U_\alpha \times \mathbb{R}^{n^{k+l}}$ by $\Phi_\alpha(A_p) = (p, A^{i_1 \dots i_k}_{j_1 \dots j_l})$. The map Φ_α is bijective because the function $\widetilde{\Phi}_\alpha \colon U_\alpha \times \mathbb{R}^{n^{k+l}} \longrightarrow \pi^{-1}(U_\alpha)$ given by

$$\widetilde{\Phi}_\alpha(p, A^{i_1 \dots i_k}_{j_1 \dots j_l}) = A_p$$

is the inverse of Φ_α.
For each $p \in U_\alpha$, $\Phi_\alpha|_{T^{(k,l)}(T_pM)} \colon T^{(k,l)}(T_pM) \longrightarrow \{p\} \times \mathbb{R}^{n^{k+l}}$ is bijective because

$$\Phi_\alpha|_{T^{(k,l)}(T_pM)}(T^{(k,l)}(T_pM)) = \{p\} \times \mathbb{R}^{n^{k+l}}$$

and it is the restriction of a bijective function to its image. Identify the fiber $\{p\} \times \mathbb{R}^{n^{k+l}}$ with $\mathbb{R}^{n^{k+l}}$ by the second projection. It suffices to prove that the second component of Φ_α is linear:
Let $a \in \mathbb{R}$ and $A_p, B_p \in T^{(k,l)}(T_pM)$, with

$$A_p = A^{i_1 \dots i_k}_{j_1 \dots j_l}(p) \partial_{i_1}\Big|_p \otimes \cdots \otimes \partial_{i_k}\Big|_p \otimes \mathbf{d}x^{j_1}|_p \otimes \cdots \otimes \mathbf{d}x^{j_l}|_p$$

and

$$B_p = B^{i_1 \dots i_k}_{j_1 \dots j_l}(p) \partial_{i_1}\Big|_p \otimes \cdots \otimes \partial_{i_k}\Big|_p \otimes \mathbf{d}x^{j_1}|_p \otimes \cdots \otimes \mathbf{d}x^{j_l}|_p,$$

We have

$$\Phi_\alpha(aA_p + B_p) = \left(p, aA^{i_1 \dots i_k}_{j_1 \dots j_l} + B^{i_1 \dots i_k}_{j_1 \dots j_l}\right).$$

Consequently,

$$\operatorname{pr}_2 \Phi_\alpha(aA_p + B_p) = a \operatorname{pr}_2 \Phi_\alpha(A_p) + \operatorname{pr}_2 \Phi_\alpha(B_p),$$

which is the required linearity.
Therefore, $\Phi_\alpha|_{T^{(k,l)}(T_pM)} \colon T^{(k,l)}(T_pM) \longrightarrow \{p\} \times \mathbb{R}^{n^{k+l}}$ is a vector space isomorphism.
Finally, if $\alpha, \beta \in J$ are such that $U_\alpha \cap U_\beta \neq \varnothing$, we must compute the map $\Phi_\alpha \circ \Phi_\beta^{-1}$.
Suppose that $\varphi_\alpha = (x^1, \dots, x^n)$ and $\varphi_\beta = (y^1, \dots, y^n)$.
If $(p, B^{a_1 \dots a_k}_{b_1 \dots b_l}) \in (U_\alpha \cap U_\beta) \times \mathbb{R}^{n^{k+l}}$, we have

$$(\Phi_\alpha \circ \Phi_\beta^{-1})(p, B^{a_1 \dots a_k}_{b_1 \dots b_l}) = \Phi_\alpha \left(B^{a_1 \dots a_k}_{b_1 \dots b_l} \partial_{a_1}\Big|_p \otimes \cdots \otimes \partial_{a_k}\Big|_p \otimes \mathbf{d}y^{b_1}|_p \otimes \cdots \otimes \mathbf{d}y^{b_l}|_p \right)$$

$$= \left(p, B^{a_1 \dots a_k}_{b_1 \dots b_l} \left(\frac{\partial x^{i_1}}{\partial y^{a_1}}\Big|_p \right) \dots \left(\frac{\partial x^{i_k}}{\partial y^{a_k}}\Big|_p \right) \left(\frac{\partial y^{b_1}}{\partial x^{j_1}}\Big|_p \right) \dots \left(\frac{\partial y^{b_l}}{\partial x^{j_l}}\Big|_p \right) \right)$$

where we have used

$$B^{a_1\dots a_k}_{b_1\dots b_l}\left(\frac{\partial x^{i_1}}{\partial y^{a_1}}\Big|_p\right)\dots\left(\frac{\partial x^{i_k}}{\partial y^{a_k}}\Big|_p\right)\left(\frac{\partial y^{b_1}}{\partial x^{j_1}}\Big|_p\right)\dots\left(\frac{\partial y^{b_l}}{\partial x^{j_l}}\Big|_p\right)\partial_{i_1}\Big|_p\otimes\dots\otimes\partial_{i_k}\Big|_p\otimes\mathbf{d}x^{j_1}|_p\otimes\dots\otimes\mathbf{d}x^{j_l}|_p$$

$$= B^{a_1\dots a_k}_{b_1\dots b_l}\partial_{a_1}\Big|_p\otimes\dots\otimes\partial_{a_k}\Big|_p\otimes\mathbf{d}y^{b_1}|_p\otimes\dots\otimes\mathbf{d}y^{b_l}|_p$$

which follows from the chain rule.
Now note that

$$\left(p, B^{a_1\dots a_k}_{b_1\dots b_l}\left(\frac{\partial x^{i_1}}{\partial y^{a_1}}\Big|_p\right)\dots\left(\frac{\partial x^{i_k}}{\partial y^{a_k}}\Big|_p\right)\left(\frac{\partial y^{b_1}}{\partial x^{j_1}}\Big|_p\right)\dots\left(\frac{\partial y^{b_l}}{\partial x^{j_l}}\Big|_p\right)\right) = (p, \tau_{\alpha\beta}(p)B^{a_1\dots a_k}_{b_1\dots b_l})$$

where

$$\tau_{\alpha\beta}(p) = \left(\left(\frac{\partial x^{i_1}}{\partial y^{a_1}}\Big|_p\right)\dots\left(\frac{\partial x^{i_k}}{\partial y^{a_k}}\Big|_p\right)\left(\frac{\partial y^{b_1}}{\partial x^{j_1}}\Big|_p\right)\dots\left(\frac{\partial y^{b_l}}{\partial x^{j_l}}\Big|_p\right)\right) \in GL(n^{k+l},\mathbb{R})$$

is smooth because its component functions are smooth.
By Lemma 1.7.8, there exist a unique topology and a unique smooth structure making $\pi\colon T^{(k,l)}(TM)\longrightarrow M$ a smooth vector bundle of rank n^{k+l} with Φ_α as smooth local trivializations for each $\alpha\in J$. The transition formula also holds when comparing a chart from this cover with any other smooth chart of M. Thus all component trivializations induced by smooth charts are smooth, and this property characterizes the constructed structure. □

Corollary 1.10.12. Let M be a smooth manifold with or without boundary of dimension n. If (U,φ) is a smooth chart of M with $\varphi=(x^1,\dots,x^n)$, then $\widetilde{\varphi}\colon \pi^{-1}(U)\longrightarrow\varphi(U)\times\mathbb{R}^{n^{k+l}}$, given by

$$\widetilde{\varphi}\left(A^{i_1\dots i_k}_{j_1\dots j_l}\partial_{i_1}\Big|_p\otimes\dots\otimes\partial_{i_k}\Big|_p\otimes\mathbf{d}x^{j_1}|_p\otimes\dots\otimes\mathbf{d}x^{j_l}|_p\right) = (x^1(p),\dots,x^n(p),A^{i_1\dots i_k}_{j_1\dots j_l})$$

makes $(\pi^{-1}(U),\widetilde{\varphi})$ a smooth chart for $T^{(k,l)}(TM)$.

Proof. By Proposition 1.10.11, $\Phi\colon\pi^{-1}(U)\longrightarrow U\times\mathbb{R}^{n^{k+l}}$, given by

$$\Phi\left(A^{i_1\dots i_k}_{j_1\dots j_l}\partial_{i_1}\Big|_p\otimes\dots\otimes\partial_{i_k}\Big|_p\otimes\mathbf{d}x^{j_1}|_p\otimes\dots\otimes\mathbf{d}x^{j_l}|_p\right) = (p,A^{i_1\dots i_k}_{j_1\dots j_l})$$

is a smooth local trivialization of the tensor bundle $T^{(k,l)}(TM)$. Moreover, Proposition 1.7.18 says that

$$\left(\partial_{i_1}\otimes\dots\otimes\partial_{i_k}\otimes\mathbf{d}x^{j_1}\otimes\dots\otimes\mathbf{d}x^{j_l}\right)$$

is a smooth local frame defined on U and associated with the local trivialization Φ. Thus Corollary 1.7.20 shows that the map $\widetilde{\varphi}\colon\pi^{-1}(U)\longrightarrow\varphi(U)\times\mathbb{R}^{n^{k+l}}$ makes $(\pi^{-1}(U),\widetilde{\varphi})$ a smooth chart of $T^{(k,l)}(TM)$. □

This construction of the product of TM and T^*M extends to the product of two or more vector bundles, as the reader can prove.

Exercise 1.10.13. Let M be a smooth manifold with or without boundary and let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be two smooth vector bundles of ranks k and l, respectively. Prove that the fiberwise tensor product

$$\mathbf{E} \otimes \mathbf{F} \longrightarrow M, \qquad (\mathbf{E} \otimes \mathbf{F})_p := \mathbf{E}_p \otimes \mathbf{F}_p,$$

admits a unique topology and a unique smooth structure making it a smooth vector bundle of rank kl over M for which the tensor trivializations induced by smooth local frames of $\mathbf{E}$ and $\mathbf{F}$ are smooth.

There is a relation between Hom bundles and tensor products.

Proposition 1.10.14. Let M be a smooth manifold with or without boundary and let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be smooth vector bundles of ranks k and l, respectively. Then there is a natural vector bundle isomorphism over M

$$\operatorname{Hom}(\mathbf{E}, \mathbf{F}) \cong \mathbf{E}^* \otimes \mathbf{F}.$$

Proof. Define a bundle map $\Phi\colon \operatorname{Hom}(\mathbf{E}, \mathbf{F}) \longrightarrow \mathbf{E}^* \otimes \mathbf{F}$ fiberwise by the canonical identification

$$\Phi_p\colon \operatorname{Hom}(\mathbf{E}_p, \mathbf{F}_p) \longrightarrow \mathbf{E}_p^* \otimes \mathbf{F}_p, \qquad \Phi_p(T_p) = \sum_{i=1}^{k} e^i \otimes T_p(e_i),$$

where $(e_i)_{i=1}^k$ is a basis for $\mathbf{E}_p$ and $(e^i)_{i=1}^k$ is the dual basis in $\mathbf{E}_p^*$. This definition is independent of the chosen basis, is linear on each fiber, and covers the identity of M.
To verify that Φ is smooth, work in local trivializations. Let $U_\alpha \subset M$ be an open set with smooth local frames $(\boldsymbol{\sigma}_{\alpha,i})_{i=1}^k$ of $\mathbf{E}$ and $(\boldsymbol{\tau}_{\alpha,j})_{j=1}^l$ of $\mathbf{F}$; denote the dual frame of $\mathbf{E}^*$ on U_α by $(\boldsymbol{\sigma}_\alpha^i)_{i=1}^k$.
In these trivializations, every $T_p \in \operatorname{Hom}(\mathbf{E}_p, \mathbf{F}_p)$ is determined by an associated matrix

$$T_\alpha(p) = (T_\alpha(p)_i^j) \in M_{l\times k}(\mathbb{R}), \qquad T_p(\boldsymbol{\sigma}_{\alpha,i}(p)) = \sum_{j=1}^{l} T_\alpha(p)_i^j \boldsymbol{\tau}_{\alpha,j}(p).$$

The trivialization of $\operatorname{Hom}(\mathbf{E}, \mathbf{F})$ on U_α is given by

$$\Theta_\alpha^{\operatorname{Hom}}(T_p) = (p, T_\alpha(p)).$$

On the other hand, in $\mathbf{E}^* \otimes \mathbf{F}$, any element of the fiber $(\mathbf{E}^* \otimes \mathbf{F})_p$ can be written as

$$\sum_{i=1}^{k}\sum_{j=1}^{l} S_i^j \boldsymbol{\sigma}_\alpha^i(p) \otimes \boldsymbol{\tau}_{\alpha,j}(p),$$

and the associated trivialization is

$$\Theta_\alpha^{\mathbf{E}^*\otimes\mathbf{F}}\Big(\sum_{\substack{1\le i\le k\\ 1\le j\le l}} S_i^j \boldsymbol{\sigma}_\alpha^i(p) \otimes \boldsymbol{\tau}_{\alpha,j}(p)\Big) = (p, (S_i^j)).$$

Now apply Φ_p to T_p. By definition,

$$\Phi_p(T_p) = \sum_{i=1}^{k} \boldsymbol{\sigma}_\alpha^i(p) \otimes T_p(\boldsymbol{\sigma}_{\alpha,i}(p)) = \sum_{i=1}^{k} \boldsymbol{\sigma}_\alpha^i(p) \otimes \Big(\sum_{j=1}^{l} T_\alpha(p)_i^j \boldsymbol{\tau}_{\alpha,j}(p) \Big).$$

Reordering the sum,

$$\Phi_p(T_p) = \sum_{i=1}^{k} \sum_{j=1}^{l} T_\alpha(p)_i^j \boldsymbol{\sigma}_\alpha^i(p) \otimes \boldsymbol{\tau}_{\alpha,j}(p).$$

In the trivialization of $\mathbf{E}^* \otimes \mathbf{F}$, this corresponds exactly to

$$\Theta_\alpha^{\mathbf{E}^*\otimes\mathbf{F}}\big(\Phi_p(T_p)\big) = (p, (T_\alpha(p)_i^j)).$$

In other words, passing through the two local trivializations, the map

$$\Theta_\alpha^{\mathbf{E}^*\otimes\mathbf{F}} \circ \Phi \circ \big(\Theta_\alpha^{\mathrm{Hom}}\big)^{-1} : U_\alpha \times M_{l\times k}(\mathbb{R}) \to U_\alpha \times M_{l\times k}(\mathbb{R})$$

is simply given by

$$(p, (T_i^j)) \longmapsto (p, (T_i^j)),$$

which is the identity, showing that Φ is smooth.
Thus Φ is smooth and locally an isomorphism of trivializations. Since each Φ_p is linear and bijective, Φ is a bijective bundle homomorphism. By Exercise 1.7.26, we conclude that

$$\Phi : \mathrm{Hom}(\mathbf{E}, \mathbf{F}) \xrightarrow{\cong} \mathbf{E}^* \otimes \mathbf{F}$$

is a smooth bundle isomorphism of rank kl.
The naturality of the construction follows directly from the fact that everything was defined fiberwise using the natural isomorphism $\mathrm{Hom}(V, W) \cong V^* \otimes W$. □

Sections of tensor bundles are tensor fields. They describe, among other objects, metrics, differential forms, curvature, and tensors arising in physical models.

Definition 1.10.15. Let M be a smooth manifold with or without boundary. A section

$$\mathbf{A} \in \Gamma\big(T^{(k,l)}(TM)\big)$$

is called a **tensor field of type** (k, l) on M.
In particular:

- If $k = 0$, we say that $\mathbf{A}$ is a l-**covariant tensor field**.
- If $l = 0$, we say that $\mathbf{A}$ is a k-**contravariant tensor field**.

Remark 1.10.16. We use the following classical notation:

- We denote the space of **vector fields** on M by $\mathfrak{X}(M) := \Gamma(T^{(1,0)}(TM))$.

- We denote the space of **1-forms** on M by $\Omega^1(M) := \Gamma(T^{(0,1)}(TM))$.

The notation $\Omega^1(M)$ will be explained in greater detail below.

The following criteria determine when a tensor field is smooth and when a map is induced by a smooth tensor field.

Proposition 1.10.17. (Smoothness criterion for tensor fields) Let M be a smooth manifold with or without boundary, and let $\mathbf{F}\colon M \longrightarrow T^{(k,l)}(TM)$ be a rough (k,l)-tensor field. Then $\mathbf{F}$ is smooth on an open set $U \subseteq M$ if and only if, for any smooth covector fields $\omega^1,\dots,\omega^k$ and smooth vector fields $\mathbf{X}_1,\dots,\mathbf{X}_l$ defined on U, the real-valued function

$$\mathbf{F}(\omega^1,\dots,\omega^k,\mathbf{X}_1,\dots,\mathbf{X}_l)(p) = \mathbf{F}_p(\omega^1|_p,\dots,\omega^k|_p,\mathbf{X}_1|_p,\dots,\mathbf{X}_l|_p)$$

is smooth on U.

Proof. If $\mathbf{F}$ is smooth, its evaluation on smooth fields is a smooth function, since in coordinates it is a finite sum of products of the smooth components of $\mathbf{F}$ and of the fields on which it is evaluated.
Conversely, suppose that every indicated evaluation is smooth, and fix $p \in U$. Choose a chart $(V, x^1,\dots,x^n)$ with $p \in V \subseteq U$, and an open set W such that $p \in W \Subset V$. Take $\rho \in C^\infty_c(V)$ equal to one on W. The fields

$$\rho\,\mathbf{d}x^1,\dots,\rho\,\mathbf{d}x^n, \qquad \rho\,\partial_1,\dots,\rho\,\partial_n$$

extend by zero to smooth fields defined on U. For indices $i_1,\dots,i_k,j_1,\dots,j_l$, the hypothesis implies that

$$\mathbf{F}\big(\rho\,\mathbf{d}x^{i_1},\dots,\rho\,\mathbf{d}x^{i_k},\rho\,\partial_{j_1},\dots,\rho\,\partial_{j_l}\big)$$

is smooth on U. On W, where $\rho = 1$, this function is precisely the coordinate component

$$F^{i_1\dots i_k}_{j_1\dots j_l} := \mathbf{F}\big(\mathbf{d}x^{i_1},\dots,\mathbf{d}x^{i_k},\partial_{j_1},\dots,\partial_{j_l}\big).$$

Thus all components of $\mathbf{F}$ are smooth in a neighborhood of p. Since p was arbitrary, $\mathbf{F}$ is smooth on U. □

Lemma 1.10.18. (Tensor characterization lemma) Let M be a smooth manifold with or without boundary. A map

$$F : \underbrace{\Omega^1(M)\times\cdots\times\Omega^1(M)}_{k\text{ times}}\times\underbrace{\mathfrak{X}(M)\times\cdots\times\mathfrak{X}(M)}_{l\text{ times}} \longrightarrow C^\infty(M)$$

is induced by a smooth (k,l)-tensor field if and only if it is multilinear over $C^\infty(M)$.
For the vector-valued statement, a map

$$F : \underbrace{\Omega^1(M)\times\cdots\times\Omega^1(M)}_{k\text{ times}}\times\underbrace{\mathfrak{X}(M)\times\cdots\times\mathfrak{X}(M)}_{l\text{ times}} \longrightarrow \mathfrak{X}(M)$$

is induced by a smooth $(k+1,l)$-tensor field if and only if it is multilinear over $C^\infty(M)$.

Proof. We first prove a locality observation valid for smooth sections of any finite-rank vector bundle. Let $\mathcal{F}$ be a map that is $C^\infty(M)$-linear in one of its arguments, and let $\mathbf{s}$ be a section that vanishes in a neighborhood of p. By Proposition 1.3.6, there exists $\vartheta \in C^\infty(M)$ with $\vartheta(p) = 1$ and support contained in that neighborhood. Then

$$\mathcal{F}(\dots,\mathbf{s},\dots)(p) = \vartheta(p)\mathcal{F}(\dots,\mathbf{s},\dots)(p) = \mathcal{F}(\dots,\vartheta\mathbf{s},\dots)(p) = 0.$$

If two sections $\mathbf{s}$ and $\widetilde{\mathbf{s}}$ have the same value at p, choose a trivialization around p and a cutoff function ρ that equals one in a neighborhood of p and has support within the trivialization. The section $\mathbf{r} := \mathbf{s} - \widetilde{\mathbf{s}}$ satisfies $\mathbf{r}(p) = 0$. The term $(1-\rho)\mathbf{r}$ vanishes near p, whereas, after extending the cutoff coefficients and the elements of a local frame by zero, we can write

$$\rho\mathbf{r} = \sum_{i=1}^{m} a_i \mathbf{e}_i, \qquad a_i \in C^\infty(M), \qquad a_i(p) = 0.$$

The preceding locality observation and $C^\infty(M)$-linearity give $\mathcal{F}(\dots,\mathbf{r},\dots)(p) = 0$. Thus the value at p depends only on the values at p of all the arguments.

Now suppose that

$$F : \Omega^1(M)^k \times \mathfrak{X}(M)^l \longrightarrow C^\infty(M)$$

is $C^\infty(M)$-multilinear. Given $\alpha^1,\dots,\alpha^k \in T_p^*M$ and $v_1,\dots,v_l \in T_pM$, choose smooth extensions and define

$$\mathbf{T}_p(\alpha^1,\dots,\alpha^k,v_1,\dots,v_l) := F(\widetilde{\boldsymbol{\alpha}}^1,\dots,\widetilde{\boldsymbol{\alpha}}^k,\widetilde{\mathbf{v}}_1,\dots,\widetilde{\mathbf{v}}_l)(p).$$

The preceding observation shows that this definition is independent of the extensions; the multilinearity of $\mathbf{T}_p$ is inherited from that of F. In a chart, choose global extensions of the coordinate coframe and frame that agree with them on a smaller open set. The components of $\mathbf{T}$ on that open set are the restrictions of the smooth functions obtained by evaluating F on those extensions. Hence $p \mapsto \mathbf{T}_p$ is a smooth (k,l)-tensor field and, by construction, induces F. Uniqueness follows by evaluating the field on arbitrary fiber values. Conversely, evaluating a smooth tensor field on smooth sections produces a smooth function and is $C^\infty(M)$-multilinear.

If the codomain of F is $\mathfrak{X}(M)$, we instead define

$$\mathbf{T}_p(\alpha^1,\dots,\alpha^k,v_1,\dots,v_l) := F(\widetilde{\boldsymbol{\alpha}}^1,\dots,\widetilde{\boldsymbol{\alpha}}^k,\widetilde{\mathbf{v}}_1,\dots,\widetilde{\mathbf{v}}_l)(p) \in T_pM.$$

The same locality argument gives independence of the extensions. The components of the vector field on the right-hand side are smooth; evaluating on local coframes and frames shows that $\mathbf{T}$ is a smooth $(k+1,l)$-tensor field. The converse implication and uniqueness follow by evaluation, exactly as in the scalar case. □

We now define the pullback of a tensor field.

Definition 1.10.19. Let M and N be smooth manifolds with or without boundary, and suppose that $F\colon M \longrightarrow N$ is a smooth map. For each point $p \in M$ and each k-covariant tensor $\alpha \in T^{(0,k)}(T_{F(p)}N)$, we define a tensor

$$dF_p^*(\alpha) \in T^{(0,k)}(T_pM),$$

called the **pullback of α by F at p**, by

$$dF_p^*(\alpha)(v_1,\dots,v_k) = \alpha\big(dF_p(v_1),\dots,dF_p(v_k)\big),$$

for any $v_1,\dots,v_k \in T_pM$.
If $\mathbf{A}$ is a k-covariant tensor field on N, that is, $\mathbf{A} \in \Gamma(T^{(0,k)}(TN))$, we define the tensor field on M

$$F^*\mathbf{A} \in \Gamma\big(T^{(0,k)}(TM)\big),$$

called the **pullback of A by** F, by

$$(F^*\mathbf{A})_p = dF_p^*(\mathbf{A}_{F(p)}),$$

that is,

$$(F^*\mathbf{A})_p(v_1,\dots,v_k) = \mathbf{A}_{F(p)}\big(dF_p(v_1),\dots,dF_p(v_k)\big),$$

for each $v_1,\dots,v_k \in T_pM$.

The pullback has the following properties:

Proposition 1.10.20. Let M, N, and P be smooth manifolds with or without boundary. Suppose that $F\colon M \longrightarrow N$ and $G\colon N \longrightarrow P$ are smooth maps. Let $k,l,r \in \mathbb{N}_0$, $\mathbf{A},\mathbf{B} \in \Gamma(T^{(0,k)}(TN))$, $\mathbf{C} \in \Gamma(T^{(0,l)}(TN))$, $\mathbf{D} \in \Gamma(T^{(0,r)}(TP))$, and $f \in C^\infty(N)$.

(a) $F^*(f\mathbf{A}) = (f\circ F)F^*\mathbf{A}$.

(b) $F^*(\mathbf{A}\otimes\mathbf{C}) = F^*\mathbf{A}\otimes F^*\mathbf{C}$.

(c) $F^*(\mathbf{A}+\mathbf{B}) = F^*\mathbf{A} + F^*\mathbf{B}$.

(d) $F^*\mathbf{A}$ is a smooth tensor field.

(e) $(G\circ F)^*\mathbf{D} = F^*(G^*\mathbf{D})$.

(f) $(\mathrm{Id}_N)^*\mathbf{A} = \mathbf{A}$.

Proof. The first equality follows by evaluating on $p \in M$:

$$\big(F^*(f\mathbf{A})\big)_p(v_1,\dots,v_k) = f(F(p))\,\mathbf{A}_{F(p)}(dF_pv_1,\dots,dF_pv_k).$$

The definition of the tensor product proves (b), and the linearity of dF_p^* proves (c). For (d), if in coordinates

$$\mathbf{A} = A_{i_1\dots i_k}\,\mathbf{d}y^{i_1}\otimes\cdots\otimes\mathbf{d}y^{i_k},$$

then

$$F^*\mathbf{A} = (A_{i_1\dots i_k}\circ F)\,d(y^{i_1}\circ F)\otimes\cdots\otimes d(y^{i_k}\circ F),$$

whose coefficients are smooth.
Substituting the chain rule $d(G\circ F)_p = dG_{F(p)}\circ dF_p$ into the pointwise definition gives $(G\circ F)^*\mathbf{D} = F^*(G^*\mathbf{D})$.
Finally, $d(\mathrm{Id}_N)_q = \mathrm{Id}_{T_qN}$, which proves (f). □

A related concept, the pushforward, requires F to be a diffeomorphism as well.
To introduce it, we first define the pushforward for vector fields:

Definition 1.10.21. Let M and N be smooth manifolds with or without boundary, and let $F\colon M \longrightarrow N$ be a diffeomorphism. For each $\mathbf{X} \in \mathfrak{X}(M)$, we define $F_*\mathbf{X} := dF \circ \mathbf{X} \circ F^{-1}$ and call it the **pushforward** of $\mathbf{X}$ by F. Pointwise, we have

$$(F_*\mathbf{X})_q = dF_{F^{-1}(q)}(\mathbf{X}_{F^{-1}(q)})$$

for each $q \in N$.

The most general form of pullback and pushforward is given by the following proposition:

Proposition 1.10.22. Let M, N, and P be smooth manifolds with or without boundary, and let $F\colon M \longrightarrow N$ and $G\colon N \longrightarrow P$ be diffeomorphisms. For each $k, l \in \mathbb{N}_0$, there are isomorphisms associated with F, called the **pushforward** and **pullback**,

$$F_*\colon \Gamma(T^{(k,l)}(TM)) \longrightarrow \Gamma(T^{(k,l)}(TN)), \qquad F^*\colon \Gamma(T^{(k,l)}(TN)) \longrightarrow \Gamma(T^{(k,l)}(TM)),$$

such that F^* agrees with the pullback of covariant tensor fields, F_* agrees with the pushforward of vector fields, and the following conditions hold:

(a) $F_* = (F^*)^{-1}$.

(b) $F^*(\mathbf{A} \otimes \mathbf{B}) = F^*\mathbf{A} \otimes F^*\mathbf{B}$ for any tensor fields $\mathbf{A}$ and $\mathbf{B}$ on N.

(c) $(G \circ F)_* = G_* \circ F_*$.

(d) $(G \circ F)^* = F^* \circ G^*$.

(e) $(\mathrm{Id}_M)^* = (\mathrm{Id}_M)_* = \mathrm{Id}\colon \Gamma(T^{(k,l)}(TM)) \longrightarrow \Gamma(T^{(k,l)}(TM))$.

(f) $F^*\big(\mathbf{A}(\mathbf{X}_1, \ldots, \mathbf{X}_k)\big) = (F^*\mathbf{A})\big((F^{-1})_*\mathbf{X}_1, \ldots, (F^{-1})_*\mathbf{X}_k\big)$ for each $\mathbf{A} \in \Gamma(T^{(0,k)}(TN))$ and any $\mathbf{X}_1, \ldots, \mathbf{X}_k \in \mathfrak{X}(N)$.

Proof. Let $q \in N$, set $p = F^{-1}(q)$, and let $\mathbf{T} \in \Gamma(T^{(k,l)}(TM))$. For $\beta^1, \ldots, \beta^k \in T^*_qN$ and $w_1, \ldots, w_l \in T_qN$, define

$$(F_*\mathbf{T})_q(\beta^1, \ldots, \beta^k, w_1, \ldots, w_l) := \mathbf{T}_p\big(dF_p^*\beta^1, \ldots, dF_p^*\beta^k, (dF_p)^{-1}w_1, \ldots, (dF_p)^{-1}w_l\big).$$

In charts, its components are finite sums of products of components of $\mathbf{T}$, dF, and dF^{-1}; it therefore defines a smooth field. For a vector field, it agrees with the pushforward already defined. Set $F^* := (F^{-1})_*$; on covariant tensors, this is the usual definition of the pullback.
Substituting the identity $d(F^{-1})_q = (dF_p)^{-1}$ into the formula shows that F_* and F^* are inverses. The same formula and the definition of the tensor product prove (b). The chain rule and

$$\big(d(G \circ F)_p\big)^{-1} = (dF_p)^{-1} \circ (dG_{F(p)})^{-1}$$

give $(G\circ F)_* = G_*\circ F_*$. Applying this equality to the inverses yields

$$(G\circ F)^* = (F^{-1}\circ G^{-1})_* = F^*\circ G^*.$$

The identity case is immediate from the formula.
Finally, if $p\in M$, the right-hand side of (f), evaluated on p, is

$$\mathbf{A}_{F(p)}\big(dF_p(dF_p)^{-1}\mathbf{X}_1(F(p)),\dots,dF_p(dF_p)^{-1}\mathbf{X}_k(F(p))\big),$$

which agrees with $\mathbf{A}(\mathbf{X}_1,\dots,\mathbf{X}_k)(F(p))$, that is, with the left-hand side evaluated on p. □

Definition 1.10.23. (Interior multiplication) Let M be a smooth manifold with or without boundary, and let $k,l\geq 0$ be nonnegative integers.

(a) Let $\mathbf{T}_p\in T^{(k,l+1)}(T_pM)$ and $\mathbf{V}\in T_pM$. We define the *interior multiplication* of $\mathbf{V}$ into $\mathbf{T}_p$ to be the tensor

$$\iota_{\mathbf{V}}\mathbf{T}_p\in T^{(k,l)}(T_pM),$$

given by

$$(\iota_{\mathbf{V}}\mathbf{T}_p)(\omega^1,\dots,\omega^k,X_1,\dots,X_l) := \mathbf{T}_p(\omega^1,\dots,\omega^k,\mathbf{V},X_1,\dots,X_l),$$

for all $\omega^1,\dots,\omega^k\in\mathbf{T}^*_pM$ and $X_1,\dots,X_l\in T_pM$.

(b) If $\mathbf{T}\in\Gamma\big(T^{(k,l+1)}(TM)\big)$ and $\mathbf{V}\in\mathfrak{X}(M)$, we define the section

$$\iota_{\mathbf{V}}\mathbf{T}\in\Gamma\big(T^{(k,l)}(TM)\big),$$

by

$$(\iota_{\mathbf{V}}\mathbf{T})(p) := \iota_{\mathbf{V}(p)}\big(\mathbf{T}(p)\big),\qquad p\in M.$$

Proposition 1.10.24. (Interior multiplication defines a tensor field) Let M be a smooth manifold with or without boundary, $\mathbf{T}\in\Gamma\big(T^{(k,l+1)}(TM)\big)$, and $\mathbf{V}\in\mathfrak{X}(M)$. Then the assignment

$$(\iota_{\mathbf{V}}\mathbf{T})(\omega^1,\dots,\omega^k,X_1,\dots,X_l) := \mathbf{T}(\omega^1,\dots,\omega^k,\mathbf{V},X_1,\dots,X_l)$$

defines a smooth (k,l)-tensor field $\iota_{\mathbf{V}}\mathbf{T}\in\Gamma\big(T^{(k,l)}(TM)\big)$.

Proof. Consider the map

$$F_{\mathbf{V},\mathbf{T}} : \underbrace{\Omega^1(M)\times\cdots\times\Omega^1(M)}_{k\text{ times}}\times\underbrace{\mathfrak{X}(M)\times\cdots\times\mathfrak{X}(M)}_{l\text{ times}}\longrightarrow C^\infty(M).$$

defined by

$$F_{\mathbf{V},\mathbf{T}}(\omega^1,\dots,\omega^k,X_1,\dots,X_l) = \mathbf{T}(\omega^1,\dots,\omega^k,\mathbf{V},X_1,\dots,X_l).$$

Since $\mathbf{T}$ is a smooth $(k,l+1)$-tensor field, the map

$$(\omega^1,\dots,\omega^k,Y,X_1,\dots,X_l)\longmapsto \mathbf{T}(\omega^1,\dots,\omega^k,Y,X_1,\dots,X_l)$$

is multilinear over $C^\infty(M)$ in its arguments. Fixing $Y=\mathbf{V}$, it follows that $F_{\mathbf{V},\mathbf{T}}$ is multilinear over $C^\infty(M)$. By Lemma 1.10.18, there exists a smooth (k,l)-tensor field $\mathbf{S}\in\Gamma\big(T^{(k,l)}(TM)\big)$ such that

$$\mathbf{S}(\omega^1,\dots,\omega^k,X_1,\dots,X_l)=F_{\mathbf{V},\mathbf{T}}(\omega^1,\dots,\omega^k,X_1,\dots,X_l).$$

Pointwise, we have

$$\mathbf{S}(p)(\omega^1_p,\dots,\omega^k_p,X_{1,p},\dots,X_{l,p})=\mathbf{T}_p(\omega^1_p,\dots,\omega^k_p,\mathbf{V}_p,X_{1,p},\dots,X_{l,p})=(\iota_{\mathbf{V}(p)}\mathbf{T}_p)(\omega^1_p,\dots,X_{l,p}),$$

so $\mathbf{S}=\iota_{\mathbf{V}}\mathbf{T}$ as sections. Therefore $\iota_{\mathbf{V}}\mathbf{T}$ is a smooth (k,l)-tensor field. □

Remark 1.10.25. If $\mathbf{T}\in\Gamma\big(T^{(k,l+1)}(TM)\big)$ and $\mathbf{V}\in\mathfrak{X}(M)$ with $\mathbf{V}=V^a\mathbf{E}_a$, then the interior multiplication $\iota_{\mathbf{V}}\mathbf{T}$ has local components

$$\begin{aligned}(\iota_{\mathbf{V}}\mathbf{T})^{i_1\dots i_k}_{j_1\dots j_l}&=(\iota_{\mathbf{V}}\mathbf{T})\big(\boldsymbol{\varepsilon}^{i_1},\dots,\boldsymbol{\varepsilon}^{i_k},\mathbf{E}_{j_1},\dots,\mathbf{E}_{j_l}\big)\\&=\mathbf{T}\big(\boldsymbol{\varepsilon}^{i_1},\dots,\boldsymbol{\varepsilon}^{i_k},\mathbf{V},\mathbf{E}_{j_1},\dots,\mathbf{E}_{j_l}\big)\\&=\mathbf{T}\big(\boldsymbol{\varepsilon}^{i_1},\dots,\boldsymbol{\varepsilon}^{i_k},V^a\mathbf{E}_a,\mathbf{E}_{j_1},\dots,\mathbf{E}_{j_l}\big)\\&=V^a\mathbf{T}\big(\boldsymbol{\varepsilon}^{i_1},\dots,\boldsymbol{\varepsilon}^{i_k},\mathbf{E}_a,\mathbf{E}_{j_1},\dots,\mathbf{E}_{j_l}\big)\\&=V^aT^{i_1\dots i_k}_{aj_1\dots j_l}.\end{aligned}$$

Thus, in any local frame, the operation $\iota_{\mathbf{V}}$ is obtained by contracting the contravariant index of $\mathbf{V}$ with the first covariant index of $\mathbf{T}$.

We can introduce two classes of tensors that will be particularly useful and that are used to define Riemannian metrics and differential forms. The first is the class of symmetric tensors:

Definition 1.10.26. Let V be a finite-dimensional vector space. A k-covariant tensor α on V is said to be **symmetric** if its value is unchanged when any two of its arguments are interchanged:

$$\alpha(v_1,\dots,v_i,\dots,v_j,\dots,v_k)=\alpha(v_1,\dots,v_j,\dots,v_i,\dots,v_k)$$

for any $1\le i<j\le k$. We denote the space of symmetric k-covariant tensors by $\Sigma^k(V^*)\subseteq T^k(V^*)$.

Definition 1.10.27. Let V be a finite-dimensional vector space. If $\alpha\in\Sigma^k(V^*)$ and $\beta\in\Sigma^l(V^*)$, we define their **symmetric product** to be the $(k+l)$-covector given by

$$\alpha\beta=\frac{1}{(k+l)!}\sum_{\sigma\in S_{k+l}}{}^\sigma(\alpha\otimes\beta)$$

where ${}^\sigma(\alpha\otimes\beta)(v_1,\dots,v_{k+l})=\alpha\otimes\beta(v_{\sigma(1)},\dots,v_{\sigma(k+l)})$.

Definition 1.10.28. A **symmetric tensor field** on a smooth manifold with or without boundary is a covariant tensor field whose value at each point is a symmetric tensor.

The second class consists of alternating tensors:

Definition 1.10.29. If V is a finite-dimensional real vector space, a k-covariant tensor α is said to be **alternating** or **antisymmetric** if, for any $v_1,\dots,v_k \in V$ and each $i,j \in \{1,\dots,k\}$ with $i \neq j$, we have

$$\alpha(v_1,\dots,v_i,\dots,v_j,\dots,v_k) = -\alpha(v_1,\dots,v_j,\dots,v_i,\dots,v_k).$$

The space of alternating k-covariant tensors is denoted by $\Lambda^k(V^*) \subseteq T^{(0,k)}(V)$.

Like the tensor spaces above, the space of alternating k-covariant tensors is a finite-dimensional vector space. Alternating k-covariant tensors are often called k-***covectors***.

Definition 1.10.30. Let V be a finite-dimensional vector space, and suppose that $(\varepsilon^1,\dots,\varepsilon^n)$ is any basis for V^*. For each multi-index $I = (i_1,\dots,i_k)$ of length k such that $1 \le i_1,\dots,i_k \le n$, define $\varepsilon^I = \varepsilon^{i_1\dots i_k}$ by

$$\varepsilon^I(v_1,\dots,v_k) = \det\begin{bmatrix} \varepsilon^{i_1}(v_1) & \cdots & \varepsilon^{i_1}(v_k) \\ \vdots & \ddots & \vdots \\ \varepsilon^{i_k}(v_1) & \cdots & \varepsilon^{i_k}(v_k) \end{bmatrix} = \det\begin{bmatrix} v_1^{i_1} & \cdots & v_k^{i_1} \\ \vdots & \ddots & \vdots \\ v_1^{i_k} & \cdots & v_k^{i_k} \end{bmatrix}$$

Remark 1.10.31. For each multi-index I, $\varepsilon^I \in \Lambda^k(V^*)$.

Proposition 1.10.32. Let V be a vector space of finite dimension n. If (ε^i) is any basis for V^*, then, for each $k \le n$, the collection of k-covectors

$$\mathscr{B} = \{\varepsilon^I \mid I \text{ is an increasing multi-index of length } k\}$$

is a basis for $\Lambda^k(V^*)$. Therefore $\dim \Lambda^k(V^*) = \binom{n}{k}$.

Proof. Let $(e_1,\dots,e_n)$ be the basis of V dual to $(\varepsilon^1,\dots,\varepsilon^n)$. If $I = (i_1 < \cdots < i_k)$ and $J = (j_1 < \cdots < j_k)$, the definition by determinants gives

$$\varepsilon^I(e_{j_1},\dots,e_{j_k}) = \begin{cases} 1, & I = J, \\ 0, & I \neq J. \end{cases}$$

Consequently, the elements of $\mathscr{B}$ are linearly independent.
Now let $\alpha \in \Lambda^k(V^*)$ and define

$$\widetilde{\alpha} := \sum_{1 \le i_1 < \cdots < i_k \le n} \alpha(e_{i_1},\dots,e_{i_k})\,\varepsilon^{i_1\dots i_k}.$$

If $j_1,\dots,j_k$ are distinct, there exists a permutation $\sigma \in S_k$ that arranges them in increasing order. The alternating property of α and $\widetilde{\alpha}$, together with the preceding equality, shows that

$$\widetilde{\alpha}(e_{j_1},\dots,e_{j_k}) = \alpha(e_{j_1},\dots,e_{j_k}).$$

If two indices coincide, both sides are zero. By multilinearity, $\widetilde{\alpha} = \alpha$ on all of V^k, so $\mathscr{B}$ spans $\Lambda^k(V^*)$. Finally, the number of strictly increasing multi-indices of length k is $\binom{n}{k}$, which proves the dimension formula. □

We define an operation on $\Lambda^k(V^*)$ as follows:

Definition 1.10.33. Let V be a finite-dimensional vector space. If $\omega \in \Lambda^k(V^*)$ and $\eta \in \Lambda^l(V^*)$, we define their **wedge product** or **exterior product** to be the $(k+l)$-covector given by

$$\omega \wedge \eta = \frac{1}{k!l!} \sum_{\sigma \in S_{k+l}} (\operatorname{sign}\sigma)({}^{\sigma}(\omega \otimes \eta)).$$

Here the combinatorial factor is included for normalization.

The wedge product has the following properties:

Proposition 1.10.34. Suppose that $\omega, \omega', \eta, \eta'$ and ξ are multicovectors on a finite-dimensional vector space V.

(a) The wedge product is bilinear over $\mathbb{R}$ and associative.

(b) If $\omega \in \Lambda^k(V^*)$ and $\eta \in \Lambda^l(V^*)$,
$$\omega \wedge \eta = (-1)^{kl} \eta \wedge \omega.$$

(c) If $\omega^1, \dots, \omega^k \in V^*$ and $v_1, \dots, v_k \in V$, then
$$\omega^1 \wedge \cdots \wedge \omega^k(v_1, \dots, v_k) = \det(\omega^j(v_i)).$$

Proof. In the sum defining $\omega \wedge \eta$, internal permutations of the first k arguments and the last l arguments yield equal terms because ω and η are alternating. Grouping these $k!l!$ terms gives the shuffle formula

$$(\omega \wedge \eta)(v_1, \dots, v_{k+l}) = \sum_{\sigma \in \mathrm{Sh}(k,l)} \operatorname{sgn}(\sigma)\, \omega(v_{\sigma(1)}, \dots, v_{\sigma(k)}) \cdot \eta(v_{\sigma(k+1)}, \dots, v_{\sigma(k+l)}),$$

where $\mathrm{Sh}(k,l)$ is the set of permutations that preserve the relative order within the two blocks. This expression immediately proves bilinearity.

For associativity, let the degrees of ω, η, ξ be k, l, m, respectively. Applying the shuffle formula twice turns both $(\omega \wedge \eta) \wedge \xi$ and $\omega \wedge (\eta \wedge \xi)$ into

$$\sum_{\sigma \in \mathrm{Sh}(k,l,m)} \operatorname{sgn}(\sigma)\, \omega(v_{\sigma(1)}, \dots, v_{\sigma(k)}) \eta(v_{\sigma(k+1)}, \dots, v_{\sigma(k+l)}) \xi(v_{\sigma(k+l+1)}, \dots, v_{\sigma(k+l+m)}),$$

where $\mathrm{Sh}(k,l,m)$ preserves the order within each of the three blocks. Thus the product is associative.

Interchanging the blocks of lengths k and l establishes a bijection between $\mathrm{Sh}(k,l)$ and $\mathrm{Sh}(l,k)$. This interchange requires kl transpositions, so the sign changes by the factor $(-1)^{kl}$. This proves

$$\omega \wedge \eta = (-1)^{kl} \eta \wedge \omega.$$

Finally, repeatedly applying the shuffle formula to 1-covectors gives

$$(\omega^1 \wedge \cdots \wedge \omega^k)(v_1,\dots,v_k) = \sum_{\sigma\in S_k} \operatorname{sgn}(\sigma) \prod_{j=1}^{k} \omega^j(v_{\sigma(j)}),$$

which is the permutation expansion of the determinant $\det(\omega^j(v_i))$. □

Definition 1.10.35. Let M be a smooth manifold with or without boundary. We define the bundle of alternating k-tensors by

$$\Lambda^k(T^*M) := \coprod_{p\in M} \Lambda^k(T_p^*M).$$

Proposition 1.10.36. Let M be a smooth manifold of dimension n with or without boundary. Then $\Lambda^k(T^*M)$ is a smooth vector bundle of rank $\binom{n}{k}$ over M.

Proof. Let $(U, x^1,\dots,x^n)$ be a smooth chart on M. For each strictly increasing multi-index $I = (i_1 < \cdots < i_k)$, set $\mathbf{d}x^I := \mathbf{d}x^{i_1} \wedge \cdots \wedge \mathbf{d}x^{i_k}$. Proposition 1.10.32, applied at each point $p \in U$, shows that

$$\left(\mathbf{d}x^I|_p\right)_{|I|=k}$$

is a basis for $\Lambda^k(T_p^*M)$. Thus the map

$$\Lambda^k(T^*M)|_U \longrightarrow U \times \mathbb{R}^{\binom{n}{k}}, \qquad \sum_{|I|=k} a_I\, \mathbf{d}x^I|_p \longmapsto \left(p, (a_I)_{|I|=k}\right),$$

is a local trivialization that is linear on the fibers.
If $(V, y^1,\dots,y^n)$ is another chart, then on $U \cap V$ each $\mathbf{d}y^J$ can be expressed as

$$\mathbf{d}y^J = \sum_{|I|=k} \det\left(\frac{\partial y^{j_a}}{\partial x^{i_b}}\right)_{a,b=1}^{k} \mathbf{d}x^I.$$

The coefficients are smooth; consequently, the transitions between these trivializations are smooth and linear on the fibers. This gives $\Lambda^k(T^*M)$ the structure of a smooth vector bundle, and the number of increasing indices I is $\binom{n}{k}$. □

Definition 1.10.37. Let M be a smooth manifold with or without boundary. A section of $\Lambda^k(T^*M)$ is called a **differential k-form** or simply a **k-form**. The integer k is called the **degree** of the form. We denote the vector space of smooth k-forms by

$$\Omega^k(M) := \Gamma(\Lambda^k(T^*M)).$$

Remark 1.10.38. Every 1-covariant tensor is alternating, so $\Omega^1(M) = \Gamma(T^{(0,1)}(TM))$.

Proposition 1.10.39. Let $F\colon M \longrightarrow N$ be a smooth map between n-manifolds with or without boundary. If (x^i) and (y^i) are smooth coordinates on $U \subseteq M$ and $V \subseteq N$, respectively, and $u \in C^\infty(V)$, then the following

holds on $U \cap F^{-1}(V)$:

$$F^*(u\,\mathbf{d}y^1 \wedge \cdots \wedge \mathbf{d}y^n) = (u \circ F)(\det DF)\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n,$$

where DF denotes the Jacobian matrix of F in these coordinates.

Proof. By the multiplicativity of pullback,

$$F^*(u\,\mathbf{d}y^1 \wedge \cdots \wedge \mathbf{d}y^n) = (u \circ F)\, d(y^1 \circ F) \wedge \cdots \wedge d(y^n \circ F).$$

In the coordinates x,

$$d(y^a \circ F) = \sum_{b=1}^{n} \frac{\partial (y^a \circ F)}{\partial x^b}\,\mathbf{d}x^b.$$

Expanding the exterior product, the terms with repeated indices vanish. The sum of the remaining terms, indexed by $\sigma \in S_n$, is

$$\det\left(\frac{\partial (y^a \circ F)}{\partial x^b}\right)_{a,b=1}^{n} \mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n,$$

by the Leibniz formula for the determinant. The matrix in parentheses is DF in the chosen charts. □

The exterior derivative extends the differential of functions while preserving its intrinsic character.

Theorem 1.10.40. (Existence and uniqueness of the exterior derivative) Let M be a smooth manifold with or without boundary. For each $k \in \mathbb{N}_0$, there exists a unique linear map

$$d\colon \Omega^k(M) \longrightarrow \Omega^{k+1}(M)$$

that, together with the operators in the other degrees, satisfies the following properties.

(a) If $f \in \Omega^0(M) = C^\infty(M)$, then df is the differential of f, that is, $df(X) = X(f)$.

(b) If $\omega \in \Omega^k(M)$ and $\eta \in \Omega^l(M)$, then

$$d(\omega \wedge \eta) = d\omega \wedge \eta + (-1)^k \omega \wedge d\eta.$$

(c) $d \circ d = 0$.

(d) If $F\colon M \longrightarrow N$ is a smooth map and $\omega \in \Omega^k(N)$, then

$$d(F^*\omega) = F^*(d\omega).$$

In a smooth chart with coordinates $(x^1, \ldots, x^n)$, its expression is

$$d\left(\sum_{i_1 < \cdots < i_k} \omega_{i_1 \ldots i_k}\,\mathbf{d}x^{i_1} \wedge \cdots \wedge \mathbf{d}x^{i_k}\right) = \sum_{i_1 < \cdots < i_k} d\omega_{i_1 \ldots i_k} \wedge \mathbf{d}x^{i_1} \wedge \cdots \wedge \mathbf{d}x^{i_k}. \tag{1.30}$$

Proof. We first construct the operator by an intrinsic formula. For $\omega \in \Omega^k(M)$ and local vector fields $X_0, \dots, X_k$, define

$$\begin{aligned}(d\omega)(X_0,\dots,X_k) = &\sum_{i=0}^{k} (-1)^i X_i\big(\omega(X_0,\dots,\widehat{X}_i,\dots,X_k)\big) \\ &+ \sum_{0\le i<j\le k} (-1)^{i+j}\,\omega\big([X_i,X_j],X_0,\dots,\widehat{X}_i,\dots,\widehat{X}_j,\dots,X_k\big).\end{aligned} \tag{1.31}$$

In the second sum, the remaining fields appear after the bracket in their original order. For $k = 0$, the second sum is empty and the formula reduces to $(df)(X) = X(f)$.

The expression is linear over $\mathbb{R}$ in ω and in each field. The apparent differential dependence on the X_i cancels, and the result is in fact linear over $C^\infty(M)$ in each argument. Let us verify this for the argument with index r. Replacing X_r by fX_r multiplies every term that does not differentiate f by a factor of f. For $i < r$, the additional term from the first sum is

$$(-1)^i X_i(f)\,\omega(X_0,\dots,\widehat{X}_i,\dots,X_r,\dots,X_k).$$

In the second sum, the term corresponding to the pair (i,r) contains

$$[X_i, fX_r] = f[X_i,X_r] + X_i(f)X_r.$$

Moving X_r from the first argument of ω to the position it occupied in the preceding expression requires $r-1$ transpositions. Its additional contribution therefore has sign $(-1)^{i+r}(-1)^{r-1} = -(-1)^i$ and cancels the preceding term. If $j > r$, the identity

$$[fX_r, X_j] = f[X_r,X_j] - X_j(f)X_r$$

yields, after moving X_r through r arguments, the sign $(-1)^{r+j+1}(-1)^r = -(-1)^j$, which cancels the term in which X_j differentiates f in the first sum. No other derivatives of f appear. This proves $C^\infty(M)$-linearity in the argument r, and r was arbitrary.

Consequently, the value of (1.31) at a point depends only on the values of the fields at that point. In particular, it is independent of the chosen local extensions. Thus the formula defines a well-defined $(k+1)$-covariant tensor field.

We now show that this tensor is alternating and smooth. In a chart with coordinates $(x^1,\dots,x^n)$, write

$$\omega = \sum_{1\le i_1<\cdots<i_k\le n} \omega_{i_1\dots i_k}\,\mathbf{d}x^{i_1}\wedge\cdots\wedge\mathbf{d}x^{i_k}.$$

Since coordinate vector fields commute, evaluating (1.31) on them gives

$$d\omega = \sum_{1\le i_1<\cdots<i_k\le n}\ \sum_{a=1}^{n} \frac{\partial \omega_{i_1\dots i_k}}{\partial x^a}\,\mathbf{d}x^a\wedge\mathbf{d}x^{i_1}\wedge\cdots\wedge\mathbf{d}x^{i_k}.$$

Both sides are tensors and agree on every tuple of coordinate vector fields, so they agree throughout the chart. The right-hand side is a smooth differential form; hence the tensor constructed is alternating and

smooth. Moreover, this equality is precisely (1.30). Since it was derived from the intrinsic formula, the expressions obtained in different charts agree on their overlaps. This proves that the operator is globally well defined and independent of coordinates.

The graded Leibniz rule can be checked in a chart. For $d, q \in \mathbb{N}_0$, write $\mathcal{J}_d^q := \{(i_1, \dots, i_q) \in \{1, \dots, d\}^q \mid i_1 < \cdots < i_q\}$, with $\mathcal{J}_d^0 = \{\varnothing\}$. If $\omega = \sum_{I \in \mathcal{J}_n^k} a_I \mathbf{d}x^I$ has degree k and $\eta = \sum_{J \in \mathcal{J}_n^\ell} b_J \mathbf{d}x^J$ has degree ℓ, the local expression and the product rule for functions give

$$\begin{aligned} d(\omega \wedge \eta) &= \sum_{\substack{I \in \mathcal{J}_n^k \\ J \in \mathcal{J}_n^\ell}} d(a_I b_J) \wedge \mathbf{d}x^I \wedge \mathbf{d}x^J \\ &= \sum_{\substack{I \in \mathcal{J}_n^k \\ J \in \mathcal{J}_n^\ell}} da_I \wedge \mathbf{d}x^I \wedge b_J \mathbf{d}x^J + \sum_{\substack{I \in \mathcal{J}_n^k \\ J \in \mathcal{J}_n^\ell}} a_I \, db_J \wedge \mathbf{d}x^I \wedge \mathbf{d}x^J \\ &= d\omega \wedge \eta + (-1)^k \omega \wedge d\eta. \end{aligned}$$

The sign in the last equality arises from moving the 1-form db_J past the k factors of $\mathbf{d}x^I$.

Applying the local expression twice, we obtain

$$d^2\omega = \sum_{I \in \mathcal{J}_n^k} \sum_{a,b=1}^{n} \frac{\partial^2 a_I}{\partial x^b \partial x^a} \mathbf{d}x^b \wedge \mathbf{d}x^a \wedge \mathbf{d}x^I.$$

The terms with $a = b$ vanish. Terms with distinct indices cancel in pairs, since mixed partial derivatives commute and $\mathbf{d}x^b \wedge \mathbf{d}x^a = -\mathbf{d}x^a \wedge \mathbf{d}x^b$. Therefore $d^2 = 0$.

To prove naturality, let $F \colon M \to N$ be smooth and, in a chart on N, let $\omega = \sum_{I \in \mathcal{J}_{\dim N}^k} a_I \, \mathbf{d}y^I$. The chain rule gives

$$d(a_I \circ F) = F^*(da_I), \qquad F^*(\mathbf{d}y^j) = d(y^j \circ F).$$

Using the graded Leibniz rule and $d^2 = 0$, we obtain

$$\begin{aligned} d(F^*\omega) &= d\left(\sum_{I \in \mathcal{J}_{\dim N}^k} (a_I \circ F) \, d(y^{i_1} \circ F) \wedge \cdots \wedge d(y^{i_k} \circ F) \right) \\ &= \sum_{I \in \mathcal{J}_{\dim N}^k} F^*(da_I) \wedge F^*(\mathbf{d}y^I) = F^*(d\omega). \end{aligned}$$

The identity is local around each point and therefore holds on all of M.

If M has boundary, the charts used are relatively open in the half-space. Their functions, forms, and fields admit the local extensions specified in the manuscript's definition of smoothness. The intrinsic formula is independent of these extensions, and the coordinate expression above is obtained by restriction. All the arguments, including those using mixed derivatives, remain valid up to the boundary.

Only uniqueness remains. Let D be another family of operators satisfying the properties in the statement. Naturality applied to the inclusion of a coordinate domain into M allows us to restrict $D\omega$ and perform the calculation entirely within that domain. There, $D(\mathbf{d}x^i) = D^2 x^i = 0$, and the graded Leibniz rule implies

$D(\mathbf{d}x^I) = 0$. Therefore

$$D\left(\sum_{I\in\mathcal{J}_n^k} a_I \mathbf{d}x^I\right) = \sum_{I\in\mathcal{J}_n^k} da_I \wedge \mathbf{d}x^I,$$

which agrees with (1.30). Thus $D = d$ in every chart and hence on the entire manifold. □

2

Riemannian manifolds

A smooth manifold has local coordinates, but by itself carries no intrinsic notion of length, angle, or volume. Introducing these quantities requires choosing an inner product on each tangent space that depends smoothly on the point. This structure is a Riemannian metric.

The metric defines the length of curves, the Riemannian distance, and the volume measure. Together with the Levi–Civita connection, it also allows us to construct the gradient, divergence, Laplacian, and covariant derivatives that will appear in the analytical chapters. Riemannian geometry therefore provides the intrinsic language in which we will formulate the Sobolev spaces, variational problems, and differential equations studied later.

Carl Friedrich Gauss
(1777–1855)

Bernhard Riemann
(1826–1866)

Henri Poincaré
(1854–1912)

Figure 2.1. Gauss, Riemann, and Poincaré were central figures in the development of modern geometry. Gauss's work on the intrinsic geometry of surfaces paved the way for Riemannian geometry, introduced by Riemann to study spaces of arbitrary dimension. Poincaré, in turn, advanced the global study of these spaces and laid some of the foundations of modern topology.

From Gauss's surfaces to Riemann's manifolds

Gauss discovered that the curvature of a surface can be calculated from the metric inherited by its coordinates, without making direct use of the ambient space. Riemann turned this observation into a much broader program: the study of spaces of arbitrary dimension from an infinitesimal rule for measuring lengths. Poincaré later showed that local geometry must coexist with global invariants. This chapter fol-

lows that evolution: it begins with the metric, constructs the connection and curvature, and ends with the tools of integration and the operators needed to carry out analysis on the manifold.

2.1 Riemannian metrics

A Riemannian metric adds an inner product on each tangent space to the smooth structure, allowing many constructions from Euclidean analysis to be transferred to the geometric setting.

Definition 2.1.1. Let M be a smooth manifold with or without boundary. A *Riemannian metric on M* is a smooth tensor field

$$\mathbf{g} \in \Gamma\big(T^{(0,2)}(TM)\big)$$

that is symmetric and positive definite at every point $p \in M$.

Definition 2.1.2. A **Riemannian manifold with or without boundary** is a pair $(M, \mathbf{g})$, where M is a smooth manifold with or without boundary and $\mathbf{g}$ is a Riemannian metric on M.

Example 2.1.3. $\mathbb{R}^n$ is a Riemannian manifold without boundary with the **Euclidean metric** $\overline{\mathbf{g}}$, given in standard coordinates by

$$\overline{\mathbf{g}} = \delta_{ij}\, \mathbf{d}x^i \otimes \mathbf{d}x^j$$

or by

$$\overline{\mathbf{g}} = (\mathbf{d}x^1)^2 + \cdots + (\mathbf{d}x^n)^2.$$

If $v, w \in T_p\mathbb{R}^n$, $\overline{\mathbf{g}}_p(v,w) = \delta_{ij} v^i w^j = \sum_{i=1}^{n} v^i w^i = v \cdot w$, which is the usual inner product on $\mathbb{R}^n \cong T_p\mathbb{R}^n$.

Remark 2.1.4. Given a Riemannian manifold $(M, \mathbf{g})$ with or without boundary, the Riemannian metric $\mathbf{g}$ defines an **inner product** on each tangent space T_pM for each $p \in M$. For $\mathbf{X}, \mathbf{Y} \in \mathfrak{X}(M)$, we sometimes denote $\mathbf{g}(\mathbf{X}, \mathbf{Y}) \in C^\infty(M)$ by $\mathbf{g}(\mathbf{X}, \mathbf{Y}) := \langle \mathbf{X}, \mathbf{Y} \rangle$. Pointwise, we have $\langle \mathbf{X}_p, \mathbf{Y}_p \rangle = \mathbf{g}_p(\mathbf{X}_p, \mathbf{Y}_p) \in \mathbb{R}$. We can also define a **norm** on T_pM by $\|v\|_{\mathbf{g}} = \sqrt{\langle v, v \rangle_{\mathbf{g}}}$.
Finally, the concept of angle between two vectors extends from $\mathbb{R}^n$ to M as follows:
The angle between two vectors $v, w \in T_pM \setminus \{0\}$ is the unique $\theta \in [0, \pi]$ satisfying

$$\cos(\theta) = \frac{\langle v, w \rangle_{\mathbf{g}}}{\|v\|_{\mathbf{g}} \|w\|_{\mathbf{g}}}.$$

Two vectors $v, w \in T_pM$ are said to be **orthogonal** if $\langle v, w \rangle_{\mathbf{g}} = 0$.

Definition 2.1.5. (Pointwise order on symmetric forms and comparison of metrics) Let $\mathbf{a}$ and $\mathbf{b}$ be two symmetric tensor fields of type $(0,2)$, and let $A \subseteq M$. The notation $\mathbf{a} \leq \mathbf{b}$ on A means that

$$\mathbf{a}_p(v,v) \leq \mathbf{b}_p(v,v) \qquad \text{for every } p \in A \text{ and every } v \in T_pM.$$

Equivalently, $(\mathbf{b} - \mathbf{a})_p(v,v) \geq 0$ for the same p and v; that is, $\mathbf{b} - \mathbf{a}$ is positive semidefinite on each fiber over

A. This is the meaning of an inequality between symmetric tensors of type $(0,2)$ in this book.
In particular, if $\mathbf{g}$ and $\widetilde{\mathbf{g}}$ are Riemannian metrics and $0 < c \le C < \infty$, writing

$$c\mathbf{g} \le \widetilde{\mathbf{g}} \le C\mathbf{g} \qquad \text{on } A$$

is shorthand for the numerical inequalities

$$c\,\mathbf{g}_p(v,v) \le \widetilde{\mathbf{g}}_p(v,v) \le C\,\mathbf{g}_p(v,v) \qquad (p \in A,\ v \in T_pM).$$

Since $\mathbf{g}_p(v,v) = |v|^2_{\mathbf{g}}$, this is exactly equivalent to

$$\sqrt{c}\,|v|_{\mathbf{g}} \le |v|_{\widetilde{\mathbf{g}}} \le \sqrt{C}\,|v|_{\mathbf{g}} \qquad (p \in A,\ v \in T_pM). \tag{2.1}$$

The constants are common to all points of A and all vectors in their fibers. When such constants exist, we say that the metrics are uniformly equivalent on A.

Remark 2.1.6. The comparison is made by evaluating both metrics on the same vector, repeated in both arguments. If $v = \sum_{i=1}^{n} v^i \partial_i$, its expression in a chart is

$$c \sum_{i,j=1}^{n} g_{ij}(p) v^i v^j \le \sum_{i,j=1}^{n} \widetilde{g}_{ij}(p) v^i v^j \le C \sum_{i,j=1}^{n} g_{ij}(p) v^i v^j \qquad \text{for every } (v^1,\dots,v^n) \in \mathbb{R}^n.$$

The matrix entries, considered individually, need not satisfy these inequalities. Nor is an inequality asserted for $\mathbf{g}_p(v,w)$ and $\widetilde{\mathbf{g}}_p(v,w)$ with arbitrary v and w. Diagonal evaluation is independent of the chart and determines the symmetric form through the polarization identity

$$\mathbf{g}_p(v,w) = \frac{1}{4}\big(\mathbf{g}_p(v+w,v+w) - \mathbf{g}_p(v-w,v-w)\big).$$

Comparison constants exist on each finite-dimensional fiber; uniformity in the base point is an additional assertion. On a compact set, it follows from continuity of the metrics, as will be proved in Lemma 7.1.8 and, for arbitrary vector bundles, in Lemma 9.1.43. The same diagonal evaluation convention is used to compare bundle metrics, with $v \in \mathbf{E}_p$; in the complex case, we compare the real values of the Hermitian forms on (v,v).

We can use the pullback of tensor fields, defined in Chapter 1, to obtain a Riemannian metric from smooth maps.

Proposition 2.1.7. Let M and N be smooth manifolds with or without boundary, let $F\colon M \longrightarrow N$ be a smooth map, and let $\mathbf{g}$ be a Riemannian metric on N. Then $F^*\mathbf{g}$ is a Riemannian metric on M if and only if F is an immersion.

Proof. By Proposition 1.10.20, we know that $F^*\mathbf{g} \in \Gamma(T^{(0,2)}(TM))$, that is, $F^*\mathbf{g}$ is a smooth 2-covariant tensor field. The definition of pullback shows that this tensor is symmetric; it only remains to determine when it is positive definite at every point.

First suppose that $F^*\mathbf{g}$ is a Riemannian metric on M. We show that F is an immersion. Take $p \in M$ and let $v \in T_pM$ with $v \neq 0$. By Definition 1.5.2, we must show that dF_p is injective. If $dF_p(v) = 0$, then

$$(F^*\mathbf{g})_p(v,v) = g_{F(p)}(dF_p(v), dF_p(v)) = 0$$

contradicting the positive definiteness of $F^*\mathbf{g}$ on p. It follows that $dF_p(v) \neq 0$ for every $v \neq 0$; thus dF_p is injective and F is an immersion.
Conversely, suppose that F is an immersion. If $p \in M$ and $v \in T_pM$ satisfy

$$0 = (F^*\mathbf{g})_p(v,v) = \mathbf{g}_{F(p)}(dF_p(v), dF_p(v)),$$

then, since $\mathbf{g}_{F(p)}$ is positive definite, the preceding equality implies $dF_p(v) = 0$. The injectivity of dF_p then gives $v = 0$, so $F^*\mathbf{g}$ is positive definite. □

Every smooth manifold, with or without boundary, admits at least one Riemannian metric.

Proposition 2.1.8. (Existence of Riemannian metrics) Every smooth manifold with or without boundary admits a Riemannian metric.

Proof. Let M be a smooth manifold with or without boundary. Let $(U_\alpha, \varphi_\alpha)_{\alpha\in J}$ be a family of charts such that $(U_\alpha)_{\alpha\in J}$ is an open cover of M. By Proposition 1.3.5, we can find a partition of unity $(\psi_\alpha)_{\alpha\in J}$ subordinate to the cover $(U_\alpha)_{\alpha\in J}$. By Proposition 2.1.7, in each coordinate chart, $\mathbf{g}_\alpha = \varphi_\alpha^*\overline{\mathbf{g}}$ defines a Riemannian metric on U_α whose coordinate expression is $\delta_{ij}\,\mathbf{d}x^i \otimes \mathbf{d}x^j$. Since $\operatorname{supp}(\psi_\alpha) \subseteq U_\alpha$, the tensor $\psi_\alpha \mathbf{g}_\alpha$ extends smoothly by zero outside U_α. Define

$$\mathbf{g} := \sum_{\alpha\in J} \psi_\alpha \mathbf{g}_\alpha,$$

where each summand is understood to have this extension. The family of supports is locally finite, so the sum is finite around each point and defines a smooth tensor field.
The field $\mathbf{g}$ is symmetric because it is a finite sum of symmetric tensors in a neighborhood of each point.
To see that it is positive definite, let $p \in M$ and $v \in T_pM \setminus \{0\}$. For each index with $\psi_\alpha(p) > 0$, we have $p \in U_\alpha$ and $(\mathbf{g}_\alpha)_p(v,v) > 0$, while all the coefficients $\psi_\alpha(p)$ are nonnegative. Since their sum is one, there exists β such that $\psi_\beta(p) > 0$. Therefore,

$$\mathbf{g}_p(v,v) = \sum_{\alpha\in J} \psi_\alpha(p)(\mathbf{g}_\alpha)_p(v,v) > 0.$$

□

If $(\mathbf{E}_1, \dots, \mathbf{E}_n)$ is a smooth local frame for TM defined on an open subset $U \subseteq M$ and $(\varepsilon^1, \dots, \varepsilon^n)$ is its dual coframe, we can write $\mathbf{g}$ locally on U as

$$\mathbf{g} = g_{ij}\,\varepsilon^i \otimes \varepsilon^j, \qquad g_{ij}(p) := \langle \mathbf{E}_i|_p, \mathbf{E}_j|_p \rangle_{\mathbf{g}}.$$

These functions are called the ***coefficients of the metric*** $\mathbf{g}$ ***with respect to the local frame*** $(\mathbf{E}_1, \dots, \mathbf{E}_n)$. We say that $(\mathbf{E}_1, \dots, \mathbf{E}_n)$ is an ***orthonormal local frame*** if the vectors $\mathbf{E}_1|_p, \dots, \mathbf{E}_n|_p$ form an orthonormal basis of T_pM for every $p \in U$. Equivalently, a local frame is orthonormal if and only if $\langle \mathbf{E}_i, \mathbf{E}_j \rangle_{\mathbf{g}} = \delta_{ij}$.

Proposition 2.1.9. (Existence of orthonormal local frames) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary. If $(\mathbf{X}_1,\dots,\mathbf{X}_n)$ is a smooth local frame for TM defined on $U \subseteq M$, then there exists a smooth orthonormal local frame $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ defined on U such that

$$\operatorname{span}\{\mathbf{E}_1|_p,\dots,\mathbf{E}_k|_p\} = \operatorname{span}\{\mathbf{X}_1|_p,\dots,\mathbf{X}_k|_p\}$$

for each $k \in \{1,\dots,n\}$ and each $p \in U$. In particular, for each $p \in M$, there exists an orthonormal local frame defined on some neighborhood of p.

Proof. By the Gram–Schmidt algorithm, for each $p \in U$, the vectors $\mathbf{E}_1|_p,\dots,\mathbf{E}_n|_p$ can be chosen recursively so that

$$\operatorname{span}\{\mathbf{E}_1|_p,\dots,\mathbf{E}_k|_p\} = \operatorname{span}\{\mathbf{X}_1|_p,\dots,\mathbf{X}_k|_p\}$$

for every k. Explicitly, $\mathbf{E}_1 = \frac{\mathbf{X}_1}{\|\mathbf{X}_1\|_{\mathbf{g}}}$ and

$$\mathbf{E}_j = \frac{\mathbf{X}_j - \sum_{i=1}^{j-1} \langle \mathbf{X}_j, \mathbf{E}_i \rangle_{\mathbf{g}} \mathbf{E}_i}{\left\| \mathbf{X}_j - \sum_{i=1}^{j-1} \langle \mathbf{X}_j, \mathbf{E}_i \rangle_{\mathbf{g}} \mathbf{E}_i \right\|_{\mathbf{g}}}, \qquad 2 \le j \le n.$$

Each denominator is a smooth, strictly positive function because $(\mathbf{X}_1,\dots,\mathbf{X}_n)$ is a frame. Therefore the fields $\mathbf{E}_i$ are smooth; the Gram–Schmidt identities show that they form an orthonormal frame and satisfy the stated equalities of subspaces. □

Riemannian metrics allow us to introduce a bundle isomorphism between TM and T^*M as follows:

Definition 2.1.10. (Musical isomorphisms) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary. For each point $p \in M$, define the maps

$$\mathbf{g}_p^\flat \colon T_pM \longrightarrow T_p^*M, \qquad X_p \mapsto \mathbf{g}_p(X_p,\cdot),$$

and

$$\mathbf{g}_p^\sharp \colon T_p^*M \longrightarrow T_pM, \qquad \omega_p \mapsto \text{the unique } X_p \text{ such that } \mathbf{g}_p(X_p,\cdot) = \omega_p.$$

These maps are inverses of one another and define bundle isomorphisms

$$\mathbf{g}^\flat \colon TM \longrightarrow T^*M, \qquad \mathbf{g}^\sharp \colon T^*M \longrightarrow TM,$$

called the *musical isomorphisms*.

Remark 2.1.11. In local coordinates $(x^1,\dots,x^n)$, if $\mathbf{X} = X^i \partial_i$ is a vector field, then

$$\mathbf{X}^\flat = g_{ij} X^i \, \mathbf{d}x^j,$$

and if $\omega = \omega_i \, \mathbf{d}x^i$ is a 1-form,

$$\omega^\sharp = g^{ij}\omega_i \partial_j,$$

where (g^{ij}) is the inverse of the metric matrix (g_{ij}). Thus $^\flat$ is interpreted as "lowering indices" and $^\sharp$ as "raising indices."

2.2 Traces of tensors

Contraction removes one covariant and one contravariant index by means of a sum independent of the basis. This operation will appear repeatedly in the definitions of divergence, Laplacians, curvature, and energy.
Given a finite-dimensional vector space V and an endomorphism $T\colon V \longrightarrow V$, if $\beta = \{e_1, \dots, e_n\}$ is a basis for V and (A_{ij}) is the matrix of T with respect to the basis β, we can define $\operatorname{tr}(T) := \sum_{i=1}^{n} A_{i,i}$. This definition is independent of the chosen basis, and we can generalize the construction to mixed tensors:

Definition 2.2.1. For the $(1,1)$-tensor $F(\omega^1, \dots, \omega^k, \cdot, v_1, \dots, v_l, \cdot) \in T^{(1,1)}(V)$, we can calculate its trace (which is independent of the chosen basis) $\operatorname{tr}(F)(\omega^1, \dots, \omega^k, v_1, \dots, v_l)$. In coordinates, the components of $\operatorname{tr}(F)$ are

$$(\operatorname{tr}(F))^{i_1 \dots i_k}_{j_1 \dots j_l} = F^{i_1 \dots i_k m}_{j_1 \dots j_l m}.$$

This construction defines an operator, independent of the chosen basis, that we call the *trace operator* $\operatorname{tr}\colon T^{(k+1,l+1)}(V) \longrightarrow T^{(k,l)}(V)$.

The trace operator is also known as ***contraction***.

In constructing the trace operator, we set the last upper and lower indices equal, which, in Einstein notation, means summing all these terms. A similar construction can be performed for any pair of indices, provided that one is covariant and the other contravariant. In general, we do not distinguish this operation notationally from the operator tr, so we use only this notation and specify the contraction explicitly when necessary.

The operator tr can be applied to any pair consisting of one contravariant and one covariant index. It is a well-defined linear map from $T^{(k+1,l+1)}(V)$ to $T^{(k,l)}(V)$. If $\mathbf{F}$ is a tensor field of type $(k+1, l+1)$ on a manifold M, its contraction is defined pointwise by

$$\operatorname{tr}(\mathbf{F})|_p := \operatorname{tr}(\mathbf{F}|_p), \qquad p \in M.$$

Now let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{F}$ be a k-covariant tensor field. The metric allows us to contract two distinct covariant indices: when positions r and s are contracted, the coordinate expression is

$$g^{i_r i_s} F_{i_1 \dots i_r \dots i_s \dots i_k}, \qquad r \neq s.$$

This expression transforms tensorially and therefore defines a $(k-2)$-covariant field independent of coordinates. We denote it by $\operatorname{tr}_{\mathbf{g}}(\mathbf{F})$; when more than one pair is possible, the two indices being contracted will be specified explicitly.

2.3 Fiberwise inner products of tensor fields

Given a Riemannian manifold $(M, \mathbf{g})$ with or without boundary, we can define several useful concepts from $\mathbf{g}$. One is the inner product of tensor fields. This is a special case of a more general construction that does not necessarily require a Riemannian structure, known as a fiberwise inner product or bundle metric on a vector bundle $\mathbf{E}$.

Definition 2.3.1. Let M be a smooth manifold with or without boundary. If $\pi\colon \mathbf{E} \longrightarrow M$ is a smooth vector bundle, a **smooth bundle metric on E** is an inner product on each fiber $\mathbf{E}_p$ that varies smoothly in the sense that, for any smooth local sections σ, τ of $\mathbf{E}$, $\langle \sigma, \tau \rangle$ is a smooth function.

The following example constructs a bundle metric on a nontrivial vector bundle.

Example 2.3.2. (Bundle metric on the Möbius bundle) Return to the bundle $\mathbf{E} \to \mathbb{S}^1$ of Example 1.7.9. For $p \in \mathbb{S}^1$, define an inner product on the fiber $\pi^{-1}(p)$ as follows. If $x_0 \in \mathbb{R}$ satisfies $\varepsilon(x_0) = p$, then

$$\pi^{-1}(p) = \{[(x_0, t)] \mid t \in \mathbb{R}\},$$

and we consider the map

$$j_p\colon \pi^{-1}(p) \longrightarrow \mathbb{R}, \qquad j_p([(x_0, t)]) = t.$$

This map is well defined since, if $(x_0, t) \sim (x_0, t')$, then $t = t'$. We then define

$$\mathbf{h}_p(u, v) = j_p(u) j_p(v), \qquad u, v \in \pi^{-1}(p).$$

In this way, each fiber is equipped with an inner product. It remains to show that $\mathbf{h}$ is a smooth bundle metric in the sense of Definition 2.3.1.
Consider the cover $U_\pm = \mathbb{S}^1 \setminus \{(\pm 1, 0)\}$ with trivializations

$$\Phi_\pm\colon \pi^{-1}(U_\pm) \longrightarrow U_\pm \times \mathbb{R}, \qquad [(x, y)] \longmapsto (\varepsilon(x), y).$$

On the overlap $U_+ \cap U_-$, we have

$$(\Phi_+ \circ \Phi_-^{-1})(p, v) = (p, \tau_{+-}(p) v), \qquad \tau_{+-}(p) \in \{\pm 1\}.$$

This means that if a local section σ is written on U_- as $\Phi_-(\sigma(p)) = (p, s_-(p))$ with $s_-\colon U_- \longrightarrow \mathbb{R}$ smooth, then, for every $p \in U_+ \cap U_-$, the following holds:

$$\Phi_+(\sigma(p)) = \big(\Phi_+ \circ \Phi_-^{-1}\big)\big(\Phi_-(\sigma(p))\big) = \big(\Phi_+ \circ \Phi_-^{-1}\big)\big(p, s_-(p)\big) = (p, \tau_{+-}(p) s_-(p)).$$

Since $\Phi_+(\sigma(p)) = (p, s_+(p))$ by definition, comparing second coordinates yields

$$s_+(p) = \tau_{+-}(p) s_-(p).$$

Similarly, if τ is another section, then on the overlap

$$t_+(p) = \tau_{+-}(p) t_-(p),$$

where $s_\pm, t_\pm$ are the functions representing σ, τ in the trivializations $U_\pm$. Consequently,

$$s_+(p)t_+(p) = \big(\tau_{+-}(p)s_-(p)\big)\big(\tau_{+-}(p)t_-(p)\big) = s_-(p)t_-(p),$$

and the local expressions for the inner product agree on the intersection.
Finally, if σ, τ are smooth local sections over $U_\pm$, we have

$$\Phi_\pm(\sigma(p)) = (p, s_\pm(p)), \qquad \Phi_\pm(\tau(p)) = (p, t_\pm(p)),$$

and the definition of $\mathbf{h}$ gives

$$\mathbf{h}_p(\sigma(p), \tau(p)) = s_\pm(p)t_\pm(p),$$

which is a smooth function on p.
We conclude that $\mathbf{h}$ defines a smooth bundle metric on $(\mathbf{E}, \pi, \mathbb{S}^1)$, independent of the chosen trivialization and obtained naturally by identifying each fiber with $\mathbb{R}$ through j_p.

Proposition 2.3.3. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. Then there exists a unique smooth bundle metric on each tensor bundle $T^{(k,l)}(TM)$ with the property that, if $\alpha_1, \dots, \alpha_{k+l}, \beta_1, \dots, \beta_{k+l}$ are vector or covector fields as appropriate, then

$$\langle \alpha_1 \otimes \cdots \otimes \alpha_{k+l}, \beta_1 \otimes \cdots \otimes \beta_{k+l} \rangle_{\mathbf{g}} = \langle \alpha_1, \beta_1 \rangle_{\mathbf{g}} \dots \langle \alpha_{k+l}, \beta_{k+l} \rangle_{\mathbf{g}}.$$

With this inner product, if $(\mathbf{E}_1, \dots, \mathbf{E}_n)$ is an orthonormal local frame for TM and $(\varepsilon^1, \dots, \varepsilon^n)$ is the corresponding dual coframe, then the collection of tensor fields

$$(\mathbf{E}_{i_1} \otimes \cdots \otimes \mathbf{E}_{i_k} \otimes \varepsilon^{j_1} \otimes \cdots \otimes \varepsilon^{j_l})_{1 \le i_1, \dots, i_k, j_1, \dots, j_l \le n}$$

forms an orthonormal local frame on $T^{(k,l)}(TM)$ (orthonormal with respect to this bundle metric). In terms of any local frame, not necessarily orthonormal, this bundle metric satisfies the following: for any $\mathbf{X}, \mathbf{Y} \in \mathfrak{X}(M)$, $\omega, \eta \in \Omega^1(M)$

$$\langle \mathbf{X}, \mathbf{Y} \rangle_{\mathbf{g}} = g_{ir} X^i Y^r, \ \langle \omega, \eta \rangle_{\mathbf{g}} = g^{js} \omega_j \eta_s.$$

Moreover, for $\mathbf{F}, \mathbf{G} \in \Gamma(T^{(k,l)}(TM))$,

$$\langle \mathbf{F}, \mathbf{G} \rangle_{\mathbf{g}} = g_{i_1 r_1} \cdots g_{i_k r_k} g^{j_1 s_1} \cdots g^{j_l s_l} F^{i_1 \dots i_k}_{j_1 \dots j_l} G^{r_1 \dots r_k}_{s_1 \dots s_l}.$$

We sometimes write $\mathbf{g}(\mathbf{F}, \mathbf{G}) := \langle \mathbf{F}, \mathbf{G} \rangle_{\mathbf{g}}$.

Proof. Consider $p \in M$, and let $(\mathbf{E}_1, \dots, \mathbf{E}_n)$ be a smooth local frame for TM defined on an open set $U \subseteq M$ such that $p \in U$. We can define the bundle metric by

$$\langle \mathbf{F}, \mathbf{G} \rangle = g_{i_1 r_1} \cdots g_{i_k r_k} g^{j_1 s_1} \cdots g^{j_l s_l} F^{i_1 \dots i_k}_{j_1 \dots j_l} G^{r_1 \dots r_k}_{s_1 \dots s_l}$$

on U for any tensor fields $\mathbf{F}, \mathbf{G} \in \Gamma(T^{(k,l)}(TM))$. This definition is local. To show that it is well defined, we must first verify that it is independent of the chosen local frame; this will also prove uniqueness:
Suppose that $(\widetilde{\mathbf{E}}_1, \dots, \widetilde{\mathbf{E}}_n)$ is another local frame defined on an open set V such that $p \in V$. On $U \cap V$, the

local frames are related by

$$\mathbf{E}_i = A_i^j \widetilde{\mathbf{E}}_j$$

where (A_i^j) is a matrix of smooth functions defined on $U \cap V$. Let $(\boldsymbol{\varepsilon}^1, \dots, \boldsymbol{\varepsilon}^n)$ and $(\widetilde{\boldsymbol{\varepsilon}}^1, \dots, \widetilde{\boldsymbol{\varepsilon}}^n)$ be the local coframes associated with these frames. Let $(A^{-1})_i^j$ be the inverse matrix of (A_j^i), where the lower index denotes rows and the upper index columns. We have $\widetilde{\mathbf{E}}_i = (A^{-1})_i^j \mathbf{E}_j$, and we can also write $\boldsymbol{\varepsilon}^i = B_m^i \widetilde{\boldsymbol{\varepsilon}}^m$, so

$$(A^{-1})_j^i = (A^{-1})_j^k \delta_k^i = (A^{-1})_j^k \boldsymbol{\varepsilon}^i(\mathbf{E}_k) = \boldsymbol{\varepsilon}^i((A^{-1})_j^k \mathbf{E}_k) = \boldsymbol{\varepsilon}^i(\widetilde{\mathbf{E}}_j) = B_m^i \widetilde{\boldsymbol{\varepsilon}}^m(\widetilde{\mathbf{E}}_j) = B_m^i \delta_j^m = B_j^i.$$

We conclude that $\boldsymbol{\varepsilon}^i = (A^{-1})_j^i \widetilde{\boldsymbol{\varepsilon}}^j$. In turn, since $\mathbf{E}_i = A_i^j \widetilde{\mathbf{E}}_j$, we deduce that $\widetilde{\boldsymbol{\varepsilon}}^i = A_j^i \boldsymbol{\varepsilon}^j$.

We now verify that the expression is independent of the local frame. Let $\mathbf{F}, \mathbf{G} \in \Gamma(T^{(k,l)}(TM))$. On $U \cap V$, we have:

$$\begin{aligned}
&g_{i_1 r_1} \cdots g_{i_k r_k} g^{j_1 s_1} \cdots g^{j_l s_l} F_{j_1 \dots j_l}^{i_1 \dots i_k} G_{s_1 \dots s_l}^{r_1 \dots r_k} \\
&= (A_{i_1}^{a_1} A_{r_1}^{b_1} \widetilde{g}_{a_1 b_1}) \cdots (A_{i_k}^{a_k} A_{r_k}^{b_k} \widetilde{g}_{a_k b_k}) ((A^{-1})_{e_1}^{j_1} (A^{-1})_{f_1}^{s_1} \widetilde{g}^{e_1 f_1}) \cdots ((A^{-1})_{e_l}^{j_l} (A^{-1})_{f_l}^{s_l} \widetilde{g}^{e_l f_l}) \\
&((A^{-1})_{c_1}^{i_1} \cdots (A^{-1})_{c_k}^{i_k} A_{j_1}^{m_1} \cdots A_{j_l}^{m_l} \widetilde{F}_{m_1 \dots m_l}^{c_1 \dots c_k}) ((A^{-1})_{d_1}^{r_1} \cdots (A^{-1})_{d_k}^{r_k} A_{s_1}^{n_1} \cdots A_{s_l}^{n_l} \widetilde{G}_{n_1 \dots n_l}^{d_1 \dots d_k}) \\
&= A_{i_1}^{a_1} (A^{-1})_{c_1}^{i_1} \cdots A_{i_k}^{a_k} (A^{-1})_{c_k}^{i_k} A_{r_1}^{b_1} (A^{-1})_{d_1}^{r_1} \cdots A_{r_k}^{b_k} (A^{-1})_{d_k}^{r_k} \widetilde{g}_{a_1 b_1} \cdots \widetilde{g}_{a_k b_k} \\
&(A^{-1})_{e_1}^{j_1} A_{j_1}^{m_1} \cdots (A^{-1})_{e_l}^{j_l} A_{j_l}^{m_l} (A^{-1})_{f_1}^{s_1} A_{s_1}^{n_1} \cdots (A^{-1})_{f_l}^{s_l} A_{s_l}^{n_l} \widetilde{g}^{e_1 f_1} \dots \widetilde{g}^{e_l f_l} \widetilde{F}_{m_1 \dots m_l}^{c_1 \dots c_k} \widetilde{G}_{n_1 \dots n_l}^{d_1 \dots d_k} \\
&= \delta_{c_1}^{a_1} \cdots \delta_{c_k}^{a_k} \delta_{d_1}^{b_1} \cdots \delta_{d_k}^{b_k} \widetilde{g}_{a_1 b_1} \cdots \widetilde{g}_{a_k b_k} \delta_{e_1}^{m_1} \cdots \delta_{e_l}^{m_l} \delta_{f_1}^{n_1} \cdots \delta_{f_l}^{n_l} \widetilde{g}^{e_1 f_1} \dots \widetilde{g}^{e_l f_l} \widetilde{F}_{m_1 \dots m_l}^{c_1 \dots c_k} \widetilde{G}_{n_1 \dots n_l}^{d_1 \dots d_k} \\
&= \widetilde{g}_{a_1 b_1} \cdots \widetilde{g}_{a_k b_k} \widetilde{g}^{e_1 f_1} \cdots \widetilde{g}^{e_l f_l} \widetilde{F}_{e_1 \dots e_l}^{a_1 \dots a_k} \widetilde{G}_{f_1 \dots f_l}^{b_1 \dots b_k}.
\end{aligned}$$

Here the penultimate equality follows from the definitions of matrix multiplication and the inverse matrix, that is, $(A^{-1})_k^i A_j^k = \delta_j^i = A_j^m (A^{-1})_m^i$.

Therefore $\langle \mathbf{F}, \mathbf{G} \rangle_{\mathbf{g}}$ is independent of the chosen local frame.

Now that the inner product is well defined, we see that it is bilinear and symmetric, so it suffices to prove positive definiteness. If $k = l = 0$, it is the usual product on $\mathbb{R}$. If only one of the two indices is zero, the calculation below remains valid after omitting the absent index families and beginning the invertibility argument with the first family present. We may therefore assume that $k, l \geq 1$. Let $(\mathbf{E}_1, \dots, \mathbf{E}_n)$ be a smooth local frame for TM defined on an open set $U \subseteq M$, and consider $\mathbf{F} \in \Gamma(T^{(k,l)}(TM))$. Since the matrix (g_{ij}) is positive definite, the spectral theorem for symmetric matrices gives a positive definite symmetric matrix R, hence invertible, such that $(g_{ij}) = R^2$.

We denote the entries of R by R_{ij} and those of R^{-1} by R^{ij}. In particular, we have $g_{ij} = \sum_{m=1}^{n} R_{im} R_{mj}$ and $g^{ij} = \sum_{m=1}^{n} R^{im} R^{mj}$.

In the following calculation, we write the sums in Einstein notation explicitly:

$$\langle \mathbf{F}, \mathbf{F} \rangle_{\mathbf{g}} = \sum_{\substack{1 \leq i_1, \dots, i_k \leq n \\ 1 \leq j_1, \dots, j_l \leq n \\ 1 \leq r_1, \dots, r_k \leq n \\ 1 \leq s_1, \dots, s_l \leq n}} g_{i_1 r_1} \cdots g_{i_k r_k} g^{j_1 s_1} \cdots g^{j_l s_l} F_{j_1 \dots j_l}^{i_1 \dots i_k} F_{s_1 \dots s_l}^{r_1 \dots r_k} =$$

$$\sum_{\substack{1\le i_1,\dots,i_k\le n\\ 1\le j_1,\dots,j_l\le n\\ 1\le r_1,\dots,r_k\le n\\ 1\le s_1,\dots,s_l\le n}} \left(\sum_{a_1=1}^{n} R_{i_1a_1}R_{a_1r_1}\right)\cdots\left(\sum_{a_k=1}^{n} R_{i_ka_k}R_{a_kr_k}\right)\left(\sum_{b_1=1}^{n} R^{j_1b_1}R^{b_1s_1}\right)\cdots\left(\sum_{b_l=1}^{n} R^{j_lb_l}R^{b_ls_l}\right) F^{i_1\dots i_k}_{j_1\dots j_l}F^{r_1\dots r_k}_{s_1\dots s_l}$$

$$= \sum_{\substack{1\le a_1,\dots,a_k\le n\\ 1\le b_1,\dots,b_l\le n}} \sum_{\substack{1\le i_1,\dots,i_k\le n\\ 1\le j_1,\dots,j_l\le n\\ 1\le r_1,\dots,r_k\le n\\ 1\le s_1,\dots,s_l\le n}} R_{i_1a_1}R_{a_1r_1}\cdots R_{i_ka_k}R_{a_kr_k}R^{j_1b_1}R^{b_1s_1}\cdots R^{j_lb_l}R^{b_ls_l}F^{i_1\dots i_k}_{j_1\dots j_l}F^{r_1\dots r_k}_{s_1\dots s_l}$$

$$= \sum_{\substack{1\le a_1,\dots,a_k\le n\\ 1\le b_1,\dots,b_l\le n}} \left(\sum_{\substack{1\le i_1,\dots,i_k\le n\\ 1\le j_1,\dots,j_l\le n}} R_{i_1a_1}\cdots R_{i_ka_k}R^{j_1b_1}\cdots R^{j_lb_l}F^{i_1\dots i_k}_{j_1\dots j_l}\right)\left(\sum_{\substack{1\le r_1,\dots,r_k\le n\\ 1\le s_1,\dots,s_l\le n}} R_{a_1r_1}\cdots R_{a_kr_k}R^{b_1s_1}\cdots R^{b_ls_l}F^{r_1\dots r_k}_{s_1\dots s_l}\right)$$

$$= \sum_{\substack{1\le a_1,\dots,a_k\le n\\ 1\le b_1,\dots,b_l\le n}} \left(\sum_{\substack{1\le i_1,\dots,i_k\le n\\ 1\le j_1,\dots,j_l\le n}} R_{i_1a_1}\cdots R_{i_ka_k}R^{j_1b_1}\cdots R^{j_lb_l}F^{i_1\dots i_k}_{j_1\dots j_l}\right)^2 \ge 0,$$

which is nonnegative, and where we have used the symmetry of the matrices R and R^{-1}. Moreover, if $\langle \mathbf{F},\mathbf{F}\rangle_{\mathbf{g}} = 0$, then

$$\sum_{\substack{1\le a_1,\dots,a_k\le n\\ 1\le b_1,\dots,b_l\le n}} \left(\sum_{\substack{1\le i_1,\dots,i_k\le n\\ 1\le j_1,\dots,j_l\le n}} R_{i_1a_1}\cdots R_{i_ka_k}R^{j_1b_1}\cdots R^{j_lb_l}F^{i_1\dots i_k}_{j_1\dots j_l}\right)^2 = 0,$$

so for any $a_1,\dots,a_k,b_1,\dots,b_l$,

$$\sum_{\substack{1\le i_1,\dots,i_k\le n\\ 1\le j_1,\dots,j_l\le n}} R_{i_1a_1}\cdots R_{i_ka_k}R^{j_1b_1}\cdots R^{j_lb_l}F^{i_1\dots i_k}_{j_1\dots j_l} = 0,$$

This can be rewritten as

$$\sum_{i_1=1}^{n} R_{i_1a_1}\left(\sum_{\substack{1\le i_2,\dots,i_k\le n\\ 1\le j_1,\dots,j_l\le n}} R_{i_2a_2}\cdots R_{i_ka_k}R^{j_1b_1}\cdots R^{j_lb_l}F^{i_1\dots i_k}_{j_1\dots j_l}\right) = 0,$$

and it holds for every $a_1\in\{1,\dots,n\}$. Varying $a_1\in\{1,\dots,n\}$ gives a system of equations in $n\times n$ with a unique solution because R is invertible, namely

$$\sum_{\substack{1\le i_2,\dots,i_k\le n\\ 1\le j_1,\dots,j_l\le n}} R_{i_2a_2}\cdots R_{i_ka_k}R^{j_1b_1}\cdots R^{j_lb_l}F^{i_1\dots i_k}_{j_1\dots j_l} = 0$$

for every $i_1\in\{1,\dots,n\}$.

Using the invertibility of R and R^{-1} and proceeding in the same way iteratively and inductively from i_2 through j_{l-1}, we conclude that

$$\sum_{j_l=1}^{n} R^{j_lb_l}F^{i_1\dots i_k}_{j_1\dots j_l} = 0$$

for any $i_1,\dots,i_k,j_1,\dots,j_{l-1} \in \{1,\dots,n\}$. Repeating the argument and using the invertibility of R^{-1}, we conclude that, for any $i_1,\dots,i_k,j_1,\dots,j_l \in \{1,\dots,n\}$,

$$F^{i_1\dots i_k}_{j_1\dots j_l} = 0.$$

Therefore $\mathbf{F} = 0$ and $\langle\ ,\ \rangle_{\mathbf{g}}$ is positive definite. Its coefficients in any tensor frame are smooth. In an orthonormal frame, the formula reduces to products of Kronecker deltas and shows that the tensor frame in the statement is orthonormal. Finally, decomposable tensors span each fiber, so the required property determines the inner product uniquely. □

We prove a property that will be useful later.

Proposition 2.3.4. Let $(M,\mathbf{g})$ be a smooth Riemannian manifold with or without boundary. If $\mathbf{F} \in \Gamma(T^{(k_1,l_1)}(TM))$ and $\mathbf{G} \in \Gamma(T^{(k_2,l_2)}(TM))$, then

$$|\mathbf{F}\otimes\mathbf{G}|_{\mathbf{g}} = |\mathbf{F}|_{\mathbf{g}}|\mathbf{G}|_{\mathbf{g}}.$$

Proof. Let $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ be a smooth local frame defined on an open set $U \subseteq M$. Suppose that $F^{i_1\dots i_{k_1}}_{j_1\dots j_{l_1}}$ and $G^{\tilde{i}_1\dots\tilde{i}_{k_2}}_{\tilde{j}_1\dots\tilde{j}_{l_2}}$ are the coordinates of $\mathbf{F}$ and $\mathbf{G}$ on U with respect to this smooth local frame. We know that the coordinates of $\mathbf{F}\otimes\mathbf{G}$ are given by

$$(\mathbf{F}\otimes\mathbf{G})^{i_1\dots i_{k_1+k_2}}_{j_1\dots j_{l_1+l_2}} = F^{i_1\dots i_{k_1}}_{j_1\dots j_{l_1}} G^{i_{k_1+1}\dots i_{k_1+k_2}}_{j_{l_1+1}\dots j_{l_1+l_2}}.$$

Then:

$$|\mathbf{F}\otimes\mathbf{G}|^2_{\mathbf{g}} =$$

$$\sum_{\substack{1\le i_1,\dots,i_{k_1+k_2}\le n\\ 1\le j_1,\dots,j_{l_1+l_2}\le n\\ 1\le r_1,\dots,r_{k_1+k_2}\le n\\ 1\le s_1,\dots s_{l_1+l_2}\le n}} g_{i_1r_1}\cdots g_{i_{k_1}r_{k_1}} g_{i_{k_1+1}r_{k_1+1}}\cdots g_{i_{k_1+k_2}r_{k_1+k_2}} g^{j_1s_1}\cdots g^{j_{l_1}s_{l_1}} g^{j_{l_1+1}s_{l_1+1}}\cdots g^{j_{l_1+l_2}s_{l_1+l_2}}$$

$$F^{i_1\dots i_{k_1}}_{j_1\dots j_{l_1}} G^{i_{k_1+1}\dots i_{k_1+k_2}}_{j_{l_1+1}\dots j_{l_1+l_2}} F^{r_1\dots r_{k_1}}_{s_1\dots s_{l_1}} G^{r_{k_1+1}\dots r_{k_1+k_2}}_{s_{l_1+1}\dots s_{l_1+l_2}} = \left(\sum_{\substack{1\le i_1,\dots,i_{k_1}\le n\\ 1\le j_1,\dots,j_{l_1}\le n\\ 1\le r_1,\dots,r_{k_1}\le n\\ 1\le s_1,\dots s_{l_1}\le n}} g_{i_1r_1}\cdots g_{i_{k_1}r_{k_1}} g^{j_1s_1}\cdots g^{j_{l_1}s_{l_1}} F^{i_1\dots i_{k_1}}_{j_1\dots j_{l_1}} F^{r_1\dots r_{k_1}}_{s_1\dots s_{l_1}}\right)$$

$$\left(\sum_{\substack{1\le i_{k_1+1},\dots,i_{k_1+k_2}\le n\\ 1\le j_{l_1+1},\dots,j_{l_1+l_2}\le n\\ 1\le r_{k_1+1},\dots,r_{k_1+k_2}\le n\\ 1\le s_{l_1+1},\dots s_{l_1+l_2}\le n}} g_{i_{k_1+1}r_{k_1+1}}\cdots g_{i_{k_1+k_2}r_{k_1+k_2}} g^{j_{l_1+1}s_{l_1+1}}\cdots g^{j_{l_1+l_2}s_{l_1+l_2}} G^{i_{k_1+1}\dots i_{k_1+k_2}}_{j_{l_1+1}\dots j_{l_1+l_2}} G^{r_{k_1+1}\dots r_{k_1+k_2}}_{s_{l_1+1}\dots s_{l_1+l_2}}\right)$$

$$= |\mathbf{F}|_{\mathbf{g}}^2 |\mathbf{G}|_{\mathbf{g}}^2.$$

□

2.4 Connections

A vector field takes values in different tangent spaces, so directly subtracting its values at two points has no intrinsic meaning. A connection resolves this problem by specifying how to differentiate a field in a direction and how to compare vectors along a curve. We begin with the Euclidean case, where the directional derivative provides the model that will later be transferred to the manifold.

Example 2.4.1. Consider the smooth manifold without boundary $\mathbb{R}^n$ and fields $\mathbf{X}, \mathbf{Y} \in \mathfrak{X}(\mathbb{R}^n)$. Recall that vector fields $\mathbf{X}$ and $\mathbf{Y}$ on $\mathbb{R}^n$ can be regarded as smooth functions $\mathbf{X}, \mathbf{Y} \colon \mathbb{R}^n \longrightarrow \mathbb{R}^n$. The concept of directional derivative tells us that, for each $p \in \mathbb{R}^n$,

$$(D_{\mathbf{X}_p}(\mathbf{Y}))(p) = \sum_{i=1}^{n} X^i(p) \frac{\partial \mathbf{Y}}{\partial x^i}(p).$$

This directional derivative gives the rate of change of $\mathbf{Y}$ at p in the direction $\mathbf{X}(p)$. Varying $p \in \mathbb{R}^n$ yields a smooth vector field whose pointwise action is $(\nabla_{\mathbf{X}}\mathbf{Y})_p := (D_{\mathbf{X}_p}\mathbf{Y})(p) = \sum_{i=1}^{n} X^i(p) \frac{\partial \mathbf{Y}}{\partial x^i}(p)$. This notion of the derivative of one vector field with respect to another relies heavily on the vector space structure of $\mathbb{R}^n$, since the definition of directional derivative involves

$$(D_{\mathbf{X}_p}(\mathbf{Y}))(p) := \lim_{t \to 0} \frac{\mathbf{Y}(p + t\mathbf{X}_p) - \mathbf{Y}(p)}{t}$$

and in general $\mathbf{Y}(p) \in T_p\mathbb{R}^n$ and $\mathbf{Y}(p + t\mathbf{X}_p) \in T_{p+t\mathbf{X}_p}\mathbb{R}^n$, with both tangent spaces canonically identified with $\mathbb{R}^n$. Although this cannot be interpreted directly on manifolds, we can abstract the properties of $\nabla_{\mathbf{X}}\mathbf{Y}$ inherited directly from directional derivatives:

(a) If $f \in C^\infty(\mathbb{R}^n)$, then $\nabla_{f\mathbf{X}}\mathbf{Y} = f\nabla_{\mathbf{X}}\mathbf{Y}$.

(b) $\nabla_{\mathbf{X}}\mathbf{Y}$ is $\mathbb{R}$-linear in $\mathbf{Y}$.

(c) For each $f \in C^\infty(\mathbb{R}^n)$,

$$\nabla_{\mathbf{X}}(f\mathbf{Y}) = f\nabla_{\mathbf{X}}\mathbf{Y} + (\mathbf{X}f)\mathbf{Y}.$$

The function $\nabla \colon \mathfrak{X}(\mathbb{R}^n) \times \mathfrak{X}(\mathbb{R}^n) \longrightarrow \mathfrak{X}(\mathbb{R}^n)$ defined in this way is called the *trivial connection* or *Euclidean connection*.

The preceding example leads to the following definition, which provides an intrinsic notion of directional derivative on manifolds:

Definition 2.4.2. Let $\pi \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle over a smooth manifold M with or without boundary. A **connection on E** is a map

$$\nabla \colon \mathfrak{X}(M) \times \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{E}), \qquad (\mathbf{X}, \mathbf{u}) \longmapsto \nabla_{\mathbf{X}}\mathbf{u},$$

satisfying:

(a) $\nabla_{\mathbf{X}}\mathbf{u}$ is $C^\infty(M)$-linear in $\mathbf{X}$.

(b) $\nabla_{\mathbf{X}}\mathbf{u}$ is $\mathbb{R}$-linear in $\mathbf{u}$.

(c) For each $f \in C^\infty(M)$,

$$\nabla_{\mathbf{X}}(f\mathbf{u}) = f\nabla_{\mathbf{X}}\mathbf{u} + (\mathbf{X}f)\mathbf{u}.$$

Exercise 2.4.3. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, and let ∇ be a connection on TM. Let $\mathbf{A}\colon \mathfrak{X}(M)\times\mathfrak{X}(M) \longrightarrow \mathfrak{X}(M)$ be a bilinear map over $C^\infty(M)$, that is, one satisfying

$$\mathbf{A}(f\mathbf{X},\mathbf{Y}) = f\mathbf{A}(\mathbf{X},\mathbf{Y}) \quad \text{and} \quad \mathbf{A}(\mathbf{X},f\mathbf{Y}) = f\mathbf{A}(\mathbf{X},\mathbf{Y}), \qquad \forall f \in C^\infty(M),\ \forall \mathbf{X},\mathbf{Y} \in \mathfrak{X}(M).$$

Show that the map

$$\widetilde{\nabla}_{\mathbf{X}}\mathbf{Y} = \nabla_{\mathbf{X}}\mathbf{Y} + \mathbf{A}(\mathbf{X},\mathbf{Y}), \qquad \mathbf{X},\mathbf{Y} \in \mathfrak{X}(M),$$

also defines a connection on TM.

Remark 2.4.4. If ∇ is a connection on TM and $(U,(x^i))$ is a coordinate chart on M, then ∇ determines n^3 smooth functions $\Gamma_{ij}^k\colon U \longrightarrow \mathbb{R}$ such that

$$\nabla_{\partial_i}\partial_j = \Gamma_{ij}^k\partial_k.$$

These functions completely describe the local behavior of the connection. They are therefore particularly important and are called the ***Christoffel symbols***.

Example 2.4.5. Let $M = \mathbb{R}^n$ be regarded as a smooth manifold without boundary, and let ∇ be the Euclidean connection defined in the preceding example. Recall that, for each $\mathbf{X},\mathbf{Y} \in \mathfrak{X}(\mathbb{R}^n)$,

$$(\nabla_{\mathbf{X}}\mathbf{Y})_p = (D_{\mathbf{X}_p}\mathbf{Y})(p) = \sum_{i=1}^n X^i(p)\frac{\partial \mathbf{Y}}{\partial x^i}(p).$$

Now consider the canonical coordinate frame $\{\partial_1,\dots,\partial_n\}$, where ∂_i denotes the constant vector field whose ith component is 1 and whose other components are 0. Since the fields ∂_i are constant, their partial derivatives vanish:

$$\frac{\partial(\partial_j)}{\partial x^i} = 0 \quad \text{for all } i,j \in \{1,\dots,n\}.$$

The definition of ∇ then gives

$$\nabla_{\partial_i}\partial_j = 0 \quad \text{for all } i,j \in \{1,\dots,n\}.$$

Thus the coefficients of the Euclidean connection in Cartesian coordinates satisfy

$$\Gamma_{ij}^k = 0, \quad \text{for all } i,j,k \in \{1,\dots,n\}.$$

Remark 2.4.6. A connection on $\mathbf{E}$ is $C^\infty(M)$-linear in $\mathbf{X}$, so each $\sigma \in \Gamma(\mathbf{E})$ defines a bundle homomorphism

$$\nabla\sigma \in \mathrm{Hom}_{C^\infty(M)}(\mathfrak{X}(M),\Gamma(\mathbf{E})).$$

By Proposition 1.7.31, there is a canonical isomorphism

$$\mathrm{Hom}_{C^\infty(M)}(\mathfrak{X}(M),\Gamma(\mathbf{E})) \cong \Gamma(\mathrm{Hom}(TM,\mathbf{E}))$$

and by Proposition 1.10.14, we know that $\mathrm{Hom}(TM,\mathbf{E}) \cong (TM)^*\otimes\mathbf{E} = T^{(0,1)}(TM)\otimes\mathbf{E}$. We therefore conclude that

$$\nabla\sigma \in \mathrm{Hom}_{C^\infty(M)}(\mathfrak{X}(M),\Gamma(\mathbf{E})) \cong \Gamma(T^{(0,1)}(TM)\otimes\mathbf{E}), \quad \forall\sigma\in\Gamma(\mathbf{E}).$$

The following additional properties uniquely characterize the Euclidean connection:

Proposition 2.4.7. Let $M=\mathbb{R}^n$, a smooth manifold without boundary, have its usual inner product $\langle\cdot,\cdot\rangle$, and let ∇ be the Euclidean connection defined, for $\mathbf{X},\mathbf{Y}\in\mathfrak{X}(\mathbb{R}^n)$, by

$$(\nabla_{\mathbf{X}}\mathbf{Y})_p = (D_{\mathbf{X}_p}\mathbf{Y})(p) = \sum_{i=1}^n X^i(p)\partial_i\mathbf{Y}(p).$$

Then ∇ satisfies the following properties:

(a) For any $\mathbf{X},\mathbf{Y},\mathbf{Z}\in\mathfrak{X}(\mathbb{R}^n)$,

$$\mathbf{X}(\langle\mathbf{Y},\mathbf{Z}\rangle) = \langle\nabla_{\mathbf{X}}\mathbf{Y},\mathbf{Z}\rangle + \langle\mathbf{Y},\nabla_{\mathbf{X}}\mathbf{Z}\rangle.$$

(b) For any $\mathbf{X},\mathbf{Y}\in\mathfrak{X}(\mathbb{R}^n)$,

$$[\mathbf{X},\mathbf{Y}] = \nabla_{\mathbf{X}}\mathbf{Y} - \nabla_{\mathbf{Y}}\mathbf{X},$$

where $[\mathbf{X},\mathbf{Y}](f) = \mathbf{X}(\mathbf{Y}(f)) - \mathbf{Y}(\mathbf{X}(f))$ for every $f\in C^\infty(\mathbb{R}^n)$.

Moreover, ∇ is the unique connection on $\mathbb{R}^n$ satisfying both properties.

Proof. Let $\mathbf{X},\mathbf{Y},\mathbf{Z}\in\mathfrak{X}(\mathbb{R}^n)$.

To prove the first property, write $\mathbf{Y}=(Y^1,\dots,Y^n)$ and $\mathbf{Z}=(Z^1,\dots,Z^n)$. Since $\langle\mathbf{Y},\mathbf{Z}\rangle = \sum_{k=1}^n Y^kZ^k$, we have

$$\begin{aligned}\mathbf{X}(\langle\mathbf{Y},\mathbf{Z}\rangle) &= \sum_{i,k=1}^n X^i\partial_i(Y^kZ^k)\\ &= \sum_{i,k=1}^n X^i\big((\partial_iY^k)Z^k + Y^k(\partial_iZ^k)\big).\end{aligned}$$

By the definition of ∇, we have $(\nabla_{\mathbf{X}}\mathbf{Y})^k = \sum_{i=1}^n X^i\partial_iY^k$ and $(\nabla_{\mathbf{X}}\mathbf{Z})^k = \sum_{i=1}^n X^i\partial_iZ^k$. Substituting,

$$\mathbf{X}(\langle\mathbf{Y},\mathbf{Z}\rangle) = \sum_{k=1}^n(\nabla_{\mathbf{X}}\mathbf{Y})^kZ^k + \sum_{k=1}^n Y^k(\nabla_{\mathbf{X}}\mathbf{Z})^k = \langle\nabla_{\mathbf{X}}\mathbf{Y},\mathbf{Z}\rangle + \langle\mathbf{Y},\nabla_{\mathbf{X}}\mathbf{Z}\rangle.$$

For the second property, recall that $[\mathbf{X},\mathbf{Y}](f) = \mathbf{X}(\mathbf{Y}(f)) - \mathbf{Y}(\mathbf{X}(f))$. Applying this to x^k,

$$\begin{aligned}[\mathbf{X},\mathbf{Y}](x^k) &= \mathbf{X}(Y^k) - \mathbf{Y}(X^k) \\ &= \sum_{i=1}^{n} \left(X^i \partial_i Y^k - Y^i \partial_i X^k\right),\end{aligned}$$

so $[\mathbf{X},\mathbf{Y}]^k = \sum_{i=1}^{n} \left(X^i \partial_i Y^k - Y^i \partial_i X^k\right)$. But also $(\nabla_{\mathbf{X}}\mathbf{Y} - \nabla_{\mathbf{Y}}\mathbf{X})^k = \sum_{i=1}^{n} \left(X^i \partial_i Y^k - Y^i \partial_i X^k\right)$, and therefore $[\mathbf{X},\mathbf{Y}] = \nabla_{\mathbf{X}}\mathbf{Y} - \nabla_{\mathbf{Y}}\mathbf{X}$.

For uniqueness, let $\widetilde{\nabla}$ be another connection satisfying (a) and (b). In the coordinate frame $\{\partial_1,\dots,\partial_n\}$, write $\widetilde{\nabla}_{\partial_i}\partial_j = \Gamma_{ij}^k \partial_k$. From (b), since $[\partial_i,\partial_j] = 0$, we obtain $\widetilde{\nabla}_{\partial_i}\partial_j = \widetilde{\nabla}_{\partial_j}\partial_i$, that is,

$$\Gamma_{ij}^k = \Gamma_{ji}^k. \tag{2.2}$$

By (a), using the fact that $\langle \partial_j, \partial_k \rangle = \delta_{jk}$ is constant,

$$0 = \partial_i \langle \partial_j, \partial_k \rangle = \langle \widetilde{\nabla}_{\partial_i}\partial_j, \partial_k \rangle + \langle \partial_j, \widetilde{\nabla}_{\partial_i}\partial_k \rangle = \Gamma_{ij}^k + \Gamma_{ik}^j, \tag{2.3}$$

whence

$$\Gamma_{ij}^k = -\Gamma_{ik}^j. \tag{2.4}$$

Let us show that (2.2) and (2.4) imply $\Gamma_{ij}^k = 0$. If $j = k$, then $\Gamma_{ij}^j = -\Gamma_{ij}^j$, hence $\Gamma_{ij}^j = 0$. If $j \neq k$, successively applying (2.2) and (2.4) gives

$$\Gamma_{ij}^k = -\Gamma_{ik}^j = -\Gamma_{ki}^j = \Gamma_{kj}^i = \Gamma_{jk}^i = -\Gamma_{ij}^k,$$

whence $\Gamma_{ij}^k = 0$.
Consequently, $\widetilde{\nabla}_{\partial_i}\partial_j = 0$, and $\widetilde{\nabla}$ agrees with the Euclidean connection. □

As the preceding example shows, these properties completely characterize the Euclidean connection and relate it to the standard Riemannian metric on $\mathbb{R}^n$. We formalize these two properties on an arbitrary Riemannian manifold as follows:

Definition 2.4.8. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let ∇ be a connection on TM. We say that:

(a) ∇ is **compatible with g** if, for any $\mathbf{X},\mathbf{Y},\mathbf{Z} \in \mathfrak{X}(M)$, $\mathbf{X}(\langle \mathbf{Y},\mathbf{Z} \rangle) = \langle \nabla_{\mathbf{X}}\mathbf{Y},\mathbf{Z} \rangle + \langle \mathbf{Y}, \nabla_{\mathbf{X}}\mathbf{Z} \rangle$.

(b) ∇ is **torsion-free** if, for any $\mathbf{X},\mathbf{Y} \in \mathfrak{X}(M)$, $[\mathbf{X},\mathbf{Y}] = \nabla_{\mathbf{X}}\mathbf{Y} - \nabla_{\mathbf{Y}}\mathbf{X}$, where

$$[\mathbf{X},\mathbf{Y}](f) = \mathbf{X}(\mathbf{Y}(f)) - \mathbf{Y}(\mathbf{X}(f)).$$

These two conditions are independent, as the following example shows:

Example 2.4.9. Let ∇ be the Euclidean connection on the manifold without boundary $(\mathbb{R}^n,\overline{\mathbf{g}})$, defined by directional derivatives.
Consider two modifications of ∇ that alter torsion and metric compatibility, respectively. These modifica-

tions are obtained by adding a $C^\infty(M)$-bilinear term to the connection, as justified by Exercise 2.4.3.

(a) *A metric-compatible connection with torsion.*

On $\mathbb{R}^3$, define, for $\mathbf{X}, \mathbf{Y} \in \mathfrak{X}(\mathbb{R}^3)$,

$$\widetilde{\nabla}_{\mathbf{X}}\mathbf{Y} = \nabla_{\mathbf{X}}\mathbf{Y} + \mathbf{X} \times \mathbf{Y},$$

where $\times$ denotes the usual cross product on $\mathbb{R}^3$. The additional term $(\mathbf{X}, \mathbf{Y}) \mapsto \mathbf{X} \times \mathbf{Y}$ is bilinear over $C^\infty(\mathbb{R}^3)$, so $\widetilde{\nabla}$ defines a connection.

To verify that $\widetilde{\nabla}$ preserves the metric, note that

$$\mathbf{X}\big(\langle \mathbf{Y}, \mathbf{Z} \rangle\big) = \langle \nabla_{\mathbf{X}}\mathbf{Y}, \mathbf{Z} \rangle + \langle \mathbf{Y}, \nabla_{\mathbf{X}}\mathbf{Z} \rangle,$$

and that the cross product satisfies

$$\langle \mathbf{X} \times \mathbf{Y}, \mathbf{Z} \rangle = -\langle \mathbf{Y}, \mathbf{X} \times \mathbf{Z} \rangle.$$

Thus,

$$\begin{aligned}\langle \widetilde{\nabla}_{\mathbf{X}}\mathbf{Y}, \mathbf{Z} \rangle + \langle \mathbf{Y}, \widetilde{\nabla}_{\mathbf{X}}\mathbf{Z} \rangle &= \langle \nabla_{\mathbf{X}}\mathbf{Y}, \mathbf{Z} \rangle + \langle \mathbf{Y}, \nabla_{\mathbf{X}}\mathbf{Z} \rangle + \langle \mathbf{X} \times \mathbf{Y}, \mathbf{Z} \rangle + \langle \mathbf{Y}, \mathbf{X} \times \mathbf{Z} \rangle \\ &= \langle \nabla_{\mathbf{X}}\mathbf{Y}, \mathbf{Z} \rangle + \langle \mathbf{Y}, \nabla_{\mathbf{X}}\mathbf{Z} \rangle = \mathbf{X}\big(\langle \mathbf{Y}, \mathbf{Z} \rangle\big),\end{aligned}$$

so $\widetilde{\nabla}$ preserves the metric.

The torsion of $\widetilde{\nabla}$ is given by

$$\begin{aligned}T(\mathbf{X}, \mathbf{Y}) &= \widetilde{\nabla}_{\mathbf{X}}\mathbf{Y} - \widetilde{\nabla}_{\mathbf{Y}}\mathbf{X} - [\mathbf{X}, \mathbf{Y}] \\ &= (\nabla_{\mathbf{X}}\mathbf{Y} - \nabla_{\mathbf{Y}}\mathbf{X} - [\mathbf{X}, \mathbf{Y}]) + (\mathbf{X} \times \mathbf{Y} - \mathbf{Y} \times \mathbf{X}) \\ &= 2\mathbf{X} \times \mathbf{Y},\end{aligned}$$

which is nonzero in general. Consequently, $\widetilde{\nabla}$ preserves the metric but is not torsion-free.

(b) *A torsion-free connection that does not preserve the metric.*

Let $\mathbf{V} \in \mathfrak{X}(\mathbb{R}^n)$ be a smooth vector field, and define

$$\widehat{\nabla}_{\mathbf{X}}\mathbf{Y} = \nabla_{\mathbf{X}}\mathbf{Y} + \langle \mathbf{X}, \mathbf{Y} \rangle \mathbf{V}.$$

The additional term $(\mathbf{X}, \mathbf{Y}) \mapsto \langle \mathbf{X}, \mathbf{Y} \rangle \mathbf{V}$ is symmetric in $\mathbf{X}$ and $\mathbf{Y}$ and bilinear over $C^\infty(\mathbb{R}^n)$, so $\widehat{\nabla}$ is also a connection.

The torsion vanishes, since

$$\begin{aligned}\widehat{\nabla}_{\mathbf{X}}\mathbf{Y} - \widehat{\nabla}_{\mathbf{Y}}\mathbf{X} - [\mathbf{X}, \mathbf{Y}] &= \nabla_{\mathbf{X}}\mathbf{Y} - \nabla_{\mathbf{Y}}\mathbf{X} - [\mathbf{X}, \mathbf{Y}] + \langle \mathbf{X}, \mathbf{Y} \rangle \mathbf{V} - \langle \mathbf{Y}, \mathbf{X} \rangle \mathbf{V} \\ &= 0.\end{aligned}$$

We now check whether $\widehat{\nabla}$ preserves the metric. We have

$$\begin{aligned}\mathbf{X}\big(\langle \mathbf{Y},\mathbf{Z}\rangle\big) &= \langle \nabla_{\mathbf{X}}\mathbf{Y},\mathbf{Z}\rangle + \langle \mathbf{Y},\nabla_{\mathbf{X}}\mathbf{Z}\rangle,\\ \langle \widehat{\nabla}_{\mathbf{X}}\mathbf{Y},\mathbf{Z}\rangle &= \langle \nabla_{\mathbf{X}}\mathbf{Y},\mathbf{Z}\rangle + \langle \mathbf{X},\mathbf{Y}\rangle\langle \mathbf{V},\mathbf{Z}\rangle,\\ \langle \mathbf{Y},\widehat{\nabla}_{\mathbf{X}}\mathbf{Z}\rangle &= \langle \mathbf{Y},\nabla_{\mathbf{X}}\mathbf{Z}\rangle + \langle \mathbf{X},\mathbf{Z}\rangle\langle \mathbf{Y},\mathbf{V}\rangle.\end{aligned}$$

Substituting,

$$\mathbf{X}\big(\langle \mathbf{Y},\mathbf{Z}\rangle\big) - \langle \widehat{\nabla}_{\mathbf{X}}\mathbf{Y},\mathbf{Z}\rangle - \langle \mathbf{Y},\widehat{\nabla}_{\mathbf{X}}\mathbf{Z}\rangle = -\langle \mathbf{X},\mathbf{Y}\rangle\langle \mathbf{V},\mathbf{Z}\rangle - \langle \mathbf{X},\mathbf{Z}\rangle\langle \mathbf{Y},\mathbf{V}\rangle,$$

which does not vanish in general. Therefore $\widehat{\nabla}$ is torsion-free but does not preserve the Euclidean metric.

Like $\mathbb{R}^n$, every Riemannian manifold admits a unique metric-compatible, torsion-free connection, known as the Levi–Civita connection. This result is called the ***fundamental theorem of Riemannian geometry***.

Theorem 2.4.10. (Fundamental theorem of Riemannian geometry) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary. Then there exists a unique connection ∇ on TM that is compatible with $\mathbf{g}$ and torsion-free. It is called the **Levi–Civita connection of g**.

Proof. If a connection is metric-compatible and torsion-free, then

$$\begin{aligned}\mathbf{X}\langle \mathbf{Y},\mathbf{Z}\rangle &= \langle \nabla_{\mathbf{X}}\mathbf{Y},\mathbf{Z}\rangle + \langle \mathbf{Y},\nabla_{\mathbf{X}}\mathbf{Z}\rangle,\\ \mathbf{Y}\langle \mathbf{Z},\mathbf{X}\rangle &= \langle \nabla_{\mathbf{Y}}\mathbf{Z},\mathbf{X}\rangle + \langle \mathbf{Z},\nabla_{\mathbf{Y}}\mathbf{X}\rangle,\\ \mathbf{Z}\langle \mathbf{X},\mathbf{Y}\rangle &= \langle \nabla_{\mathbf{Z}}\mathbf{X},\mathbf{Y}\rangle + \langle \mathbf{X},\nabla_{\mathbf{Z}}\mathbf{Y}\rangle.\end{aligned}$$

Add the first two identities, subtract the third, and use $\nabla_{\mathbf{X}}\mathbf{Y}-\nabla_{\mathbf{Y}}\mathbf{X} = [\mathbf{X},\mathbf{Y}]$. This necessarily gives the Koszul formula

$$\begin{aligned}2\langle \nabla_{\mathbf{X}}\mathbf{Y},\mathbf{Z}\rangle = \mathbf{X}\langle \mathbf{Y},\mathbf{Z}\rangle + \mathbf{Y}\langle \mathbf{Z},\mathbf{X}\rangle - \mathbf{Z}\langle \mathbf{X},\mathbf{Y}\rangle\\ - \langle \mathbf{Y},[\mathbf{X},\mathbf{Z}]\rangle - \langle \mathbf{Z},[\mathbf{Y},\mathbf{X}]\rangle + \langle \mathbf{X},[\mathbf{Z},\mathbf{Y}]\rangle.\end{aligned}$$

Since the metric is nondegenerate, this identity determines $\nabla_{\mathbf{X}}\mathbf{Y}$ uniquely.
For existence, denote the right-hand side of the preceding formula by $\mathcal{K}(\mathbf{X},\mathbf{Y},\mathbf{Z})$. Substituting the identities

$$[f\mathbf{X},\mathbf{Z}] = f[\mathbf{X},\mathbf{Z}] - \mathbf{Z}(f)\mathbf{X}, \qquad [\mathbf{Z},f\mathbf{Y}] = f[\mathbf{Z},\mathbf{Y}] + \mathbf{Z}(f)\mathbf{Y}$$

and canceling the terms containing derivatives of f shows that

$$\mathcal{K}(f\mathbf{X},\mathbf{Y},\mathbf{Z}) = f\mathcal{K}(\mathbf{X},\mathbf{Y},\mathbf{Z}), \qquad \mathcal{K}(\mathbf{X},\mathbf{Y},f\mathbf{Z}) = f\mathcal{K}(\mathbf{X},\mathbf{Y},\mathbf{Z}).$$

Likewise,

$$\mathcal{K}(\mathbf{X},f\mathbf{Y},\mathbf{Z}) = f\mathcal{K}(\mathbf{X},\mathbf{Y},\mathbf{Z}) + 2\mathbf{X}(f)\langle \mathbf{Y},\mathbf{Z}\rangle.$$

Therefore, for each $\mathbf{X},\mathbf{Y}$, the function $\mathbf{Z}\mapsto \frac{1}{2}\mathcal{K}(\mathbf{X},\mathbf{Y},\mathbf{Z})$ is $C^\infty(M)$-linear. Nondegeneracy of the metric defines a unique vector field $\nabla_{\mathbf{X}}\mathbf{Y}$ by

$$2\langle \nabla_{\mathbf{X}}\mathbf{Y},\mathbf{Z}\rangle = \mathcal{K}(\mathbf{X},\mathbf{Y},\mathbf{Z}) \quad \text{for every } \mathbf{Z}.$$

The preceding three identities prove the connection rules

$$\nabla_{f\mathbf{X}}\mathbf{Y} = f\nabla_{\mathbf{X}}\mathbf{Y}, \qquad \nabla_{\mathbf{X}}(f\mathbf{Y}) = f\nabla_{\mathbf{X}}\mathbf{Y} + \mathbf{X}(f)\mathbf{Y}.$$

Smoothness is checked by evaluating on a local frame, since the resulting components are combinations of smooth functions and their derivatives.
Finally, the Koszul formula itself gives

$$\mathcal{K}(\mathbf{X},\mathbf{Y},\mathbf{Z}) + \mathcal{K}(\mathbf{X},\mathbf{Z},\mathbf{Y}) = 2\mathbf{X}\langle \mathbf{Y},\mathbf{Z}\rangle$$

and

$$\mathcal{K}(\mathbf{X},\mathbf{Y},\mathbf{Z}) - \mathcal{K}(\mathbf{Y},\mathbf{X},\mathbf{Z}) = 2\langle [\mathbf{X},\mathbf{Y}],\mathbf{Z}\rangle.$$

The first identity proves metric compatibility; the second, together with nondegeneracy, proves that the torsion vanishes. □

The Levi–Civita connection will be fundamental in nonlinear analysis on manifolds, since most spaces we work with require a metric-compatible connection. The following corollary collects its local expressions and basic properties.

Corollary 2.4.11. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let ∇ be its Levi–Civita connection.

(a) For any $\mathbf{X},\mathbf{Y},\mathbf{Z} \in \mathfrak{X}(M)$, the ***Koszul formula*** holds:

$$\langle \nabla_{\mathbf{X}}\mathbf{Y},\mathbf{Z}\rangle = \frac{1}{2}\left(\mathbf{X}\langle \mathbf{Y},\mathbf{Z}\rangle + \mathbf{Y}\langle \mathbf{Z},\mathbf{X}\rangle - \mathbf{Z}\langle \mathbf{X},\mathbf{Y}\rangle - \langle \mathbf{Y},[\mathbf{X},\mathbf{Z}]\rangle - \langle \mathbf{Z},[\mathbf{Y},\mathbf{X}]\rangle + \langle \mathbf{X},[\mathbf{Z},\mathbf{Y}]\rangle\right).$$

(b) In any coordinate chart (U,φ), we have

$$\Gamma_{ij}^{k} = \frac{1}{2}g^{kl}\left(\partial_i g_{jl} + \partial_j g_{il} - \partial_l g_{ij}\right).$$

(c) In a local frame $(\mathbf{E}_i)$ defined on $U \subseteq M$, if $c_{ij}^{k}\colon U \longrightarrow \mathbb{R}$ are the n^3 smooth functions defined by

$$[\mathbf{E}_i,\mathbf{E}_j] = c_{ij}^{k}\mathbf{E}_k,$$

then the coefficients of the Levi–Civita connection with respect to this frame are

$$\Gamma_{ij}^{k} = \frac{1}{2}g^{kl}\left(\mathbf{E}_i g_{jl} + \mathbf{E}_j g_{il} - \mathbf{E}_l g_{ij} - g_{jm}c_{il}^{m} - g_{lm}c_{ji}^{m} + g_{im}c_{lj}^{m}\right).$$

(d) If $(\mathbf{E}_i)$ is orthonormal, the expression reduces to $\Gamma_{ij}^{k} = \frac{1}{2}\left(c_{ij}^{k} - c_{ik}^{j} - c_{jk}^{i}\right)$.

Proof. Part (1) is the formula obtained in the proof of the preceding theorem. In a coordinate frame, the brackets $[\partial_i,\partial_j]$ vanish. Taking $\mathbf{X} = \partial_i$, $\mathbf{Y} = \partial_j$, and $\mathbf{Z} = \partial_l$ gives

$$2g_{kl}\Gamma_{ij}^{k} = \partial_i g_{jl} + \partial_j g_{il} - \partial_l g_{ij}.$$

Contracting with g^{lr} gives (2).
For an arbitrary frame $(\mathbf{E}_i)$, substitute $[\mathbf{E}_i, \mathbf{E}_j] = c_{ij}^k \mathbf{E}_k$ into the Koszul formula. We obtain

$$2g_{kl}\Gamma_{ij}^k = \mathbf{E}_i g_{jl} + \mathbf{E}_j g_{il} - \mathbf{E}_l g_{ij} - g_{jm}c_{il}^m - g_{lm}c_{ji}^m + g_{im}c_{lj}^m,$$

and contraction with the inverse metric proves (3). If the frame is orthonormal, $g_{ij} = \delta_{ij}$ and its derivatives vanish; the formula reduces to

$$\Gamma_{ij}^k = \frac{1}{2}\left(c_{ij}^k - c_{ik}^j - c_{jk}^i\right),$$

which is (4). □

The following lemma collects the transformation rules for the Christoffel symbols, the components of the metric, and the components of its inverse.

Lemma 2.4.12. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. Let (U, φ) and (V, ψ) be two charts on M such that $U \cap V \neq \varnothing$. Denote by g_{ij}, g^{ij}, and Γ_{ij}^k the components of the metric, the inverse metric, and the Christoffel symbols of the Levi–Civita connection in the coordinates $\varphi = (x^1, \dots, x^n)$, and by $\widetilde{g}_{ab}$, $\widetilde{g}^{ab}$, and $\widetilde{\Gamma}_{ab}^c$ the corresponding components in the coordinates $\psi = (y^1, \dots, y^n)$. Then, for every $p \in U \cap V$, the following formulas hold:

(a) The metric components transform according to

$$g_{ij}(p) = \frac{\partial y^a}{\partial x^i}(p)\frac{\partial y^b}{\partial x^j}(p)\,\widetilde{g}_{ab}(p).$$

(b) The inverse metric components transform according to

$$g^{ij}(p) = \frac{\partial x^i}{\partial y^a}(p)\frac{\partial x^j}{\partial y^b}(p)\,\widetilde{g}^{ab}(p).$$

(c) The Christoffel symbols transform according to

$$\Gamma_{ij}^k(p) = \frac{\partial x^k}{\partial y^c}(p)\frac{\partial y^a}{\partial x^i}(p)\frac{\partial y^b}{\partial x^j}(p)\,\widetilde{\Gamma}_{ab}^c(p) + \frac{\partial x^k}{\partial y^c}(p)\frac{\partial^2 y^c}{\partial x^i \partial x^j}(p).$$

Proof. Let $p \in U \cap V$. We begin with the metric. By the chain rule,

$$\partial_i\Big|_p = \frac{\partial y^a}{\partial x^i}(p)\,\partial_a\Big|_p.$$

Therefore,

$$g_{ij}(p) = \mathbf{g}_p\left(\partial_i\Big|_p, \partial_j\Big|_p\right) = \frac{\partial y^a}{\partial x^i}(p)\frac{\partial y^b}{\partial x^j}(p)\,\mathbf{g}_p\left(\partial_a\Big|_p, \partial_b\Big|_p\right).$$

Since $\mathbf{g}_p\left(\partial_a\big|_p, \partial_b\big|_p\right) = \widetilde{g}_{ab}(p)$, we obtain

$$g_{ij}(p) = \frac{\partial y^a}{\partial x^i}(p)\frac{\partial y^b}{\partial x^j}(p)\,\widetilde{g}_{ab}(p).$$

We turn to the inverse metric. The preceding identity can be written in matrix form as

$$G(p) = J(p)^T\,\widetilde{G}(p)\,J(p),$$

where $G(p) = \left(g_{ij}(p)\right)$, $\widetilde{G}(p) = \left(\widetilde{g}_{ab}(p)\right)$, and $J(p) = \left(\dfrac{\partial y^a}{\partial x^i}(p)\right)$. Taking inverses in this equality gives

$$G(p)^{-1} = J(p)^{-1}\,\widetilde{G}(p)^{-1}\left(J(p)^T\right)^{-1}.$$

Since

$$J(p)^{-1} = \left(\frac{\partial x^i}{\partial y^a}(p)\right),$$

it follows that

$$g^{ij}(p) = \frac{\partial x^i}{\partial y^a}(p)\frac{\partial x^j}{\partial y^b}(p)\,\widetilde{g}^{ab}(p).$$

Finally, we prove the transformation formula for the Christoffel symbols. By definition,

$$\nabla_{\partial_i}\partial_j = \Gamma_{ij}^k\partial_k.$$

Using again the relation between the coordinate vector fields,

$$\partial_i = \frac{\partial y^a}{\partial x^i}\partial_a, \qquad \partial_j = \frac{\partial y^b}{\partial x^j}\partial_b,$$

and the Leibniz rule for the connection, we have

$$\nabla_{\partial_i}\partial_j = \nabla_{\frac{\partial y^a}{\partial x^i}\partial_a}\left(\frac{\partial y^b}{\partial x^j}\partial_b\right) = \frac{\partial y^a}{\partial x^i}\frac{\partial y^b}{\partial x^j}\nabla_{\partial_a}\partial_b + \frac{\partial y^a}{\partial x^i}\partial_a\left(\frac{\partial y^c}{\partial x^j}\right)\partial_c.$$

Since $\nabla_{\partial_a}\partial_b = \widetilde{\Gamma}_{ab}^c\partial_c$, this gives

$$\nabla_{\partial_i}\partial_j = \left(\frac{\partial y^a}{\partial x^i}\frac{\partial y^b}{\partial x^j}\widetilde{\Gamma}_{ab}^c + \frac{\partial^2 y^c}{\partial x^i\partial x^j}\right)\partial_c.$$

On the other hand, $\partial_c = \dfrac{\partial x^k}{\partial y^c}\partial_k$. Substituting this identity into the preceding expression, we obtain

$$\nabla_{\partial_i}\partial_j = \left(\frac{\partial x^k}{\partial y^c}\frac{\partial y^a}{\partial x^i}\frac{\partial y^b}{\partial x^j}\widetilde{\Gamma}_{ab}^c + \frac{\partial x^k}{\partial y^c}\frac{\partial^2 y^c}{\partial x^i\partial x^j}\right)\partial_k.$$

Comparing with $\nabla_{\partial_i}\partial_j = \Gamma_{ij}^k\partial_k$, we conclude that

$$\Gamma_{ij}^k(p) = \frac{\partial x^k}{\partial y^c}(p)\frac{\partial y^a}{\partial x^i}(p)\frac{\partial y^b}{\partial x^j}(p)\,\widetilde{\Gamma}_{ab}^c(p) + \frac{\partial x^k}{\partial y^c}(p)\frac{\partial^2 y^c}{\partial x^i\partial x^j}(p).$$

This completes the proof. □

The connection on TM induces connections on all tensor bundles. The construction begins with the dual and the tensor product.

Proposition 2.4.13. (Induced connections on tensor bundles) Let M be a smooth manifold with or without boundary, and let ∇ be a connection on TM. Then there exists a unique family of connections, also denoted by ∇, on

$$T^{(k,l)}(TM) = TM^{\otimes k} \otimes (T^*M)^{\otimes l}, \qquad k, l \in \mathbb{N}_0,$$

with the following properties.

(a) On TM it agrees with the original connection, and on $T^{(0,0)}(TM) = M \times \mathbb{R}$ it is given by $\nabla_{\mathbf{X}} f = \mathbf{X}(f)$.

(b) The dual connection satisfies

$$(\nabla_{\mathbf{X}} \omega)(\mathbf{Y}) = \mathbf{X}\big(\omega(\mathbf{Y})\big) - \omega(\nabla_{\mathbf{X}} \mathbf{Y}), \tag{2.5}$$

and hence the natural pairing is parallel:

$$\mathbf{X}\big(\omega(\mathbf{Y})\big) = (\nabla_{\mathbf{X}} \omega)(\mathbf{Y}) + \omega(\nabla_{\mathbf{X}} \mathbf{Y}).$$

(c) If $\mathbf{S} \in \Gamma(T^{(r,s)}(TM))$ and $\mathbf{T} \in \Gamma(T^{(p,q)}(TM))$, then

$$\nabla_{\mathbf{X}}(\mathbf{S} \otimes \mathbf{T}) = (\nabla_{\mathbf{X}} \mathbf{S}) \otimes \mathbf{T} + \mathbf{S} \otimes (\nabla_{\mathbf{X}} \mathbf{T}). \tag{2.6}$$

(d) If $\mathbf{T} \in \Gamma(T^{(k,l)}(TM))$, then

$$\begin{aligned} &(\nabla_{\mathbf{X}} \mathbf{T})(\omega^1, \dots, \omega^k, \mathbf{Y}_1, \dots, \mathbf{Y}_l) \\ &\quad = \mathbf{X}\big(\mathbf{T}(\omega^1, \dots, \omega^k, \mathbf{Y}_1, \dots, \mathbf{Y}_l)\big) \\ &\qquad - \sum_{a=1}^{k} \mathbf{T}(\omega^1, \dots, \nabla_{\mathbf{X}} \omega^a, \dots, \omega^k, \mathbf{Y}_1, \dots, \mathbf{Y}_l) \\ &\qquad - \sum_{b=1}^{l} \mathbf{T}(\omega^1, \dots, \omega^k, \mathbf{Y}_1, \dots, \nabla_{\mathbf{X}} \mathbf{Y}_b, \dots, \mathbf{Y}_l). \end{aligned} \tag{2.7}$$

(e) The connection commutes with every contraction between a contravariant and a covariant index. If C denotes one of these contractions,

$$\nabla_{\mathbf{X}}(CT) = C(\nabla_{\mathbf{X}} \mathbf{T}).$$

It also commutes with permutations of factors, symmetrization, and alternation. In particular, for differential forms,

$$\nabla_{\mathbf{X}}(\omega \wedge \eta) = (\nabla_{\mathbf{X}} \omega) \wedge \eta + \omega \wedge (\nabla_{\mathbf{X}} \eta).$$

If $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ is a local frame with dual coframe $(\varepsilon^1,\dots,\varepsilon^n)$ and $\nabla_{\mathbf{E}_a}\mathbf{E}_i = \Gamma_{ai}^{s}\mathbf{E}_s$, then

$$(\nabla_{\mathbf{E}_a}\mathbf{T})^{i_1\dots i_k}_{j_1\dots j_l} = \mathbf{E}_a\big(T^{i_1\dots i_k}_{j_1\dots j_l}\big) + \sum_{r=1}^{k}\Gamma_{as}^{i_r}T^{i_1\dots s\dots i_k}_{j_1\dots j_l} - \sum_{t=1}^{l}\Gamma_{aj_t}^{s}T^{i_1\dots i_k}_{j_1\dots s\dots j_l}. \tag{2.8}$$

Proof. We first construct the dual connection. For $\mathbf{X},\mathbf{Y}\in\mathfrak{X}(M)$ and $\omega\in\Omega^1(M)$, define $\nabla_{\mathbf{X}}\omega$ by (2.5). The right-hand side is linear over $C^\infty(M)$ in $\mathbf{Y}$. If $f\in C^\infty(M)$, then

$$\begin{aligned}\mathbf{X}\big(\omega(f\mathbf{Y})\big) - \omega(\nabla_{\mathbf{X}}(f\mathbf{Y})) &= \mathbf{X}(f)\omega(\mathbf{Y}) + f\mathbf{X}\big(\omega(\mathbf{Y})\big)\\ &\quad - \mathbf{X}(f)\omega(\mathbf{Y}) - f\,\omega(\nabla_{\mathbf{X}}\mathbf{Y})\\ &= f\left[\mathbf{X}(\omega(\mathbf{Y})) - \omega(\nabla_{\mathbf{X}}\mathbf{Y})\right].\end{aligned}$$

By the tensor criterion, this determines a 1-form. It is smooth because its evaluations on the elements of a local frame are smooth functions. Moreover,

$$\nabla_{f\mathbf{X}}\omega = f\nabla_{\mathbf{X}}\omega, \qquad \nabla_{\mathbf{X}}(f\omega) = \mathbf{X}(f)\omega + f\nabla_{\mathbf{X}}\omega,$$

as follows by substitution into (2.5). Thus it is a connection on T^*M. The pairing identity is the defining formula itself and uniquely determines $\nabla_{\mathbf{X}}\omega$, so the dual connection is unique.
Now consider, more generally, two smooth vector bundles $\mathbf{E},\mathbf{F}\to M$ equipped with connections $\nabla^{\mathbf{E}}$ and $\nabla^{\mathbf{F}}$. On decomposable local sections, we propose

$$\nabla^{\mathbf{E}\otimes\mathbf{F}}_{\mathbf{X}}(\sigma\otimes\tau) = (\nabla^{\mathbf{E}}_{\mathbf{X}}\sigma)\otimes\tau + \sigma\otimes(\nabla^{\mathbf{F}}_{\mathbf{X}}\tau). \tag{2.9}$$

This rule respects the balancing relation. Indeed,

$$\nabla_{\mathbf{X}}((f\sigma)\otimes\tau) = \mathbf{X}(f)\sigma\otimes\tau + f(\nabla^{\mathbf{E}}_{\mathbf{X}}\sigma)\otimes\tau + f\sigma\otimes\nabla^{\mathbf{F}}_{\mathbf{X}}\tau,$$

whereas

$$\nabla_{\mathbf{X}}(\sigma\otimes(f\tau)) = f(\nabla^{\mathbf{E}}_{\mathbf{X}}\sigma)\otimes\tau + \mathbf{X}(f)\sigma\otimes\tau + f\sigma\otimes\nabla^{\mathbf{F}}_{\mathbf{X}}\tau.$$

Thus both representations of the same tensor yield the same result. On a trivializing open set, the isomorphism

$$\Gamma(\mathbf{E}|_U)\otimes_{C^\infty(U)}\Gamma(\mathbf{F}|_U)\longrightarrow\Gamma((\mathbf{E}\otimes\mathbf{F})|_U)$$

allows us to extend (2.9) by additivity to every section. This explicitly proves independence of the representation as a sum of decomposable tensors. In local frames, the formula contains only smooth coefficients and their derivatives, so it produces a smooth section. It also directly gives

$$\nabla_{f\mathbf{X}}\mathbf{S} = f\nabla_{\mathbf{X}}\mathbf{S}, \qquad \nabla_{\mathbf{X}}(f\mathbf{S}) = \mathbf{X}(f)\mathbf{S} + f\nabla_{\mathbf{X}}\mathbf{S}.$$

The local definitions agree on overlaps because they are characterized by the same rule on decomposable sections; they therefore glue to a global connection. Since these sections locally generate $\Gamma(\mathbf{E}\otimes\mathbf{F})$, the rule

determines the connection uniquely.

Apply this construction successively to TM and to the dual connection on T^*M. We obtain connections on $TM^{\otimes k} \otimes (T^*M)^{\otimes l}$. Uniqueness of the product connection shows that these connections are compatible with the canonical associative identifications, so they do not depend on how the tensor product is parenthesized. To obtain (2.7), contract $\mathbf{T} \otimes \omega^1 \otimes \cdots \otimes \omega^k \otimes \mathbf{Y}_1 \otimes \cdots \otimes \mathbf{Y}_l$ to a function. The tensor product rule and the parallel pairing identity give

$$\begin{aligned}\mathbf{X}\big(\mathbf{T}(\omega^1,\dots,\omega^k,\mathbf{Y}_1,\dots,\mathbf{Y}_l)\big) &= (\nabla_{\mathbf{X}}\mathbf{T})(\omega^1,\dots,\omega^k,\mathbf{Y}_1,\dots,\mathbf{Y}_l)\\ &\quad + \sum_{a=1}^{k} \mathbf{T}(\omega^1,\dots,\nabla_{\mathbf{X}}\omega^a,\dots,\omega^k,\mathbf{Y}_1,\dots,\mathbf{Y}_l)\\ &\quad + \sum_{b=1}^{l} \mathbf{T}(\omega^1,\dots,\omega^k,\mathbf{Y}_1,\dots,\nabla_{\mathbf{X}}\mathbf{Y}_b,\dots,\mathbf{Y}_l).\end{aligned}$$

Solving for the first term yields the intrinsic formula, including the negative signs of all the contravariant and covariant arguments on which $\mathbf{T}$ is evaluated.

An elementary contraction pairs a factor TM with a factor T^*M. When a decomposable tensor is differentiated, the two terms in which the connection acts on these factors combine, by (2.5), into the derivative of their pairing. The other factors remain unchanged. By linearity, it follows that $\nabla_{\mathbf{X}}(CT) = C(\nabla_{\mathbf{X}}\mathbf{T})$ for every contraction C.

If P_σ permutes factors of the same type, the product formula applied to a decomposable tensor shows term by term that $\nabla_{\mathbf{X}} P_\sigma = P_\sigma \nabla_{\mathbf{X}}$. Symmetrization and alternation are linear combinations of these operators and therefore also commute with the connection. Since the wedge product is the normalized alternation of the tensor product, we obtain

$$\nabla_{\mathbf{X}}(\boldsymbol{\omega} \wedge \eta) = (\nabla_{\mathbf{X}}\boldsymbol{\omega}) \wedge \eta + \boldsymbol{\omega} \wedge (\nabla_{\mathbf{X}}\eta).$$

Finally, the identity $\boldsymbol{\varepsilon}^j(\mathbf{E}_i) = \delta_i^j$ and compatibility with the pairing give

$$0 = \mathbf{E}_a(\delta_i^j) = (\nabla_{\mathbf{E}_a}\boldsymbol{\varepsilon}^j)(\mathbf{E}_i) + \boldsymbol{\varepsilon}^j(\nabla_{\mathbf{E}_a}\mathbf{E}_i),$$

and consequently

$$\nabla_{\mathbf{E}_a}\boldsymbol{\varepsilon}^j = -\Gamma_{as}^j \boldsymbol{\varepsilon}^s.$$

Differentiating

$$\mathbf{T} = T^{i_1\dots i_k}_{j_1\dots j_l}\, \mathbf{E}_{i_1} \otimes \cdots \otimes \mathbf{E}_{i_k} \otimes \boldsymbol{\varepsilon}^{j_1} \otimes \cdots \otimes \boldsymbol{\varepsilon}^{j_l}$$

produces a positive sign for each factor $\mathbf{E}_{i_r}$ and a negative sign for each factor $\boldsymbol{\varepsilon}^{j_t}$. Reindexing these terms gives exactly (2.8).

The preceding rules determine the connection on all elements of a local tensor frame, and the Leibniz rule determines its action on coefficients. This also proves uniqueness of the entire family of induced connections. □

With this proposition, compatibility of the metric with the Levi–Civita connection can be rewritten as follows:

Theorem 2.4.14. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, and let ∇ be its Levi–Civita connection. The Levi–Civita connection is compatible with $\mathbf{g}$ in the sense that $\nabla_{\mathbf{X}}\mathbf{g} = 0$ for every

$\mathbf{X} \in \mathfrak{X}(M)$.

Proof. By Definition 2.4.8, since ∇ is a connection compatible with $\mathbf{g}$, we know that, for any $\mathbf{X}, \mathbf{Y}, \mathbf{Z} \in \mathfrak{X}(M)$,

$$\nabla_{\mathbf{X}}\langle \mathbf{Y}, \mathbf{Z}\rangle = \langle \nabla_{\mathbf{X}}\mathbf{Y}, \mathbf{Z}\rangle + \langle \mathbf{Y}, \nabla_{\mathbf{X}}\mathbf{Z}\rangle,$$

so Proposition 2.4.13 gives

$$\nabla_{\mathbf{X}}\mathbf{g}(\mathbf{Y}, \mathbf{Z}) = \mathbf{X}(\mathbf{g}(\mathbf{Y}, \mathbf{Z})) - \mathbf{g}(\nabla_{\mathbf{X}}\mathbf{Y}, \mathbf{Z}) - \mathbf{g}(\mathbf{Y}, \nabla_{\mathbf{X}}\mathbf{Z})$$

$$= \nabla_{\mathbf{X}}\langle \mathbf{Y}, \mathbf{Z}\rangle - \langle \nabla_{\mathbf{X}}\mathbf{Y}, \mathbf{Z}\rangle - \langle \mathbf{Y}, \nabla_{\mathbf{X}}\mathbf{Z}\rangle = 0.$$

□

In local coordinates, the covariant derivative of a tensor field takes the following form:

Lemma 2.4.15. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, and let ∇ be a connection on TM. Let $(\mathbf{E}_1, \dots, \mathbf{E}_n)$ be a smooth local frame of TM over $U \subseteq M$, and let $(\varepsilon^1, \dots, \varepsilon^n)$ be its dual coframe. If $\mathbf{F}$ is a tensor field of type (k, l) written in this frame as

$$\mathbf{F} = \sum_{\substack{1 \le i_1, \dots, i_k \le n \\ 1 \le j_1, \dots, j_l \le n}} F^{i_1 \dots i_k}_{j_1 \dots j_l}\, \mathbf{E}_{i_1} \otimes \cdots \otimes \mathbf{E}_{i_k} \otimes \varepsilon^{j_1} \otimes \cdots \otimes \varepsilon^{j_l},$$

then, for each $a \in \{1, \dots, n\}$,

$$\left(\nabla_{\mathbf{E}_a}\mathbf{F}\right)^{i_1 \dots i_k}_{j_1 \dots j_l} = \mathbf{E}_a\left(F^{i_1 \dots i_k}_{j_1 \dots j_l}\right) + \sum_{r=1}^{k} \Gamma^{i_r}_{as}\, F^{i_1 \dots s \dots i_k}_{j_1 \dots j_l} - \sum_{t=1}^{l} \Gamma^{s}_{a j_t}\, F^{i_1 \dots i_k}_{j_1 \dots s \dots j_l},$$

where Γ^c_{ai} are the connection coefficients of ∇ relative to the frame $(\mathbf{E}_1, \dots, \mathbf{E}_n)$, that is, $\nabla_{\mathbf{E}_a}\mathbf{E}_i = \Gamma^c_{ai}\mathbf{E}_c$.

Proof. Let $(\mathbf{E}_1, \dots, \mathbf{E}_n)$ be a smooth local frame of TM over U, and let $(\varepsilon^1, \dots, \varepsilon^n)$ be the dual coframe, so that $\langle \varepsilon^j, \mathbf{E}_i\rangle = \delta^j_i$. Fix $a \in \{1, \dots, n\}$.
Since $\nabla_{\mathbf{E}_a}\mathbf{E}_i = \Gamma^s_{ai}\mathbf{E}_s$, the product rule for the pairing (Proposition 2.4.13) applied to $\langle \varepsilon^j, \mathbf{E}_i\rangle$ gives

$$0 = \mathbf{E}_a(\delta^j_i) = \nabla_{\mathbf{E}_a}\langle \varepsilon^j, \mathbf{E}_i\rangle = \langle \nabla_{\mathbf{E}_a}\varepsilon^j, \mathbf{E}_i\rangle + \langle \varepsilon^j, \nabla_{\mathbf{E}_a}\mathbf{E}_i\rangle = \langle \nabla_{\mathbf{E}_a}\varepsilon^j, \mathbf{E}_i\rangle + \Gamma^j_{ai},$$

and therefore $\langle \nabla_{\mathbf{E}_a}\varepsilon^j, \mathbf{E}_i\rangle = -\Gamma^j_{ai}$ for every i, which is equivalent to

$$\nabla_{\mathbf{E}_a}\varepsilon^j = -\Gamma^j_{as}\varepsilon^s.$$

Writing the tensor field $\mathbf{F}$ in the frame as

$$\mathbf{F} = \sum_{i_1, \dots, i_k = 1}^{n} \sum_{j_1, \dots, j_l = 1}^{n} F^{i_1 \dots i_k}_{j_1 \dots j_l}\, \mathbf{E}_{i_1} \otimes \cdots \otimes \mathbf{E}_{i_k} \otimes \varepsilon^{j_1} \otimes \cdots \otimes \varepsilon^{j_l},$$

and using the Leibniz rule for tensor products together with $\nabla_{\mathbf{E}_a} f = \mathbf{E}_a(f)$ yields a linear combination of

tensor fields in the frame, with terms arising from differentiating the coefficients and each factor $\mathbf{E}_{i_r}$ and $\boldsymbol{\varepsilon}^{j_t}$. Substituting $\nabla_{\mathbf{E}_a}\mathbf{E}_{i_r} = \Gamma^s_{ai_r}\mathbf{E}_s$ and $\nabla_{\mathbf{E}_a}\boldsymbol{\varepsilon}^{j_t} = -\Gamma^{j_t}_{as}\boldsymbol{\varepsilon}^s$ and rewriting in the basis of tensor fields associated with the frame, we conclude that

$$\left(\nabla_{\mathbf{E}_a}\mathbf{F}\right)^{i_1\dots i_k}_{j_1\dots j_l} = \mathbf{E}_a\left(F^{i_1\dots i_k}_{j_1\dots j_l}\right) + \sum_{r=1}^{k}\Gamma^{i_r}_{as}F^{i_1\dots s\dots i_k}_{j_1\dots j_l} - \sum_{t=1}^{l}\Gamma^{s}_{aj_t}F^{i_1\dots i_k}_{j_1\dots s\dots j_l}.$$

□

With this proposition, Theorem 2.4.14 takes the following form:

Corollary 2.4.16. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, with Levi–Civita connection ∇. In a local frame $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ with dual coframe $(\boldsymbol{\varepsilon}^1,\dots,\boldsymbol{\varepsilon}^n)$, we have

$$\mathbf{E}_a(g_{ij}) = \Gamma^s_{ai}g_{sj} + \Gamma^s_{aj}g_{is}.$$

Proof. Applying Theorem 2.4.14 and Lemma 2.4.15 to the $(0,2)$-tensor field $\mathbf{g}$ gives

$$0 = (\nabla_a\mathbf{g})_{ij} = \mathbf{E}_a(g_{ij}) - \Gamma^s_{ai}g_{sj} - \Gamma^s_{aj}g_{is}.$$

It follows directly that

$$\mathbf{E}_a(g_{ij}) = \Gamma^s_{ai}g_{sj} + \Gamma^s_{aj}g_{is}.$$

□

Corollary 2.4.17. Under the same hypotheses as Corollary 2.4.16, the inverse metric g^{ij} satisfies the relation

$$\mathbf{E}_a(g^{ij}) = -\left(\Gamma^i_{as}g^{sj} + \Gamma^j_{as}g^{is}\right).$$

Proof. Start from the identity $g^{ik}g_{kj} = \delta^i_j$. Applying E_a and using the Leibniz rule gives

$$E_a(g^{ik})g_{kj} + g^{ik}E_a(g_{kj}) = 0.$$

Substituting the expression for $E_a(g_{kj})$ given by Corollary 2.4.16, we have

$$E_a(g^{ik})g_{kj} + g^{ik}\left(\Gamma^s_{ak}g_{sj} + \Gamma^s_{aj}g_{ks}\right) = 0.$$

Expanding and using $g^{ik}g_{ks} = \delta^i_s$ yields

$$E_a(g^{ik})g_{kj} + g^{ik}\Gamma^s_{ak}g_{sj} + \Gamma^i_{aj} = 0.$$

Multiplying on the right by g^{jm} gives

$$E_a(g^{ik})\delta^m_k + g^{ik}\Gamma^s_{ak}\delta^m_s + \Gamma^i_{aj}g^{jm} = 0.$$

That is,

$$E_a(g^{im}) + g^{ik}\Gamma^m_{ak} + \Gamma^i_{aj}g^{jm} = 0.$$

Renaming dummy indices and rearranging, we conclude that

$$E_a(g^{ij}) = -\left(\Gamma^i_{as}g^{sj} + \Gamma^j_{as}g^{is}\right).$$

□

The connection on tensor bundles induced by the Levi–Civita connection is compatible with the induced inner product on tensors:

Proposition 2.4.18. (Compatibility of the Levi–Civita connection with the tensor inner product) Suppose that $(M, \mathbf{g})$ is a Riemannian manifold with or without boundary. The connection induced on each tensor bundle by the Levi–Civita connection is compatible with the inner product of tensor fields in the following sense:

$$\mathbf{X}\langle \mathbf{F}, \mathbf{G}\rangle = \langle \nabla_{\mathbf{X}}\mathbf{F}, \mathbf{G}\rangle + \langle \mathbf{F}, \nabla_{\mathbf{X}}\mathbf{G}\rangle$$

for any $\mathbf{X} \in \mathfrak{X}(M)$ and any $\mathbf{F}, \mathbf{G} \in \Gamma(T^{(k,l)}(TM))$.

Proof. The induced connection commutes with tensor products and contractions. It therefore suffices to verify the identity on simple tensors. Let

$$\mathbf{F} = \mathbf{Y}_1 \otimes \cdots \otimes \mathbf{Y}_k \otimes \boldsymbol{\alpha}^1 \otimes \cdots \otimes \boldsymbol{\alpha}^l$$

and use an analogous expression for $\mathbf{G}$, with factors $\mathbf{Z}_i$ and $\boldsymbol{\beta}^a$. Their inner product is the product of the pairings of their factors:

$$\langle \mathbf{F}, \mathbf{G}\rangle = \prod_{i=1}^{k}\langle \mathbf{Y}_i, \mathbf{Z}_i\rangle \prod_{a=1}^{l}\langle \boldsymbol{\alpha}^a, \boldsymbol{\beta}^a\rangle.$$

The ordinary Leibniz rule expresses $\mathbf{X}\langle \mathbf{F}, \mathbf{G}\rangle$ as a sum of terms in which one of these factors is differentiated. Compatibility of the Levi–Civita connection on TM gives

$$\mathbf{X}\langle \mathbf{Y}_i, \mathbf{Z}_i\rangle = \langle \nabla_{\mathbf{X}}\mathbf{Y}_i, \mathbf{Z}_i\rangle + \langle \mathbf{Y}_i, \nabla_{\mathbf{X}}\mathbf{Z}_i\rangle.$$

On the dual, the definition

$$(\nabla_{\mathbf{X}}\boldsymbol{\alpha})(\mathbf{Y}) = \mathbf{X}(\boldsymbol{\alpha}(\mathbf{Y})) - \boldsymbol{\alpha}(\nabla_{\mathbf{X}}\mathbf{Y})$$

and metric compatibility give the same identity for covectors. Grouping the terms in which a factor of $\mathbf{F}$ is differentiated and those in which a factor of $\mathbf{G}$ is differentiated yields exactly

$$\mathbf{X}\langle \mathbf{F}, \mathbf{G}\rangle = \langle \nabla_{\mathbf{X}}\mathbf{F}, \mathbf{G}\rangle + \langle \mathbf{F}, \nabla_{\mathbf{X}}\mathbf{G}\rangle.$$

Bilinearity extends the equality to arbitrary tensor fields. □

The total covariant derivative combines the derivatives in all directions into a single tensor and will serve as the geometric analogue of higher-order total derivatives.

Proposition 2.4.19. (The total covariant derivative) Let M be a smooth manifold with or without boundary, and let ∇ be a connection on TM. For each $\mathbf{F} \in \Gamma(T^{(k,l)}(TM))$, the map

$$\nabla\mathbf{F}\colon \underbrace{\Omega^1(M)\times\cdots\times\Omega^1(M)}_{k \text{ times}}\times\underbrace{\mathfrak{X}(M)\times\cdots\times\mathfrak{X}(M)}_{(l+1) \text{ times}} \longrightarrow C^\infty(M)$$

given by

$$(\nabla\mathbf{F})(\omega^1,\dots,\omega^k,\mathbf{X},\mathbf{Y}_1,\dots,\mathbf{Y}_l) = (\nabla_{\mathbf{X}}\mathbf{F})(\omega^1,\dots,\omega^k,\mathbf{Y}_1,\dots,\mathbf{Y}_l)$$

defines a smooth $(k,l+1)$-tensor field on M, called the **total covariant derivative of F**.

Proof. By Lemma 1.10.18, since $\nabla_{\mathbf{X}}\mathbf{F}$ is a (k,l)-tensor field, it is $C^\infty(M)$-multilinear in its $k+l$ arguments and is linear over $C^\infty(M)$ in $\mathbf{X}$ by the definition of a connection. Thus $\nabla\mathbf{F}$ defines a smooth $(k,l+1)$-tensor field on M. □

Lemma 2.4.15 can be expressed in terms of the total covariant derivative as follows:

Corollary 2.4.20. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, with a connection ∇, and let $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ be a smooth local frame of TM over $U \subseteq M$, with dual coframe $(\varepsilon^1,\dots,\varepsilon^n)$. If $\mathbf{F}$ is a tensor field of type (k,l), its total covariant derivative $\nabla\mathbf{F}$ takes the following form in this frame:

$$\nabla\mathbf{F} = \sum_{a=1}^{n}\sum_{\substack{1\le i_1,\dots,i_k\le n\\ 1\le j_1,\dots,j_l\le n}} (\nabla_a\mathbf{F})^{i_1\dots i_k}_{j_1\dots j_l}\mathbf{E}_{i_1}\otimes\cdots\otimes\mathbf{E}_{i_k}\otimes\varepsilon^a\otimes\varepsilon^{j_1}\otimes\cdots\otimes\varepsilon^{j_l}.$$

In particular, its components are

$$(\nabla\mathbf{F})^{i_1\dots i_k}_{aj_1\dots j_l} = (\nabla_a\mathbf{F})^{i_1\dots i_k}_{j_1\dots j_l} = \mathbf{E}_a\left(F^{i_1\dots i_k}_{j_1\dots j_l}\right) + \sum_{r=1}^{k}\Gamma^{i_r}_{as}F^{i_1\dots s\dots i_k}_{j_1\dots j_l} - \sum_{t=1}^{l}\Gamma^{s}_{aj_t}F^{i_1\dots i_k}_{j_1\dots s\dots j_l},$$

where $\nabla_a := \nabla_{\mathbf{E}_a}$ and the connection coefficients Γ^c_{ab} are defined by $\nabla_{\mathbf{E}_a}\mathbf{E}_b = \Gamma^c_{ab}\mathbf{E}_c$.

Proof. The definition of the total covariant derivative implies

$$(\nabla\mathbf{F})(\varepsilon^{i_1},\dots,\varepsilon^{i_k},\mathbf{E}_a,\mathbf{E}_{j_1},\dots,\mathbf{E}_{j_l}) = (\nabla_{\mathbf{E}_a}\mathbf{F})(\varepsilon^{i_1},\dots,\varepsilon^{i_k},\mathbf{E}_{j_1},\dots,\mathbf{E}_{j_l}).$$

Lemma 2.4.15 computes the right-hand side as

$$\mathbf{E}_a\left(F^{i_1\dots i_k}_{j_1\dots j_l}\right) + \sum_{r=1}^{k}\Gamma^{i_r}_{as}F^{i_1\dots s\dots i_k}_{j_1\dots j_l} - \sum_{t=1}^{l}\Gamma^{s}_{aj_t}F^{i_1\dots i_k}_{j_1\dots s\dots j_l}.$$

These are precisely the components of $\nabla\mathbf{F}$ in the indicated frame and coframe; reconstructing the tensor from its components gives the first formula in the statement. □

Remark 2.4.21. Since $\nabla\mathbf{F}$ has been defined for a (k,l)-tensor field and is a $(k,l+1)$-tensor field, we can define $\nabla^2\mathbf{F} = \nabla(\nabla\mathbf{F})$, which is a $(k,l+2)$-tensor field. In general, we write $\nabla^s\mathbf{F} := \underbrace{\nabla(\nabla(\dots(\nabla\mathbf{F})))}_{s \text{ times}} \in \Gamma(T^{(k,l+s)}(TM))$.

For a function $u \in C^\infty(M)$, regarded as a tensor of type $(0,0)$, the same construction defines its iterated covariant derivatives $\nabla^s u$.

Connections on TM and its tensor bundles are related to the wedge product as follows:

Proposition 2.4.22. (Compatibility of the connection with the wedge product) Let M be a smooth manifold with or without boundary, and let ∇ be a connection on TM. Then, for any $k, l \geq 0$, if $\omega \in \Gamma(\Lambda^k T^*M)$ and $\eta \in \Gamma(\Lambda^l T^*M)$, we have

$$\nabla_X(\omega \wedge \eta) = (\nabla_X \omega) \wedge \eta + \omega \wedge (\nabla_X \eta) \qquad \text{for every } X \in \mathfrak{X}(M).$$

Proof. Let $\omega \in \Gamma(\Lambda^k T^*M)$ and $\eta \in \Gamma(\Lambda^l T^*M)$. By definition,

$$\omega \wedge \eta = \frac{1}{k!l!} \sum_{\sigma \in S_{k+l}} (\operatorname{sgn}\sigma)^\sigma(\omega \otimes \eta),$$

where, for $\mathbf{T} \in \Gamma(T^{(0,k+l)}(TM))$ and $\sigma \in S_{k+l}$, we define

$$({}^\sigma\mathbf{T})(v_1, \dots, v_{k+l}) = \mathbf{T}(v_{\sigma(1)}, \dots, v_{\sigma(k+l)}).$$

For $\mathbf{T} \in \Gamma(T^{(0,k+l)}(TM))$, by (2.7),

$$(\nabla_X \mathbf{T})(w_1, \dots, w_{k+l}) = X(\mathbf{T}(w_1, \dots, w_{k+l})) - \sum_{j=1}^{k+l} \mathbf{T}(w_1, \dots, \nabla_X w_j, \dots, w_{k+l}).$$

Applying this to ${}^\sigma\mathbf{T}$ and evaluating on $(v_1, \dots, v_{k+l})$ gives

$$(\nabla_X({}^\sigma\mathbf{T}))(v_1, \dots, v_{k+l}) = X(\mathbf{T}(v_{\sigma(1)}, \dots, v_{\sigma(k+l)})) - \sum_{j=1}^{k+l} \mathbf{T}(v_{\sigma(1)}, \dots, \nabla_X v_{\sigma(j)}, \dots, v_{\sigma(k+l)})$$

$$= (\nabla_X \mathbf{T})(v_{\sigma(1)}, \dots, v_{\sigma(k+l)}) = ({}^\sigma(\nabla_X \mathbf{T}))(v_1, \dots, v_{k+l}),$$

whence $\nabla_X({}^\sigma\mathbf{T}) = {}^\sigma(\nabla_X \mathbf{T})$.
Differentiating the expression for $\omega \wedge \eta$ and using linearity,

$$\nabla_X(\omega \wedge \eta) = \frac{1}{k!l!} \sum_{\sigma \in S_{k+l}} (\operatorname{sgn}\sigma) \nabla_X\big({}^\sigma(\omega \otimes \eta)\big).$$

From the preceding calculation,

$$\nabla_X(\omega \wedge \eta) = \frac{1}{k!l!} \sum_{\sigma \in S_{k+l}} (\operatorname{sgn}\sigma)^\sigma\big(\nabla_X(\omega \otimes \eta)\big).$$

By (2.6),

$$\nabla_X(\omega \otimes \eta) = (\nabla_X \omega) \otimes \eta + \omega \otimes (\nabla_X \eta).$$

Substituting,

$$\nabla_{\mathbf{X}}(\omega\wedge\eta)=\frac{1}{k!l!}\sum_{\sigma\in S_{k+l}}(\operatorname{sgn}\sigma)^{\sigma}\left((\nabla_{\mathbf{X}}\omega)\otimes\eta+\omega\otimes(\nabla_{\mathbf{X}}\eta)\right)$$

$$=\frac{1}{k!l!}\sum_{\sigma\in S_{k+l}}(\operatorname{sgn}\sigma)^{\sigma}((\nabla_{\mathbf{X}}\omega)\otimes\eta)+\frac{1}{k!l!}\sum_{\sigma\in S_{k+l}}(\operatorname{sgn}\sigma)^{\sigma}(\omega\otimes(\nabla_{\mathbf{X}}\eta)).$$

Recognizing the definition of the wedge product in each term, we conclude that

$$\nabla_{\mathbf{X}}(\omega\wedge\eta)=(\nabla_{\mathbf{X}}\omega)\wedge\eta+\omega\wedge(\nabla_{\mathbf{X}}\eta).$$

□

Another operation satisfying the Leibniz rule with respect to connections is interior multiplication:

Lemma 2.4.23. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, ∇ a connection on TM, and $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ a smooth local frame of TM with dual coframe $(\varepsilon^1,\dots,\varepsilon^n)$. For every tensor field $\mathbf{F}\in\Gamma(T^{(k,l+1)}(TM))$, we have

$$\nabla_a\left(\iota_{\mathbf{E}_a}\mathbf{F}\right)=\iota_{\nabla_a\mathbf{E}_a}\mathbf{F}+\iota_{\mathbf{E}_a}(\nabla_a\mathbf{F}).$$

Proof. By Proposition 1.10.24, if $\mathbf{F}$ has components $F^{i_1\dots i_k}_{j_1\dots j_{l+1}}$ in the frames $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ and $(\varepsilon^1,\dots,\varepsilon^n)$, then the components of $\iota_{\mathbf{E}_a}\mathbf{F}$ are $(\iota_{\mathbf{E}_a}\mathbf{F})^{i_1\dots i_k}_{j_1\dots j_l}=F^{i_1\dots i_k}_{aj_1\dots j_l}$. Applying Lemma 2.4.15 gives

$$(\nabla_a(\iota_{\mathbf{E}_a}\mathbf{F}))^{i_1\dots i_k}_{j_1\dots j_l}=\mathbf{E}_a\left(F^{i_1\dots i_k}_{aj_1\dots j_l}\right)+\sum_{r=1}^{k}\Gamma^{i_r}_{as}F^{i_1\dots s\dots i_k}_{aj_1\dots j_l}-\sum_{t=1}^{l}\Gamma^{s}_{aj_t}F^{i_1\dots i_k}_{aj_1\dots s\dots j_l}. \tag{2.10}$$

On the other hand, Remark 1.10.25 gives $\nabla_a\mathbf{E}_a=\Gamma^s_{aa}\mathbf{E}_s$, so we have

$$\left(\iota_{\nabla_a\mathbf{E}_a}\mathbf{F}\right)^{i_1\dots i_k}_{j_1\dots j_l}=\Gamma^s_{aa}F^{i_1\dots i_k}_{sj_1\dots j_l}.$$

Finally, by Lemma 2.4.15,

$$\left(\iota_{\mathbf{E}_a}(\nabla_a\mathbf{F})\right)^{i_1\dots i_k}_{j_1\dots j_l}=(\nabla_a\mathbf{F})^{i_1\dots i_k}_{aj_1\dots j_l}$$

$$=\mathbf{E}_a\left(F^{i_1\dots i_k}_{aj_1\dots j_l}\right)+\sum_{r=1}^{k}\Gamma^{i_r}_{as}F^{i_1\dots s\dots i_k}_{aj_1\dots j_l}-\Gamma^s_{aa}F^{i_1\dots i_k}_{sj_1\dots j_l}-\sum_{t=1}^{l}\Gamma^{s}_{aj_t}F^{i_1\dots i_k}_{aj_1\dots s\dots j_l}.$$

Therefore

$$(\nabla_a(\iota_{\mathbf{E}_a}\mathbf{F}))^{i_1\dots i_k}_{j_1\dots j_l}=\left(\iota_{\nabla_a\mathbf{E}_a}\mathbf{F}\right)^{i_1\dots i_k}_{j_1\dots j_l}+\left(\iota_{\mathbf{E}_a}(\nabla_a\mathbf{F})\right)^{i_1\dots i_k}_{j_1\dots j_l}.$$

□

The notion of a connection on tensor bundles can be generalized to the tensor product of two vector bundles as follows:

Proposition 2.4.24. Let $\mathbf{E},\mathbf{F}\longrightarrow M$ be smooth vector bundles over a smooth manifold M with or without boundary, equipped with connections $\nabla^{\mathbf{E}}$ and $\nabla^{\mathbf{F}}$ in the sense of Definition 2.4.2. Then:

(a) If $\mathbf{E}$ and $\mathbf{F}$ have connections $\nabla^{\mathbf{E}}$ and $\nabla^{\mathbf{F}}$, the tensor bundle $\mathbf{E}\otimes\mathbf{F}$ admits a unique connection

$\nabla^{\mathbf{E}\otimes\mathbf{F}}\colon \mathfrak{X}(M)\times\Gamma(\mathbf{E}\otimes\mathbf{F})\longrightarrow\Gamma(\mathbf{E}\otimes\mathbf{F})$ determined by the rule

$$\nabla^{\mathbf{E}\otimes\mathbf{F}}_{\mathbf{X}}(\sigma\otimes\tau)=(\nabla^{\mathbf{E}}_{\mathbf{X}}\sigma)\otimes\tau+\sigma\otimes(\nabla^{\mathbf{F}}_{\mathbf{X}}\tau),\qquad \mathbf{X}\in\mathfrak{X}(M),\ \sigma\in\Gamma(\mathbf{E}),\ \tau\in\Gamma(\mathbf{F}),$$

and extended by bilinearity and the property

$$\nabla_{\mathbf{X}}(f\,\mathbf{T})=f\,\nabla_{\mathbf{X}}\mathbf{T}+(\mathbf{X}f)\,\mathbf{T},\qquad f\in C^\infty(M).$$

(b) The connection $\nabla^{\mathbf{E}}$ induces a unique connection $\nabla^{\mathbf{E}^*}\colon \mathfrak{X}(M)\times\Gamma(\mathbf{E}^*)\longrightarrow\Gamma(\mathbf{E}^*)$ characterized by the identity

$$\mathbf{X}\langle\mathbf{v},\mathbf{u}\rangle=\langle\nabla^{\mathbf{E}^*}_{\mathbf{X}}\mathbf{v},\mathbf{u}\rangle+\langle\mathbf{v},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}\rangle,\qquad \mathbf{u}\in\Gamma(\mathbf{E}),\ \mathbf{v}\in\Gamma(\mathbf{E}^*),\ \mathbf{X}\in\mathfrak{X}(M).$$

(c) The connection $\nabla^{\mathbf{E}}$ induces a connection $\nabla^{\mathrm{End}(\mathbf{E})}$ on $\mathrm{End}(\mathbf{E})\cong\mathbf{E}^*\otimes\mathbf{E}$, defined for every $\mathbf{T}\in\Gamma(\mathrm{End}(\mathbf{E}))$ by

$$(\nabla^{\mathrm{End}(\mathbf{E})}_{\mathbf{X}}\mathbf{T})(\mathbf{u})=\nabla^{\mathbf{E}}_{\mathbf{X}}(\mathbf{T}\mathbf{u})-\mathbf{T}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}),\qquad \mathbf{u}\in\Gamma(\mathbf{E}),\ \mathbf{X}\in\mathfrak{X}(M).$$

(d) The connections $\nabla^{\mathbf{E}}$ and $\nabla^{\mathbf{F}}$ induce a connection $\nabla^{\mathrm{Hom}(\mathbf{E},\mathbf{F})}$ on the bundle $\mathrm{Hom}(\mathbf{E},\mathbf{F})\cong\mathbf{E}^*\otimes\mathbf{F}$, determined by the rule

$$(\nabla^{\mathrm{Hom}(\mathbf{E},\mathbf{F})}_{\mathbf{X}}\mathbf{\Phi})(\mathbf{u})=\nabla^{\mathbf{F}}_{\mathbf{X}}(\mathbf{\Phi}(\mathbf{u}))-\mathbf{\Phi}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}),\qquad \mathbf{\Phi}\in\Gamma(\mathrm{Hom}(\mathbf{E},\mathbf{F})),\ \mathbf{u}\in\Gamma(\mathbf{E}),\ \mathbf{X}\in\mathfrak{X}(M).$$

Equivalently, in intrinsic terms, if $\mathbf{\Phi}\in\Gamma(\mathbf{E}^*\otimes\mathbf{F})$, then $\nabla^{\mathrm{Hom}(\mathbf{E},\mathbf{F})}$ is the connection induced by those on $\mathbf{E}^*$ and $\mathbf{F}$ through the tensor product.

Proof. For the tensor product, define the connection on decomposable local sections by the formula in part (a). If $f\in C^\infty(M)$, the two expansions

$$\nabla_{\mathbf{X}}((f\,\mathbf{u})\otimes\mathbf{v})=\mathbf{X}(f)\mathbf{u}\otimes\mathbf{v}+f(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{v}+f\,\mathbf{u}\otimes\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{v},$$
$$\nabla_{\mathbf{X}}(\mathbf{u}\otimes(f\,\mathbf{v}))=f(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{v}+\mathbf{X}(f)\mathbf{u}\otimes\mathbf{v}+f\,\mathbf{u}\otimes\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{v}$$

agree. The rule therefore respects the balancing relations and is independent of the representation of a section as a sum of decomposable tensors. In local frames, it produces smooth coefficients and satisfies the two rules for a connection. Uniqueness follows because decomposable sections locally generate $\mathbf{E}\otimes\mathbf{F}$.
For the dual, set

$$(\nabla^{\mathbf{E}^*}_{\mathbf{X}}\mathbf{v})(\mathbf{u}):=\mathbf{X}(\mathbf{v}(\mathbf{u}))-\mathbf{v}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}).$$

The same calculation

$$\mathbf{X}(\mathbf{v}(f\,\mathbf{u}))-\mathbf{v}(\nabla^{\mathbf{E}}_{\mathbf{X}}(f\,\mathbf{u}))=f\left[\mathbf{X}(\mathbf{v}(\mathbf{u}))-\mathbf{v}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\right]$$

shows that the right-hand side is linear over $C^\infty(M)$ in $\mathbf{u}$ and defines a smooth section of $\mathbf{E}^*$. Linearity over $C^\infty(M)$ in $\mathbf{X}$ and the rule $\nabla^{\mathbf{E}^*}_{\mathbf{X}}(f\,\mathbf{v})=\mathbf{X}(f)\mathbf{v}+f\nabla^{\mathbf{E}^*}_{\mathbf{X}}\mathbf{v}$ are verified directly. The pairing identity determines this connection uniquely.
The product connection on $\mathbf{E}^*\otimes\mathbf{E}$ induces the connection on $\mathrm{End}(\mathbf{E})$. Differentiating the identity $\mathbf{T}\mathbf{u}$ and

using the parallelism of the pairing gives

$$(\nabla_{\mathbf{X}}^{\mathrm{End}(\mathbf{E})}\mathbf{T})(\mathbf{u}) = \nabla_{\mathbf{X}}^{\mathbf{E}}(\mathbf{T}\mathbf{u}) - \mathbf{T}(\nabla_{\mathbf{X}}^{\mathbf{E}}\mathbf{u}).$$

The same argument on $\mathbf{E}^* \otimes \mathbf{F}$ gives

$$(\nabla_{\mathbf{X}}^{\mathrm{Hom}(\mathbf{E},\mathbf{F})}\mathbf{\Phi})(\mathbf{u}) = \nabla_{\mathbf{X}}^{\mathbf{F}}(\mathbf{\Phi}(\mathbf{u})) - \mathbf{\Phi}(\nabla_{\mathbf{X}}^{\mathbf{E}}\mathbf{u}).$$

These formulas also prove uniqueness in the last two cases. □

A connection can equivalently be defined as an operator between sections of certain vector bundles, as the following proposition shows. In global analysis, most authors use this equivalence in nearly every setting involving connections.

Proposition 2.4.25. Let M be a smooth manifold with or without boundary, and let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle. Giving a connection on $\mathbf{E}$ in the sense of Definition 2.4.2 is equivalent to giving an operator

$$\nabla\colon \Gamma(\mathbf{E}) \longrightarrow \Gamma\big(T^{(0,1)}(TM) \otimes \mathbf{E}\big),$$

that is linear over $\mathbb{R}$ and satisfies the Leibniz rule

$$\nabla(f\sigma) = df \otimes \sigma + f\nabla\sigma, \qquad f \in C^\infty(M), \sigma \in \Gamma(\mathbf{E}).$$

The relationship between the two formulations is described using the canonical isomorphism

$$\Upsilon : \Gamma\big(T^{(0,1)}(TM) \otimes \mathbf{E}\big) \xrightarrow{\cong} \mathrm{Hom}_{C^\infty(M)}\big(\mathfrak{X}(M), \Gamma(\mathbf{E})\big).$$

Under this identification, for $\mathbf{X} \in \mathfrak{X}(M)$ and $\sigma \in \Gamma(\mathbf{E})$, we have

$$\Upsilon(\nabla\sigma)(\mathbf{X}) = \nabla_{\mathbf{X}}\sigma.$$

Proof. By Proposition 1.10.14, applied to TM and $\mathbf{E}$, there is a canonical vector bundle isomorphism

$$\Phi : T^{(0,1)}(TM) \otimes \mathbf{E} \xrightarrow{\cong} \mathrm{Hom}(TM, \mathbf{E}), \qquad \Phi_p(\omega_p \otimes v)(\mathbf{X}_p) = \omega_p(\mathbf{X}_p)v,$$

for all $p \in M$, $\omega_p \in T_p^*M$, $v \in \mathbf{E}_p$, and $\mathbf{X}_p \in T_pM$.
Passing to sections gives

$$\Gamma(\Phi)\colon \Gamma\big(T^{(0,1)}(TM) \otimes \mathbf{E}\big) \longrightarrow \Gamma\big(\mathrm{Hom}(TM, \mathbf{E})\big), \qquad \big(\Gamma(\Phi)(\mathbf{s})\big)(p) = \Phi_p\big(\mathbf{s}(p)\big).$$

Composing with the identification of Proposition 1.7.31,

$$\Theta : \Gamma\big(\mathrm{Hom}(TM, \mathbf{E})\big) \xrightarrow{\cong} \mathrm{Hom}_{C^\infty(M)}\big(\mathfrak{X}(M), \Gamma(\mathbf{E})\big), \qquad \Theta(\mathbf{A})(\mathbf{X})(p) = \mathbf{A}(p)\big(\mathbf{X}_p\big),$$

we obtain the isomorphism of $C^\infty(M)$-modules

$$\Upsilon := \Theta \circ \Gamma(\Phi) : \Gamma\big(T^{(0,1)}(TM) \otimes \mathbf{E}\big) \xrightarrow{\cong} \mathrm{Hom}_{C^\infty(M)}\big(\mathfrak{X}(M), \Gamma(\mathbf{E})\big),$$

given explicitly by

$$\big(\Upsilon(\mathbf{s})\big)(\mathbf{X})(p) = \Theta\big(\Gamma(\Phi)(\mathbf{s})\big)(\mathbf{X})(p) = \Gamma(\Phi)(\mathbf{s})(p)\big(\mathbf{X}_p\big) = \Phi_p\big(\mathbf{s}(p)\big)\big(\mathbf{X}_p\big).$$

We denote its inverse by Υ^{-1}.
($\Rightarrow$) Suppose we have a connection in the sense of Definition 2.4.2. For fixed $\sigma \in \Gamma(\mathbf{E})$, the map

$$F_\sigma\colon\ \mathfrak{X}(M) \longrightarrow \Gamma(\mathbf{E}), \qquad \mathbf{X} \longmapsto \nabla_{\mathbf{X}}\sigma,$$

is $C^\infty(M)$-linear in $\mathbf{X}$. Therefore $F_\sigma \in \mathrm{Hom}_{C^\infty(M)}\big(\mathfrak{X}(M), \Gamma(\mathbf{E})\big)$ and, by the isomorphism Υ^{-1}, there exists a unique section $\mathbf{s} = \nabla\sigma \in \Gamma\big(T^{(0,1)}(TM)\otimes\mathbf{E}\big)$ such that

$$\Upsilon(\nabla\sigma)(\mathbf{X}) \ = \ \nabla_{\mathbf{X}}\sigma, \qquad \forall \mathbf{X} \in \mathfrak{X}(M).$$

In particular, for all $p \in M$ and $\mathbf{X}_p \in T_pM$,

$$\Phi_p\big((\nabla\sigma)(p)\big)(\mathbf{X}_p) \ = \ \nabla_{\mathbf{X}}\sigma(p).$$

Now let $f \in C^\infty(M)$. Using the Leibniz rule for the connection,

$$\Upsilon\big(\nabla(f\sigma)\big)(\mathbf{X}) = \nabla_{\mathbf{X}}(f\sigma) = (\mathbf{X}f)\sigma + f\nabla_{\mathbf{X}}\sigma.$$

On the other hand,

$$\Upsilon(df\otimes\sigma)(\mathbf{X})(p) = \Phi_p\big((df\otimes\sigma)(p)\big)(\mathbf{X}_p) = df_p(\mathbf{X}_p)\sigma(p) = (\mathbf{X}f)(p)\sigma(p),$$

and, since Υ is $C^\infty(M)$-linear,

$$\Upsilon(f\nabla\sigma)(\mathbf{X}) = f\cdot\Upsilon(\nabla\sigma)(\mathbf{X}) = f\nabla_{\mathbf{X}}\sigma.$$

Thus,

$$\Upsilon\big(\nabla(f\sigma)\big)(\mathbf{X}) = \Upsilon\big(df\otimes\sigma + f\nabla\sigma\big)(\mathbf{X}), \qquad \forall \mathbf{X} \in \mathfrak{X}(M).$$

Since Υ is an isomorphism, we conclude that

$$\nabla(f\sigma) = df\otimes\sigma + f\nabla\sigma.$$

($\Leftarrow$) Conversely, let $\nabla\colon \Gamma(\mathbf{E}) \longrightarrow \Gamma\big(T^{(0,1)}(TM)\otimes\mathbf{E}\big)$ be an operator linear over $\mathbb{R}$ satisfying

$$\nabla(f\sigma) = df\otimes\sigma + f\nabla\sigma.$$

For $\mathbf{X} \in \mathfrak{X}(M)$ and $\sigma \in \Gamma(\mathbf{E})$, define

$$\nabla_{\mathbf{X}}\sigma \ := \ \Upsilon(\nabla\sigma)(\mathbf{X}), \quad \text{that is} \quad \nabla_{\mathbf{X}}\sigma(p) = \Phi_p\big((\nabla\sigma)(p)\big)(\mathbf{X}_p).$$

Then $\nabla_{\mathbf{X}}$ is linear in σ. Moreover, using the Leibniz identity on sections and the $C^\infty(M)$-linearity of Υ,

$$\nabla_{\mathbf{X}}(f\sigma) = \Upsilon\big(\nabla(f\sigma)\big)(\mathbf{X}) = \Upsilon\big(df\otimes\sigma + f\nabla\sigma\big)(\mathbf{X}) = \Upsilon(df\otimes\sigma)(\mathbf{X}) + f\Upsilon(\nabla\sigma)(\mathbf{X}) = (\mathbf{X}f)\sigma + f\nabla_{\mathbf{X}}\sigma.$$

Finally, since $\Upsilon(\nabla\sigma) \in \mathrm{Hom}_{C^\infty(M)}(\mathfrak{X}(M), \Gamma(\mathbf{E}))$ is $C^\infty(M)$-linear in $\mathbf{X}$, we have

$$\nabla_{f\mathbf{X}}\sigma = \Upsilon(\nabla\sigma)(f\mathbf{X}) = f\Upsilon(\nabla\sigma)(\mathbf{X}) = f\nabla_{\mathbf{X}}\sigma.$$

Therefore $(\mathbf{X}, \sigma) \mapsto \nabla_{\mathbf{X}}\sigma$ satisfies the properties of Definition 2.4.2 and defines a connection.

□

Since the two approaches are equivalent, we will sometimes use the two descriptions of a connection interchangeably.

Example 2.4.26. (Trivial connection) Let M be a smooth manifold with or without boundary, and let $\underline{\mathbb{R}}^k_M = M \times \mathbb{R}^k$ be the trivial bundle of rank k over M. The space of sections $\Gamma(\underline{\mathbb{R}}^k_M)$ agrees with the space $C^\infty(M, \mathbb{R}^k)$ of smooth functions taking values in $\mathbb{R}^k$, and we have $(\underline{\mathbb{R}}^k_M)_p \cong \mathbb{R}^k$ (the fiber spaces of the trivial bundle).
Let $(e_1, \dots, e_k)$ be the canonical basis of $\mathbb{R}^k$, and denote the corresponding constant sections by $\mathbf{e}_i(p) := (p, e_i)$. If $\sigma = (\sigma_1, \dots, \sigma_k) \in C^\infty(M, \mathbb{R}^k)$, define

$$\nabla\sigma \;:=\; \sum_{i=1}^{k} d\sigma_i \otimes \mathbf{e}_i \;\in\; \Gamma\big(T^*M \otimes \underline{\mathbb{R}}^k_M\big).$$

In other words, for each $p \in M$,

$$(\nabla\sigma)(p) \;=\; \sum_{i=1}^{k} d\sigma_i(p) \otimes \mathbf{e}_i(p) \;\in\; T^*_pM \otimes \mathbb{R}^k.$$

If $\mathbf{X} \in \mathfrak{X}(M)$ is a vector field, then

$$(\nabla\sigma)_p(\mathbf{X}) \;=\; \sum_{i=1}^{k} d\sigma_i(p)(\mathbf{X}_p)\mathbf{e}_i(p) = \; (\mathbf{X}\sigma_1(p), \dots, \mathbf{X}\sigma_k(p)),$$

that is, the result is obtained by differentiating the section σ coordinate by coordinate.
The Leibniz rule is verified directly: for $f \in C^\infty(M)$,

$$\nabla(f\sigma) = \sum_{i=1}^{k} d(f\sigma_i) \otimes \mathbf{e}_i = \sum_{i=1}^{k} \big((df)\sigma_i + f\,d\sigma_i\big) \otimes \mathbf{e}_i = df \otimes \sigma + f\nabla\sigma.$$

Therefore ∇ defines a connection on $\underline{\mathbb{R}}^k_M$, called the *trivial connection*.

Connections and bundle metrics must be compatible with tensor operations. The following constructions allow us to differentiate tensors, duals, and homomorphisms, and will be needed to define Sobolev spaces of sections.

Proposition 2.4.27. (Induced connections on tensor products, duals, and homomorphisms) Let M be a smooth manifold with or without boundary, and let $\mathbf{E}, \mathbf{F} \to M$ be smooth vector bundles with connections $\nabla^{\mathbf{E}}$ and $\nabla^{\mathbf{F}}$.

(a) There exists a unique connection $\nabla^{\mathbf{E}\otimes\mathbf{F}}$ on $\mathbf{E}\otimes\mathbf{F}$ such that, for any $\mathbf{X}\in\mathfrak{X}(M)$, $\mathbf{u}\in\Gamma(\mathbf{E})$, and $\mathbf{v}\in\Gamma(\mathbf{F})$,

$$\nabla^{\mathbf{E}\otimes\mathbf{F}}_{\mathbf{X}}(\mathbf{u}\otimes\mathbf{v}) = (\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{v} + \mathbf{u}\otimes(\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{v}). \tag{2.11}$$

(b) There exists a unique connection $\nabla^{\mathbf{E}^*}$ on the dual bundle $\mathbf{E}^*$ characterized by

$$\mathbf{X}\big(\boldsymbol{\alpha}(\mathbf{u})\big) = (\nabla^{\mathbf{E}^*}_{\mathbf{X}}\boldsymbol{\alpha})(\mathbf{u}) + \boldsymbol{\alpha}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}) \tag{2.12}$$

for any $\mathbf{X}\in\mathfrak{X}(M)$, $\boldsymbol{\alpha}\in\Gamma(\mathbf{E}^*)$, and $\mathbf{u}\in\Gamma(\mathbf{E})$.

(c) The bundle $\operatorname{Hom}(\mathbf{E},\mathbf{F})\cong\mathbf{E}^*\otimes\mathbf{F}$ has the induced connection determined by

$$(\nabla^{\operatorname{Hom}(\mathbf{E},\mathbf{F})}_{\mathbf{X}}\mathbf{T})(\mathbf{u}) = \nabla^{\mathbf{F}}_{\mathbf{X}}(\mathbf{T}\mathbf{u}) - \mathbf{T}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}). \tag{2.13}$$

In particular, taking $\mathbf{F}=\mathbf{E}$ gives the connection on $\operatorname{End}(\mathbf{E})$ and

$$(\nabla^{\operatorname{End}(\mathbf{E})}_{\mathbf{X}}\mathbf{T})(\mathbf{u}) = [\nabla^{\mathbf{E}}_{\mathbf{X}},\mathbf{T}]\mathbf{u}.$$

These constructions are compatible with iterated tensor products and with the canonical identifications between tensor bundles.

Proof. We begin with the tensor product. On a trivializing open set U, every section of $\mathbf{E}\otimes\mathbf{F}$ is a finite sum of simple tensor sections. Define the right-hand side of (2.11) on these sections and extend it by additivity. We must check that the definition respects the balancing relations of the tensor product. For $f\in C^\infty(U)$,

$$\begin{aligned}&\nabla^{\mathbf{E}\otimes\mathbf{F}}_{\mathbf{X}}((f\mathbf{u})\otimes\mathbf{v})\\ &\quad= \mathbf{X}(f)\mathbf{u}\otimes\mathbf{v} + f(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{v} + f\mathbf{u}\otimes\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{v},\end{aligned}$$

whereas

$$\begin{aligned}&\nabla^{\mathbf{E}\otimes\mathbf{F}}_{\mathbf{X}}(\mathbf{u}\otimes(f\mathbf{v}))\\ &\quad= (\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes f\mathbf{v} + \mathbf{u}\otimes\mathbf{X}(f)\mathbf{v} + \mathbf{u}\otimes f\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{v}.\end{aligned}$$

The two expressions agree after using $(f\mathbf{u})\otimes\mathbf{v}=\mathbf{u}\otimes(f\mathbf{v})$. The definition is therefore independent of the representation of a section as a sum of simple tensors. The properties

$$\nabla^{\mathbf{E}\otimes\mathbf{F}}_{f\mathbf{X}}\mathbf{S} = f\nabla^{\mathbf{E}\otimes\mathbf{F}}_{\mathbf{X}}\mathbf{S}$$

and

$$\nabla^{\mathbf{E}\otimes\mathbf{F}}_{\mathbf{X}}(f\mathbf{S}) = \mathbf{X}(f)\mathbf{S} + f\nabla^{\mathbf{E}\otimes\mathbf{F}}_{\mathbf{X}}\mathbf{S}$$

are checked first on simple tensors and then by additivity. This proves existence of the connection. Uniqueness follows because simple tensor sections locally generate the module of sections of $\mathbf{E}\otimes\mathbf{F}$.
For the dual bundle, define, for $\boldsymbol{\alpha}\in\Gamma(\mathbf{E}^*)$,

$$(\nabla^{\mathbf{E}^*}_{\mathbf{X}}\boldsymbol{\alpha})(\mathbf{u}) := \mathbf{X}\big(\boldsymbol{\alpha}(\mathbf{u})\big) - \boldsymbol{\alpha}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}). \tag{2.14}$$

The right-hand side is $C^\infty(M)$-linear in $\mathbf{u}$. For $f \in C^\infty(M)$,

$$\begin{aligned}
&\mathbf{X}\big(\boldsymbol{\alpha}(f\mathbf{u})\big) - \boldsymbol{\alpha}(\nabla^{\mathbf{E}}_{\mathbf{X}}(f\mathbf{u})) \\
&\quad = \mathbf{X}(f)\boldsymbol{\alpha}(\mathbf{u}) + f\mathbf{X}\big(\boldsymbol{\alpha}(\mathbf{u})\big) - \mathbf{X}(f)\boldsymbol{\alpha}(\mathbf{u}) - f\,\boldsymbol{\alpha}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}) \\
&\quad = f\left[\mathbf{X}\big(\boldsymbol{\alpha}(\mathbf{u})\big) - \boldsymbol{\alpha}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\right].
\end{aligned}$$

Thus (2.14) defines a section of $\mathbf{E}^*$. The $C^\infty(M)$-linearity in $\mathbf{X}$ and the Leibniz rule in $\boldsymbol{\alpha}$ follow directly from the same formula. By construction, (2.12) holds, and this identity determines $\nabla^{\mathbf{E}^*}$ uniquely.

Now identify $\operatorname{Hom}(\mathbf{E},\mathbf{F})$ with $\mathbf{E}^* \otimes \mathbf{F}$ and use the product connection already constructed. If locally $\mathbf{T} = \sum_{a=1}^{N} \boldsymbol{\alpha}_a \otimes \mathbf{v}_a$, then

$$\mathbf{T}\mathbf{u} = \sum_{a=1}^{N} \boldsymbol{\alpha}_a(\mathbf{u})\mathbf{v}_a.$$

The Leibniz rules and (2.12) give

$$\begin{aligned}
\nabla^{\mathbf{F}}_{\mathbf{X}}(\mathbf{T}\mathbf{u}) = &\sum_{a=1}^{N} (\nabla^{\mathbf{E}^*}_{\mathbf{X}}\boldsymbol{\alpha}_a)(\mathbf{u})\mathbf{v}_a + \sum_{a=1}^{N} \boldsymbol{\alpha}_a(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\mathbf{v}_a \\
&+ \sum_{a=1}^{N} \boldsymbol{\alpha}_a(\mathbf{u})\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{v}_a.
\end{aligned}$$

The first and third terms combine to give $(\nabla^{\operatorname{Hom}(\mathbf{E},\mathbf{F})}_{\mathbf{X}}\mathbf{T})(\mathbf{u})$, while the second is $\mathbf{T}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})$. This proves (2.13). The endomorphism case is the specialization $\mathbf{F} = \mathbf{E}$. Finally, iterations are obtained by successively applying the tensor product construction, and their compatibility with the canonical identifications follows from the uniqueness just proved. □

Lemma 2.4.28. Let M be a smooth manifold with or without boundary equipped with a connection ∇ on TM, and let $\pi_{\mathbf{E}}\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle of rank r equipped with a connection $\nabla^{\mathbf{E}}$. Let $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ be a local frame of TM over an open set $U \subseteq M$, $(\boldsymbol{\varepsilon}^1,\dots,\boldsymbol{\varepsilon}^n)$ its dual coframe, and $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ a local frame of $\mathbf{E}\restriction_U$.

Let $\mathbf{F} \in \Gamma(T^{(k,l)}(TM)\otimes\mathbf{E})$ be written in these frames as

$$\mathbf{F} = \sum_{\substack{1\le i_1,\dots,i_k\le n\\ 1\le j_1,\dots,j_l\le n\\ 1\le a\le r}} F^{i_1\dots i_k\,a}_{j_1\dots j_l}\,\mathbf{E}_{i_1}\otimes\cdots\otimes\mathbf{E}_{i_k}\otimes\boldsymbol{\varepsilon}^{j_1}\otimes\cdots\otimes\boldsymbol{\varepsilon}^{j_l}\otimes\mathbf{e}_a.$$

Then, for each $c \in \{1,\dots,n\}$, the components of the covariant derivative

$$\nabla_{\partial_c}\mathbf{F} := \big(\nabla^{\mathbf{T}^{(k,l)}\otimes\mathbf{E}}\big)_{\partial_c}\mathbf{F}$$

are given by

$$(\nabla_{\partial_c}\mathbf{F})^{i_1\dots i_k\,a}_{j_1\dots j_l} = \partial_c\big(F^{i_1\dots i_k\,a}_{j_1\dots j_l}\big) + \sum_{r=1}^{k}\Gamma^{i_r}_{cs}\,F^{i_1\dots s\dots i_k\,a}_{j_1\dots j_l} - \sum_{t=1}^{l}\Gamma^{s}_{cj_t}\,F^{i_1\dots i_k\,a}_{j_1\dots s\dots j_l} + \sum_{b=1}^{r}(A_c)^a_b\,F^{i_1\dots i_k\,b}_{j_1\dots j_l},$$

where $\nabla_{\partial_c}\mathbf{E}_i = \Gamma_{ci}^s \mathbf{E}_s$ and $\nabla^{\mathbf{E}}_{\partial_c}\mathbf{e}_b = (A_c)_b^a \mathbf{e}_a$.

Proof. By Proposition 2.4.24, the connection ∇ on TM induces a connection on $T^{(k,l)}(TM)$ characterized by the product rule for the contravariant and covariant factors. In the frame

$$\left\{\mathbf{E}_{i_1}\otimes\cdots\otimes\mathbf{E}_{i_k}\otimes\boldsymbol{\varepsilon}^{j_1}\otimes\cdots\otimes\boldsymbol{\varepsilon}^{j_l}\right\}$$

we have, for every $\mathbf{T}\in\Gamma\left(T^{(k,l)}(TM)\right)$,

$$(\nabla_{\partial_c}\mathbf{T})^{i_1\ldots i_k}_{j_1\ldots j_l} = \partial_c\left(T^{i_1\ldots i_k}_{j_1\ldots j_l}\right) + \sum_{r=1}^{k}\Gamma^{i_r}_{cs}\,T^{i_1\ldots s\ldots i_k}_{j_1\ldots j_l} - \sum_{t=1}^{l}\Gamma^{s}_{cj_t}\,T^{i_1\ldots i_k}_{j_1\ldots s\ldots j_l}.$$

Now write $\mathbf{F} = \sum_{a=1}^{r}\mathbf{F}^{(a)}\otimes\mathbf{e}_a$, where, for each $a\in\{1,\ldots,r\}$, the tensor field $\mathbf{F}^{(a)}\in\Gamma\left(T^{(k,l)}(TM)\right)$ has components $\left(\mathbf{F}^{(a)}\right)^{i_1\ldots i_k}_{j_1\ldots j_l} = F^{i_1\ldots i_k\,a}_{j_1\ldots j_l}$.
The induced connection on $T^{(k,l)}(TM)\otimes\mathbf{E}$ is determined by

$$\nabla_{\partial_c}(\mathbf{S}\otimes\boldsymbol{\sigma}) = (\nabla_{\partial_c}\mathbf{S})\otimes\boldsymbol{\sigma} + \mathbf{S}\otimes\nabla^{\mathbf{E}}_{\partial_c}\boldsymbol{\sigma}, \qquad \mathbf{S}\in\Gamma\left(T^{(k,l)}(TM)\right),\ \boldsymbol{\sigma}\in\Gamma(\mathbf{E}),$$

so, for $\mathbf{F} = \sum_{a=1}^{r}\mathbf{F}^{(a)}\otimes\mathbf{e}_a$, we obtain

$$\nabla_{\partial_c}\mathbf{F} = \sum_{a=1}^{r}\left((\nabla_{\partial_c}\mathbf{F}^{(a)})\otimes\mathbf{e}_a + \mathbf{F}^{(a)}\otimes\nabla^{\mathbf{E}}_{\partial_c}\mathbf{e}_a\right).$$

In the frame $(\mathbf{E}_1,\ldots,\mathbf{E}_n)$, we have $\nabla_{\partial_c}\mathbf{E}_i = \Gamma_{ci}^s\mathbf{E}_s$, and, by the definition of the coefficients of the connection $\nabla^{\mathbf{E}}$ in the frame $(\mathbf{e}_1,\ldots,\mathbf{e}_r)$, $\nabla^{\mathbf{E}}_{\partial_c}\mathbf{e}_b = (A_c)_b^a\mathbf{e}_a$.
Applying Lemma 2.4.15 to each $\mathbf{F}^{(a)}$ gives

$$(\nabla_{\partial_c}\mathbf{F}^{(a)})^{i_1\ldots i_k}_{j_1\ldots j_l} = \partial_c\left(F^{i_1\ldots i_k\,a}_{j_1\ldots j_l}\right) + \sum_{r=1}^{k}\Gamma^{i_r}_{cs}\,F^{i_1\ldots s\ldots i_k\,a}_{j_1\ldots j_l} - \sum_{t=1}^{l}\Gamma^{s}_{cj_t}\,F^{i_1\ldots i_k\,a}_{j_1\ldots s\ldots j_l}.$$

On the other hand, using the local expression for the connection on $\mathbf{E}$, $\nabla^{\mathbf{E}}_{\partial_c}\mathbf{e}_a = \sum_{b=1}^{r}(A_c)_a^b\mathbf{e}_b$, we obtain

$$\mathbf{F}^{(a)}\otimes\nabla^{\mathbf{E}}_{\partial_c}\mathbf{e}_a = \sum_{b=1}^{r}(A_c)_a^b\left(\mathbf{F}^{(a)}\otimes\mathbf{e}_b\right).$$

Each of these terms is expressed in the basis

$$\left\{\mathbf{E}_{i_1}\otimes\cdots\otimes\mathbf{E}_{i_k}\otimes\boldsymbol{\varepsilon}^{j_1}\otimes\cdots\otimes\boldsymbol{\varepsilon}^{j_l}\otimes\mathbf{e}_a\right\},$$

since $\mathbf{F}^{(a)}\otimes\mathbf{e}_b = F^{i_1\ldots i_k\,a}_{j_1\ldots j_l}\,\mathbf{E}_{i_1}\otimes\cdots\otimes\mathbf{E}_{i_k}\otimes\boldsymbol{\varepsilon}^{j_1}\otimes\cdots\otimes\boldsymbol{\varepsilon}^{j_l}\otimes\mathbf{e}_b$.

Consequently, the term $\mathbf{F}^{(a)} \otimes \nabla^{\mathbf{E}}_{\partial_c} \mathbf{e}_a$ contributes the sum

$$\sum_{b=1}^{r} (A_c)^a_b \, F^{i_1 \dots i_k \, b}_{j_1 \dots j_l}.$$

to the components with output index a.
To obtain the components of $\nabla_{\partial_c} \mathbf{F}$, we now need only fix $a \in \{1, \dots, r\}$ and add the contributions of the two preceding blocks to the basis tensor with last factor $\mathbf{e}_a$:

- the block $(\nabla_{\partial_c} \mathbf{F}^{(a)}) \otimes \mathbf{e}_a$ contributes

$$\mathbf{E}_c \big(F^{i_1 \dots i_k \, a}_{j_1 \dots j_l} \big) + \sum_{r=1}^{k} \Gamma^{i_r}_{cs} \, F^{i_1 \dots s \dots i_k \, a}_{j_1 \dots j_l} - \sum_{t=1}^{l} \Gamma^{s}_{c j_t} \, F^{i_1 \dots i_k \, a}_{j_1 \dots s \dots j_l},$$

- and the block $\mathbf{F}^{(b)} \otimes \nabla^{\mathbf{E}}_{\partial_c} \mathbf{e}_b$ contributes

$$\sum_{b=1}^{r} (A_c)^a_b \, F^{i_1 \dots i_k \, b}_{j_1 \dots j_l}.$$

Grouping these contributions gives

$$(\nabla_{\partial_c} \mathbf{F})^{i_1 \dots i_k \, a}_{j_1 \dots j_l} = \partial_c \big(F^{i_1 \dots i_k \, a}_{j_1 \dots j_l} \big) + \sum_{r=1}^{k} \Gamma^{i_r}_{cs} \, F^{i_1 \dots s \dots i_k \, a}_{j_1 \dots j_l} - \sum_{t=1}^{l} \Gamma^{s}_{c j_t} \, F^{i_1 \dots i_k \, a}_{j_1 \dots s \dots j_l} + \sum_{b=1}^{r} (A_c)^a_b \, F^{i_1 \dots i_k \, b}_{j_1 \dots j_l},$$

which is the desired formula. □

Proposition 2.4.29. (Formulas for the second and third covariant derivatives) Let M be a smooth manifold with or without boundary equipped with a connection ∇^M on TM, and let $\mathbf{E} \to M$ be a smooth vector bundle with a connection $\nabla^{\mathbf{E}}$. On the bundles $T^{(0,q)}(TM) \otimes \mathbf{E}$, use the product connections induced by ∇^M and $\nabla^{\mathbf{E}}$. For $\mathbf{u} \in \Gamma(\mathbf{E})$, define

$$\nabla^0 \mathbf{u} := \mathbf{u}, \qquad \nabla^{q+1} \mathbf{u} := \nabla(\nabla^q \mathbf{u}), \qquad q \in \mathbb{N}_0.$$

Thus,

$$\nabla^q \mathbf{u} \in \Gamma\big(T^{(0,q)}(TM) \otimes \mathbf{E}\big),$$

and the new covariant index introduced at each step is placed in the first argument. Equivalently,

$$(\nabla^{q+1} \mathbf{u})(\mathbf{X}_0, \mathbf{X}_1, \dots, \mathbf{X}_q) = \big(\nabla_{\mathbf{X}_0}(\nabla^q \mathbf{u})\big)(\mathbf{X}_1, \dots, \mathbf{X}_q).$$

In particular, for any $\mathbf{X}, \mathbf{Y} \in \mathfrak{X}(M)$,

$$(\nabla^2 \mathbf{u})(\mathbf{X}, \mathbf{Y}) = \nabla^{\mathbf{E}}_{\mathbf{X}} \nabla^{\mathbf{E}}_{\mathbf{Y}} \mathbf{u} - \nabla^{\mathbf{E}}_{\nabla^M_{\mathbf{X}} \mathbf{Y}} \mathbf{u}. \tag{2.15}$$

Moreover, for any $\mathbf{X}, \mathbf{Y}, \mathbf{Z} \in \mathfrak{X}(M)$,

$$\begin{aligned} (\nabla^3 \mathbf{u})(\mathbf{X}, \mathbf{Y}, \mathbf{Z}) = {} & \nabla^{\mathbf{E}}_{\mathbf{X}} \nabla^{\mathbf{E}}_{\mathbf{Y}} \nabla^{\mathbf{E}}_{\mathbf{Z}} \mathbf{u} - \nabla^{\mathbf{E}}_{\mathbf{X}} \nabla^{\mathbf{E}}_{\nabla^M_{\mathbf{Y}} \mathbf{Z}} \mathbf{u} - \nabla^{\mathbf{E}}_{\nabla^M_{\mathbf{X}} \mathbf{Y}} \nabla^{\mathbf{E}}_{\mathbf{Z}} \mathbf{u} \\ & + \nabla^{\mathbf{E}}_{\nabla^M_{\mathbf{X}} \nabla^M_{\mathbf{Y}} \mathbf{Z}} \mathbf{u} - \nabla^{\mathbf{E}}_{\mathbf{Y}} \nabla^{\mathbf{E}}_{\nabla^M_{\mathbf{X}} \mathbf{Z}} \mathbf{u} + \nabla^{\mathbf{E}}_{\nabla^M_{\mathbf{Y}} \nabla^M_{\mathbf{X}} \mathbf{Z}} \mathbf{u}. \end{aligned} \tag{2.16}$$

Proof. The first covariant derivative is interpreted as the 1-form with values in $\mathbf{E}$ given by

$$(\nabla \mathbf{u})(\mathbf{X}) = \nabla^{\mathbf{E}}_{\mathbf{X}} \mathbf{u}.$$

The product connection on $T^*M \otimes \mathbf{E}$ satisfies the Leibniz rule for evaluation. Hence,

$$\begin{aligned}(\nabla^2 \mathbf{u})(\mathbf{X},\mathbf{Y}) &= \big(\nabla_{\mathbf{X}}(\nabla \mathbf{u})\big)(\mathbf{Y}) = \nabla^{\mathbf{E}}_{\mathbf{X}}\big((\nabla \mathbf{u})(\mathbf{Y})\big) - (\nabla \mathbf{u})(\nabla^M_{\mathbf{X}} \mathbf{Y}) \\ &= \nabla^{\mathbf{E}}_{\mathbf{X}} \nabla^{\mathbf{E}}_{\mathbf{Y}} \mathbf{u} - \nabla^{\mathbf{E}}_{\nabla^M_{\mathbf{X}} \mathbf{Y}} \mathbf{u}.\end{aligned}$$

which proves (2.15).
For the third order, regard $\nabla^2 \mathbf{u}$ as a 2-covariant tensor with values in $\mathbf{E}$. The definition of the induced connection gives

$$(\nabla^3 \mathbf{u})(\mathbf{X},\mathbf{Y},\mathbf{Z}) = \nabla^{\mathbf{E}}_{\mathbf{X}}\big((\nabla^2 \mathbf{u})(\mathbf{Y},\mathbf{Z})\big) - (\nabla^2 \mathbf{u})(\nabla^M_{\mathbf{X}} \mathbf{Y},\mathbf{Z}) - (\nabla^2 \mathbf{u})(\mathbf{Y},\nabla^M_{\mathbf{X}} \mathbf{Z}). \tag{2.17}$$

Expand the three terms separately. By (2.15),

$$\nabla^{\mathbf{E}}_{\mathbf{X}}\big((\nabla^2 \mathbf{u})(\mathbf{Y},\mathbf{Z})\big) = \nabla^{\mathbf{E}}_{\mathbf{X}} \nabla^{\mathbf{E}}_{\mathbf{Y}} \nabla^{\mathbf{E}}_{\mathbf{Z}} \mathbf{u} - \nabla^{\mathbf{E}}_{\mathbf{X}} \nabla^{\mathbf{E}}_{\nabla^M_{\mathbf{Y}} \mathbf{Z}} \mathbf{u}.$$

Likewise,

$$(\nabla^2 \mathbf{u})(\nabla^M_{\mathbf{X}} \mathbf{Y},\mathbf{Z}) = \nabla^{\mathbf{E}}_{\nabla^M_{\mathbf{X}} \mathbf{Y}} \nabla^{\mathbf{E}}_{\mathbf{Z}} \mathbf{u} - \nabla^{\mathbf{E}}_{\nabla^M_{\nabla^M_{\mathbf{X}} \mathbf{Y}} \mathbf{Z}} \mathbf{u},$$

and

$$(\nabla^2 \mathbf{u})(\mathbf{Y},\nabla^M_{\mathbf{X}} \mathbf{Z}) = \nabla^{\mathbf{E}}_{\mathbf{Y}} \nabla^{\mathbf{E}}_{\nabla^M_{\mathbf{X}} \mathbf{Z}} \mathbf{u} - \nabla^{\mathbf{E}}_{\nabla^M_{\mathbf{Y}} \nabla^M_{\mathbf{X}} \mathbf{Z}} \mathbf{u}.$$

Substituting these three identities into (2.17), keeping the two negative signs in its second line, yields exactly (2.16). □

Remark 2.4.30. (On the use of normal coordinates at third order) Even if normal coordinates centered at a point p are chosen, the identity

$$(\nabla^2 \mathbf{u})(\mathbf{X},\mathbf{Y})(p) = \nabla^{\mathbf{E}}_{\mathbf{X}} \nabla^{\mathbf{E}}_{\mathbf{Y}} \mathbf{u}(p)$$

holds only for extensions of $\mathbf{X}$ and $\mathbf{Y}$ whose first covariant derivatives vanish at p. It cannot be differentiated as though it were an equality valid in a neighborhood of p. Indeed, formula (2.16) contains terms with second covariant derivatives of the auxiliary fields, such as $\nabla^M_{\mathbf{Y}} \nabla^M_{\mathbf{X}} \mathbf{Z}$, which do not vanish merely because normal coordinates were chosen. For this reason, when contracting or commuting higher-order covariant derivatives, we will first establish tensor identities and only then evaluate them in a normal frame. The operators obtained by such contractions will be defined in the chapter on differential operators on bundles.

Lemma 2.4.31. (Leibniz rule for interior multiplication) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary equipped with a connection ∇ on TM. Let $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ be a smooth local frame of TM with dual coframe $(\varepsilon^1,\dots,\varepsilon^n)$. Let $\mathbf{E} \to M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$.
For every tensor

$$\mathbf{F} \in \Gamma\big(T^{(k,l+1)}(TM) \otimes \mathbf{E}\big),$$

we have

$$\nabla_a\big(\iota_{\mathbf{E}_a}\mathbf{F}\big) = \iota_{\nabla_a\mathbf{E}_a}\mathbf{F} + \iota_{\mathbf{E}_a}(\nabla_a\mathbf{F}),$$

where $\nabla_a = \nabla_{\mathbf{E}_a}$ is the total connection on $T^{(k,l+1)}(TM)\otimes\mathbf{E}$, and $\iota_{\mathbf{E}_a}$ acts only on the covariant block of the tensor.

Proof. The identity holds for each index a before Einstein summation is performed. Fix a point p, and evaluate both sides on arbitrary covectors and vectors in the remaining indices of $\mathbf{F}$. Extend these arguments locally so that their covariant derivatives in the direction $\mathbf{E}_a$ vanish at p. By the definitions of the induced connection and contraction,

$$\big(\iota_{\mathbf{E}_a}\mathbf{F}\big)(\omega^1,\dots,\omega^k,\mathbf{X}_1,\dots,\mathbf{X}_l) = \mathbf{F}(\omega^1,\dots,\omega^k,\mathbf{E}_a,\mathbf{X}_1,\dots,\mathbf{X}_l).$$

Differentiating this equality in the direction $\mathbf{E}_a$ and evaluating at p, the Leibniz rule for the connection produces exactly two terms:

$$\begin{aligned}\nabla_a\big(\iota_{\mathbf{E}_a}\mathbf{F}\big)(\omega^1,\dots,\mathbf{X}_l) = \mathbf{F}(\omega^1,\dots,\nabla_a\mathbf{E}_a,\mathbf{X}_1,\dots,\mathbf{X}_l)\\ + (\nabla_a\mathbf{F})(\omega^1,\dots,\mathbf{E}_a,\mathbf{X}_1,\dots,\mathbf{X}_l).\end{aligned}$$

The first summand is $\big(\iota_{\nabla_a\mathbf{E}_a}\mathbf{F}\big)(\omega^1,\dots,\mathbf{X}_l)$ and the second is $\big(\iota_{\mathbf{E}_a}\nabla_a\mathbf{F}\big)(\omega^1,\dots,\mathbf{X}_l)$. Since the point and arguments were arbitrary, we obtain the tensor identity; summing over a gives the formula in the statement. □

Consider the following Leibniz rule:

Proposition 2.4.32. (Leibniz rule for $(0,2)$ tensors) Let M be a smooth manifold with or without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$. If $\mathbf{T}\in\Gamma(\mathbf{E}^*\otimes\mathbf{E}^*)$, then, for every $\mathbf{u},\mathbf{v}\in\Gamma(\mathbf{E})$ and every $\mathbf{X}\in\mathfrak{X}(M)$, we have

$$\mathbf{X}\big(\mathbf{T}(\mathbf{u},\mathbf{v})\big) = (\nabla^{\mathbf{E}^*\otimes\mathbf{E}^*}_{\mathbf{X}}\mathbf{T})(\mathbf{u},\mathbf{v}) + \mathbf{T}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u},\mathbf{v}) + \mathbf{T}(\mathbf{u},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{v}).$$

Proof. By definition, for $\mathbf{u},\mathbf{v}\in\Gamma(\mathbf{E})$ the function $\mathbf{T}(\mathbf{u},\mathbf{v})\in C^\infty(M)$ is given by

$$\mathbf{T}(\mathbf{u},\mathbf{v})(p) = \mathbf{T}_p(\mathbf{u}_p,\mathbf{v}_p), \qquad p\in M.$$

Since $\Gamma(\mathbf{E}^*\otimes\mathbf{E}^*)$ is a $C^\infty(M)$-module generated by simple tensors, it suffices to prove the identity when $\mathbf{T}=\boldsymbol{\alpha}\otimes\boldsymbol{\beta}$ with $\boldsymbol{\alpha},\boldsymbol{\beta}\in\Gamma(\mathbf{E}^*)$ and then conclude by linearity. In this case,

$$\mathbf{T}(\mathbf{u},\mathbf{v}) = \langle\boldsymbol{\alpha},\mathbf{u}\rangle\langle\boldsymbol{\beta},\mathbf{v}\rangle.$$

Applying the product rule for functions and the characterization of the induced connection on the dual (Proposition 2.4.27),

$$\begin{aligned}\mathbf{X}\big(\mathbf{T}(\mathbf{u},\mathbf{v})\big) &= \mathbf{X}\big(\langle\boldsymbol{\alpha},\mathbf{u}\rangle\langle\boldsymbol{\beta},\mathbf{v}\rangle\big)\\ &= \mathbf{X}\langle\boldsymbol{\alpha},\mathbf{u}\rangle\langle\boldsymbol{\beta},\mathbf{v}\rangle + \langle\boldsymbol{\alpha},\mathbf{u}\rangle\mathbf{X}\langle\boldsymbol{\beta},\mathbf{v}\rangle\\ &= \big(\langle\nabla^{\mathbf{E}^*}_{\mathbf{X}}\boldsymbol{\alpha},\mathbf{u}\rangle + \langle\boldsymbol{\alpha},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}\rangle\big)\langle\boldsymbol{\beta},\mathbf{v}\rangle + \langle\boldsymbol{\alpha},\mathbf{u}\rangle\big(\langle\nabla^{\mathbf{E}^*}_{\mathbf{X}}\boldsymbol{\beta},\mathbf{v}\rangle + \langle\boldsymbol{\beta},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{v}\rangle\big)\end{aligned}$$

$$= \underbrace{\langle \nabla^{\mathbf{E}^*}_{\mathbf{X}} \boldsymbol{\alpha}, \mathbf{u}\rangle\langle \boldsymbol{\beta}, \mathbf{v}\rangle + \langle \boldsymbol{\alpha}, \mathbf{u}\rangle\langle \nabla^{\mathbf{E}^*}_{\mathbf{X}} \boldsymbol{\beta}, \mathbf{v}\rangle}_{(\nabla^{\mathbf{E}^*\otimes\mathbf{E}^*}_{\mathbf{X}}(\boldsymbol{\alpha}\otimes\boldsymbol{\beta}))(\mathbf{u},\mathbf{v}) \text{ by Proposition 2.4.27.}} + \underbrace{\langle \boldsymbol{\alpha}, \nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}\rangle\langle \boldsymbol{\beta}, \mathbf{v}\rangle}_{\mathbf{T}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u},\mathbf{v})} + \underbrace{\langle \boldsymbol{\alpha}, \mathbf{u}\rangle\langle \boldsymbol{\beta}, \nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{v}\rangle}_{\mathbf{T}(\mathbf{u},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{v})}.$$

Consequently,

$$\mathbf{X}\big(\mathbf{T}(\mathbf{u},\mathbf{v})\big) = (\nabla^{\mathbf{E}^*\otimes\mathbf{E}^*}_{\mathbf{X}}\mathbf{T})(\mathbf{u},\mathbf{v}) + \mathbf{T}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u},\mathbf{v}) + \mathbf{T}(\mathbf{u},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{v})$$

for $\mathbf{T} = \boldsymbol{\alpha}\otimes\boldsymbol{\beta}$. By linearity of every term, the equality extends to all $\mathbf{T} \in \Gamma(\mathbf{E}^*\otimes\mathbf{E}^*)$. □

This Leibniz rule motivates the following more general concept, which describes when a bundle homomorphism respects the structures given by the connection.

Definition 2.4.33. (Parallel smooth bundle homomorphisms) Let M be a smooth manifold with or without boundary, and let $\mathbf{E},\mathbf{F},\mathbf{G} \to M$ be smooth vector bundles with connections $\nabla^{\mathbf{E}},\nabla^{\mathbf{F}},\nabla^{\mathbf{G}}$. A smooth bundle homomorphism $\Phi\colon \mathbf{E}\otimes\mathbf{F} \longrightarrow \mathbf{G}$ is said to be parallel if, for all $\mathbf{u} \in \Gamma(\mathbf{E})$, $\mathbf{v} \in \Gamma(\mathbf{F})$, and $\mathbf{X} \in \mathfrak{X}(M)$, we have

$$\nabla^{\mathbf{G}}_{\mathbf{X}}\big(\Phi(\mathbf{u}\otimes\mathbf{v})\big) = \Phi\big((\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{v}\big) + \Phi\big(\mathbf{u}\otimes(\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{v})\big).$$

This can be written equivalently as shown in the following proposition:

Proposition 2.4.34. Let M be a smooth manifold with or without boundary, and let $\mathbf{E},\mathbf{F},\mathbf{G} \to M$ be smooth vector bundles with connections $\nabla^{\mathbf{E}},\nabla^{\mathbf{F}},\nabla^{\mathbf{G}}$. Let

$$\Phi\colon \mathbf{E}\otimes\mathbf{F} \longrightarrow \mathbf{G}$$

be a smooth bundle homomorphism. Then Φ is a parallel smooth bundle homomorphism in the sense of Definition 2.4.33 if and only if, when regarded as a section of $\mathrm{Hom}(\mathbf{E}\otimes\mathbf{F},\mathbf{G})$, it satisfies $\nabla_{\mathbf{X}}\Phi = 0$, $\forall \mathbf{X} \in \mathfrak{X}(M)$, where ∇ is the induced connection on $\mathrm{Hom}(\mathbf{E}\otimes\mathbf{F},\mathbf{G})$.

Proof. By the definition of the connection on $\mathrm{Hom}(\mathbf{E}\otimes\mathbf{F},\mathbf{G})$, we have

$$(\nabla_{\mathbf{X}}\Phi)(\mathbf{u}\otimes\mathbf{v}) = \nabla^{\mathbf{G}}_{\mathbf{X}}\big(\Phi(\mathbf{u}\otimes\mathbf{v})\big) - \Phi\big(\nabla_{\mathbf{X}}(\mathbf{u}\otimes\mathbf{v})\big),$$

for all $\mathbf{u} \in \Gamma(\mathbf{E})$, $\mathbf{v} \in \Gamma(\mathbf{F})$, and $\mathbf{X} \in \mathfrak{X}(M)$.
Since $\nabla_{\mathbf{X}}(\mathbf{u}\otimes\mathbf{v}) = (\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{v} + \mathbf{u}\otimes(\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{v})$, we obtain

$$(\nabla_{\mathbf{X}}\Phi)(\mathbf{u}\otimes\mathbf{v}) = \nabla^{\mathbf{G}}_{\mathbf{X}}\big(\Phi(\mathbf{u}\otimes\mathbf{v})\big) - \Phi\big((\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{v}\big) - \Phi\big(\mathbf{u}\otimes(\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{v})\big).$$

Therefore $(\nabla_{\mathbf{X}}\Phi)(\mathbf{u}\otimes\mathbf{v}) = 0$ for every $\mathbf{u},\mathbf{v}$ if and only if

$$\nabla^{\mathbf{G}}_{\mathbf{X}}\big(\Phi(\mathbf{u}\otimes\mathbf{v})\big) = \Phi\big((\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{v}\big) + \Phi\big(\mathbf{u}\otimes(\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{v})\big),$$

that is, if and only if Φ is a parallel smooth bundle homomorphism in the sense of Definition 2.4.33.
Since these simple tensor fields generate $\Gamma(\mathbf{E}\otimes\mathbf{F})$, the equivalence holds for every section, completing the proof. □

Example 2.4.35. (Evaluation) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$, and let $\nabla^{\mathbf{E}^*}$ be the induced connection on the dual.
Define the smooth bundle homomorphism called the *evaluation homomorphism*

$$\mathrm{ev}\colon \mathbf{E}^* \otimes \mathbf{E} \longrightarrow M \times \mathbb{R}$$

pointwise by

$$\mathrm{ev}_p(\mathbf{v}_p \otimes \mathbf{u}_p) = \langle \mathbf{v}_p, \mathbf{u}_p \rangle, \qquad p \in M, \mathbf{v}_p \in \mathbf{E}^*_p, \mathbf{u}_p \in \mathbf{E}_p.$$

The trivial bundle $M \times \mathbb{R}$ carries the trivial connection; that is, regarding $f \in C^\infty(M)$ as a section of $M \times \mathbb{R}$, we have

$$\nabla^{M\times\mathbb{R}}_{\mathbf{X}} f = \mathbf{X}(f).$$

Let $\mathbf{v} \in \Gamma(\mathbf{E}^*)$, $\mathbf{u} \in \Gamma(\mathbf{E})$, and $\mathbf{X} \in \mathfrak{X}(M)$. On the left-hand side:

$$\nabla^{M\times\mathbb{R}}_{\mathbf{X}}(\mathrm{ev}(\mathbf{v} \otimes \mathbf{u})) = \nabla^{M\times\mathbb{R}}_{\mathbf{X}}\big(p \mapsto \langle \mathbf{v}_p, \mathbf{u}_p \rangle\big) = \mathbf{X}(\langle \mathbf{v}, \mathbf{u} \rangle).$$

On the right-hand side:

$$\mathrm{ev}\big((\nabla^{\mathbf{E}^*}_{\mathbf{X}} \mathbf{v}) \otimes \mathbf{u} + \mathbf{v} \otimes \nabla^{\mathbf{E}}_{\mathbf{X}} \mathbf{u}\big) = \langle \nabla^{\mathbf{E}^*}_{\mathbf{X}} \mathbf{v}, \mathbf{u} \rangle + \langle \mathbf{v}, \nabla^{\mathbf{E}}_{\mathbf{X}} \mathbf{u} \rangle.$$

By the definition of the induced connection on $\mathbf{E}^*$,

$$\mathbf{X}(\langle \mathbf{v}, \mathbf{u} \rangle) = \langle \nabla^{\mathbf{E}^*}_{\mathbf{X}} \mathbf{v}, \mathbf{u} \rangle + \langle \mathbf{v}, \nabla^{\mathbf{E}}_{\mathbf{X}} \mathbf{u} \rangle.$$

Thus,

$$\nabla^{M\times\mathbb{R}}_{\mathbf{X}}\big(\mathrm{ev}(\mathbf{v} \otimes \mathbf{u})\big) = \mathrm{ev}\big((\nabla^{\mathbf{E}^*}_{\mathbf{X}} \mathbf{v}) \otimes \mathbf{u} + \mathbf{v} \otimes \nabla^{\mathbf{E}}_{\mathbf{X}} \mathbf{u}\big),$$

and we conclude that evaluation is a parallel smooth bundle homomorphism.

Example 2.4.36. (Contraction) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$, and let $\mathbf{F} \to M$ be another bundle with connection $\nabla^{\mathbf{F}}$.
Define the smooth homomorphism called the *contraction homomorphism*

$$\mathrm{contr}\colon \mathbf{E}^* \otimes \mathbf{E} \otimes \mathbf{F} \longrightarrow \mathbf{F}$$

pointwise by

$$\mathrm{contr}_p(\mathbf{v}_p \otimes \mathbf{u}_p \otimes \mathbf{w}_p) = \langle \mathbf{v}_p, \mathbf{u}_p \rangle \mathbf{w}_p, \qquad p \in M, \mathbf{v}_p \in \mathbf{E}^*_p, \mathbf{u}_p \in \mathbf{E}_p, \mathbf{w}_p \in \mathbf{F}_p.$$

The notion of a parallel homomorphism extends naturally to three factors: a homomorphism

$$\Phi\colon \mathbf{E}^* \otimes \mathbf{E} \otimes \mathbf{F} \longrightarrow \mathbf{G}$$

is parallel if, for all $\mathbf{v} \in \Gamma(\mathbf{E}^*)$, $\mathbf{u} \in \Gamma(\mathbf{E})$, $\mathbf{w} \in \Gamma(\mathbf{F})$, and $\mathbf{X} \in \mathfrak{X}(M)$, we have

$$\nabla^{\mathbf{G}}_{\mathbf{X}}(\Phi(\mathbf{v} \otimes \mathbf{u} \otimes \mathbf{w})) = \Phi\big((\nabla^{\mathbf{E}^*}_{\mathbf{X}} \mathbf{v}) \otimes \mathbf{u} \otimes \mathbf{w}\big) + \Phi\big(\mathbf{v} \otimes (\nabla^{\mathbf{E}}_{\mathbf{X}} \mathbf{u}) \otimes \mathbf{w}\big) + \Phi\big(\mathbf{v} \otimes \mathbf{u} \otimes \nabla^{\mathbf{F}}_{\mathbf{X}} \mathbf{w}\big).$$

Let us verify that contraction satisfies this property.

For the left-hand side, we have

$$\begin{aligned}\nabla^{\mathbf{F}}_{\mathbf{X}}(\operatorname{contr}(\mathbf{v}\otimes\mathbf{u}\otimes\mathbf{w})) &= \nabla^{\mathbf{F}}_{\mathbf{X}}\big(p\mapsto\langle\mathbf{v}_p,\mathbf{u}_p\rangle\mathbf{w}_p\big)\\ &= \nabla^{\mathbf{F}}_{\mathbf{X}}(\langle\mathbf{v},\mathbf{u}\rangle\cdot\mathbf{w}).\end{aligned}$$

The Leibniz rule on $\mathbf{F}$ gives

$$\nabla^{\mathbf{F}}_{\mathbf{X}}(\langle\mathbf{v},\mathbf{u}\rangle\cdot\mathbf{w}) = \mathbf{X}(\langle\mathbf{v},\mathbf{u}\rangle)\mathbf{w} + \langle\mathbf{v},\mathbf{u}\rangle\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{w},$$

so

$$\nabla^{\mathbf{F}}_{\mathbf{X}}(\operatorname{contr}(\mathbf{v}\otimes\mathbf{u}\otimes\mathbf{w})) = \mathbf{X}(\langle\mathbf{v},\mathbf{u}\rangle)\mathbf{w} + \langle\mathbf{v},\mathbf{u}\rangle\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{w}.$$

We wish to calculate

$$\operatorname{contr}\big((\nabla^{\mathbf{E}^*}_{\mathbf{X}}\mathbf{v})\otimes\mathbf{u}\otimes\mathbf{w}\big) + \operatorname{contr}\big(\mathbf{v}\otimes(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{w}\big) + \operatorname{contr}\big(\mathbf{v}\otimes\mathbf{u}\otimes\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{w}\big).$$

Evaluating each term using the definition of contraction gives

$$\begin{aligned}\operatorname{contr}\big((\nabla^{\mathbf{E}^*}_{\mathbf{X}}\mathbf{v})\otimes\mathbf{u}\otimes\mathbf{w}\big) &= \langle\nabla^{\mathbf{E}^*}_{\mathbf{X}}\mathbf{v},\mathbf{u}\rangle\mathbf{w},\\ \operatorname{contr}\big(\mathbf{v}\otimes(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{w}\big) &= \langle\mathbf{v},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}\rangle\mathbf{w},\\ \operatorname{contr}\big(\mathbf{v}\otimes\mathbf{u}\otimes\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{w}\big) &= \langle\mathbf{v},\mathbf{u}\rangle\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{w}.\end{aligned}$$

Thus,

$$\operatorname{contr}\big((\nabla^{\mathbf{E}^*}_{\mathbf{X}}\mathbf{v})\otimes\mathbf{u}\otimes\mathbf{w}\big) + \operatorname{contr}\big(\mathbf{v}\otimes(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{w}\big) + \operatorname{contr}\big(\mathbf{v}\otimes\mathbf{u}\otimes\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{w}\big) = \langle\nabla^{\mathbf{E}^*}_{\mathbf{X}}\mathbf{v},\mathbf{u}\rangle\mathbf{w} + \langle\mathbf{v},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}\rangle\mathbf{w} + \langle\mathbf{v},\mathbf{u}\rangle\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{w}.$$

Finally, by the definition of the connection on the dual $\mathbf{E}^*$, we have

$$\mathbf{X}(\langle\mathbf{v},\mathbf{u}\rangle) = \langle\nabla^{\mathbf{E}^*}_{\mathbf{X}}\mathbf{v},\mathbf{u}\rangle + \langle\mathbf{v},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}\rangle.$$

Equating the two terms, we obtain

$$\nabla^{\mathbf{F}}_{\mathbf{X}}(\operatorname{contr}(\mathbf{v}\otimes\mathbf{u}\otimes\mathbf{w})) = \operatorname{contr}\big((\nabla^{\mathbf{E}^*}_{\mathbf{X}}\mathbf{v})\otimes\mathbf{u}\otimes\mathbf{w}\big) + \operatorname{contr}\big(\mathbf{v}\otimes(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{w}\big) + \operatorname{contr}\big(\mathbf{v}\otimes\mathbf{u}\otimes\nabla^{\mathbf{F}}_{\mathbf{X}}\mathbf{w}\big).$$

Therefore contraction is a parallel smooth bundle homomorphism.

Proposition 2.4.37. (Compatibility of the connection with contractions) Let M be a smooth manifold with or without boundary, let $\mathbf{E}_1,\dots,\mathbf{E}_N,\mathbf{F}\to M$ be smooth vector bundles equipped with connections, and let

$$C\colon \mathbf{E}_1\otimes\cdots\otimes\mathbf{E}_N \longrightarrow \mathbf{F}$$

be a parallel smooth bundle homomorphism. Then, for every section $\mathbf{T}\in\Gamma(\mathbf{E}_1\otimes\cdots\otimes\mathbf{E}_N)$ and every $\mathbf{X}\in\mathfrak{X}(M)$,

$$\nabla^{\mathbf{F}}_{\mathbf{X}}\big(C(\mathbf{T})\big) = C(\nabla_{\mathbf{X}}\mathbf{T}). \tag{2.18}$$

In particular, induced connections commute with evaluation, permutations of factors, and all canonical contractions.

If $(M, \mathbf{g})$ is Riemannian and ∇^M is the Levi–Civita connection, metric contraction is parallel. Therefore, for every tensor S with two covariant indices that can be contracted,

$$\nabla\big(\operatorname{tr}_{\mathbf{g}} S\big) = \operatorname{tr}_{\mathbf{g}}(\nabla S). \tag{2.19}$$

The same identity holds for any finite composition of metric contractions.

Proof. By Proposition 2.4.34, the condition that C be parallel is equivalent to $\nabla C = 0$ when C is regarded as a section of the corresponding homomorphism bundle. The Leibniz rule for evaluation gives

$$\nabla^{\mathbf{F}}_{\mathbf{X}}(C(\mathbf{T})) = (\nabla_{\mathbf{X}} C)(\mathbf{T}) + C(\nabla_{\mathbf{X}}\mathbf{T}) = C(\nabla_{\mathbf{X}}\mathbf{T}),$$

which proves (2.18).
Evaluation and contraction are parallel by the preceding examples. Permutations of factors are parallel because the product connection differentiates each factor, while the permutation only changes their order. In the Riemannian case, $\nabla^M g = 0$ and also $\nabla^M g^{-1} = 0$; hence raising indices and contracting them with g^{-1} are parallel homomorphisms. Identity (2.19) is therefore an instance of (2.18). The assertion for a finite composition follows by applying the same argument successively. □

Finally, we give an example showing why parallelism of homomorphisms is more general than the Leibniz rule for tensor fields of type $(0,2)$:

Example 2.4.38. (Evaluation and the Leibniz rule) Let M be a smooth manifold with or without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$. Define the map

$$\widetilde{\mathrm{ev}}\colon (\mathbf{E}^*\otimes\mathbf{E}^*)\otimes(\mathbf{E}\otimes\mathbf{E}) \longrightarrow M\times\mathbb{R}, \qquad \widetilde{\mathrm{ev}}_p(\beta_p\otimes(\mathbf{u}_p\otimes\mathbf{v}_p)) = \langle\beta_p, \mathbf{u}_p\otimes\mathbf{v}_p\rangle = \beta_p(\mathbf{u}_p,\mathbf{v}_p).$$

Then, for all $\mathbf{T}\in\Gamma(\mathbf{E}^*\otimes\mathbf{E}^*)$, $\mathbf{u},\mathbf{v}\in\Gamma(\mathbf{E})$, and $\mathbf{X}\in\mathfrak{X}(M)$, the Leibniz rule

$$\mathbf{X}\big(\mathbf{T}(\mathbf{u},\mathbf{v})\big) = (\nabla^{\mathbf{E}^*\otimes\mathbf{E}^*}_{\mathbf{X}}\mathbf{T})(\mathbf{u},\mathbf{v}) + \mathbf{T}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u},\mathbf{v}) + \mathbf{T}(\mathbf{u},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{v})$$

is equivalent to $\widetilde{\mathrm{ev}}$ being a parallel smooth bundle homomorphism, that is,

$$\nabla^{M\times\mathbb{R}}_{\mathbf{X}}\big(\widetilde{\mathrm{ev}}(\mathbf{T}\otimes(\mathbf{u}\otimes\mathbf{v}))\big) = \widetilde{\mathrm{ev}}\big((\nabla^{\mathbf{E}^*\otimes\mathbf{E}^*}_{\mathbf{X}}\mathbf{T})\otimes(\mathbf{u}\otimes\mathbf{v})\big) + \widetilde{\mathrm{ev}}\big(\mathbf{T}\otimes((\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{v})\big) + \widetilde{\mathrm{ev}}\big(\mathbf{T}\otimes(\mathbf{u}\otimes\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{v})\big).$$

Proof. By the pointwise definition,

$$\widetilde{\mathrm{ev}}(\mathbf{T}\otimes(\mathbf{u}\otimes\mathbf{v})) = \langle\mathbf{T},\mathbf{u}\otimes\mathbf{v}\rangle = \mathbf{T}(\mathbf{u},\mathbf{v}), \qquad \nabla^{M\times\mathbb{R}}_{\mathbf{X}} f = \mathbf{X}(f) \text{ for } f\in C^\infty(M).$$

If $\widetilde{\mathrm{ev}}$ is parallel, then

$$\begin{aligned}
\mathbf{X}\big(\mathbf{T}(\mathbf{u},\mathbf{v})\big) &= \nabla^{M\times\mathbb{R}}_{\mathbf{X}}\big(\widetilde{\mathrm{ev}}(\mathbf{T}\otimes(\mathbf{u}\otimes\mathbf{v}))\big)\\
&= \widetilde{\mathrm{ev}}\big((\nabla^{\mathbf{E}^*\otimes\mathbf{E}^*}_{\mathbf{X}}\mathbf{T})\otimes(\mathbf{u}\otimes\mathbf{v})\big) + \widetilde{\mathrm{ev}}\big(\mathbf{T}\otimes((\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{v})\big) + \widetilde{\mathrm{ev}}\big(\mathbf{T}\otimes(\mathbf{u}\otimes\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{v})\big)\\
&= \langle\nabla^{\mathbf{E}^*\otimes\mathbf{E}^*}_{\mathbf{X}}\mathbf{T},\mathbf{u}\otimes\mathbf{v}\rangle + \langle\mathbf{T},(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})\otimes\mathbf{v}\rangle + \langle\mathbf{T},\mathbf{u}\otimes\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{v}\rangle\\
&= (\nabla^{\mathbf{E}^*\otimes\mathbf{E}^*}_{\mathbf{X}}\mathbf{T})(\mathbf{u},\mathbf{v}) + \mathbf{T}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u},\mathbf{v}) + \mathbf{T}(\mathbf{u},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{v}).
\end{aligned}$$

This recovers the Leibniz rule.
Conversely, if the Leibniz rule holds for every $\mathbf{T}, \mathbf{u}, \mathbf{v}$, then

$$\nabla_{\mathbf{X}}^{M\times\mathbb{R}}\big(\widetilde{\mathrm{ev}}(\mathbf{T}\otimes(\mathbf{u}\otimes\mathbf{v}))\big) = \mathbf{X}\big(\mathbf{T}(\mathbf{u},\mathbf{v})\big)$$

$$= (\nabla_{\mathbf{X}}^{\mathbf{E}^*\otimes\mathbf{E}^*}\mathbf{T})(\mathbf{u},\mathbf{v}) + \mathbf{T}(\nabla_{\mathbf{X}}^{\mathbf{E}}\mathbf{u},\mathbf{v}) + \mathbf{T}(\mathbf{u},\nabla_{\mathbf{X}}^{\mathbf{E}}\mathbf{v})$$

$$= \langle\nabla_{\mathbf{X}}^{\mathbf{E}^*\otimes\mathbf{E}^*}\mathbf{T}, \mathbf{u}\otimes\mathbf{v}\rangle + \langle\mathbf{T}, (\nabla_{\mathbf{X}}^{\mathbf{E}}\mathbf{u})\otimes\mathbf{v}\rangle + \langle\mathbf{T}, \mathbf{u}\otimes\nabla_{\mathbf{X}}^{\mathbf{E}}\mathbf{v}\rangle$$

$$= \widetilde{\mathrm{ev}}\big((\nabla_{\mathbf{X}}^{\mathbf{E}^*\otimes\mathbf{E}^*}\mathbf{T})\otimes(\mathbf{u}\otimes\mathbf{v})\big) + \widetilde{\mathrm{ev}}\big(\mathbf{T}\otimes((\nabla_{\mathbf{X}}^{\mathbf{E}}\mathbf{u})\otimes\mathbf{v})\big) + \widetilde{\mathrm{ev}}\big(\mathbf{T}\otimes(\mathbf{u}\otimes\nabla_{\mathbf{X}}^{\mathbf{E}}\mathbf{v})\big).$$

This proves that the Leibniz rule is equivalent to $\widetilde{\mathrm{ev}}$ being parallel. □

The condition that a connection ∇ on a smooth vector bundle $\mathbf{E}$ be compatible with a bundle metric $\mathbf{h}$ can be stated compactly as follows:

Definition 2.4.39. Let M be a smooth manifold with or without boundary, let $\mathbf{E}\to M$ be a smooth vector bundle, let ∇ be a connection on $\mathbf{E}$, and let $\mathbf{h}$ be a bundle metric on $\mathbf{E}$. We say that ∇ is compatible with $\mathbf{h}$ if

$$\nabla^{\mathbf{E}^*\otimes\mathbf{E}^*}\mathbf{h} = 0.$$

In this case, the metric $\mathbf{h}$ is also said to be *parallel* with respect to ∇.

This condition is equivalent to the one given in Proposition 2.4.18:

Proposition 2.4.40. Let M be a smooth manifold with or without boundary, let $\mathbf{E}\longrightarrow M$ be a smooth vector bundle, let ∇ be a connection on $\mathbf{E}$, and let $\mathbf{h}$ be a bundle metric on $\mathbf{E}$. Then ∇ is compatible with $\mathbf{h}$ if and only if, for any $\mathbf{u},\mathbf{v}\in\Gamma(\mathbf{E})$ and any $\mathbf{X}\in\mathfrak{X}(M)$,

$$\mathbf{X}\big(\mathbf{h}(\mathbf{u},\mathbf{v})\big) = \mathbf{h}(\nabla_{\mathbf{X}}\mathbf{u},\mathbf{v}) + \mathbf{h}(\mathbf{u},\nabla_{\mathbf{X}}\mathbf{v}).$$

Proof. By Proposition 2.4.32, the covariant derivative of the section $\mathbf{h}\in\Gamma(T^{(0,2)}(\mathbf{E}))$ satisfies

$$(\nabla_{\mathbf{X}}\mathbf{h})(\mathbf{u},\mathbf{v}) = \mathbf{X}\big(\mathbf{h}(\mathbf{u},\mathbf{v})\big) - \mathbf{h}(\nabla_{\mathbf{X}}\mathbf{u},\mathbf{v}) - \mathbf{h}(\mathbf{u},\nabla_{\mathbf{X}}\mathbf{v}).$$

Metric compatibility is the identity $\nabla\mathbf{h} = 0$. Thus this identity is exactly equivalent to the formula in the statement for all $\mathbf{X}$, $\mathbf{u}$, and $\mathbf{v}$. □

2.5 Hermitian bundles and conjugation of connections

The bundle metrics introduced at the beginning of the chapter are real. We now fix their complex version and the precise relationship between conjugation, duals, and connections. Throughout this section, vector fields on the base are real, and Hermitian products are linear in the first variable.

Definition 2.5.1. (Hermitian bundle metric) Let M be a smooth manifold with or without boundary, and let $\mathbf{E}\to M$ be a smooth complex vector bundle. A *Hermitian bundle metric* is a smooth family $\mathbf{h}_{\mathbf{E}}$ of positive definite Hermitian forms on the fibers, linear in the first variable and antilinear in the second. Equivalently,

the bilinear map

$$\widetilde{\mathbf{h}}_{\mathbf{E}} \colon \mathbf{E} \times_M \overline{\mathbf{E}} \longrightarrow \underline{\mathbb{C}}_M, \qquad \widetilde{\mathbf{h}}_{\mathbf{E}}(v, \overline{w}) = \mathbf{h}_{\mathbf{E}}(v, w),$$

is a smooth section of $\mathbf{E}^* \otimes (\overline{\mathbf{E}})^*$ and is positive definite in the sense that $\widetilde{\mathbf{h}}_{\mathbf{E}}(v, \overline{v}) > 0$ for $v \neq 0$.

Proposition 2.5.2. (Metric on the conjugate bundle) The formula

$$\mathbf{h}_{\overline{\mathbf{E}}}(\overline{v}, \overline{w}) := \overline{\mathbf{h}_{\mathbf{E}}(v, w)} \tag{2.20}$$

defines a smooth Hermitian metric on $\overline{\mathbf{E}}$, linear in the first variable and antilinear in the second. Under the identification $\overline{\overline{\mathbf{E}}} \cong \mathbf{E}$, the twice-conjugated metric is $\mathbf{h}_{\mathbf{E}}$.

Proof. If $\lambda, \mu \in \mathbb{C}$, the scalar structure of $\overline{\mathbf{E}}$ and the convention for $\mathbf{h}_{\mathbf{E}}$ give

$$\mathbf{h}_{\overline{\mathbf{E}}}(\lambda \overline{v}, \mu \overline{w}) = \overline{\mathbf{h}_{\mathbf{E}}(\overline{\lambda} v, \overline{\mu} w)} = \lambda \overline{\mu} \, \overline{\mathbf{h}_{\mathbf{E}}(v, w)}.$$

Hermitian symmetry, positivity, and smoothness follow by conjugating the corresponding properties of $\mathbf{h}_{\mathbf{E}}$. Conjugating twice recovers the original formula. □

Proposition 2.5.3. (Fiberwise Riesz isomorphism) The map

$$\mathcal{R}_{\mathbf{E}} \colon \overline{\mathbf{E}} \longrightarrow \mathbf{E}^*, \qquad \mathcal{R}_{\mathbf{E}}(\overline{v})(w) := \mathbf{h}_{\mathbf{E}}(w, v), \tag{2.21}$$

is a smooth complex-linear bundle isomorphism compatible with restrictions. For each $\overline{v}$, the functional $w \mapsto \mathbf{h}_{\mathbf{E}}(w, v)$ is complex-linear. In a unitary local frame $(\mathbf{e}_1, \dots, \mathbf{e}_r)$, if $\ell = \sum_{a=1}^{r} \ell_a \mathbf{e}^a$, then

$$\mathcal{R}_{\mathbf{E}}^{-1}(\ell) = \overline{\sum_{a=1}^{r} \overline{\ell_a} \, \mathbf{e}_a}. \tag{2.22}$$

In particular, the map $\mathbf{E} \to \mathbf{E}^*$, $v \mapsto \mathbf{h}_{\mathbf{E}}(\cdot, v)$, is antilinear, whereas $\mathcal{R}_{\mathbf{E}} \colon \overline{\mathbf{E}} \to \mathbf{E}^*$ is complex-linear. In the real case, conjugation disappears and we recover the usual real identification.

Proof. Linearity in w is part of the Hermitian convention. For linearity in $\overline{v}$, using $\lambda \overline{v} = \overline{\overline{\lambda} v}$, we obtain

$$\mathcal{R}_{\mathbf{E}}(\lambda \overline{v})(w) = \mathbf{h}_{\mathbf{E}}(w, \overline{\lambda} v) = \lambda \mathbf{h}_{\mathbf{E}}(w, v).$$

In a unitary frame, $\mathbf{h}_{\mathbf{E}}(\sum_{a=1}^{r} w^a \mathbf{e}_a, \sum_{a=1}^{r} v^a \mathbf{e}_a) = \sum_{a=1}^{r} w^a \overline{v^a}$; this directly gives (2.22). The formula proves both bijectivity and local smoothness of $\mathcal{R}_{\mathbf{E}}$ and its inverse. Since the definition is intrinsic, the local formulas glue and commute with every restriction to an open set. The assertion about $\mathbf{E} \to \mathbf{E}^*$ follows from $\mathbf{h}_{\mathbf{E}}(w, \lambda v) = \overline{\lambda} \mathbf{h}_{\mathbf{E}}(w, v)$. □

Definition 2.5.4. (Complex, dual, and conjugate connections) Let M be a smooth manifold with or without boundary, and let $\mathbf{E} \longrightarrow M$ be a smooth complex vector bundle. A *complex connection* on $\mathbf{E}$ is a map

$$\nabla^{\mathbf{E}} \colon \mathfrak{X}(M) \times \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{E})$$

that is $C^\infty(M,\mathbb{R})$-linear in the real vector field, additive in the section, satisfies

$$\nabla^{\mathbf{E}}_{\mathbf{X}}(f\mathbf{u}) = \mathbf{X}(f)\mathbf{u} + f\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}, \qquad f \in C^\infty(M,\mathbb{C}),$$

and is complex-linear in $\mathbf{u}$ for fixed $\mathbf{X}$.
The dual connection $\nabla^{\mathbf{E}^*}$ and the conjugate connection $\nabla^{\overline{\mathbf{E}}}$ are defined, respectively, by

$$(\nabla^{\mathbf{E}^*}_{\mathbf{X}}\boldsymbol{\ell})(\mathbf{u}) := \mathbf{X}(\boldsymbol{\ell}(\mathbf{u})) - \boldsymbol{\ell}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}), \tag{2.23}$$

$$\nabla^{\overline{\mathbf{E}}}_{\mathbf{X}}\overline{\mathbf{u}} := \overline{\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}}. \tag{2.24}$$

Proposition 2.5.5. (Well-definedness and naturality) Let M be a smooth manifold with or without boundary, and let $\mathbf{E},\mathbf{F} \longrightarrow M$ be smooth complex vector bundles equipped with complex connections. Formulas (2.23) and (2.24) define complex connections. They commute with restrictions, and double conjugation recovers $\nabla^{\mathbf{E}}$. If $\mathbf{A}\colon \mathbf{E} \to \mathbf{F}$ is parallel, that is, $\nabla^{\mathbf{F}}_{\mathbf{X}}(\mathbf{A}\mathbf{u}) = \mathbf{A}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u})$, then $\overline{\mathbf{A}}$ is parallel for the conjugate connections. In conjugate frames, the matrix of $\nabla^{\overline{\mathbf{E}}}$ is the conjugate of the matrix of $\nabla^{\mathbf{E}}$.

Proof. Only the Leibniz rule for the conjugate connection requires attention. If $f \in C^\infty(M,\mathbb{C})$, then $f\overline{\mathbf{u}} = \overline{\overline{f}\,\mathbf{u}}$, and, since $\mathbf{X}$ is real, $\mathbf{X}(\overline{f}) = \overline{\mathbf{X}(f)}$. Hence

$$\begin{aligned}\nabla^{\overline{\mathbf{E}}}_{\mathbf{X}}(f\overline{\mathbf{u}}) &= \overline{\nabla^{\mathbf{E}}_{\mathbf{X}}(\overline{f}\,\mathbf{u})} = \overline{\overline{\mathbf{X}(f)}\mathbf{u} + \overline{f}\,\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u}} \\ &= \mathbf{X}(f)\overline{\mathbf{u}} + f\nabla^{\overline{\mathbf{E}}}_{\mathbf{X}}\overline{\mathbf{u}}.\end{aligned}$$

The properties of the dual connection follow by expanding $\mathbf{X}(\boldsymbol{\ell}(f\mathbf{u}))$ and using the Leibniz rule for $\nabla^{\mathbf{E}}$; canceling $\mathbf{X}(f)\boldsymbol{\ell}(\mathbf{u})$ leaves $(\nabla^{\mathbf{E}^*}_{\mathbf{X}}\boldsymbol{\ell})(f\mathbf{u}) = f(\nabla^{\mathbf{E}^*}_{\mathbf{X}}\boldsymbol{\ell})(\mathbf{u})$. The remaining assertions are verified directly on local sections. □

Definition 2.5.6. (Hermitian connection) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \longrightarrow M$ be a smooth complex vector bundle with Hermitian bundle metric $\mathbf{h}_{\mathbf{E}}$, and let $\nabla^{\mathbf{E}}$ be a complex connection. The connection $\nabla^{\mathbf{E}}$ is *compatible with* $\mathbf{h}_{\mathbf{E}}$, or *Hermitian*, if, for all $\mathbf{X} \in \mathfrak{X}(M)$ and $\mathbf{u},\mathbf{v} \in \Gamma(\mathbf{E})$,

$$\mathbf{X}\big(\mathbf{h}_{\mathbf{E}}(\mathbf{u},\mathbf{v})\big) = \mathbf{h}_{\mathbf{E}}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u},\mathbf{v}) + \mathbf{h}_{\mathbf{E}}(\mathbf{u},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{v}). \tag{2.25}$$

Proposition 2.5.7. (Parallelism of the Riesz isomorphism) Let M be a smooth manifold with or without boundary, and let $\mathbf{E} \longrightarrow M$ be a smooth complex vector bundle with Hermitian bundle metric $\mathbf{h}_{\mathbf{E}}$ and complex connection $\nabla^{\mathbf{E}}$. The connection $\nabla^{\mathbf{E}}$ is Hermitian if and only if the Riesz isomorphism is parallel:

$$\nabla^{\mathbf{E}^*}_{\mathbf{X}}\big(\mathcal{R}_{\mathbf{E}}(\overline{\mathbf{v}})\big) = \mathcal{R}_{\mathbf{E}}\big(\nabla^{\overline{\mathbf{E}}}_{\mathbf{X}}\overline{\mathbf{v}}\big), \qquad \mathbf{X} \in \mathfrak{X}(M), \quad \mathbf{v} \in \Gamma(\mathbf{E}). \tag{2.26}$$

In this case, $\nabla^{\overline{\mathbf{E}}}$ is compatible with $\mathbf{h}_{\overline{\mathbf{E}}}$, and $\mathcal{R}_{\mathbf{E}}^{-1}$ is also parallel.

Proof. Evaluating the left-hand side of (2.26) on $\mathbf{u}$ and using the dual connection gives

$$\mathbf{X}(\mathbf{h}_{\mathbf{E}}(\mathbf{u},\mathbf{v})) - \mathbf{h}_{\mathbf{E}}(\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{u},\mathbf{v}).$$

The right-hand side evaluated on $\mathbf{u}$ is $\mathbf{h}_{\mathbf{E}}(\mathbf{u},\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{v})$. Consequently, equality for all $\mathbf{u},\mathbf{v},\mathbf{X}$ is exactly equivalent to (2.25). Conjugating this identity proves compatibility of the conjugate connection with $\mathbf{h}_{\overline{\mathbf{E}}}$. Finally, differentiating $\mathcal{R}^{-1}_{\mathbf{E}}\mathcal{R}_{\mathbf{E}} = \mathrm{id}_{\overline{\mathbf{E}}}$ and using (2.26) proves parallelism of the inverse. □

2.6 Principal bundles and principal connections

A vector bundle describes vectors varying over the base, but a local trivialization also requires choosing a frame in each fiber. The various frames are related by the structure group, and this information is not represented by any particular vector in the bundle. A principal bundle records all admissible frames simultaneously, together with the group action that transforms them.

This description also clarifies why a connection is needed. To compare data in different fibers, one must specify which displacements in the total space are regarded as horizontal. The resulting parallel transport generally depends on the path; curvature measures this dependence infinitesimally. Later, principal connections and their curvature will be the natural variables of Yang–Mills theory, while gauge transformations will express changes of frame.

Throughout this section, all principal bundles carry a right action. The conventions are chosen so that, if $\mathbf{s}_\beta = \mathbf{s}_\alpha g_{\alpha\beta}$ are two local sections, the connection potentials satisfy

$$\mathbf{A}_\beta = \mathrm{Ad}_{g^{-1}_{\alpha\beta}}\mathbf{A}_\alpha + g^{-1}_{\alpha\beta}dg_{\alpha\beta}.$$

This is also the convention that will later produce the right gauge action $\mathbf{A}\triangleleft\mathbf{u} = \mathbf{u}^{-1}\mathbf{A}\mathbf{u} + \mathbf{u}^{-1}d\mathbf{u}$. For a compatible external treatment of principal bundles and their connections, see [21, Ch. 15]; the transition, curvature, and gauge identities needed in this book are verified below using the right-action convention fixed above.

Definition 2.6.1. (Principal bundle) Let G be a Lie group and M a smooth manifold with or without boundary. A *right principal bundle with structure group* G consists of a smooth manifold $\mathbf{P}$, a smooth surjective map $\pi\colon \mathbf{P}\to M$, and a smooth right action

$$R\colon \mathbf{P}\times G\longrightarrow \mathbf{P}, \qquad (p,g)\longmapsto p\cdot g,$$

such that:

(a) $\pi(p\cdot g) = \pi(p)$ for every $p\in\mathbf{P}$ and $g\in G$;

(b) the action is free;

(c) each $x\in M$ has an open neighborhood $U\ni x$ and a G-equivariant diffeomorphism

$$\Phi\colon \pi^{-1}(U)\longrightarrow U\times G, \qquad \Phi(p\cdot g) = \big(\pi(p),\mathrm{pr}_2(\Phi(p))g\big),$$

such that $\mathrm{pr}_1\circ\Phi = \pi$.

Every trivialization determines a local section $\mathbf{s}\colon U \to \mathbf{P}$, $\mathbf{s}(x) = \Phi^{-1}(x, e)$, and each $p \in \pi^{-1}(U)$ can be written uniquely as

$$p = \mathbf{s}(x) \cdot g, \qquad x = \pi(p).$$

If $\mathbf{s}_\alpha$ and $\mathbf{s}_\beta$ are local sections, there exists a unique smooth map

$$g_{\alpha\beta}\colon U_\alpha \cap U_\beta \longrightarrow G$$

such that

$$\mathbf{s}_\beta = \mathbf{s}_\alpha g_{\alpha\beta}. \tag{2.27}$$

Proposition 2.6.2. (Cocycles, reconstruction, and triviality) Let M be a smooth manifold with or without boundary, and let $\mathbf{P} \to M$ be a right principal bundle. The transition functions satisfy

$$g_{\alpha\alpha} = e, \qquad g_{\beta\alpha} = g_{\alpha\beta}^{-1}, \qquad g_{\alpha\gamma} = g_{\alpha\beta} g_{\beta\gamma}$$

on their respective domains. Conversely, a cover (U_α) and smooth maps satisfying these identities determine a right principal bundle up to principal bundle isomorphism: glue the $U_\alpha \times G$ by

$$(x, h)_\beta \sim (x, g_{\alpha\beta}(x)h)_\alpha. \tag{2.28}$$

Moreover, a principal bundle is trivial if and only if it admits a smooth global section.

Proof. The first two identities follow from uniqueness in (2.27); on a triple intersection, $\mathbf{s}_\gamma = \mathbf{s}_\beta g_{\beta\gamma} = \mathbf{s}_\alpha g_{\alpha\beta} g_{\beta\gamma}$ proves the third. These same identities make (2.28) an equivalence relation. The local quotients glue smoothly, the action $[x, h]_\alpha \cdot k = [x, hk]_\alpha$ is well defined, and the charts $[x, h]_\alpha \mapsto (x, h)$ are principal trivializations. Two realizations obtained in this way admit a principal bundle isomorphism that is the identity in the prescribed charts. Uniqueness is understood relative to these charts, since a bundle may have nontrivial gauge automorphisms.
If $\mathbf{s}\colon M \to \mathbf{P}$ is global, every $p \in \mathbf{P}_x$ can be written uniquely as $p = \mathbf{s}(x)g$, and $\mathbf{P} \to M \times G$, $\mathbf{s}(x)g \mapsto (x, g)$, is a principal trivialization. The section $x \mapsto (x, e)$ proves the converse. □

Definition 2.6.3. (Principal bundle morphisms and pullbacks) Let M and N be smooth manifolds with or without boundary, let $\mathbf{P} \to M$ and $\mathbf{Q} \to N$ be principal bundles with the same group G, and let $f\colon M \to N$ be a smooth map. A morphism between principal bundles with the same group is a smooth map $\Phi\colon \mathbf{P} \to \mathbf{Q}$ covering f and satisfying $\Phi(pg) = \Phi(p)g$. The pullback of $\mathbf{Q} \to N$ by f is

$$f^*\mathbf{Q} := \{(x, q) \in M \times \mathbf{Q} \mid f(x) = \pi_{\mathbf{Q}}(q)\}, \qquad (x, q)g = (x, qg).$$

With the projection onto M, it is a principal bundle, and $(x, q) \mapsto q$ is the universal morphism covering f.

Proof. A trivialization of $\mathbf{Q}$ over $V \subseteq N$ induces $f^{-1}(V) \times G \cong (f^*\mathbf{Q})|_{f^{-1}(V)}$, proving the local assertion. If $\Psi\colon \mathbf{R} \to \mathbf{Q}$ covers $f \circ \pi_{\mathbf{R}}$, the unique morphism $\mathbf{R} \to f^*\mathbf{Q}$ over M projecting to Ψ is $r \mapsto (\pi_{\mathbf{R}}(r), \Psi(r))$. □

Definition 2.6.4. (Associated bundle) Let M be a smooth manifold with or without boundary, let $\mathbf{P} \to M$ be a right principal bundle with group G, and let $\rho\colon G \to GL(V)$ be a finite-dimensional real or complex linear representation. Define

$$\mathbf{P} \times_\rho V := (\mathbf{P} \times V)/\!\sim,$$

where

$$(p \cdot g, v) \sim (p, \rho(g)v).$$

We write $[p, v]_\rho$ for the class of (p, v). The projection

$$[p, v]_\rho \longmapsto \pi(p)$$

makes $\mathbf{P} \times_\rho V$ a smooth vector bundle over M.

Proposition 2.6.5. (Associated trivializations and cocycles) Let M be a smooth manifold with or without boundary, and let $\mathbf{P} \to M$ be a right principal bundle. If $\mathbf{s}_\alpha$ is a local principal section, then

$$\Psi_\alpha\colon (\mathbf{P} \times_\rho V)|_{U_\alpha} \longrightarrow U_\alpha \times V, \qquad \Psi_\alpha([\mathbf{s}_\alpha(x)g, v]) = (x, \rho(g)v),$$

is well defined and is a vector bundle trivialization. If $\mathbf{s}_\beta = \mathbf{s}_\alpha g_{\alpha\beta}$, the coordinates are related by

$$v_\beta = \rho(g_{\alpha\beta}^{-1})v_\alpha.$$

Thus the associated bundle depends only on the principal bundle and the representation, and is independent of the chosen local sections.

Proof. The relation $(pg, v) \sim (p, \rho(g)v)$ shows that $[\mathbf{s}_\alpha gh, v] = [\mathbf{s}_\alpha g, \rho(h)v]$; both representatives have the same image under Ψ_α. The inverse is $(x, v) \mapsto [\mathbf{s}_\alpha(x), v]$. Finally, $[\mathbf{s}_\beta, v_\beta] = [\mathbf{s}_\alpha, \rho(g_{\alpha\beta})v_\beta]$, so $v_\alpha = \rho(g_{\alpha\beta})v_\beta$, which is equivalent to the stated formula. □

Proposition 2.6.6. Let M be a smooth manifold with or without boundary, and let $\mathbf{E} = \mathbf{P} \times_\rho V \to M$ be an associated bundle. Smooth sections of $\mathbf{E}$ are in bijective correspondence with smooth maps $\widetilde{u}\colon \mathbf{P} \to V$ satisfying

$$\widetilde{u}(p \cdot g) = \rho(g^{-1})\widetilde{u}(p). \tag{2.29}$$

The correspondence is given by

$$\mathbf{u}(x) = [p, \widetilde{u}(p)]_\rho, \qquad p \in \mathbf{P}_x.$$

Proof. If p is replaced by $p \cdot g$, then

$$[p \cdot g, \widetilde{u}(p \cdot g)]_\rho = [p, \rho(g)\rho(g^{-1})\widetilde{u}(p)]_\rho = [p, \widetilde{u}(p)]_\rho.$$

Thus the formula defines a section. Conversely, given $\mathbf{u}(x)$ and $p \in \mathbf{P}_x$, there is a unique $v \in V$ such that $\mathbf{u}(x) = [p, v]_\rho$; set $\widetilde{u}(p) = v$. Uniqueness of v gives (2.29). Smoothness in both directions is checked in a principal trivialization. □

Definition 2.6.7. (Adjoint and adjoint group bundles) Let M be a smooth manifold with or without boundary, and let $\mathbf{P} \to M$ be a right principal bundle with group G. Define two distinct bundles:

(a) The *adjoint group bundle*

$$\mathrm{Ad}(\mathbf{P}) := \mathbf{P} \times_{\mathrm{Conj}} G, \qquad \mathrm{Conj}_g(h) = ghg^{-1}.$$

Its fibers are groups; in general, it is not a vector bundle.

(b) The *adjoint bundle*

$$\mathrm{ad}(\mathbf{P}) := \mathbf{P} \times_{\mathrm{Ad}} \mathfrak{g}.$$

This is a vector bundle, of rank $\dim \mathfrak{g}$.

Fiberwise multiplication on $\mathrm{Ad}(\mathbf{P})$ is well defined. Its sections $\mathbf{u}$ are identified with smooth maps $\widehat{u}\colon \mathbf{P} \to G$ satisfying

$$\widehat{u}(p \cdot g) = g^{-1}\widehat{u}(p)g. \tag{2.30}$$

By contrast, sections ξ of $\mathrm{ad}(\mathbf{P})$ are identified with maps $\widehat{\xi}\colon \mathbf{P} \to \mathfrak{g}$ such that

$$\widehat{\xi}(p \cdot g) = \mathrm{Ad}_{g^{-1}}\,\widehat{\xi}(p).$$

Definition 2.6.8. (Horizontal and equivariant forms) Let M be a smooth manifold with or without boundary, let $\mathbf{P} \to M$ be a right principal bundle with group G, and let $\rho\colon G \to GL(V)$ be a representation. A form $\boldsymbol{\alpha} \in \Omega^k(\mathbf{P}; V)$ is *horizontal* if it vanishes whenever at least one of its arguments belongs to

$$\mathbf{V}_p\mathbf{P} := \ker(d\pi_p).$$

It is *ρ-equivariant* if

$$R_{\mathbf{g}}^*\boldsymbol{\alpha} = \rho(g^{-1})\boldsymbol{\alpha} \qquad (g \in G).$$

Proposition 2.6.9. (Forms with values in an associated bundle) Let M be a smooth manifold with or without boundary, and let $\mathbf{E} = \mathbf{P} \times_\rho V \to M$ be an associated bundle. There is a natural isomorphism

$$\Omega^k(M; \mathbf{E}) \cong \{\boldsymbol{\alpha} \in \Omega^k(\mathbf{P}; V) \mid \boldsymbol{\alpha} \text{ is horizontal and } \rho\text{-equivariant}\}.$$

If $\boldsymbol{\alpha}$ belongs to the second space, the associated form $\underline{\boldsymbol{\alpha}}$ is defined by

$$\underline{\boldsymbol{\alpha}}_x(X_1, \dots, X_k) := [p, \boldsymbol{\alpha}_p(\widetilde{X}_1, \dots, \widetilde{X}_k)]_\rho, \tag{2.31}$$

where $p \in \mathbf{P}_x$ and $d\pi_p \widetilde{X}_i = X_i$.

Proof. Horizontality shows that (2.31) is independent of the lifts $\widetilde{X}_i$. If p is replaced by $p \cdot g$, we may choose the lifts $(dR_{\mathbf{g}})_p \widetilde{X}_i$; equivariance then gives

$$\boldsymbol{\alpha}_{p\cdot g}\big((dR_{\mathbf{g}})\widetilde{X}_1, \dots, (dR_{\mathbf{g}})\widetilde{X}_k\big) = \rho(g^{-1})\boldsymbol{\alpha}_p(\widetilde{X}_1, \dots, \widetilde{X}_k),$$

and the equivalence relation of the associated bundle shows that the class in (2.31) is unchanged.

Conversely, given $\beta \in \Omega^k(M;\mathbf{E})$ and $p \in \mathbf{P}_x$, there is a unique $v \in V$ such that

$$\beta_x(d\pi\,\widetilde{X}_1,\dots,d\pi\,\widetilde{X}_k) = [p,v]_\rho.$$

Define $\alpha_p(\widetilde{X}_1,\dots,\widetilde{X}_k) := v$. This form is horizontal, and uniqueness of v proves equivariance. In a principal trivialization, both constructions reduce to the usual identifications with V-valued forms, proving smoothness and that the two operations are inverses. □

For $\xi \in \mathfrak{g}$, denote by

$$\xi_{\mathbf{P}}(p) := \left.\frac{d}{dt}\right|_0 p \cdot \exp_G(t\xi)$$

the positive fundamental vector field of the right action. By (1.27),

$$[\xi_{\mathbf{P}}, \eta_{\mathbf{P}}] = [\xi,\eta]_{\mathbf{P}}.$$

For each p, the map $\xi \mapsto \xi_{\mathbf{P}}(p)$ is an isomorphism $\mathfrak{g} \to \mathbf{V}_p\mathbf{P}$.

Definition 2.6.10. (Principal connection) Let M be a smooth manifold with or without boundary, and let $\mathbf{P} \to M$ be a right principal bundle. A *principal connection form* on $\mathbf{P}$ is a form $\omega \in \Omega^1(\mathbf{P};\mathfrak{g})$ such that

$$\omega(\xi_{\mathbf{P}}) = \xi, \tag{2.32}$$

$$R_{\mathbf{g}}^*\omega = \mathrm{Ad}_{g^{-1}}\,\omega. \tag{2.33}$$

The corresponding horizontal distribution is

$$\mathbf{H}_p\mathbf{P} := \ker \omega_p.$$

Then

$$T_p\mathbf{P} = \mathbf{H}_p\mathbf{P} \oplus \mathbf{V}_p\mathbf{P}, \qquad (dR_{\mathbf{g}})_p\mathbf{H}_p\mathbf{P} = \mathbf{H}_{p\cdot g}\mathbf{P}.$$

Proposition 2.6.11. (Horizontal distributions and connection forms) Let M be a smooth manifold with or without boundary, and let $\mathbf{P} \to M$ be a right principal bundle. The assignment $\mathbf{H}_p\mathbf{P} = \ker\omega_p$ establishes a bijection between principal connection forms and smooth distributions $\mathbf{H} \subset T\mathbf{P}$ such that

$$T_p\mathbf{P} = \mathbf{H}_p \oplus \mathbf{V}_p\mathbf{P}, \qquad (dR_{\mathbf{g}})_p\mathbf{H}_p = \mathbf{H}_{pg}.$$

The form corresponding to $\mathbf{H}$ is obtained by writing uniquely $Z = Z^{\mathbf{H}} + \xi_{\mathbf{P}}(p)$ and setting $\omega_p(Z) = \xi$.

Proof. For a connection form, the first property implies that $\omega_p|_{\mathbf{V}_p\mathbf{P}}\colon \mathbf{V}_p\mathbf{P} \to \mathfrak{g}$ is the inverse of $\xi \mapsto \xi_{\mathbf{P}}(p)$, giving the direct sum. The second property implies invariance of the kernels.
Conversely, the smooth isomorphism $\mathfrak{g} \to \mathbf{V}_p\mathbf{P}$, $\xi \mapsto \xi_{\mathbf{P}}(p)$, and the smooth projection onto $\mathbf{V}_p\mathbf{P}$ along $\mathbf{H}_p\mathbf{P}$ define the indicated form. We have $\omega(\xi_{\mathbf{P}}) = \xi$. Invariance of $\mathbf{H}$ and the identity $(dR_{\mathbf{g}})_p\xi_{\mathbf{P}}(p) = (\mathrm{Ad}_{g^{-1}}\xi)_{\mathbf{P}}(pg)$ imply $R_{\mathbf{g}}^*\omega = \mathrm{Ad}_{g^{-1}}\omega$. The two constructions are inverses by uniqueness of the horizontal–vertical decomposition. □

Definition 2.6.12. (Wedge bracket) Let N be a smooth manifold with or without boundary. For $\alpha \in \Omega^k(N;\mathfrak{g})$ and $\beta \in \Omega^\ell(N;\mathfrak{g})$, define

$$[\alpha \wedge \beta](\mathbf{X}_1,\dots,\mathbf{X}_{k+\ell}) := \sum_{\sigma \in \mathrm{Sh}(k,\ell)} \operatorname{sgn}(\sigma)\left[\alpha(\mathbf{X}_{\sigma(1)},\dots,\mathbf{X}_{\sigma(k)}),\beta(\mathbf{X}_{\sigma(k+1)},\dots,\mathbf{X}_{\sigma(k+\ell)})\right],$$

where $\mathrm{Sh}(k,\ell)$ is the set of (k,ℓ)-shuffle permutations. In particular,

$$[\alpha \wedge \beta](\mathbf{X},\mathbf{Y}) = [\alpha(\mathbf{X}),\beta(\mathbf{Y})] - [\alpha(\mathbf{Y}),\beta(\mathbf{X})]$$

for $\alpha,\beta \in \Omega^1(N;\mathfrak{g})$.

Lemma 2.6.13. (Graded algebra of the wedge bracket) Let N be a smooth manifold with or without boundary. Homogeneous forms on N satisfy

$$[\beta \wedge \alpha] = -(-1)^{k\ell}[\alpha \wedge \beta], \tag{2.34}$$

$$d[\alpha \wedge \beta] = [d\alpha \wedge \beta] + (-1)^k[\alpha \wedge d\beta], \tag{2.35}$$

and the graded Jacobi identity. In particular, if $\mathbf{A} \in \Omega^1(N;\mathfrak{g})$, then

$$[\mathbf{A} \wedge [\mathbf{A} \wedge \mathbf{A}]] = 0. \tag{2.36}$$

Proof. The first two identities follow by reordering the finite sets of shuffles and using, respectively, antisymmetry of the bracket on $\mathfrak{g}$ and the Leibniz rule for the exterior product. For each ordered partition of the arguments, the cyclic sum defining the graded Jacobi identity groups into a Jacobi identity in $\mathfrak{g}$. Taking the degree-one form $\mathbf{A}$ three times makes the three terms of the graded Jacobi identity equal, giving (2.36). □

Definition 2.6.14. (Principal curvature) Let M be a smooth manifold with or without boundary, and let ω be a principal connection on $\mathbf{P} \to M$. The curvature of ω is

$$\mathbf{\Omega}_\omega := d\omega + \frac{1}{2}[\omega \wedge \omega] \in \Omega^2(\mathbf{P};\mathfrak{g}). \tag{2.37}$$

We will use an elementary identity for forms and flows.

Lemma 2.6.15. (Cartan's formula) Let N be a smooth manifold with or without boundary, let $\mathbf{X}$ be a vector field whose local flow remains in N, and let α be a differential form. Then

$$\mathcal{L}_{\mathbf{X}}\alpha := \left.\frac{d}{dt}\right|_0 \Phi_t^*\alpha = d(\iota_{\mathbf{X}}\alpha) + \iota_{\mathbf{X}}(d\alpha).$$

Proof. Both sides are graded derivations of degree zero for the exterior product and commute with restrictions. For a function f, both sides equal $\mathbf{X}f$. In coordinates, every form is a sum of products of functions and differentials $\mathbf{d}x^i$; on the latter,

$$\mathcal{L}_{\mathbf{X}}(\mathbf{d}x^i) = d(\mathbf{X}x^i) = d(\iota_{\mathbf{X}}\mathbf{d}x^i).$$

The Leibniz rule establishes the identity for every form. □

Proposition 2.6.16. Let M be a smooth manifold with or without boundary, and let ω be a principal connection on $\mathbf{P} \to M$. The curvature $\mathbf{\Omega}_\omega$ is horizontal and Ad-equivariant:

$$R_{\mathbf{g}}^* \mathbf{\Omega}_\omega = \mathrm{Ad}_{g^{-1}} \mathbf{\Omega}_\omega.$$

Thus, by Proposition 2.6.9, it determines a global form

$$\mathbf{F}_\omega \in \Omega^2(M; \mathrm{ad}(\mathbf{P})).$$

Proof. Equivariance follows from $R_{\mathbf{g}}^* d\omega = d(R_{\mathbf{g}}^* \omega)$ and from the fact that $\mathrm{Ad}_{g^{-1}}$ preserves the bracket. The flow of $\xi_{\mathbf{P}}$ is $R_{\exp(t\xi)}$. Differentiating the equivariance of ω gives

$$\mathcal{L}_{\xi_{\mathbf{P}}} \omega = -\mathrm{ad}_\xi \, \omega = -[\xi, \omega].$$

Since $\iota_{\xi_{\mathbf{P}}} \omega = \xi$ is constant, Cartan's formula gives

$$\iota_{\xi_{\mathbf{P}}} d\omega = -[\xi, \omega].$$

On the other hand, the definition of the wedge bracket implies

$$\frac{1}{2} \iota_{\xi_{\mathbf{P}}} [\omega \wedge \omega] = [\xi, \omega].$$

The two terms cancel, so $\iota_{\xi_{\mathbf{P}}} \mathbf{\Omega}_\omega = 0$. Every vertical vector has the form $\xi_{\mathbf{P}}(p)$, and hence the curvature is horizontal. □

Proposition 2.6.17. (Local potentials and curvatures) Let M be a smooth manifold with or without boundary, let ω be a principal connection on $\mathbf{P} \to M$, and let $\mathbf{s}_\alpha : U_\alpha \to \mathbf{P}$ be a local section. Define

$$\mathbf{A}_\alpha := \mathbf{s}_\alpha^* \omega \in \Omega^1(U_\alpha; \mathfrak{g}), \qquad \mathbf{F}_\alpha := \mathbf{s}_\alpha^* \mathbf{\Omega}_\omega.$$

Then

$$\mathbf{F}_\alpha = d\mathbf{A}_\alpha + \frac{1}{2}[\mathbf{A}_\alpha \wedge \mathbf{A}_\alpha]. \tag{2.38}$$

If $\mathbf{s}_\beta = \mathbf{s}_\alpha g_{\alpha\beta}$, then

$$\mathbf{A}_\beta = \mathrm{Ad}_{g_{\alpha\beta}^{-1}} \mathbf{A}_\alpha + g_{\alpha\beta}^{-1} dg_{\alpha\beta}, \tag{2.39}$$

$$\mathbf{F}_\beta = \mathrm{Ad}_{g_{\alpha\beta}^{-1}} \mathbf{F}_\alpha. \tag{2.40}$$

Here $g^{-1}dg$ denotes the pullback of the left Maurer–Cartan form of G.

Proof. The first identity is the pullback of (2.37). Let $X \in T_x M$ and write $g = g_{\alpha\beta}(x)$. Differentiating $\mathbf{s}_\beta = \mathbf{s}_\alpha g_{\alpha\beta}$ gives

$$d(\mathbf{s}_\beta)_x X = (dR_{\mathbf{g}})_{\mathbf{s}_\alpha(x)} d(\mathbf{s}_\alpha)_x X + \big(g^{-1} dg(X)\big)_{\mathbf{P}}\big|_{\mathbf{s}_\beta(x)}.$$

Applying ω and using (2.32)–(2.33) yields (2.39).
For curvature, the second summand of the preceding expression is vertical, while $\mathbf{\Omega}_\omega$ is horizontal. The

horizontal summands transform by $dR_{\mathbf{g}}$, and equivariance of $\mathbf{\Omega}_\omega$ gives (2.40). □

Definition 2.6.18. (Exterior covariant derivative) Let M be a smooth manifold with or without boundary, let ω be a principal connection on $\mathbf{P} \to M$, let $\rho\colon G \to GL(V)$ be a representation, and let $\rho_*\colon \mathfrak{g} \to \mathrm{End}(V)$ be its differential. For a horizontal, ρ-equivariant form $\boldsymbol{\alpha} \in \Omega^k(\mathbf{P}; V)$, define

$$D_\omega \boldsymbol{\alpha} := d\boldsymbol{\alpha} + \rho_*(\omega) \wedge \boldsymbol{\alpha}. \tag{2.41}$$

The second operation is given by

$$\big(\rho_*(\omega) \wedge \boldsymbol{\alpha}\big)(\mathbf{X}_0, \dots, \mathbf{X}_k) = \sum_{i=0}^{k} (-1)^i \rho_*(\omega(\mathbf{X}_i))\boldsymbol{\alpha}(\mathbf{X}_0, \dots, \widehat{\mathbf{X}}_i, \dots, \mathbf{X}_k).$$

Proposition 2.6.19. Let M be a smooth manifold with or without boundary, and let ω, ρ, and $\boldsymbol{\alpha}$ be as in the preceding definition. The form $D_\omega \boldsymbol{\alpha}$ is again horizontal and ρ-equivariant. Consequently, it descends to an operator

$$d_\omega\colon \Omega^k(M; \mathbf{P} \times_\rho V) \longrightarrow \Omega^{k+1}(M; \mathbf{P} \times_\rho V).$$

In a local section $\mathbf{s}_\alpha$, if $\mathbf{a}_\alpha := \mathbf{s}_\alpha^* \boldsymbol{\alpha}$, then

$$(d_\omega \mathbf{a})_\alpha = d_{\mathbf{A}_\alpha} \mathbf{a}_\alpha := d\mathbf{a}_\alpha + \rho_*(\mathbf{A}_\alpha) \wedge \mathbf{a}_\alpha. \tag{2.42}$$

If $\mathbf{a}_\beta = \rho(g_{\alpha\beta}^{-1})\mathbf{a}_\alpha$, then

$$d_{\mathbf{A}_\beta} \mathbf{a}_\beta = \rho(g_{\alpha\beta}^{-1}) d_{\mathbf{A}_\alpha} \mathbf{a}_\alpha. \tag{2.43}$$

For the adjoint representation,

$$d_{\mathbf{A}} \mathbf{a} = d\mathbf{a} + [\mathbf{A} \wedge \mathbf{a}].$$

Proof. Equivariance of $D_\omega \boldsymbol{\alpha}$ follows by applying $R_{\mathbf{g}}^*$ to (2.41) and using

$$\rho_*(\mathrm{Ad}_{g^{-1}} \xi) = \rho(g^{-1}) \rho_*(\xi) \rho(g).$$

To prove horizontality, let $\boldsymbol{\xi}_{\mathbf{P}}$ be a fundamental vertical vector field. Infinitesimal equivariance of $\boldsymbol{\alpha}$ gives

$$\mathcal{L}_{\boldsymbol{\xi}_{\mathbf{P}}} \boldsymbol{\alpha} = -\rho_*(\xi) \boldsymbol{\alpha}.$$

Since $\iota_{\boldsymbol{\xi}_{\mathbf{P}}} \boldsymbol{\alpha} = 0$, Cartan's formula implies

$$\iota_{\boldsymbol{\xi}_{\mathbf{P}}} d\boldsymbol{\alpha} = -\rho_*(\xi) \boldsymbol{\alpha}.$$

On the other hand,

$$\iota_{\boldsymbol{\xi}_{\mathbf{P}}} \big(\rho_*(\omega) \wedge \boldsymbol{\alpha}\big) = \rho_*(\xi) \boldsymbol{\alpha},$$

and the terms cancel. Thus $D_\omega \boldsymbol{\alpha}$ descends by Proposition 2.6.9.
The local formula follows by pulling back by $\mathbf{s}_\alpha$. The covariance identity expresses that two local pullbacks represent the same global form. It can also be checked directly by substituting (2.39) and $\mathbf{a}_\beta = \rho(g_{\alpha\beta}^{-1})\mathbf{a}_\alpha$. For $\rho = \mathrm{Ad}$, we have $\rho_*(\xi)\eta = [\xi, \eta]$. □

Corollary 2.6.20. (Induced connection on an associated bundle) Let M be a smooth manifold with or without boundary, let ω be a principal connection on $\mathbf{P} \to M$, and let $\rho\colon G \to GL(V)$ be a representation. For $\mathbf{E} = \mathbf{P} \times_\rho V$, the degree-zero operator

$$\nabla^{\mathbf{E},\omega} := d_\omega\colon \Gamma(\mathbf{E}) = \Omega^0(M;\mathbf{E}) \longrightarrow \Omega^1(M;\mathbf{E})$$

is a complex or real connection according to V. If u_α are the local components of a section $\mathbf{u}$, then

$$(\nabla^{\mathbf{E},\omega}\mathbf{u})_\alpha = du_\alpha + \rho_*(\mathbf{A}_\alpha)u_\alpha. \tag{2.44}$$

Equivalently, if $\widetilde{u}\colon \mathbf{P} \to V$ is the associated equivariant map and $\widetilde{\mathbf{X}}$ is the horizontal lift of a vector field $\mathbf{X}$, then

$$(\nabla^{\mathbf{E},\omega}_{\mathbf{X}}\mathbf{u})(x) = [p, d\widetilde{u}_p(\widetilde{\mathbf{X}}_p)]_\rho.$$

Proof. The local formula (2.42) with $k = 0$ is (2.44). It gives linearity and $\nabla(f\mathbf{u}) = df \otimes \mathbf{u} + f\nabla\mathbf{u}$. The covariance identity (2.43) shows that the expressions glue. In the equivariant model, $\omega(\widetilde{\mathbf{X}}) = 0$, so $D_\omega\widetilde{u}(\widetilde{\mathbf{X}}) = d\widetilde{u}(\widetilde{\mathbf{X}})$; the descent of forms proves the final formula. □

Theorem 2.6.21. (Square of the covariant derivative and the Bianchi identity) Let M be a smooth manifold with or without boundary, and let $\mathbf{A}$ be a local potential for a principal connection on $\mathbf{P} \to M$. For every representation ρ and every local form $\mathbf{a}$ with values in V,

$$d^2_{\mathbf{A}}\mathbf{a} = \rho_*(\mathbf{F}_\mathbf{A}) \wedge \mathbf{a}. \tag{2.45}$$

In particular, for forms with values in $\mathrm{ad}(\mathbf{P})$,

$$d^2_{\mathbf{A}}\mathbf{a} = [\mathbf{F}_\mathbf{A} \wedge \mathbf{a}]. \tag{2.46}$$

The curvature satisfies the Bianchi identity

$$d_\mathbf{A}\mathbf{F}_\mathbf{A} = d\mathbf{F}_\mathbf{A} + [\mathbf{A} \wedge \mathbf{F}_\mathbf{A}] = 0. \tag{2.47}$$

These identities are compatible with changes of local section and are therefore global.

Proof. Write $\mathbf{B} = \rho_*(\mathbf{A})$. Using the exterior Leibniz rule,

$$(d + \mathbf{B}\wedge)^2\mathbf{a} = d\mathbf{B} \wedge \mathbf{a} + \mathbf{B} \wedge \mathbf{B} \wedge \mathbf{a}.$$

Since ρ_* is a Lie algebra homomorphism,

$$\mathbf{B} \wedge \mathbf{B} = \frac{1}{2}\rho_*([\mathbf{A} \wedge \mathbf{A}]).$$

This proves (2.45), and the adjoint representation gives (2.46).

For the Bianchi identity, by $\mathbf{F_A} = d\mathbf{A} + \frac{1}{2}[\mathbf{A} \wedge \mathbf{A}]$ and Lemma 2.6.13,

$$d\mathbf{F_A} = \frac{1}{2}\big([d\mathbf{A} \wedge \mathbf{A}] - [\mathbf{A} \wedge d\mathbf{A}]\big) = -[\mathbf{A} \wedge d\mathbf{A}].$$

Moreover,

$$[\mathbf{A} \wedge \mathbf{F_A}] = [\mathbf{A} \wedge d\mathbf{A}] + \frac{1}{2}[\mathbf{A} \wedge [\mathbf{A} \wedge \mathbf{A}]] = [\mathbf{A} \wedge d\mathbf{A}].$$

The sum is zero. The covariance identities (2.43) and (2.40) show that all these identities glue. □

Theorem 2.6.22. (Existence of principal connections) Let M be a smooth manifold with or without boundary. Every smooth principal bundle $\mathbf{P} \to M$ admits a principal connection.

Proof. Let $\{U_\alpha\}_{\alpha \in I}$ be a trivializing cover. On $\pi^{-1}(U_\alpha) \cong U_\alpha \times G$, define

$$\omega_\alpha(X, \zeta) := \theta^L_g(\zeta), \qquad (X, \zeta) \in T_x U_\alpha \oplus T_g G,$$

where $\theta^L_g = (dL_{g^{-1}})_g$ is the left Maurer–Cartan form. A direct verification gives

$$\omega_\alpha(\boldsymbol{\xi}_\mathbf{P}) = \xi, \qquad R_h^* \omega_\alpha = \mathrm{Ad}_{h^{-1}}\, \omega_\alpha;$$

therefore ω_α is a local principal connection.
Let $\{\chi_\alpha\}_{\alpha \in I}$ be a smooth partition of unity subordinate to $\{U_\alpha\}$, whose existence is given by Theorem 1.3.5. Each form $(\pi^* \chi_\alpha)\omega_\alpha$, extended by zero outside $\pi^{-1}(U_\alpha)$, is smooth, and the family is locally finite. Define

$$\omega := \sum_{\alpha \in I} (\pi^* \chi_\alpha)\omega_\alpha.$$

Since $\sum_{\alpha \in I} \chi_\alpha = 1$,

$$\omega(\boldsymbol{\xi}_\mathbf{P}) = \sum_{\alpha \in I} (\pi^* \chi_\alpha)\xi = \xi.$$

The functions $\pi^* \chi_\alpha$ are invariant under the right action and each ω_α is equivariant, so $R_\mathbf{g}^* \omega = \mathrm{Ad}_{g^{-1}}\, \omega$. Therefore ω is a global principal connection. □

Theorem 2.6.23. (Affine structure of the space of connections) Let M be a smooth manifold with or without boundary, and let $\mathbf{P} \to M$ be a principal bundle. Let $\mathrm{Conn}(\mathbf{P})$ be the set of principal connections on $\mathbf{P}$. If $\omega_0, \omega_1 \in \mathrm{Conn}(\mathbf{P})$, then

$$\mathbf{a} := \omega_1 - \omega_0$$

is horizontal and Ad-equivariant, and therefore corresponds to a unique element of

$$\Omega^1(M; \mathrm{ad}(\mathbf{P})).$$

Conversely, if ω_0 is a connection and $\mathbf{a} \in \Omega^1(M; \mathrm{ad}(\mathbf{P}))$, the corresponding horizontal equivariant form $\widetilde{\mathbf{a}}$ satisfies the condition that

$$\omega_0 + \widetilde{\mathbf{a}}$$

is a principal connection. Consequently, $\mathrm{Conn}(\mathbf{P})$ is an affine space modeled on $\Omega^1(M;\mathrm{ad}(\mathbf{P}))$.

Proof. For every $\xi \in \mathfrak{g}$,

$$\mathbf{a}(\xi_{\mathbf{P}}) = \omega_1(\xi_{\mathbf{P}}) - \omega_0(\xi_{\mathbf{P}}) = \xi - \xi = 0,$$

so $\mathbf{a}$ is horizontal. Equivariance follows by subtracting the equivariance identities for ω_1 and ω_0. Proposition 2.6.9 then identifies $\mathbf{a}$ with a form in $\Omega^1(M;\mathrm{ad}(\mathbf{P}))$.
Conversely, a horizontal equivariant form vanishes on fundamental vector fields and satisfies the same transformation law as a connection form. Therefore,

$$(\omega_0 + \widetilde{\mathbf{a}})(\xi_{\mathbf{P}}) = \xi, \qquad R_{\mathbf{g}}^*(\omega_0 + \widetilde{\mathbf{a}}) = \mathrm{Ad}_{g^{-1}}(\omega_0 + \widetilde{\mathbf{a}}).$$

□

Corollary 2.6.24. Let M be a smooth manifold with or without boundary, and let $\mathbf{P} \to M$ be a principal bundle with compact group G. Any Ad-invariant inner product given by Corollary 1.9.23 induces a well-defined bundle metric on $\mathrm{ad}(\mathbf{P})$ by

$$\langle [p,\xi],[p,\eta]\rangle_{\mathrm{ad}(\mathbf{P})} := \langle \xi,\eta\rangle_{\mathfrak{g}}.$$

Proof. Replacing p by $p \cdot g$ replaces the representatives by $\mathrm{Ad}_{g^{-1}}\xi$ and $\mathrm{Ad}_{g^{-1}}\eta$. Invariance of the inner product shows that the value does not change. □

2.6.1 Parallel transport and holonomy

Theorem 2.6.25. (Horizontal lift) Let M be a smooth manifold with or without boundary, let ω be a principal connection on $\mathbf{P} \to M$, let $\gamma\colon [a,b] \to M$ be a piecewise smooth curve, and let $p_0 \in \mathbf{P}_{\gamma(a)}$. There exists a unique piecewise smooth curve $\widetilde{\gamma}_{p_0}\colon [a,b] \to \mathbf{P}$ such that

$$\widetilde{\gamma}_{p_0}(a) = p_0, \qquad \pi \circ \widetilde{\gamma}_{p_0} = \gamma, \qquad \dot{\widetilde{\gamma}}_{p_0}(t) \in \mathbf{H}_{\widetilde{\gamma}_{p_0}(t)}\mathbf{P}$$

on each interval of smoothness. Moreover,

$$\widetilde{\gamma}_{p_0 g}(t) = \widetilde{\gamma}_{p_0}(t)g.$$

Proof. In a trivialization, write $\widetilde{\gamma}(t) = \mathbf{s}(\gamma(t))g(t)$ and $\mathbf{A} = \mathbf{s}^*\omega$. The horizontality condition is the differential equation on G

$$\theta^L_{g(t)}\dot{g}(t) = -\mathrm{Ad}_{g(t)^{-1}}\mathbf{A}_{\gamma(t)}(\dot{\gamma}(t)),$$

with prescribed initial data. Existence and uniqueness for differential equations gives a solution while the curve remains in the trivialization. A finite subdivision of $[a,b]$ into trivializing domains glues the unique solutions. The invariance $(dR_{\mathbf{g}})\mathbf{H} = \mathbf{H}$ shows that $\widetilde{\gamma}_{p_0}g$ is the horizontal lift with initial data $p_0 g$, and uniqueness proves the final formula. □

Definition 2.6.26. (Principal parallel transport) Let M be a smooth manifold with or without boundary, let ω be a principal connection on $\mathbf{P} \to M$, and let $\gamma\colon [a,b] \to M$ be a piecewise smooth curve. The **principal parallel transport** of γ is

$$\mathcal{P}^{\omega}_{\gamma} : \mathbf{P}_{\gamma(a)} \longrightarrow \mathbf{P}_{\gamma(b)}, \qquad \mathcal{P}^{\omega}_{\gamma}(p) := \widetilde{\gamma}_p(b).$$

Proposition 2.6.27. (Laws of principal transport) Let M be a smooth manifold with or without boundary, and let ω be a principal connection on $\mathbf{P} \to M$. Principal transport is G-equivariant and satisfies

$$\mathcal{P}^{\omega}_{\gamma^{-1}} = (\mathcal{P}^{\omega}_{\gamma})^{-1}, \qquad \mathcal{P}^{\omega}_{\gamma_2 * \gamma_1} = \mathcal{P}^{\omega}_{\gamma_2} \circ \mathcal{P}^{\omega}_{\gamma_1},$$

where $\gamma_2 * \gamma_1$ traverses γ_1 first and then γ_2. It is also invariant under orientation-preserving reparametrizations.

Proof. Equivariance is the final assertion of the preceding theorem. Reversing the parameter of a horizontal lift produces a horizontal lift of the reversed curve. For a concatenation, glue the lift of γ_1 to the lift of γ_2 whose initial point is the endpoint of the first; uniqueness gives the formula. The same argument proves invariance under reparametrization. □

Definition 2.6.28. (Principal holonomy group) Let M be a smooth manifold with or without boundary, let ω be a principal connection on $\mathbf{P} \to M$, and let $x = \pi(p)$. The **holonomy group of ω based at p** is

$$\mathrm{Hol}_p(\omega) := \{g \in G \mid \mathcal{P}^{\omega}_{\gamma}(p) = pg \text{ for some piecewise smooth loop } \gamma \text{ based at } x\}.$$

Proposition 2.6.29. (Structure and change of base point for holonomy) Let M be a smooth manifold with or without boundary, let ω be a principal connection on $\mathbf{P} \to M$, and let $p \in \mathbf{P}$. The set $\mathrm{Hol}_p(\omega)$ is a subgroup of G. If $h \in G$, then

$$\mathrm{Hol}_{ph}(\omega) = h^{-1}\,\mathrm{Hol}_p(\omega)\,h.$$

If λ is a curve from x to y and $q = \mathcal{P}^{\omega}_{\lambda}(p)$, then $\mathrm{Hol}_q(\omega) = \mathrm{Hol}_p(\omega)$. For another choice $qh \in \mathbf{P}_y$, the groups are conjugate by h.

Proof. The constant loop represents e. If the loops α, β represent g, h, respectively, traversing β and then α takes us, by equivariance, from p to pgh; reversing a loop representing g produces g^{-1}. This proves the subgroup property. Starting at ph, the lift of a loop that starts at p and ends at pg instead ends at $pgh = (ph)(h^{-1}gh)$, giving the conjugation formula. Finally, conjugating a loop based at y by λ and λ^{-1} preserves the element of G when q is the transport of p. The final assertion combines this fact with the formula within a single fiber. □

Proposition 2.6.30. (Holonomy of an associated bundle) Let M be a smooth manifold with or without boundary, let ω be a principal connection on $\mathbf{P} \to M$, and let $\mathbf{E} = \mathbf{P} \times_{\rho} V$. The transport induced by ω is

$$\mathcal{P}^{\mathbf{E},\omega}_{\gamma}[p, v] := [\mathcal{P}^{\omega}_{\gamma}(p), v].$$

It is well defined, linear, and satisfies the inversion and concatenation laws. Therefore,

$$\mathrm{Hol}_x(\mathbf{E},\omega) := \{\mathcal{P}_\gamma^{\mathbf{E},\omega} \mid \gamma \text{ is a loop based at } x\} \subseteq GL(\mathbf{E}_x)$$

is a subgroup. If $\mathcal{P}_\gamma^\omega(p) = pg$, the identification $\mathbf{E}_x \cong V$ determined by p represents $\mathcal{P}_\gamma^{\mathbf{E},\omega}$ by $\rho(g)$. When the base point changes, the vector bundle holonomy groups are conjugate through parallel transport along a curve joining the points.

Proof. If $[pg, v] = [p, \rho(g)v]$, principal equivariance gives

$$[\mathcal{P}_\gamma^\omega(pg), v] = [\mathcal{P}_\gamma^\omega(p)g, v] = [\mathcal{P}_\gamma^\omega(p), \rho(g)v],$$

so the definition is independent of the representative. The remaining assertions follow from Proposition 2.6.27. □

Definition 2.6.31. (Parallel section of the adjoint group bundle) Let M be a smooth manifold with or without boundary, and let ω be a principal connection on $\mathbf{P} \to M$. A section $\mathbf{u} \in \Gamma(\mathrm{Ad}(\mathbf{P}))$ is **ω-parallel** if its equivariant map $\widehat{u}\colon \mathbf{P} \to G$ is constant along every horizontal curve. Denote the group of these sections by $\Gamma^\omega_{\mathrm{par}}(\mathrm{Ad}(\mathbf{P}))$.

Theorem 2.6.32. (Parallel sections and the centralizer of holonomy) Let M be a connected smooth manifold with or without boundary, let ω be a principal connection on $\mathbf{P} \to M$, and fix $p \in \mathbf{P}$. Evaluation

$$\mathrm{ev}_p\colon \Gamma^\omega_{\mathrm{par}}(\mathrm{Ad}(\mathbf{P})) \longrightarrow G, \qquad \mathbf{u} \longmapsto \widehat{u}(p),$$

is a group isomorphism onto $Z_G(\mathrm{Hol}_p(\omega))$.

Proof. Let $\mathbf{u}$ be parallel, let $\widehat{u}$ be its equivariant representative, and set $c = \widehat{u}(p)$. If a loop has a horizontal lift from p to pg, constancy along horizontal curves and equivariance give

$$c = \widehat{u}(p) = \widehat{u}(pg) = g^{-1}\widehat{u}(p)g = g^{-1}cg.$$

Therefore c centralizes $\mathrm{Hol}_p(\omega)$.
Conversely, let $c \in Z_G(\mathrm{Hol}_p(\omega))$. For $q \in \mathbf{P}_y$, choose a curve γ from $\pi(p)$ to y and write uniquely

$$q = \mathcal{P}_\gamma^\omega(p)h.$$

Define $\widehat{u}(q) := h^{-1}ch$. If another curve produces $q = \mathcal{P}_{\gamma'}^\omega(p)h'$, then $\mathcal{P}_{\gamma'}^\omega(p) = \mathcal{P}_\gamma^\omega(p)a$ for some $a \in \mathrm{Hol}_p(\omega)$ and $h' = a^{-1}h$. Since $ac = ca$, the two formulas for $\widehat{u}(q)$ agree. The construction satisfies $\widehat{u}(qk) = k^{-1}\widehat{u}(q)k$ and is constant along horizontal lifts. In a trivializing neighborhood, choose paths depending smoothly on the point; smooth dependence of transport shows that $\widehat{u}$ is smooth.
The construction is inverse to evaluation. It also shows that a parallel section equal to e at p is the identity section, so evaluation is injective. Since multiplication is pointwise, it is a group isomorphism. □

Definition 2.6.33. (Gauge group and right action on connections) Let M be a smooth manifold with or without boundary, and let $\mathbf{P} \to M$ be a right principal bundle. A *gauge transformation* $\mathbf{u}$ is a section of $\mathrm{Ad}(\mathbf{P})$ or, equivalently, is represented by a smooth map $\widehat{u}\colon \mathbf{P} \to G$ satisfying

$$\widehat{u}(p \cdot g) = g^{-1}\widehat{u}(p)g.$$

The corresponding principal automorphism is

$$\Phi_{\mathbf{u}}\colon \mathbf{P} \longrightarrow \mathbf{P}, \qquad \Phi_{\mathbf{u}}(p) := p \cdot \widehat{u}(p).$$

Define the right gauge action on connections by

$$\omega \triangleleft \mathbf{u} := \Phi_{\mathbf{u}}^{*}\omega.$$

Proposition 2.6.34. (Three models of the gauge group) Let M be a smooth manifold with or without boundary, and let $\mathbf{P} \to M$ be a right principal bundle. There is a group correspondence between:

(a) principal automorphisms $\Phi\colon \mathbf{P} \to \mathbf{P}$ covering id_M;

(b) smooth equivariant maps $\widehat{u}\colon \mathbf{P} \to G$ with $\widehat{u}(pg) = g^{-1}\widehat{u}(p)g$;

(c) smooth sections $\mathbf{u}$ of $\mathrm{Ad}(\mathbf{P})$.

The correspondence between the first two models is $\Phi_{\mathbf{u}}(p) = p \cdot \widehat{u}(p)$. For a connection ω, the stabilizer is

$$\mathrm{Stab}(\omega) := \{\mathbf{u} \in \mathcal{G}(\mathbf{P}) \mid \omega \triangleleft \mathbf{u} = \omega\}.$$

If $\xi \in \Gamma(\mathrm{ad}(\mathbf{P}))$ and $\mathbf{u}_t$ is the gauge transformation with equivariant representative $\widehat{u_t}(p) = \exp_G(t\widehat{\xi}(p))$, the differential at the identity of the right gauge action is

$$\left.\frac{d}{dt}\right|_0 (\omega \triangleleft \mathbf{u}_t) = d_\omega \xi; \tag{2.48}$$

therefore the space of infinitesimal directions annihilating the orbit map at ω is $\ker d_\omega$. The identification of this kernel with the Lie algebra of the Sobolev stabilizer will be proved later, once that Lie group structure has been constructed.

Proof. If Φ covers the identity, freeness and transitivity of the action on each fiber give a unique $\widehat{u}(p)$ with $\Phi(p) = p \cdot \widehat{u}(p)$. From $\Phi(pg) = \Phi(p)g$, we obtain $(p \cdot g) \cdot \widehat{u}(p \cdot g) = (p \cdot \widehat{u}(p)) \cdot g$ and, by freeness, $\widehat{u}(pg) = g^{-1}\widehat{u}(p)g$. In trivializations, the function $\widehat{u}$ is smooth. The converse is checked by substituting the equivariance law, and Proposition 2.6.6, applied to the conjugation action, gives the third model.
In a local section, let $\mathbf{A}$ be the connection potential and ξ_U the local representative of ξ. Differentiating $u_t^{-1}\mathbf{A}u_t + u_t^{-1}du_t$ for $u_t = \exp_G(t\xi_U)$ gives $d\xi_U + [\mathbf{A}, \xi_U] = d_{\mathbf{A}}\xi_U$. Thus the kernel of the differential of the orbit map at the identity is exactly $\ker d_\omega$, which is the infinitesimal assertion in the statement. □

Proposition 2.6.35. (Gauge formulas) Let M be a smooth manifold with or without boundary, let ω be a principal connection on $\mathbf{P} \to M$, and let $\mathbf{u}, \mathbf{v} \in \mathcal{G}(\mathbf{P})$. With pointwise multiplication of gauge transforma-

tions,

$$\Phi_{\mathbf{u}} \circ \Phi_{\mathbf{v}} = \Phi_{\mathbf{uv}}, \qquad (\omega \triangleleft \mathbf{u}) \triangleleft \mathbf{v} = \omega \triangleleft (\mathbf{uv}).$$

If $\mathbf{s}\colon U \to \mathbf{P}$ is a local section, $\mathbf{A} = \mathbf{s}^*\omega$, and $u_U = \widehat{u} \circ \mathbf{s}$, then

$$\mathbf{A} \triangleleft u_U := \mathbf{s}^*(\omega \triangleleft \mathbf{u}) = \mathrm{Ad}_{u_U^{-1}} \mathbf{A} + u_U^{-1} du_U, \tag{2.49}$$

$$\mathbf{F}_{\mathbf{A} \triangleleft u_U} = \mathrm{Ad}_{u_U^{-1}} \mathbf{F}_{\mathbf{A}}. \tag{2.50}$$

For a matrix group,

$$\mathbf{A} \triangleleft u = u^{-1}\mathbf{A}u + u^{-1}du, \qquad \mathbf{F}_{\mathbf{A} \triangleleft u} = u^{-1}\mathbf{F}_{\mathbf{A}}u.$$

Proof. Equivariance of the representatives $\widehat{u}$ and $\widehat{v}$ gives

$$\Phi_{\mathbf{u}}(\Phi_{\mathbf{v}}(p)) = p\,\widehat{v}(p)\,\widehat{u}(p\widehat{v}(p)) = p\,\widehat{v}(p)\,\widehat{v}(p)^{-1}\widehat{u}(p)\widehat{v}(p) = p\,\widehat{u}(p)\widehat{v}(p) = \Phi_{\mathbf{uv}}(p).$$

By contravariance of pullback,

$$\Phi_{\mathbf{v}}^*\Phi_{\mathbf{u}}^*\omega = (\Phi_{\mathbf{u}} \circ \Phi_{\mathbf{v}})^*\omega = \Phi_{\mathbf{uv}}^*\omega,$$

which proves the right action law.
Moreover,

$$\Phi_{\mathbf{u}} \circ \mathbf{s} = \mathbf{s}\,u_U.$$

The local transformation formula (2.39), applied to the sections $\mathbf{s}$ and $\mathbf{s}\,u_U$, gives (2.49). Horizontality and equivariance of curvature, or equivalently (2.40), give (2.50). □

Theorem 2.6.36. (Smooth stabilizer and holonomy) Let M be a connected smooth manifold with or without boundary, let ω be a principal connection on $\mathbf{P} \to M$, and fix $p \in \mathbf{P}$. For a smooth gauge transformation $\mathbf{u}$ with equivariant representative $\widehat{u}$, the following are equivalent:

(a) $\omega \triangleleft \mathbf{u} = \omega$;

(b) the equivariant map $\widehat{u}\colon \mathbf{P} \to G$ is constant along every horizontal curve;

(c) the section $\mathbf{u}$ of $\mathrm{Ad}(\mathbf{P})$ is ω-parallel.

Consequently, evaluation at p induces an isomorphism

$$\mathrm{Stab}_{C^\infty}(\omega) \xrightarrow{\cong} Z_G(\mathrm{Hol}_p(\omega)). \tag{2.51}$$

Moreover, evaluation identifies the infinitesimal directions:

$$\ker\big(d_\omega\colon \Omega^0(M;\mathrm{ad}(\mathbf{P})) \to \Omega^1(M;\mathrm{ad}(\mathbf{P}))\big) \cong \mathrm{Lie}\, Z_G(\mathrm{Hol}_p(\omega)). \tag{2.52}$$

Proof. On a horizontal vector $X \in \mathbf{H}_q\mathbf{P}$, the global transformation formula for a connection reduces to

$$(\Phi_{\mathbf{u}}^*\omega)_q(X) = \theta^L_{\widehat{u}(q)}(d\widehat{u}_q X),$$

because $\omega_q(X) = 0$. Therefore $\Phi_{\mathbf{u}}^*\omega = \omega$ implies $d\widehat{u}(X) = 0$ for every horizontal vector. Conversely, this last

condition makes both connection forms vanish on $\mathbf{H}$; on vertical vectors, both reproduce the infinitesimal generator. Since $T\mathbf{P} = \mathbf{H} \oplus \mathbf{V}$, the forms agree. This proves the equivalence of (a)–(c).
The isomorphism (2.51) is now Theorem 2.6.32. For the infinitesimal statement, the formula for the induced connection on $\mathrm{ad}(\mathbf{P})$ shows that $d_\omega \xi = 0$ if and only if the equivariant map $\widehat{\xi}\colon \mathbf{P} \to \mathfrak{g}$ is constant along horizontal curves. The same evaluation argument identifies it with the vectors fixed by $\mathrm{Ad}(\mathrm{Hol}_p(\omega))$, which form the Lie algebra of the centralizer by (1.24). □

2.7 Covariant differentiation along curves and parallel transport

In many geometric constructions, differentiating sections defined on open sets of the manifold is not enough. We often need to study objects defined only along a curve. This occurs, for example, when comparing elements belonging to different fibers, studying the variation of a section along a path, or, in the particular case of the tangent bundle, defining the covariant acceleration of a curve.

The difficulty is that, if $\pi\colon \mathbf{E} \longrightarrow M$ is a smooth vector bundle and $\gamma\colon I \longrightarrow M$ is a smooth curve, a section of $\mathbf{E}$ along γ assigns to each $t \in I$ a vector in the fiber $\mathbf{E}_{\gamma(t)}$. Since these fibers are, in principle, different vector spaces, differentiating such a section by directly subtracting its values makes no sense. A connection resolves this problem: it gives an intrinsic way of differentiating sections in tangent directions and thereby induces a derivative for sections defined only along the curve.

Before formalizing this construction, we recall the pullback of a vector bundle.

Definition 2.7.1. (Pullbacks of vector bundles) Let M and N be smooth manifolds with or without boundary, let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle of rank k, and let $f\colon N \longrightarrow M$ be a smooth map. Define the *pullback* of $\mathbf{E}$ by f to be the set

$$f^*\mathbf{E} := \{(y, e) \in N \times \mathbf{E} \mid \pi(e) = f(y)\}.$$

Equip $f^*\mathbf{E}$ with the projection $\pi_{f^*\mathbf{E}}\colon f^*\mathbf{E} \longrightarrow N$ given by $\pi_{f^*\mathbf{E}}(y, e) := y$. For each $y \in N$, the fiber of $f^*\mathbf{E}$ over y is given by $(f^*\mathbf{E})_y = \{(y, e) \in f^*\mathbf{E} \mid e \in \mathbf{E}_{f(y)}\}$. Using the natural identification $(y, e) \mapsto e$, we identify $(f^*\mathbf{E})_y$ with $\mathbf{E}_{f(y)}$.

Proposition 2.7.2. Let M and N be smooth manifolds with or without boundary, let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle of rank k, and let $f\colon N \longrightarrow M$ be a smooth map. Then $f^*\mathbf{E} \longrightarrow N$ admits a natural structure of a smooth vector bundle of rank k.

Proof. Recall that $f^*\mathbf{E} = \{(y, e) \in N \times \mathbf{E} \mid \pi(e) = f(y)\}$, with projection $\pi_{f^*\mathbf{E}}(y, e) = y$. For each $y \in N$, the fiber of $f^*\mathbf{E}$ over y is given by $(f^*\mathbf{E})_y = \{(y, e) \mid e \in \mathbf{E}_{f(y)}\}$, which we identify with $\mathbf{E}_{f(y)}$ through $(y, e) \mapsto e$.
Let $\{U_\alpha\}_{\alpha \in A}$ be a trivializing cover of $\mathbf{E}$, with trivializations $\Phi_\alpha\colon \pi^{-1}(U_\alpha) \longrightarrow U_\alpha \times \mathbb{K}^k$. Then $\{f^{-1}(U_\alpha)\}_{\alpha \in A}$ is an open cover of N because f is continuous.
For each α, define

$$\widetilde{\Phi}_\alpha : \pi^{-1}_{f^*\mathbf{E}}(f^{-1}(U_\alpha)) \longrightarrow f^{-1}(U_\alpha) \times \mathbb{K}^k$$

by

$$\widetilde{\Phi}_\alpha(y, e) := \big(y, \mathrm{pr}_2(\Phi_\alpha(e))\big),$$

where $\mathrm{pr}_2\colon U_\alpha \times \mathbb{K}^k \longrightarrow \mathbb{K}^k$ is the second projection. This expression is well defined because, if $(y, e) \in f^*\mathbf{E}$ and $y \in f^{-1}(U_\alpha)$, then $f(y) \in U_\alpha$ and, since $\pi(e) = f(y)$, we have $e \in \pi^{-1}(U_\alpha)$.

Let us show that $\widetilde{\Phi}_\alpha$ is bijective. Let $(y,v) \in f^{-1}(U_\alpha) \times \mathbb{K}^k$. Since $f(y) \in U_\alpha$, there is a unique $e \in \mathbf{E}_{f(y)}$ such that $\Phi_\alpha(e) = (f(y), v)$. Therefore $(y,e) \in f^*\mathbf{E}$ and $\widetilde{\Phi}_\alpha(y,e) = (y,v)$. This proves surjectivity.
If $\widetilde{\Phi}_\alpha(y,e) = \widetilde{\Phi}_\alpha(y',e')$, then $y = y'$ and $\mathrm{pr}_2(\Phi_\alpha(e)) = \mathrm{pr}_2(\Phi_\alpha(e'))$. Moreover, since (y,e) and (y,e') belong to $f^*\mathbf{E}$, we have $\pi(e) = f(y) = \pi(e')$. Therefore the first components of $\Phi_\alpha(e)$ and $\Phi_\alpha(e')$ also agree. Thus $\Phi_\alpha(e) = \Phi_\alpha(e')$. Since Φ_α is injective, we obtain $e = e'$. Hence $\widetilde{\Phi}_\alpha$ is injective. In fact, its inverse is given by

$$\widetilde{\Phi}_\alpha^{-1}(y,v) = \big(y, \Phi_\alpha^{-1}(f(y),v)\big).$$

Moreover, the restriction of $\widetilde{\Phi}_\alpha$ to each fiber $(f^*\mathbf{E})_y$ is a linear isomorphism onto $\{y\} \times \mathbb{K}^k$, since it agrees with the trivialization of $\mathbf{E}$ on the fiber $\mathbf{E}_{f(y)}$ under the natural identification $(f^*\mathbf{E})_y \cong \mathbf{E}_{f(y)}$.
Now consider α, β such that $f^{-1}(U_\alpha) \cap f^{-1}(U_\beta) \neq \varnothing$. On $U_\alpha \cap U_\beta$, the trivializations of $\mathbf{E}$ satisfy

$$\Phi_\alpha \circ \Phi_\beta^{-1}(p,v) = (p, \tau_{\alpha\beta}(p)v),$$

where $\tau_{\alpha\beta} \colon U_\alpha \cap U_\beta \longrightarrow GL(k,\mathbb{K})$ is smooth. Then, for $y \in f^{-1}(U_\alpha \cap U_\beta)$, we have

$$\widetilde{\Phi}_\alpha \circ \widetilde{\Phi}_\beta^{-1}(y,v) = \big(y, \tau_{\alpha\beta}(f(y))v\big).$$

Thus the transition functions of the system $\{\widetilde{\Phi}_\alpha\}$ are given by $\widetilde{\tau}_{\alpha\beta}(y) = \tau_{\alpha\beta}(f(y))$. Since $\tau_{\alpha\beta}$ and f are smooth, $\widetilde{\tau}_{\alpha\beta}$ is also smooth.
By Lemma 1.7.8, there exist a unique topology and smooth structure on $f^*\mathbf{E}$ making it a smooth vector bundle of rank k over N, with projection $\pi_{f^*\mathbf{E}}$ and local trivializations $\widetilde{\Phi}_\alpha$. □

Definition 2.7.3. (Sections along a curve) Let M be a smooth manifold with or without boundary, let $\pi \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle, and let $\gamma \colon I \longrightarrow M$ be a smooth curve. A section of $\mathbf{E}$ along γ is a section of the pullback bundle $\gamma^*\mathbf{E} \longrightarrow I$.
Using the natural identification $(\gamma^*\mathbf{E})_t \cong \mathbf{E}_{\gamma(t)}$, we regard a section of $\mathbf{E}$ along γ as a map $\mathbf{u} \colon I \longrightarrow \mathbf{E}$ such that $\mathbf{u}(t) \in \mathbf{E}_{\gamma(t)}$ for every $t \in I$. Under this identification, we write $\Gamma^k(\gamma^*\mathbf{E})$ for the space of sections of class C^k of $\mathbf{E}$ along γ, and we write $\Gamma(\gamma^*\mathbf{E}) = \Gamma^\infty(\gamma^*\mathbf{E})$.
We say that $\mathbf{u} \in \Gamma^k(\gamma^*\mathbf{E})$ is extendible if there exists a section $\widetilde{\mathbf{u}} \in \Gamma^k(\mathbf{E})$, defined on a neighborhood of $\gamma(I)$, such that $\mathbf{u}(t) = \widetilde{\mathbf{u}}(\gamma(t))$ for every $t \in I$.

Remark 2.7.4. When $\mathbf{E} = TM$, the elements of $\Gamma^k(\gamma^*TM)$ are precisely vector fields of class C^k along γ. More generally, if $\mathbf{E} = T^{(r,s)}(TM)$ carries the connection induced by a connection on TM, we obtain the notion of a tensor field of type (r,s) along γ.

The following result introduces covariant differentiation along a curve. The essential condition is that, if a section along γ is obtained by restricting a section $\widetilde{\mathbf{u}}$ of $\mathbf{E}$, its derivative along the curve must agree with $\nabla^{\mathbf{E}}_{\dot\gamma}\widetilde{\mathbf{u}}$. The result states that this condition uniquely determines a derivative for every section of class C^1 of $\gamma^*\mathbf{E}$.

Theorem 2.7.5. (Covariant derivative along a curve) Let M be a smooth manifold with or without boundary, let $\pi \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$, and let $\gamma \colon I \longrightarrow M$ be a smooth curve. There exists a unique operator

$$\frac{D}{dt} \colon \Gamma^1(\gamma^*\mathbf{E}) \longrightarrow \Gamma^0(\gamma^*\mathbf{E})$$

satisfying the following properties:

(a) $\dfrac{D}{dt}(a\mathbf{u}+b\mathbf{v}) = a\dfrac{D\mathbf{u}}{dt} + b\dfrac{D\mathbf{v}}{dt}$ for every $a,b\in\mathbb{K}$ and every $\mathbf{u},\mathbf{v}\in\Gamma^1(\gamma^*\mathbf{E})$.

(b) $\dfrac{D}{dt}(f\mathbf{u}) = \dfrac{df}{dt}\mathbf{u} + f\dfrac{D\mathbf{u}}{dt}$ for every $f\in C^1(I)$ and every $\mathbf{u}\in\Gamma^1(\gamma^*\mathbf{E})$.

(c) If $\mathbf{u}$ is extendible and $\widetilde{\mathbf{u}}$ is an extension of class C^1 of $\mathbf{u}$ to a neighborhood of $\gamma(I)$, then $\dfrac{D\mathbf{u}}{dt}(t) = \nabla^{\mathbf{E}}_{\dot\gamma(t)}\widetilde{\mathbf{u}}$ for every $t\in I$.

If $\mathbf{u}\in\Gamma^k(\gamma^*\mathbf{E})$ with $k\geq 1$, then $\dfrac{D\mathbf{u}}{dt}\in\Gamma^{k-1}(\gamma^*\mathbf{E})$. In particular, this operator restricts to an operator $\dfrac{D}{dt}\colon\Gamma(\gamma^*\mathbf{E})\longrightarrow\Gamma(\gamma^*\mathbf{E})$.

Proof. We first construct the operator in a local trivialization and then prove independence of the choices. Let $t_0\in I$. Choose a smooth chart (U,φ) on M, with local coordinates $(x^1,\dots,x^n)$, such that $\gamma(t_0)\in U$, and choose a smooth local frame $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ of $\mathbf{E}$ over U. Since $\gamma^{-1}(U)$ is open in I and contains t_0, there is an interval $J\subseteq I$, open in I, such that $t_0\in J$ and $\gamma(J)\subseteq U$.
On J, every section $\mathbf{u}\in\Gamma^1(\gamma^*\mathbf{E})$ can be written uniquely as $\mathbf{u}(t) = u^\alpha(t)\mathbf{e}_\alpha(\gamma(t))$, where $u^1,\dots,u^r$ are functions of class C^1 on J. Define the local connection coefficients by $\nabla^{\mathbf{E}}_{\partial_i}\mathbf{e}_\beta = \Gamma^\alpha_{i\beta}\mathbf{e}_\alpha$. Then define locally

$$\frac{D\mathbf{u}}{dt}(t) = \left(\frac{du^\alpha}{dt}(t) + \frac{d\gamma^i}{dt}(t)\Gamma^\alpha_{i\beta}(\gamma(t))u^\beta(t)\right)\mathbf{e}_\alpha(\gamma(t)). \tag{2.53}$$

We show that this definition is independent of the local frame. Let $(\widetilde{\mathbf{e}}_1,\dots,\widetilde{\mathbf{e}}_r)$ be another local frame of $\mathbf{E}$ over the same open set, and write $\widetilde{\mathbf{e}}_a = B^\beta_a\mathbf{e}_\beta$, where $B=(B^\beta_a)$ is a matrix of smooth functions with values in $GL(r,\mathbb{K})$. If

$$\mathbf{u}(t) = u^\alpha(t)\mathbf{e}_\alpha(\gamma(t)) = \widetilde{u}^a(t)\widetilde{\mathbf{e}}_a(\gamma(t)),$$

then $u^\alpha(t) = B^\alpha_a(\gamma(t))\widetilde{u}^a(t)$. On the other hand, if $\nabla^{\mathbf{E}}_{\partial_i}\widetilde{\mathbf{e}}_b = \widetilde{\Gamma}^a_{ib}\widetilde{\mathbf{e}}_a$, then, using $\widetilde{\mathbf{e}}_b = B^\beta_b\mathbf{e}_\beta$, we obtain

$$\nabla^{\mathbf{E}}_{\partial_i}\widetilde{\mathbf{e}}_b = (\partial_i B^\alpha_b)\mathbf{e}_\alpha + B^\beta_b\nabla^{\mathbf{E}}_{\partial_i}\mathbf{e}_\beta = (\partial_i B^\alpha_b + B^\beta_b\Gamma^\alpha_{i\beta})\mathbf{e}_\alpha.$$

Since also

$$\nabla^{\mathbf{E}}_{\partial_i}\widetilde{\mathbf{e}}_b = \widetilde{\Gamma}^a_{ib}\widetilde{\mathbf{e}}_a = \widetilde{\Gamma}^a_{ib}B^\alpha_a\mathbf{e}_\alpha,$$

we have

$$\partial_i B^\alpha_b + B^\beta_b\Gamma^\alpha_{i\beta} = B^\alpha_a\widetilde{\Gamma}^a_{ib}.$$

Differentiating $u^\alpha = B^\alpha_a(\gamma)\widetilde{u}^a$ with respect to t gives

$$\frac{du^\alpha}{dt} = \frac{d\gamma^i}{dt}(\partial_i B^\alpha_a)(\gamma)\widetilde{u}^a + B^\alpha_a(\gamma)\frac{d\widetilde{u}^a}{dt}.$$

Therefore,

$$\frac{du^\alpha}{dt} + \frac{d\gamma^i}{dt}\Gamma^\alpha_{i\beta}(\gamma)u^\beta = B^\alpha_a(\gamma)\frac{d\widetilde{u}^a}{dt} + \frac{d\gamma^i}{dt}\big(\partial_i B^\alpha_b + B^\beta_b\Gamma^\alpha_{i\beta}\big)(\gamma)\widetilde{u}^b.$$

Using the preceding relation between the connection coefficients yields

$$\frac{du^\alpha}{dt} + \frac{d\gamma^i}{dt}\Gamma^\alpha_{i\beta}(\gamma)u^\beta = B^\alpha_a(\gamma)\left(\frac{d\widetilde{u}^a}{dt} + \frac{d\gamma^i}{dt}\widetilde{\Gamma}^a_{ib}(\gamma)\widetilde{u}^b\right).$$

Multiplying by $\mathbf{e}_\alpha(\gamma(t))$ and using $B^\alpha_a\mathbf{e}_\alpha = \widetilde{\mathbf{e}}_a$ gives exactly the expression for (2.53) in the frame $\widetilde{\mathbf{e}}_a$. Thus the definition is independent of the local frame.

Since the resulting expression is intrinsic with respect to the frame, it also agrees on overlaps of local trivializations. It therefore defines a global section $\dfrac{D\mathbf{u}}{dt} \in \Gamma^0(\gamma^*\mathbf{E})$. If $\mathbf{u} \in \Gamma^k(\gamma^*\mathbf{E})$, the local formula shows that $\dfrac{D\mathbf{u}}{dt} \in \Gamma^{k-1}(\gamma^*\mathbf{E})$.

Linearity over $\mathbb{K}$ is checked directly in the local formula. For the Leibniz rule, let $f \in C^1(I)$. The components of $f\mathbf{u}$ are fu^α, and then

$$\frac{D(f\mathbf{u})}{dt} = \left(\frac{d(fu^\alpha)}{dt} + \frac{d\gamma^i}{dt}\Gamma^\alpha_{i\beta}(\gamma)fu^\beta\right)\mathbf{e}_\alpha(\gamma(t)).$$

Since $\dfrac{d(fu^\alpha)}{dt} = \dfrac{df}{dt}u^\alpha + f\dfrac{du^\alpha}{dt}$, we obtain $\dfrac{D(f\mathbf{u})}{dt} = \dfrac{df}{dt}\mathbf{u} + f\dfrac{D\mathbf{u}}{dt}$.

We now prove compatibility with extensions. Suppose that $\mathbf{u}(t) = \widetilde{\mathbf{u}}(\gamma(t))$, where $\widetilde{\mathbf{u}}$ is a section of class C^1 of $\mathbf{E}$ defined on a neighborhood of $\gamma(I)$. In a local frame, write $\widetilde{\mathbf{u}} = \widetilde{u}^\alpha\mathbf{e}_\alpha$. The components of $\mathbf{u}$ along γ are then $\widetilde{u}^\alpha(\gamma(t))$. By the chain rule,

$$\frac{d}{dt}\big(\widetilde{u}^\alpha(\gamma(t))\big) = \frac{d\gamma^i}{dt}(t)\partial_i\widetilde{u}^\alpha(\gamma(t)).$$

Substituting into (2.53) gives

$$\frac{D\mathbf{u}}{dt}(t) = \frac{d\gamma^i}{dt}(t)\left(\partial_i\widetilde{u}^\alpha(\gamma(t)) + \Gamma^\alpha_{i\beta}(\gamma(t))\widetilde{u}^\beta(\gamma(t))\right)\mathbf{e}_\alpha(\gamma(t)).$$

The expression in parentheses is the local expression for $\nabla^{\mathbf{E}}_{\partial_i}\widetilde{\mathbf{u}}$ in the frame $\mathbf{e}_\alpha$. Therefore $\dfrac{D\mathbf{u}}{dt}(t) = \nabla^{\mathbf{E}}_{\dot\gamma(t)}\widetilde{\mathbf{u}}$.

Finally, we prove uniqueness. Suppose that $\mathcal{D}$ is another operator satisfying the three properties in the statement. On an interval J with $\gamma(J) \subseteq U$, write $\mathbf{u}(t) = u^\alpha(t)\mathbf{e}_\alpha(\gamma(t))$. Since each $\mathbf{e}_\alpha \circ \gamma$ is extendible, the properties of $\mathcal{D}$ imply

$$\mathcal{D}\mathbf{u} = \frac{du^\alpha}{dt}\mathbf{e}_\alpha(\gamma(t)) + u^\alpha(t)\mathcal{D}(\mathbf{e}_\alpha \circ \gamma).$$

By compatibility with extensions, $\mathcal{D}(\mathbf{e}_\alpha \circ \gamma)(t) = \nabla^{\mathbf{E}}_{\dot\gamma(t)}\mathbf{e}_\alpha$. Using $\dot\gamma(t) = \frac{d\gamma^i}{dt}(t)\partial_i|_{\gamma(t)}$ and $\nabla^{\mathbf{E}}_{\partial_i}\mathbf{e}_\beta = \Gamma^\alpha_{i\beta}\mathbf{e}_\alpha$ gives precisely formula (2.53). Therefore $\mathcal{D} = \frac{D}{dt}$ locally. Since t_0 was arbitrary, $\mathcal{D} = \frac{D}{dt}$ on all of I. □

Remark 2.7.6. For the induced connections on $\mathbf{E}^*$, on tensor products, and in particular on tensor bundles constructed from TM, covariant differentiation along curves commutes with contractions and satisfies the Leibniz rule for the tensor product. In particular, taking $\mathbf{E} = T^{(r,s)}(TM)$ gives covariant differentiation of tensor fields of type (r,s) along a curve.

Proposition 2.7.7. (Local expression for the covariant derivative along a curve) Let M be a smooth manifold with or without boundary, let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle of rank r with connection $\nabla^{\mathbf{E}}$, and let $\gamma\colon I \longrightarrow M$ be a smooth curve. Suppose that $\gamma(J) \subseteq U$, where (U,φ) is a smooth chart on M with coordinates $(x^1,\dots,x^n)$, and let $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ be a smooth local frame of $\mathbf{E}$ over U.

If $\mathbf{u}(t) = u^\alpha(t)\mathbf{e}_\alpha(\gamma(t))$, with $t \in J$, and the local connection coefficients are given by $\nabla^{\mathbf{E}}_{\partial_i}\mathbf{e}_\beta = \Gamma^\alpha_{i\beta}\mathbf{e}_\alpha$, then

$$\frac{D\mathbf{u}}{dt}(t) = \left(\frac{du^\alpha}{dt}(t) + \frac{d\gamma^i}{dt}(t)\Gamma^\alpha_{i\beta}(\gamma(t))u^\beta(t)\right)\mathbf{e}_\alpha(\gamma(t)).$$

Proof. Write $\mathbf{u} = u^\alpha\mathbf{e}_\alpha \circ \gamma$. By the Leibniz rule,

$$\frac{D\mathbf{u}}{dt} = \frac{du^\alpha}{dt}\mathbf{e}_\alpha(\gamma(t)) + u^\alpha\frac{D(\mathbf{e}_\alpha \circ \gamma)}{dt}.$$

Since $\mathbf{e}_\alpha \circ \gamma$ is extendible, we have $\dfrac{D(\mathbf{e}_\alpha \circ \gamma)}{dt}(t) = \nabla^{\mathbf{E}}_{\dot\gamma(t)}\mathbf{e}_\alpha$. Using $\dot\gamma(t) = \frac{d\gamma^i}{dt}(t)\partial_i|_{\gamma(t)}$ and $\nabla^{\mathbf{E}}_{\partial_i}\mathbf{e}_\beta = \Gamma^\alpha_{i\beta}\mathbf{e}_\alpha$, we obtain

$$\frac{D(\mathbf{e}_\beta \circ \gamma)}{dt}(t) = \frac{d\gamma^i}{dt}(t)\Gamma^\alpha_{i\beta}(\gamma(t))\mathbf{e}_\alpha(\gamma(t)).$$

Substituting this expression into the formula for $\frac{D\mathbf{u}}{dt}$ gives

$$\frac{D\mathbf{u}}{dt}(t) = \frac{du^\alpha}{dt}(t)\mathbf{e}_\alpha(\gamma(t)) + u^\beta(t)\frac{d\gamma^i}{dt}(t)\Gamma^\alpha_{i\beta}(\gamma(t))\mathbf{e}_\alpha(\gamma(t)).$$

Grouping the coefficients of $\mathbf{e}_\alpha(\gamma(t))$ yields the desired formula. □

The preceding result shows that the covariant derivative of a section along a curve is calculated using a local system of ordinary functions. In particular, if a global section is restricted to a curve, its derivative along the curve depends only on the values of the section along that curve and on the curve's velocity.

Proposition 2.7.8. Let M be a smooth manifold with or without boundary, and let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$. Let $p \in M$, $v \in T_pM$, and let $\mathbf{s}, \widetilde{\mathbf{s}}$ be sections of class C^1 of $\mathbf{E}$ defined on a neighborhood of p. Suppose that there exist a smooth curve $\gamma\colon I \longrightarrow M$ and a point $t_0 \in I$ such that $\gamma(t_0) = p$, $\dot\gamma(t_0) = v$, and $\mathbf{s}(\gamma(t)) = \widetilde{\mathbf{s}}(\gamma(t))$ for every t in a neighborhood of t_0. Then $\nabla^{\mathbf{E}}_v\mathbf{s} = \nabla^{\mathbf{E}}_v\widetilde{\mathbf{s}}$.

Proof. Define a section $\mathbf{u}$ of $\gamma^*\mathbf{E}$ near t_0 by $\mathbf{u}(t) = \mathbf{s}(\gamma(t)) = \widetilde{\mathbf{s}}(\gamma(t))$. Then $\mathbf{s}$ and $\widetilde{\mathbf{s}}$ are two local extensions of $\mathbf{u}$. By compatibility with extensions in Theorem 2.7.5, we have

$$\nabla^{\mathbf{E}}_{\dot\gamma(t_0)}\mathbf{s} = \frac{D\mathbf{u}}{dt}(t_0) = \nabla^{\mathbf{E}}_{\dot\gamma(t_0)}\widetilde{\mathbf{s}}.$$

Since $\dot\gamma(t_0) = v$, we conclude that $\nabla^{\mathbf{E}}_v\mathbf{s} = \nabla^{\mathbf{E}}_v\widetilde{\mathbf{s}}$. □

Definition 2.7.9. (Parallel sections along a curve) Let M be a smooth manifold with or without boundary, let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$, and let $\gamma\colon I \longrightarrow M$ be a smooth curve. A section $\mathbf{u} \in \Gamma^1(\gamma^*\mathbf{E})$ is said to be parallel along γ if $\dfrac{D\mathbf{u}}{dt} \equiv 0$.

In a local frame, the parallelism condition becomes a linear system of ordinary differential equations. If $\mathbf{u}(t) = u^\alpha(t)\mathbf{e}_\alpha(\gamma(t))$, then $\mathbf{u}$ is parallel along γ if and only if

$$\frac{du^\alpha}{dt}(t) = -\frac{d\gamma^i}{dt}(t)\Gamma^\alpha_{i\beta}(\gamma(t))u^\beta(t), \qquad \alpha \in \{1,\dots,r\}. \tag{2.54}$$

This observation reduces existence and uniqueness of parallel sections to a classical existence and uniqueness theorem for linear systems of ordinary differential equations.

Proposition 2.7.10. Let M be a smooth manifold with or without boundary, let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$, and let $\mathbf{s} \in \Gamma^1(\mathbf{E})$. Then $\nabla^{\mathbf{E}}\mathbf{s} = 0$ if and only if, for every smooth curve $\gamma\colon I \longrightarrow M$, the section $\mathbf{s} \circ \gamma$ of $\gamma^*\mathbf{E}$ is parallel along γ.

Proof. First suppose that $\nabla^{\mathbf{E}}\mathbf{s} = 0$. For every smooth curve $\gamma\colon I \longrightarrow M$, the section $\mathbf{s} \circ \gamma$ is extendible by $\mathbf{s}$. By Theorem 2.7.5, we have $\dfrac{D(\mathbf{s} \circ \gamma)}{dt}(t) = \nabla^{\mathbf{E}}_{\dot\gamma(t)}\mathbf{s} = 0$. Thus $\mathbf{s} \circ \gamma$ is parallel along γ.
Conversely, suppose that $\mathbf{s} \circ \gamma$ is parallel along every smooth curve γ. Let $p \in M$ and $v \in T_pM$. Choose a smooth curve γ defined near 0 such that $\gamma(0) = p$ and $\dot\gamma(0) = v$. Then

$$\nabla^{\mathbf{E}}_v\mathbf{s} = \nabla^{\mathbf{E}}_{\dot\gamma(0)}\mathbf{s} = \frac{D(\mathbf{s} \circ \gamma)}{dt}(0) = 0.$$

Since p and v were arbitrary, we conclude that $\nabla^{\mathbf{E}}\mathbf{s} = 0$. □

Theorem 2.7.11. (Existence, uniqueness, and smoothness for linear ODEs) Let $I \subseteq \mathbb{R}$ be an open interval and, for $1 \le \beta, \alpha \le r$, let $A^\alpha_\beta\colon I \longrightarrow \mathbb{K}$ be a smooth function. For every $t_0 \in I$ and every initial vector $c = (c^1, \dots, c^r) \in \mathbb{K}^r$, the linear initial value problem

$$\begin{cases} \dfrac{dU^\alpha}{dt}(t) = A^\alpha_\beta(t)U^\beta(t), \\ U^\alpha(t_0) = c^\alpha, \end{cases} \tag{2.55}$$

has a unique smooth solution defined on all of I. Moreover, for fixed t_0, the solution depends smoothly on $(t, c) \in I \times \mathbb{K}^r$.

Proof. We first prove the result when $t_0 = 0$ and $0 \in I$. To simplify notation, we present the argument over $\mathbb{R}$. In the complex case, apply the same reasoning to the real and imaginary parts, identifying $\mathbb{C}^r$ with $\mathbb{R}^{2r}$. Let $(x^0, x^1, \dots, x^r)$ be the standard coordinates on $I \times \mathbb{R}^r$. Consider the smooth vector field

$$\mathbf{Y} = \partial_0 + A^\alpha_\beta(x^0)x^\beta\partial_\alpha$$

on $I \times \mathbb{R}^r$.
If $U(t) = (U^1(t), \dots, U^r(t))$ is a solution of (2.55) defined on an interval $I_0 \subseteq I$, then $\eta(t) = (t, U^1(t), \dots, U^r(t))$ is an integral curve of $\mathbf{Y}$. The first component satisfies $\dot\eta^0(t) = 1$, and the others satisfy

$$\dot\eta^\alpha(t) = \frac{dU^\alpha}{dt}(t) = A^\alpha_\beta(t)U^\beta(t) = A^\alpha_\beta(\eta^0(t))\eta^\beta(t).$$

Conversely, if $\eta(t) = (\eta^0(t), \eta^1(t), \dots, \eta^r(t))$ is an integral curve of Y with $\eta(0) = (0, c^1, \dots, c^r)$, then $\dot\eta^0(t) = 1$ and $\eta^0(0) = 0$. Therefore $\eta^0(t) = t$. Defining $U(t) = (\eta^1(t), \dots, \eta^r(t))$ gives a solution of the system (2.55) with initial condition $U(0) = c$. Thus solutions of the linear system correspond to integral curves of Y passing through $(0, c)$.
By Theorem 1.8.15, there exists a unique maximal integral curve of Y with initial condition $(0, c)$, defined

on a maximal open interval $I_0 \subseteq I$ containing 0. By the preceding argument, this is equivalent to existence and uniqueness of a maximal solution $U\colon I_0 \longrightarrow \mathbb{R}^r$ of the linear system. It remains to show that $I_0 = I$.
Write $I = (a,b)$ and $I_0 = (a_0,b_0)$, with $a,b,a_0,b_0 \in \mathbb{R}\cup\{-\infty,\infty\}$. Suppose, for a contradiction, that $b_0 < b$. Then b_0 is finite and $[0,b_0] \subseteq I$. For $t \in [0,b_0)$, we have

$$\frac{d}{dt}\|U(t)\|^2 = 2\frac{dU^\alpha}{dt}(t)U^\alpha(t) = 2A^\alpha_\beta(t)U^\beta(t)U^\alpha(t).$$

Using the Cauchy–Schwarz inequality for the Frobenius norm, we obtain $\frac{d}{dt}\|U(t)\|^2 \le 2\|A(t)\|_F\|U(t)\|^2$. Since the functions A^α_β are continuous, there exists $C > 0$ such that $\|A(t)\|_F \le C$ for every $t \in [0,b_0]$. Therefore,

$$\frac{d}{dt}\left(e^{-2Ct}\|U(t)\|^2\right) = e^{-2Ct}\left(\frac{d}{dt}\|U(t)\|^2 - 2C\|U(t)\|^2\right) \le 0.$$

Thus $e^{-2Ct}\|U(t)\|^2 \le \|U(0)\|^2$ for every $t \in [0,b_0)$, and hence $\|U(t)\| \le e^{Cb_0}\|U(0)\|$. Consequently, the corresponding integral curve remains in the compact set

$$[0,b_0]\times\overline{B}_{\mathrm{euc}}(0,R) \subseteq I\times\mathbb{R}^r, \qquad R = e^{Cb_0}\|U(0)\|.$$

This contradicts Lemma 1.8.18. Therefore $b_0 = b$.
To prove that $a_0 = a$, consider the reparametrized solution $W(s) = U(-s)$, which satisfies the linear system $\frac{dW^\alpha}{ds}(s) = -A^\alpha_\beta(-s)W^\beta(s)$. The preceding argument, applied to W, shows that the solution cannot cease to exist before reaching the left endpoint of I either. We conclude that $I_0 = I$.
Smooth dependence on (t,c) follows from smooth dependence of the flow of Y on time and initial conditions, since the solution $U(t)$ is the $\mathbb{R}^r$-component of the integral curve of Y starting at $(0,c)$.
Finally, consider the general case $t_0 \in I$. Define $\widetilde{I} = I - t_0$ and $\widetilde{A}^\alpha_\beta(s) = A^\alpha_\beta(s+t_0)$. The translated system

$$\frac{d\widetilde{U}^\alpha}{ds}(s) = \widetilde{A}^\alpha_\beta(s)\widetilde{U}^\beta(s), \qquad \widetilde{U}^\alpha(0) = c^\alpha,$$

has a unique smooth solution on all of $\widetilde{I}$. Defining $U(t) = \widetilde{U}(t-t_0)$ gives the solution of the original system on all of I. Uniqueness and smooth dependence are preserved under the change of variable $s = t - t_0$. □

Theorem 2.7.12. (Existence and uniqueness of parallel transport) Let M be a smooth manifold with or without boundary, and let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$. Let $\gamma\colon I \longrightarrow M$ be a smooth curve, let $t_0 \in I$, and let $v \in \mathbf{E}_{\gamma(t_0)}$. Then there exists a unique parallel section $\mathbf{u} \in \Gamma(\gamma^*\mathbf{E})$ such that $\mathbf{u}(t_0) = v$.

Proof. We first solve the problem locally. Suppose that $\gamma(J) \subseteq U$, where $J \subseteq I$ is an interval and $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ is a smooth local frame of $\mathbf{E}$ over U. If $\mathbf{u}(t) = u^\alpha(t)\mathbf{e}_\alpha(\gamma(t))$, then, by (2.54), the condition $\frac{D\mathbf{u}}{dt} = 0$ is equivalent to the linear system

$$\frac{du^\alpha}{dt}(t) = -\frac{d\gamma^i}{dt}(t)\Gamma^\alpha_{i\beta}(\gamma(t))u^\beta(t).$$

Defining $A^\alpha_\beta(t) = -\frac{d\gamma^i}{dt}(t)\Gamma^\alpha_{i\beta}(\gamma(t))$ gives a system of the form $\frac{du^\alpha}{dt}(t) = A^\alpha_\beta(t)u^\beta(t)$. Since γ and the coefficients $\Gamma^\alpha_{i\beta}$ are smooth, the functions A^α_β are smooth on J. By Theorem 2.7.11, for every initial condition at a point of J, there exists a unique smooth solution on all of J. Thus, on any parameter interval whose image lies in

a single local trivialization of $\mathbf{E}$, there exists a unique parallel section with prescribed initial value.
We now prove global existence and uniqueness to the right of t_0; the left endpoint is treated by reversing the parameter. Let $b = \sup I$ and consider the set

$$\mathcal{S} = \{s \in I \mid s > t_0 \text{ and there is a unique parallel section on } [t_0, s] \text{ with initial value } v\}.$$

This set is nonempty. Choose a local trivialization of $\mathbf{E}$ on a neighborhood U of $\gamma(t_0)$. Since $\gamma^{-1}(U)$ is open in I and contains t_0, there exists $\varepsilon > 0$ such that $\gamma((t_0 - \varepsilon, t_0 + \varepsilon) \cap I) \subseteq U$. By the local case, there is a unique parallel section on $[t_0, s]$ for every $s \in I$ with $t_0 < s < t_0 + \varepsilon$.
Let $\beta = \sup \mathcal{S}$. For each $s \in \mathcal{S}$, denote by $\mathbf{u}_s$ the unique parallel section on $[t_0, s]$ with $\mathbf{u}_s(t_0) = v$. If $s_1, s_2 \in \mathcal{S}$ and $s_1 < s_2$, then $\mathbf{u}_{s_2}|_{[t_0,s_1]}$ is a parallel section on $[t_0, s_1]$ with initial value v. By the uniqueness defining $s_1 \in \mathcal{S}$, we have $\mathbf{u}_{s_2}|_{[t_0,s_1]} = \mathbf{u}_{s_1}$. Thus the solutions $\mathbf{u}_s$ are mutually compatible.
Using this compatibility, define a section $\mathbf{u}$ on $[t_0, \beta)$ as follows. If $t \in [t_0, \beta)$, choose $s \in \mathcal{S}$ such that $t \le s < \beta$ and set $\mathbf{u}(t) = \mathbf{u}_s(t)$. The definition is independent of the choice of s precisely because of the preceding compatibility. Moreover, $\mathbf{u}$ is smooth and parallel on $[t_0, \beta)$ because it locally agrees with one of the smooth parallel sections $\mathbf{u}_s$.
Let us show that $\beta = b$. Suppose, for a contradiction, that $\beta < b$. Then $\beta \in I$. Choose a local trivialization of $\mathbf{E}$ over a neighborhood U of $\gamma(\beta)$. Since $\gamma^{-1}(U)$ is open in I and contains β, there exists $\delta > 0$ such that $\gamma((\beta - \delta, \beta + \delta) \cap I) \subseteq U$. Choose $\tau \in \mathcal{S}$ with $\beta - \frac{\delta}{2} < \tau < \beta$. By the local case, there is a unique parallel section $\widetilde{\mathbf{u}}$ along γ on $(\beta - \delta, \beta + \delta) \cap I$ such that $\widetilde{\mathbf{u}}(\tau) = \mathbf{u}(\tau)$.
We claim that $\widetilde{\mathbf{u}} = \mathbf{u}$ on $[\tau, \beta)$. Let $t \in [\tau, \beta)$. Choose $s \in \mathcal{S}$ such that $t \le s < \beta$. On the interval $[\tau, s]$, both $\widetilde{\mathbf{u}}$ and $\mathbf{u}_s$ are parallel sections with the same value at τ. By local uniqueness within the trivialization over U, we have $\widetilde{\mathbf{u}} = \mathbf{u}_s$ on $[\tau, s]$. Since $\mathbf{u} = \mathbf{u}_s$ on $[\tau, s]$, we conclude that $\widetilde{\mathbf{u}}(t) = \mathbf{u}(t)$. Since t was arbitrary, $\widetilde{\mathbf{u}} = \mathbf{u}$ on $[\tau, \beta)$.
Now choose $\varepsilon > 0$ such that $\beta + \varepsilon \in I$ and $\varepsilon < \delta$. Define a section $\widehat{\mathbf{u}}$ on $[t_0, \beta + \varepsilon]$ by

$$\widehat{\mathbf{u}}(t) = \begin{cases} \mathbf{u}(t), & t \in [t_0, \tau], \\ \widetilde{\mathbf{u}}(t), & t \in [\tau, \beta + \varepsilon]. \end{cases}$$

This definition is smooth because $\mathbf{u}$ and $\widetilde{\mathbf{u}}$ agree on an interval to the right of τ. Moreover, $\widehat{\mathbf{u}}$ is parallel because it locally agrees with parallel sections.
We also prove uniqueness of $\widehat{\mathbf{u}}$. Let $\mathbf{w}$ be another parallel section on $[t_0, \beta + \varepsilon]$ with $\mathbf{w}(t_0) = v$. Then $\mathbf{w}|_{[t_0,\tau]}$ is a parallel section with the same initial value as $\mathbf{u}_\tau$. By uniqueness on $[t_0, \tau]$, we have $\mathbf{w} = \mathbf{u}$ on $[t_0, \tau]$. In particular, $\mathbf{w}(\tau) = \mathbf{u}(\tau) = \widetilde{\mathbf{u}}(\tau)$. By local uniqueness in the trivialization over U, we obtain $\mathbf{w} = \widetilde{\mathbf{u}}$ on $[\tau, \beta + \varepsilon]$. Therefore, $\mathbf{w} = \widehat{\mathbf{u}}$ on all of $[t_0, \beta + \varepsilon]$.
This shows that $\beta + \varepsilon \in \mathcal{S}$, contradicting the definition of $\beta = \sup \mathcal{S}$. Therefore $\beta = b$, and there is a unique parallel section to the right of t_0.
The same argument to the left, using intervals of the form $[s, t_0]$ with $s < t_0$, shows that there is a unique parallel section to the left of t_0. Gluing the two sections gives a unique parallel section on all of I with initial value v. □

Definition 2.7.13. (Parallel transport) Let M be a smooth manifold with or without boundary, let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$, and let $\gamma\colon I \longrightarrow M$ be a smooth curve. Given $t_0, t_1 \in I$,

define parallel transport from t_0 to t_1 along γ to be the map

$$P^{\mathbf{E}}_{\gamma,t_0\to t_1} : \mathbf{E}_{\gamma(t_0)} \longrightarrow \mathbf{E}_{\gamma(t_1)}$$

given by $P^{\mathbf{E}}_{\gamma,t_0\to t_1}(v) = \mathbf{u}(t_1)$, where $\mathbf{u}$ is the unique parallel section along γ such that $\mathbf{u}(t_0) = v$.
When the bundle is clear from context, we omit the superscript and write $P_{\gamma,t_0\to t_1}$.

Proposition 2.7.14. Let M be a smooth manifold with or without boundary, let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$, and let $\gamma\colon I \longrightarrow M$ be a smooth curve. For any $t_0, t_1 \in I$, parallel transport $P^{\mathbf{E}}_{\gamma,t_0\to t_1} : \mathbf{E}_{\gamma(t_0)} \longrightarrow \mathbf{E}_{\gamma(t_1)}$ is a linear isomorphism. Moreover, $P^{\mathbf{E}}_{\gamma,t_1\to t_0} = (P^{\mathbf{E}}_{\gamma,t_0\to t_1})^{-1}$. More generally, if $t_0, t_1, t_2 \in I$, then

$$P^{\mathbf{E}}_{\gamma,t_1\to t_2} \circ P^{\mathbf{E}}_{\gamma,t_0\to t_1} = P^{\mathbf{E}}_{\gamma,t_0\to t_2}.$$

Proof. Linearity follows from linearity of the parallelism equation. If $\mathbf{u}$ and $\mathbf{w}$ are the parallel sections with initial conditions v and z at t_0, then $a\mathbf{u} + b\mathbf{w}$ is parallel and satisfies $(a\mathbf{u} + b\mathbf{w})(t_0) = av + bz$. By uniqueness, $a\mathbf{u} + b\mathbf{w}$ is the parallel section corresponding to the initial data $av + bz$. Evaluating at t_1 gives

$$P^{\mathbf{E}}_{\gamma,t_0\to t_1}(av + bz) = aP^{\mathbf{E}}_{\gamma,t_0\to t_1}(v) + bP^{\mathbf{E}}_{\gamma,t_0\to t_1}(z).$$

To prove the inverse formula, let $v \in \mathbf{E}_{\gamma(t_0)}$ and let $\mathbf{u}$ be the parallel section with $\mathbf{u}(t_0) = v$. Then $\mathbf{u}(t_1) = P^{\mathbf{E}}_{\gamma,t_0\to t_1}(v)$. If we transport $\mathbf{u}(t_1)$ from t_1 to t_0, the resulting parallel section must again be $\mathbf{u}$, by uniqueness. Therefore,

$$P^{\mathbf{E}}_{\gamma,t_1\to t_0}(P^{\mathbf{E}}_{\gamma,t_0\to t_1}(v)) = v.$$

The same argument, interchanging t_0 and t_1, shows that composition in the other order is also the identity. Thus $P^{\mathbf{E}}_{\gamma,t_1\to t_0} = (P^{\mathbf{E}}_{\gamma,t_0\to t_1})^{-1}$.
Finally, let $\mathbf{u}$ be the parallel section with $\mathbf{u}(t_0) = v$. Then $P^{\mathbf{E}}_{\gamma,t_0\to t_1}(v) = \mathbf{u}(t_1)$. Transporting this vector from t_1 to t_2 again gives the value $\mathbf{u}(t_2)$, by uniqueness. Therefore,

$$P^{\mathbf{E}}_{\gamma,t_1\to t_2}(P^{\mathbf{E}}_{\gamma,t_0\to t_1}(v)) = \mathbf{u}(t_2) = P^{\mathbf{E}}_{\gamma,t_0\to t_2}(v).$$

Since v was arbitrary, the composition identity follows. □

Remark 2.7.15. (Parallel frames along a curve) Let $(b_1, \dots, b_r)$ be a basis of $\mathbf{E}_{\gamma(t_0)}$. For each $\alpha \in \{1, \dots, r\}$, let $\mathbf{E}_\alpha$ be the parallel section along γ such that $\mathbf{E}_\alpha(t_0) = b_\alpha$. Since parallel transport is a linear isomorphism, for each $t \in I$ the family $(\mathbf{E}_1(t), \dots, \mathbf{E}_r(t))$ is a basis of $\mathbf{E}_{\gamma(t)}$. This family of parallel sections is called a parallel frame along γ.
If $\mathbf{u} \in \Gamma^1(\gamma^*\mathbf{E})$, then there is a unique family of functions $u^1, \dots, u^r$ of class C^1 such that $\mathbf{u}(t) = u^\alpha(t)\mathbf{E}_\alpha(t)$. Since $\frac{D\mathbf{E}_\alpha}{dt} = 0$, we obtain

$$\frac{D\mathbf{u}}{dt}(t) = \frac{du^\alpha}{dt}(t)\mathbf{E}_\alpha(t).$$

Consequently, a section $\mathbf{u}$ is parallel along γ if and only if its components in a parallel frame are constant.

Parallel transport along a single curve produces a frame along that curve. In a normal neighborhood, it can be performed simultaneously along all radial geodesics; this construction will provide the natural trivialization for

spaces of sections on manifolds of bounded geometry.

Definition 2.7.16. (Synchronous frame) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, let $p \in M$, and let U be a normal neighborhood of p. For $q \in U$, let

$$\gamma_q(t) := \exp_p\bigl(t \exp_p^{-1}(q)\bigr), \qquad 0 \le t \le 1.$$

If $\pi_{\mathbf{E}} \colon \mathbf{E} \longrightarrow M$ is a vector bundle with connection $\nabla^{\mathbf{E}}$ and $(b_1,\dots,b_r)$ is a basis of $\mathbf{E}_p$, the frame

$$\mathbf{e}_a(q) := P^{\mathbf{E}}_{\gamma_q,0\to 1}(b_a), \qquad a \in \{1,\dots,r\},$$

is called the *synchronous frame centered at* p.

Proposition 2.7.17. (Properties of synchronous frames) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, let $p \in M$, let U be a normal neighborhood of p, and let $\pi_{\mathbf{E}} \colon \mathbf{E} \longrightarrow M$ be a vector bundle with connection $\nabla^{\mathbf{E}}$. The synchronous frame centered at p is smooth, and its restriction to every radial geodesic is parallel. If the connection is compatible with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and the initial basis is orthonormal, the frame is orthonormal throughout U. In normal coordinates centered at p, if $\nabla^{\mathbf{E}} = d + \mathbf{A}$ and $\mathbf{A} = A_i\,\mathbf{d}x^i$, then

$$\sum_{i=1}^{n} x^i A_i(x) = 0, \qquad A_i(0) = 0 \quad (i \in \{1,\dots,n\}).$$

Proof. In a fixed trivialization, transport of b_a satisfies

$$\frac{dv_a}{dt}(t,q) = -\Gamma_i\bigl(\gamma_q(t)\bigr)\dot\gamma_q^i(t) v_a(t,q), \qquad v_a(0,q) = b_a.$$

Smooth dependence of solutions on parameters proves smoothness of the frame, and uniqueness proves radial parallelism. Metric compatibility gives $\frac{d}{dt}\mathbf{h}_{\mathbf{E}}(\mathbf{e}_a,\mathbf{e}_b) = 0$. In normal coordinates, the ray ending at x is $t \mapsto tx$; parallelism implies

$$0 = \nabla^{\mathbf{E}}_{\sum_{i=1}^{n} x^i \partial_i} \mathbf{e}_a = \left(\sum_{i=1}^{n} x^i A_i(x)\right)\mathbf{e}_a.$$

The radial identity follows because the $\mathbf{e}_a$ form a basis. Substituting $x = tv$, dividing by $t > 0$, and letting $t \to 0$ gives $A_i(0) = 0$. □

Proposition 2.7.18. (Local equation for parallel transport) Let M be a smooth manifold with or without boundary, let $\pi \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$, let $\gamma \colon I \longrightarrow M$ be a smooth curve, and suppose that $\gamma(J) \subseteq U$, where $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ is a local frame of $\mathbf{E}$ over U. Fix $t_0 \in J$, and represent parallel transport $R(t) := P^{\mathbf{E}}_{\gamma,t_0\to t} \colon \mathbf{E}_{\gamma(t_0)} \longrightarrow \mathbf{E}_{\gamma(t)}$ by a matrix $r(t)$ in the frame $\mathbf{e}_1,\dots,\mathbf{e}_r$. That is, if $v = v^\beta \mathbf{e}_\beta(\gamma(t_0))$, then

$$R(t)v = r^\alpha_\beta(t) v^\beta \mathbf{e}_\alpha(\gamma(t)).$$

Then $r(t)$ satisfies

$$\frac{dr}{dt}(t) + \dot\gamma^i(t)\Gamma_i(\gamma(t))r(t) = 0, \qquad r(t_0) = I,$$

where $\Gamma_i = (\Gamma_{i\beta}^{\alpha})_{\alpha,\beta}$. In particular, if $\dot\gamma(t_0) = \partial_i|_{\gamma(t_0)}$, then $r'(t_0) = -\Gamma_i(\gamma(t_0))$.
Moreover, if $Q(t) := R(t)^{-1} = P^{\mathbf{E}}_{\gamma,t\to t_0}$ and $q(t) = r(t)^{-1}$ is its matrix, then $q(t)$ depends smoothly on t and satisfies

$$\frac{dq}{dt}(t) = q(t)\dot\gamma^i(t)\Gamma_i(\gamma(t)).$$

Proof. Let $v = v^\beta \mathbf{e}_\beta(\gamma(t_0))$. By definition, $\mathbf{u}(t) := R(t)v$ is the parallel section along γ with $\mathbf{u}(t_0) = v$. In the local frame, write $\mathbf{u}(t) = u^\alpha(t)\mathbf{e}_\alpha(\gamma(t))$, where $u^\alpha(t) = r^\alpha_\beta(t)v^\beta$.
Since $\mathbf{u}$ is parallel, the local equation (2.54) gives

$$\frac{du^\alpha}{dt}(t) = -\dot\gamma^i(t)\Gamma^\alpha_{i\mu}(\gamma(t))u^\mu(t).$$

Substituting $u^\alpha(t) = r^\alpha_\beta(t)v^\beta$, we obtain

$$\frac{dr^\alpha_\beta}{dt}(t)v^\beta = -\dot\gamma^i(t)\Gamma^\alpha_{i\mu}(\gamma(t))r^\mu_\beta(t)v^\beta.$$

Since v is arbitrary, it follows that

$$\frac{dr^\alpha_\beta}{dt}(t) + \dot\gamma^i(t)\Gamma^\alpha_{i\mu}(\gamma(t))r^\mu_\beta(t) = 0.$$

In matrix form, this is $\dfrac{dr}{dt}(t) + \dot\gamma^i(t)\Gamma_i(\gamma(t))r(t) = 0$. Moreover, since $R(t_0)$ is the identity on $\mathbf{E}_{\gamma(t_0)}$, we have $r(t_0) = I$. If $\dot\gamma(t_0) = \partial_i|_{\gamma(t_0)}$, then $\dot\gamma^j(t_0) = \delta^j_i$, and evaluating the equation at t_0 gives $r'(t_0) = -\Gamma_i(\gamma(t_0))$.
Finally, $q(t) = r(t)^{-1}$ is smooth because $r(t)$ is smooth and takes values in $GL(r,\mathbb{K})$. Differentiating the identity $q(t)r(t) = I$ gives $q'(t)r(t) + q(t)r'(t) = 0$. Therefore $q'(t) = -q(t)r'(t)r(t)^{-1}$. Using $r'(t) = -\dot\gamma^i(t)\Gamma_i(\gamma(t))r(t)$ yields $q'(t) = q(t)\dot\gamma^i(t)\Gamma_i(\gamma(t))$. □

Theorem 2.7.19. (Covariant derivative through parallel transport) Let M be a smooth manifold with or without boundary, let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$, let $\gamma\colon I \longrightarrow M$ be a smooth curve, and let $\mathbf{u} \in \Gamma^1(\gamma^*\mathbf{E})$. Then, for every $t_0 \in I$,

$$\frac{D\mathbf{u}}{dt}(t_0) = \lim_{t\to t_0} \frac{P^{\mathbf{E}}_{\gamma,t\to t_0}\mathbf{u}(t) - \mathbf{u}(t_0)}{t - t_0}.$$

The limit is taken in the fixed vector space $\mathbf{E}_{\gamma(t_0)}$. If t_0 is an endpoint of the interval of definition, the limit is understood to be one-sided.

Proof. Choose a parallel frame $(\mathbf{E}_1,\dots,\mathbf{E}_r)$ along γ. Write $\mathbf{u}(t) = u^\alpha(t)\mathbf{E}_\alpha(t)$. By the preceding remark,

$$\frac{D\mathbf{u}}{dt}(t_0) = \frac{du^\alpha}{dt}(t_0)\mathbf{E}_\alpha(t_0).$$

On the other hand, since $\mathbf{E}_\alpha$ is parallel, parallel transport of $\mathbf{E}_\alpha(t)$ from t to t_0 is $\mathbf{E}_\alpha(t_0)$. By linearity of parallel transport,

$$P^{\mathbf{E}}_{\gamma,t\to t_0}\mathbf{u}(t) = u^\alpha(t)\mathbf{E}_\alpha(t_0).$$

Then

$$\frac{P^{\mathbf{E}}_{\gamma,t\to t_0}\mathbf{u}(t)-\mathbf{u}(t_0)}{t-t_0}=\frac{u^\alpha(t)-u^\alpha(t_0)}{t-t_0}\mathbf{E}_\alpha(t_0).$$

Taking the limit as $t\to t_0$ gives

$$\lim_{t\to t_0}\frac{P^{\mathbf{E}}_{\gamma,t\to t_0}\mathbf{u}(t)-\mathbf{u}(t_0)}{t-t_0}=\frac{du^\alpha}{dt}(t_0)\mathbf{E}_\alpha(t_0)=\frac{D\mathbf{u}}{dt}(t_0).$$

□

Corollary 2.7.20. Let M be a smooth manifold with or without boundary, and let $\pi\colon \mathbf{E}\longrightarrow M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$. Let $\mathbf{s}\in\Gamma^1(\mathbf{E})$, let $p\in M$, and let $\mathbf{X}\in\mathfrak{X}(M)$. If γ is a smooth curve defined near 0 such that $\gamma(0)=p$ and $\dot\gamma(0)=\mathbf{X}_p$, then

$$\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{s}(p)=\lim_{h\to 0}\frac{P^{\mathbf{E}}_{\gamma,h\to 0}\mathbf{s}(\gamma(h))-\mathbf{s}(p)}{h}.$$

Proof. Define a section $\mathbf{u}$ of $\gamma^*\mathbf{E}$ by $\mathbf{u}(h)=\mathbf{s}(\gamma(h))$. Since $\mathbf{u}$ is the restriction of the section $\mathbf{s}$ to the curve γ, Theorem 2.7.5 implies that

$$\frac{D\mathbf{u}}{dt}(0)=\nabla^{\mathbf{E}}_{\dot\gamma(0)}\mathbf{s}=\nabla^{\mathbf{E}}_{\mathbf{X}_p}\mathbf{s}=\nabla^{\mathbf{E}}_{\mathbf{X}}\mathbf{s}(p).$$

Using Theorem 2.7.19 at $t_0=0$, we obtain

$$\frac{D\mathbf{u}}{dt}(0)=\lim_{h\to 0}\frac{P^{\mathbf{E}}_{\gamma,h\to 0}\mathbf{u}(h)-\mathbf{u}(0)}{h}.$$

Since $\mathbf{u}(h)=\mathbf{s}(\gamma(h))$ and $\mathbf{u}(0)=\mathbf{s}(p)$, the formula follows. □

Lemma 2.7.21. (Fundamental theorem of covariant calculus) Let M be a smooth manifold with or without boundary, and let $\pi_{\mathbf{F}}\colon \mathbf{F}\longrightarrow M$ be a smooth vector bundle equipped with a connection $\nabla^{\mathbf{F}}$. Let $\gamma\colon [a,b]\longrightarrow M$ be a smooth curve, and let $\mathbf{s}\in\Gamma^1(\gamma^*\mathbf{F})$. For $t,t_0\in[a,b]$, denote by $P^{\mathbf{F}}_{\gamma,t\to t_0}\colon \mathbf{F}_{\gamma(t)}\longrightarrow\mathbf{F}_{\gamma(t_0)}$ parallel transport along γ from $\gamma(t)$ to $\gamma(t_0)$. Then

$$P^{\mathbf{F}}_{\gamma,t\to t_0}(\mathbf{s}(t))-\mathbf{s}(t_0)=\int_{t_0}^{t}P^{\mathbf{F}}_{\gamma,\tau\to t_0}\left(\frac{D\mathbf{s}}{d\tau}(\tau)\right)d\tau.$$

The integral is taken in the finite-dimensional vector space $\mathbf{F}_{\gamma(t_0)}$.

Proof. Fix $t_0\in[a,b]$. Choose a basis $v_1,\dots,v_r$ of the fiber $\mathbf{F}_{\gamma(t_0)}$. For each $\mu\in\{1,\dots,r\}$, let $\mathbf{e}_\mu$ be the parallel section of $\mathbf{F}$ along γ satisfying $\mathbf{e}_\mu(t_0)=v_\mu$. Then $\mathbf{e}_1(t),\dots,\mathbf{e}_r(t)$ is a basis of $\mathbf{F}_{\gamma(t)}$ for every $t\in[a,b]$.

Since $\mathbf{s}$ is a section of $\mathbf{F}$ along γ, there exist functions $a^1,\dots,a^r\in C^1([a,b])$ such that $\mathbf{s}(t)=\sum_{\mu=1}^{r}a^\mu(t)\mathbf{e}_\mu(t)$. Each $\mathbf{e}_\mu$ is parallel, so its covariant derivative along γ vanishes, and therefore $\frac{D\mathbf{s}}{dt}(t)=\sum_{\mu=1}^{r}\frac{da^\mu}{dt}(t)\mathbf{e}_\mu(t)$.

Moreover, by the definition of parallel transport, $P^{\mathbf{F}}_{\gamma,t\to t_0}(\mathbf{e}_\mu(t))=\mathbf{e}_\mu(t_0)=v_\mu$. Consequently, $P^{\mathbf{F}}_{\gamma,t\to t_0}(\mathbf{s}(t))=$

$\sum_{\mu=1}^{r} a^\mu(t)v_\mu$ and $P^{\mathbf{F}}_{\gamma,t\to t_0}\left(\frac{D\mathbf{s}}{dt}(t)\right) = \sum_{\mu=1}^{r}\frac{da^\mu}{dt}(t)v_\mu$.
Applying the fundamental theorem of calculus componentwise in the basis $(v_1,\dots,v_r)$ of $\mathbf{F}_{\gamma(t_0)}$, we obtain

$$P^{\mathbf{F}}_{\gamma,t\to t_0}(\mathbf{s}(t)) - \mathbf{s}(t_0) = \sum_{\mu=1}^{r}(a^\mu(t) - a^\mu(t_0))\,v_\mu.$$

Since $a^\mu(t) - a^\mu(t_0) = \int_{t_0}^{t}\frac{da^\mu}{d\tau}(\tau)\,d\tau$, it follows that

$$P^{\mathbf{F}}_{\gamma,t\to t_0}(\mathbf{s}(t)) - \mathbf{s}(t_0) = \int_{t_0}^{t} P^{\mathbf{F}}_{\gamma,\tau\to t_0}\left(\frac{D\mathbf{s}}{d\tau}(\tau)\right)d\tau,$$

which proves the identity. □

Lemma 2.7.22. (Integral criterion for the covariant derivative) Let M be a smooth manifold with or without boundary, and let $\pi_{\mathbf{F}}\colon \mathbf{F}\longrightarrow M$ be a smooth vector bundle equipped with a connection $\nabla^{\mathbf{F}}$. Let $\mathbf{s}\in\Gamma^0(\mathbf{F})$ and $\mathbf{A}\in\Gamma^0(T^*M\otimes\mathbf{F})$.
Suppose that, for every smooth curve $\gamma\colon[a,b]\longrightarrow M$ and any $t,t_0\in[a,b]$, we have

$$P^{\mathbf{F}}_{\gamma,t\to t_0}(\mathbf{s}(\gamma(t))) - \mathbf{s}(\gamma(t_0)) = \int_{t_0}^{t} P^{\mathbf{F}}_{\gamma,\tau\to t_0}\left(\mathbf{A}_{\gamma(\tau)}(\dot\gamma(\tau))\right)d\tau.$$

Then $\mathbf{s}\in\Gamma^1(\mathbf{F})$ and $\nabla^{\mathbf{F}}\mathbf{s} = \mathbf{A}$.

Proof. Fix $p\in M$. Choose a chart (U,φ) around p, with $\varphi = (x^1,\dots,x^d)$, and a smooth local frame $\mathbf{e}_1,\dots,\mathbf{e}_r$ of $\mathbf{F}$ over U.
Write $\mathbf{s} = \sum_{\mu=1}^{r} s^\mu\mathbf{e}_\mu$, where the functions $s^\mu\colon U\longrightarrow\mathbb{K}$ are continuous. Likewise, write

$$\mathbf{A} = \sum_{i=1}^{d}\sum_{\mu=1}^{r} A_i^\mu\,\mathbf{d}x^i\otimes\mathbf{e}_\mu,$$

where the functions $A_i^\mu\colon U\longrightarrow\mathbb{K}$ are continuous.
Denote by $\Gamma_{i\nu}^{\mu}$ the coefficients of the connection $\nabla^{\mathbf{F}}$ in the chosen frame, that is,

$$\nabla^{\mathbf{F}}_{\partial_i}\mathbf{e}_\nu = \sum_{\mu=1}^{r}\Gamma_{i\nu}^{\mu}\mathbf{e}_\mu, \qquad \partial_i := \partial_i.$$

Fix $i\in\{1,\dots,d\}$. We work with the coordinate curve in the direction i. If p is an interior point, choose $\delta>0$ so that

$$\gamma_i\colon(-\delta,\delta)\longrightarrow U, \qquad \gamma_i(t) := \varphi^{-1}\left(\varphi(p)+te_i\right),$$

is well defined. If $p\in\partial M$ and a coordinate direction is defined only on one side within the boundary chart, take the corresponding one-sided interval. The following argument applies unchanged, replacing ordinary

limits by one-sided limits in that direction. In all cases, $\gamma_i(0) = p$ and $\dot\gamma_i(t) = \partial_i|_{\gamma_i(t)}$ for the admissible values of t.

Let $R_i(t)\colon \mathbf{F}_p \longrightarrow \mathbf{F}_{\gamma_i(t)}$ be parallel transport from $p = \gamma_i(0)$ to $\gamma_i(t)$, and let $Q_i(t) := R_i(t)^{-1} = P^{\mathbf{F}}_{\gamma_i,t\to 0}$. In the local frame $\mathbf{e}_1,\dots,\mathbf{e}_r$, represent $R_i(t)$ and $Q_i(t)$ by matrices denoted by $r_i(t)$ and $q_i(t)$, respectively. Thus $q_i(t) = r_i(t)^{-1}$ and $r_i(0) = q_i(0) = I$.

By Proposition 2.7.18, the local differential equation for parallel transport gives

$$r_i'(t) + \Gamma_i(\gamma_i(t))\, r_i(t) = 0,$$

where $\Gamma_i := \left(\Gamma_{i\nu}^{\mu}\right)_{\mu,\nu}$. In particular, $r_i'(0) = -\Gamma_i(p)$.

Use the hypothesis of the lemma with the curve γ_i and with $t_0 = 0$. Since $\dot\gamma_i(t) = \partial_i|_{\gamma_i(t)}$, we obtain

$$P^{\mathbf{F}}_{\gamma_i,t\to 0}(\mathbf{s}(\gamma_i(t))) - \mathbf{s}(p) = \int_0^t P^{\mathbf{F}}_{\gamma_i,\tau\to 0}\left(\mathbf{A}_{\gamma_i(\tau)}(\partial_i)\right) d\tau.$$

Express this identity in the local frame. Define

$$\widehat{s} := \begin{pmatrix} s^1 \\ \vdots \\ s^r \end{pmatrix}, \qquad \widehat{A}_i := \begin{pmatrix} A_i^1 \\ \vdots \\ A_i^r \end{pmatrix}.$$

Then

$$q_i(t)\,\widehat{s}(\gamma_i(t)) - \widehat{s}(p) = \int_0^t q_i(\tau)\,\widehat{A}_i(\gamma_i(\tau))\, d\tau.$$

Multiplying by $r_i(t)$ gives

$$\widehat{s}(\gamma_i(t)) = r_i(t)\widehat{s}(p) + r_i(t)\int_0^t q_i(\tau)\,\widehat{A}_i(\gamma_i(\tau))\, d\tau.$$

Subtract $\widehat{s}(p)$ and divide by $t \neq 0$:

$$\frac{\widehat{s}(\gamma_i(t)) - \widehat{s}(p)}{t} = \frac{r_i(t) - I}{t}\,\widehat{s}(p) + r_i(t)\,\frac{1}{t}\int_0^t q_i(\tau)\,\widehat{A}_i(\gamma_i(\tau))\, d\tau.$$

Let $t \to 0$ through the admissible parameter values of the curve. Since r_i is differentiable and $r_i'(0) = -\Gamma_i(p)$, we have

$$\frac{r_i(t) - I}{t} \longrightarrow -\Gamma_i(p).$$

Moreover, $r_i(t) \to I$, $q_i(t) \to I$, and $\widehat{A}_i(\gamma_i(t)) \to \widehat{A}_i(p)$ by continuity. Therefore the function $\tau \mapsto q_i(\tau)\widehat{A}_i(\gamma_i(\tau))$ is continuous at 0, and consequently

$$\frac{1}{t}\int_0^t q_i(\tau)\,\widehat{A}_i(\gamma_i(\tau))\, d\tau \longrightarrow \widehat{A}_i(p).$$

We conclude that

$$\frac{\widehat{s}(\gamma_i(t)) - \widehat{s}(p)}{t} \longrightarrow -\Gamma_i(p)\widehat{s}(p) + \widehat{A}_i(p).$$

The left-hand side is the difference quotient of the components of $\mathbf{s}$ in the coordinate direction ∂_i. Therefore $\partial_i\widehat{s}(p)$ exists, in the usual sense if p is interior and in the corresponding one-sided sense if p lies in a

boundary chart, and satisfies

$$\partial_i \widehat{s}(p) = \widehat{A}_i(p) - \Gamma_i(p)\widehat{s}(p).$$

Since $p \in U$ was arbitrary, we obtain the identity $\partial_i \widehat{s} = \widehat{A}_i - \Gamma_i \widehat{s}$ throughout U. The right-hand side is continuous because $\widehat{A}_i$, Γ_i, and $\widehat{s}$ are continuous. Thus the partial derivatives of the components s^μ exist and are continuous in the corresponding charts. Therefore $\mathbf{s}$ is of class C^1 on U.
Finally, the local formula for the covariant derivative gives

$$\nabla^{\mathbf{F}}_{\partial_i} \mathbf{s} = \sum_{\mu=1}^{r} \left(\partial_i s^\mu + \sum_{\nu=1}^{r} \Gamma_{i\nu}^{\mu} s^\nu \right) \mathbf{e}_\mu.$$

The identity $\partial_i \widehat{s} = \widehat{A}_i - \Gamma_i \widehat{s}$ implies

$$\nabla^{\mathbf{F}}_{\partial_i} \mathbf{s} = \sum_{\mu=1}^{r} A_i^\mu \mathbf{e}_\mu = \mathbf{A}(\partial_i).$$

Since this holds for every $i \in \{1, \dots, d\}$, we conclude that $\nabla^{\mathbf{F}} \mathbf{s} = \mathbf{A}$ on U.
Since $p \in M$ was arbitrary, it follows that $\mathbf{s} \in \Gamma^1(\mathbf{F})$ and $\nabla^{\mathbf{F}} \mathbf{s} = \mathbf{A}$ on all of M. □

Remark 2.7.23. In the particular case $\mathbf{E} = TM$, parallel transport allows us to compare tangent vectors at different points of a curve. If ∇ is a connection on TM, the velocity $\dot\gamma$ of a smooth curve γ is a section of $\gamma^* TM$, so it makes sense to consider $\dfrac{D\dot\gamma}{dt}$. This leads to the notion of a geodesic: a curve whose velocity is parallel along itself, that is, a curve satisfying $\dfrac{D\dot\gamma}{dt} = 0$.

2.7.1 Horizontal–vertical decomposition induced by a connection

Covariant differentiation along curves also describes the geometry of the total space of a vector bundle. The following construction is first carried out for an arbitrary bundle; the cotangent decomposition used later in symbolic calculus will be a specialization.

Let M be a finite-dimensional smooth manifold with or without boundary, let $\pi_{\mathbf{E}} \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle of finite rank over $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$, and let $\nabla^{\mathbf{E}}$ be a linear connection on $\mathbf{E}$. For $e \in \mathbf{E}_x$, define the **vertical space** at e by

$$V_e \mathbf{E} := \ker(d\pi_{\mathbf{E}})_e \subseteq T_e \mathbf{E}. \tag{2.56}$$

If $w \in \mathbf{E}_x$, the curve $t \mapsto e + tw$ remains in $\mathbf{E}_x$ and determines the **vertical lift**

$$w_e^{\mathrm{V}} := \left. \frac{d}{dt} \right|_{t=0} (e + tw) \in V_e \mathbf{E}. \tag{2.57}$$

Here, including in the complex case, the real tangent space is used; the complex structure of $\mathbf{E}_x$ canonically induces the corresponding complex structure on $V_e \mathbf{E}$.

Proposition 2.7.24. (Vertical subbundle and vertical lift) Let M be a finite-dimensional smooth manifold with or without boundary, and let $\pi_{\mathbf{E}} \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle of finite rank. The set

$$V\mathbf{E} := \coprod_{e \in \mathbf{E}} V_e \mathbf{E}$$

is a smooth vector subbundle of $T\mathbf{E} \to \mathbf{E}$. For each $e \in \mathbf{E}_x$, the map

$$\mathbf{E}_x \longrightarrow V_e\mathbf{E}, \qquad w \longmapsto w_e^{\mathrm{V}}, \tag{2.58}$$

is a canonical linear isomorphism.

Proof. Let $U \subseteq M$ be a trivializing open set, and write a point of $\mathbf{E}|_U$ as $(x,u) \in U \times \mathbb{K}^r$. The differential of the projection is

$$(d\pi_{\mathbf{E}})_{(x,u)}(X,W) = X, \qquad (X,W) \in T_xM \times \mathbb{K}^r.$$

Therefore,

$$V_{(x,u)}\mathbf{E} = \{(0,W) \mid W \in \mathbb{K}^r\}.$$

These local descriptions show that $V\mathbf{E}$ has constant rank and smooth trivializations. In the same coordinates, the curve $t \mapsto (x, u+tw)$ gives

$$w^{\mathrm{V}}_{(x,u)} = (0,w).$$

Thus (2.58) is a linear isomorphism. The definition in terms of addition and scalar multiplication in the fiber uses no trivialization; hence the isomorphism is canonical. □

The connection selects a complement to the vertical subbundle. To construct it without choosing coordinates, we associate to each tangent vector of the total space the covariant derivative of the fiber vector representing it.

Definition 2.7.25. (Connection map and horizontal subbundle) Let M be a finite-dimensional smooth manifold with or without boundary, and let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a connection $\nabla^{\mathbf{E}}$. Let $v \in T_e\mathbf{E}$, with $e \in \mathbf{E}_x$. In local bundle coordinates associated with a frame $(\mathbf{e}_1, \dots, \mathbf{e}_r)$, write

$$e = u^\beta \mathbf{e}_\beta(x), \qquad v = X^i \partial_i\Big|_e + W^\alpha \partial_{u^\alpha}\Big|_e, \qquad \nabla^{\mathbf{E}}_{\partial_i}\mathbf{e}_\beta = \Gamma^\alpha_{i\beta}\mathbf{e}_\alpha.$$

The **connection map** is defined by

$$K^{\nabla^{\mathbf{E}}}(v) := \big(W^\alpha + \Gamma^\alpha_{i\beta}(x) X^i u^\beta\big)\mathbf{e}_\alpha(x) \in \mathbf{E}_x. \tag{2.59}$$

The transformation law for the connection coefficients makes this expression independent of the coordinates and frame. If $\mathbf{s}(t) \in \mathbf{E}_{\gamma(t)}$ is a smooth curve with $\mathbf{s}(0) = e$ and $\dot{\mathbf{s}}(0) = v$, then $K^{\nabla^{\mathbf{E}}}(v) = \frac{D\mathbf{s}}{dt}\Big|_{t=0}$. The **horizontal space** at e is

$$H^{\nabla^{\mathbf{E}}}_e\mathbf{E} := \ker K^{\nabla^{\mathbf{E}}}_e, \tag{2.60}$$

where $K^{\nabla^{\mathbf{E}}}_e$ denotes the restriction to $T_e\mathbf{E}$.

Proposition 2.7.26. (Horizontal–vertical decomposition) Let M be a finite-dimensional smooth manifold with or without boundary, and let $\pi_{\mathbf{E}}\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle of finite rank equipped with a connection $\nabla^{\mathbf{E}}$. The local expressions (2.59) are compatible on overlaps and define a smooth map $K^{\nabla^{\mathbf{E}}}\colon T\mathbf{E} \to \mathbf{E}$ covering $\pi_{\mathbf{E}}$, and each

$$K^{\nabla^{\mathbf{E}}}_e\colon T_e\mathbf{E} \longrightarrow \mathbf{E}_x$$

is linear over $\mathbb{R}$; its restriction to the vertical subspace is linear over $\mathbb{K}$ under the isomorphism (2.58).

Moreover,

$$K_e^{\nabla^{\mathbf{E}}}(w_e^{\mathrm{V}}) = w, \qquad w \in \mathbf{E}_x,$$

and we have the smooth decompositions

$$T_e\mathbf{E} = H_e^{\nabla^{\mathbf{E}}}\mathbf{E} \oplus V_e\mathbf{E}, \qquad T\mathbf{E} = H^{\nabla^{\mathbf{E}}}\mathbf{E} \oplus V\mathbf{E}. \tag{2.61}$$

The restriction

$$(d\pi_{\mathbf{E}})_e\big|_{H_e^{\nabla^{\mathbf{E}}}\mathbf{E}} \colon H_e^{\nabla^{\mathbf{E}}}\mathbf{E} \longrightarrow T_xM \tag{2.62}$$

is an isomorphism. Its inverse sends $X \in T_xM$ to the **horizontal lift** X_e^{H}.

Proof. Choose coordinates $(x^1, \dots, x^n)$ on an open set $U \subseteq M$ and a local frame $(\mathbf{e}_1, \dots, \mathbf{e}_r)$ of $\mathbf{E}|_U$. Write

$$\nabla^{\mathbf{E}}_{\partial_i}\mathbf{e}_\beta = \Gamma_{i\beta}^{\alpha}\mathbf{e}_\alpha.$$

If $\mathbf{s}(t) = u^\alpha(t)\mathbf{e}_\alpha(\gamma(t))$, the local formula for covariant differentiation along a curve, obtained in (2.53), gives

$$K^{\nabla^{\mathbf{E}}}(x, u; X, W) = \left(x, W^\alpha + \Gamma_{i\beta}^{\alpha}(x)X^i u^\beta\right). \tag{2.63}$$

The right-hand side depends only on $(x, u; X, W) = \dot{\mathbf{s}}(0)$ and not on the higher-order terms of the curve. This proves independence of the representing curve. The same formula proves smoothness and linearity of $K_e^{\nabla^{\mathbf{E}}}$ in (X, W).

For a vertical vector, $X = 0$; therefore,

$$K^{\nabla^{\mathbf{E}}}(x, u; 0, W) = (x, W).$$

By (2.58), the restriction of $K_e^{\nabla^{\mathbf{E}}}$ to $V_e\mathbf{E}$ is precisely the inverse of the vertical lift. In particular, $H_e^{\nabla^{\mathbf{E}}}\mathbf{E} \cap V_e\mathbf{E} = \{0\}$. For $v \in T_e\mathbf{E}$, set

$$v^{\mathrm{V}} := \left(K^{\nabla^{\mathbf{E}}}(v)\right)_e^{\mathrm{V}}.$$

Then $v - v^{\mathrm{V}} \in H_e^{\nabla^{\mathbf{E}}}\mathbf{E}$ and $v = (v - v^{\mathrm{V}}) + v^{\mathrm{V}}$. This proves the first equality in (2.61). The local formula (2.63) also shows that the kernels $H_e^{\nabla^{\mathbf{E}}}\mathbf{E}$ vary smoothly, giving the equality of subbundles.

If a horizontal vector belongs to the kernel of $(d\pi_{\mathbf{E}})_e$, it is also vertical and hence, by the direct sum, zero. The restriction (2.62) is therefore injective. For $X = X^i\partial_i|_x$, the formula

$$X_e^{\mathrm{H}} = X^i\left(\partial_i - \Gamma_{i\beta}^{\alpha}(x)u^\beta\partial_{u^\alpha}\right)_{(x,u)} \tag{2.64}$$

defines a horizontal vector projecting to X. This proves surjectivity and completes the proof. □

A curve $\mathbf{s}(t) \in \mathbf{E}$ is horizontal if $\dot{\mathbf{s}}(t)$ belongs to $H_{\mathbf{s}(t)}^{\nabla^{\mathbf{E}}}\mathbf{E}$ for every t. By the definition of the connection map, this is equivalent to $\frac{D\mathbf{s}}{dt} = 0$; that is, $\mathbf{s}$ is horizontal if and only if the fiber vector it represents is parallel along $\pi_{\mathbf{E}} \circ \mathbf{s}$. Consequently, $H^{\nabla^{\mathbf{E}}}\mathbf{E}$ is the Ehresmann connection induced by the linear connection $\nabla^{\mathbf{E}}$. The subbundle $V\mathbf{E}$ is canonical, whereas $H^{\nabla^{\mathbf{E}}}\mathbf{E}$ depends on the chosen connection. This construction should not be confused with the nonlinear connections introduced in Finsler geometry: here the horizontal distribution comes from a linear connection on a vector bundle.

We now specialize the construction to the cotangent bundle. Let ∇ be a linear connection on TM, and equip T^*M with the dual connection characterized in Proposition 2.4.27. Let $\pi\colon T^*M \to M$ be the projection. Then

$$V(T^*M) = \ker d\pi, \qquad H^{\nabla}(T^*M) := H^{\nabla^{T^*M}}(T^*M).$$

Proposition 2.7.27. (Horizontal lift in the cotangent bundle) Let M be a finite-dimensional smooth manifold with or without boundary, let ∇ be a linear connection on TM, and let $(x^1,\dots,x^n)$ be local coordinates. Write

$$\nabla_{\partial_i}\partial_j = \Gamma_{ij}^k \partial_k, \qquad \boldsymbol{\xi} = \xi_j\, \mathbf{d}x^j.$$

With these conventions, the horizontal lift of ∂_i to T^*M is

$$\mathbf{H}_i = \partial_i + \Gamma_{ij}^k(x)\xi_k \frac{\partial}{\partial \xi_j}. \tag{2.65}$$

Proof. Let $x(t)$ be a curve, and let $\boldsymbol{\xi}(t) = \xi_j(t)\mathbf{d}x^j|_{x(t)}$ be a section of the cotangent bundle along it. The dual connection satisfies

$$(\nabla_{\dot x}\boldsymbol{\xi})_j = \dot\xi_j - \Gamma_{ij}^k(x(t))\dot x^i \xi_k.$$

The curve $(x(t),\boldsymbol{\xi}(t))$ is horizontal if and only if the left-hand side vanishes. Therefore,

$$\dot\xi_j = \Gamma_{ij}^k(x(t))\dot x^i \xi_k.$$

If $\dot x(0) = \partial_i|_x$, the vertical component of the velocity is $\Gamma_{ij}^k(x)\xi_k\partial_{\xi_j}$, proving (2.65) and, in particular, fixing its sign. By contrast, for $v = v^j\partial_j \in T_xM$, the equation $\nabla_{\dot x}v = 0$ gives $\dot v^k = -\Gamma_{ij}^k \dot x^i v^j$; according to (2.64), the lift in TM has the opposite sign. □

It remains to specify how this decomposition acts on sections of the pullback of a homomorphism bundle. Let $\mathbf{E},\mathbf{F} \to M$ be smooth vector bundles of finite rank with connections $\nabla^{\mathbf{E}}$ and $\nabla^{\mathbf{F}}$. The induced connection $\nabla^{\mathrm{Hom}(\mathbf{E},\mathbf{F})}$ is characterized by (2.13). The pullback connection on $\pi^*\mathrm{Hom}(\mathbf{E},\mathbf{F}) \to T^*M$ is the unique connection that, for a local section $\mathbf{A}$ of $\mathrm{Hom}(\mathbf{E},\mathbf{F})$ and $\mathbf{Z} \in \mathfrak{X}(T^*M)$, satisfies

$$(\pi^*\nabla^{\mathrm{Hom}(\mathbf{E},\mathbf{F})})_{\mathbf{Z}}(\pi^*\mathbf{A}) = \pi^*\left(\nabla^{\mathrm{Hom}(\mathbf{E},\mathbf{F})}_{d\pi(\mathbf{Z})}\mathbf{A}\right), \tag{2.66}$$

and extends to all sections by the Leibniz rule. Existence and uniqueness are verified in the pullback frames associated with the trivializations of Proposition 2.7.2; the local connection forms are the forms of $\nabla^{\mathrm{Hom}(\mathbf{E},\mathbf{F})}$ composed with π.

For

$$\mathbf{a} \in \Gamma(\pi^*\mathrm{Hom}(\mathbf{E},\mathbf{F})), \quad X \in T_xM, \quad \eta \in T_x^*M, \quad \xi \in T_x^*M,$$

define, at the point (x,ξ),

$$\nabla^{\mathrm{H}}_X\mathbf{a} := (\pi^*\nabla^{\mathrm{Hom}(\mathbf{E},\mathbf{F})})_{X^{\mathrm{H}}_{(x,\xi)}}\mathbf{a}, \qquad \nabla^{\mathrm{V}}_\eta\mathbf{a} := (\pi^*\nabla^{\mathrm{Hom}(\mathbf{E},\mathbf{F})})_{\eta^{\mathrm{V}}_{(x,\xi)}}\mathbf{a}. \tag{2.67}$$

These are, respectively, the **horizontal covariant derivative** and the **vertical covariant derivative** of $\mathbf{a}$.

Proposition 2.7.28. (Local formulas in the cotangent bundle) Let M be a smooth manifold with or without boundary. In the preceding coordinates, choose local frames of $\mathbf{E}$ and $\mathbf{F}$, and denote their connection matrices by $\omega_i^{\mathbf{E}}$ and $\omega_i^{\mathbf{F}}$. If $a(x,\xi)$ is the local matrix of a section of $\pi^*\operatorname{Hom}(\mathbf{E},\mathbf{F})$, then

$$\nabla_j^{\mathrm{V}} a = \frac{\partial a}{\partial \xi_j}, \qquad \nabla_i^{\mathrm{H}} a = \frac{\partial a}{\partial x^i} + \Gamma_{ij}^k \xi_k \frac{\partial a}{\partial \xi_j} + \omega_i^{\mathbf{F}} a - a\omega_i^{\mathbf{E}}. \tag{2.68}$$

The two derivatives defined in (2.67) are independent of the coordinates and frames used to calculate these expressions.

Proof. The vertical vector ∂_{ξ_j} projects to zero. By (2.66), the pullback connection therefore contributes no connection term, leaving $\nabla_j^{\mathrm{V}} a = \frac{\partial a}{\partial \xi_j}$. For the horizontal direction, (2.65) differentiates the components of a by

$$\partial_i + \Gamma_{ij}^k \xi_k \frac{\partial}{\partial \xi_j}.$$

The connection on $\operatorname{Hom}(\mathbf{E},\mathbf{F})$, given by (2.13), adds exactly $\omega_i^{\mathbf{F}} a - a\omega_i^{\mathbf{E}}$. This proves (2.68). Finally, X^{H} and η^{V} were defined as intrinsic lifts, and the pullback connection is also intrinsic. Thus a change of coordinates or frames merely transforms the matrices in the formula according to the laws for these objects and does not alter the resulting derivatives. □

2.8 Geodesics

Straight lines in Euclidean space have several equivalent characterizations. On the one hand, they are the curves that locally realize the shortest length between sufficiently close points. On the other, they can be described as curves whose velocity remains constant, in the sense that their acceleration vanishes, that is, they satisfy $\gamma''(t) = 0$.

On a Riemannian manifold, it is natural to seek an analogue of these curves. The Euclidean notion of a straight line no longer makes sense directly, but the metric structure allows us to measure lengths and formulate the problem of finding curves that connect two points with minimal length. These curves are known as *geodesics*.

Figure 2.2. Geodesics on the torus. They may close up periodically or fill the torus densely.

However, to obtain an intrinsic characterization analogous to the condition $\gamma''(t) = 0$ in $\mathbb{R}^n$, we cannot simply

differentiate the curve as though all its velocities belonged to the same vector space. If $\gamma\colon I \longrightarrow M$ is a smooth curve, its velocity $\dot\gamma(t)$ belongs to the tangent space $T_{\gamma(t)}M$, which depends on the point $\gamma(t)$. Thus it makes no sense to compare $\dot\gamma(t)$ directly with $\dot\gamma(t+h)$ by ordinary subtraction.

The preceding section resolves precisely this difficulty: a connection on TM induces a covariant derivative on sections of γ^*TM. Since the velocity $\dot\gamma$ is a section of γ^*TM, we may consider its covariant derivative $\frac{D\dot\gamma}{dt}$. This allows us to formulate the condition of vanishing covariant acceleration and thereby define the geodesics associated with a connection.

Definition 2.8.1. Let M be a smooth manifold with or without boundary and let ∇ be a connection on TM. We say that a smooth curve $\gamma\colon I \longrightarrow M$ is a **geodesic** if

$$\frac{D\dot\gamma}{dt} \equiv 0.$$

Equivalently, if (U,φ) is a smooth chart such that $\gamma(I)\subset U$ and

$$x(t) = (\varphi\circ\gamma)(t) = (x^1(t),\dots,x^n(t)),$$

then γ is a geodesic if and only if it satisfies the geodesic equations

$$\frac{d^2x^k}{dt^2}(t) + \frac{dx^i}{dt}(t)\frac{dx^j}{dt}(t)\Gamma^k_{ij}(x(t)) = 0. \tag{2.69}$$

We have defined geodesics, which in coordinates are described by a system of second-order ordinary differential equations. Before studying them in greater depth, we must ask whether such curves actually exist for every initial condition. Geodesics exist locally, as guaranteed by the fundamental theorem on flows. To see this geometrically, we first introduce the *geodesic vector field*.

Proposition 2.8.2. (Geodesic vector field) Let M be a smooth manifold without boundary and let ∇ be a connection on TM. Then there exists a unique smooth vector field $\mathbf{G}\in\mathfrak{X}(TM)$ with the following property: for every smooth curve

$$\zeta\colon I\longrightarrow TM, \qquad \zeta(t) = \big(\gamma(t),\mathbf{V}(t)\big),$$

ζ is an integral curve of $\mathbf{G}$ if and only if

$$\mathbf{V}(t) = \dot\gamma(t) \quad\text{and}\quad \frac{D\mathbf{V}}{dt}(t) = 0$$

for every $t\in I$.
Moreover, if (U,φ) is a smooth chart of M and $(x^1,\dots,x^n,v^1,\dots,v^n)$ are the induced coordinates on $\pi^{-1}(U)\subset TM$, then $\mathbf{G}$ is given by

$$\mathbf{G} = v^k\partial_{x^k} - v^iv^j\Gamma^k_{ij}(x)\partial_{v^k}.$$

In particular, if $\zeta\colon I\longrightarrow TM$ is given by $\zeta(t) = \big(\gamma(t),\dot\gamma(t)\big)$, then ζ is an integral curve of $\mathbf{G}$ if and only if γ is a geodesic.

Proof. Let (U,φ) be a smooth chart of M. On $\pi^{-1}(U)$, consider the vector field given, in the induced coor-

Figure 2.3. Schematic representation of the geodesic vector field on TM. The curve $\zeta(t) = (\gamma(t), \mathbf{V}(t))$ is an integral curve of $\mathbf{G}$ if and only if $\mathbf{V}(t) = \dot\gamma(t)$ and $\frac{D\mathbf{V}}{dt}(t) = 0$; in particular, when $\mathbf{V}(t) = \dot\gamma(t)$, the integral curves of $\mathbf{G}$ correspond to the geodesics of M.

dinates $(x^1,\dots,x^n,v^1,\dots,v^n)$, by

$$\mathbf{G}_U = v^k \partial_{x^k} - v^i v^j \Gamma_{ij}^k(x)\partial_{v^k}.$$

Let us first determine which curves are integral curves of $\mathbf{G}_U$. Let $\zeta\colon I \longrightarrow \pi^{-1}(U)$ be a smooth curve and write $\zeta(t) = \big(\gamma(t), \mathbf{V}(t)\big)$, where $\gamma = \pi\circ\zeta$ and $\mathbf{V}(t) \in T_{\gamma(t)}M$ for every $t \in I$. Let $\widetilde{\varphi}\colon \pi^{-1}(U) \longrightarrow \varphi(U)\times\mathbb{R}^n$ be the diffeomorphism defining the induced coordinates on TM. Write the coordinate representation of ζ as $\widetilde{\varphi}\circ\zeta = (\xi^1,\dots,\xi^n,\eta^1,\dots,\eta^n)\colon I \longrightarrow \varphi(U)\times\mathbb{R}^n$. Then $\varphi\circ\gamma = (\xi^1,\dots,\xi^n)$ and $\mathbf{V}(t) = \eta^k(t)\partial_k|_{\gamma(t)}$.
By the definition of an integral curve, ζ is an integral curve of $\mathbf{G}_U$ if and only if

$$\frac{d\xi^k}{dt}(t) = \eta^k(t), \qquad \frac{d\eta^k}{dt}(t) = -\Gamma_{ij}^k(\xi(t))\eta^i(t)\eta^j(t)$$

for every $t \in I$.
The first equation is equivalent to $\mathbf{V}(t) = \dot\gamma(t)$. Since $\varphi\circ\gamma = (\xi^1,\dots,\xi^n)$, we have $\dot\gamma(t) = \frac{d\xi^k}{dt}(t)\partial_k|_{\gamma(t)}$, so $\dot\gamma(t) = \mathbf{V}(t)$ if and only if $\frac{d\xi^k}{dt}(t) = \eta^k(t)$ for every k.

On the other hand, by Proposition 2.7.7,

$$\frac{D\mathbf{V}}{dt}(t) = \left(\frac{d\eta^k}{dt}(t) + \frac{d\xi^i}{dt}(t)\eta^j(t)\Gamma_{ij}^k(\xi(t)) \right) \partial_k\big|_{\gamma(t)}.$$

If, in addition, $\mathbf{V}(t) = \dot{\gamma}(t)$, then $\frac{d\xi^i}{dt}(t) = \eta^i(t)$, and consequently $\frac{D\mathbf{V}}{dt}(t) = 0$ is equivalent to

$$\frac{d\eta^k}{dt}(t) = -\Gamma_{ij}^k(\xi(t))\eta^i(t)\eta^j(t).$$

We have therefore proved that ζ is an integral curve of $\mathbf{G}_U$ if and only if $\mathbf{V}(t) = \dot{\gamma}(t)$ and $\frac{D\mathbf{V}}{dt}(t) = 0$ for every $t \in I$.

We now prove that these local vector fields agree on overlaps. Let (U, φ) and $(\widetilde{U}, \widetilde{\varphi})$ be two smooth charts with $U \cap \widetilde{U} \neq \varnothing$, and let $F = \widetilde{\varphi} \circ \varphi^{-1}$. If $(x^1, \dots, x^n, v^1, \dots, v^n)$ and $(\widetilde{x}^1, \dots, \widetilde{x}^n, \widetilde{v}^1, \dots, \widetilde{v}^n)$ denote the corresponding induced coordinates, then $\widetilde{x}^a = F^a(x)$ and $\widetilde{v}^a = \frac{\partial F^a}{\partial x^i}(x)v^i$.

Let ζ be an integral curve of $\mathbf{G}_U$ contained in $\pi^{-1}(U \cap \widetilde{U})$. If we write its coordinate representation in the system (x, v) as $\widetilde{\varphi}_U \circ \zeta = (\xi^1, \dots, \xi^n, \eta^1, \dots, \eta^n)$, then

$$\frac{d\xi^k}{dt}(t) = \eta^k(t), \qquad \frac{d\eta^k}{dt}(t) = -\Gamma_{ij}^k(\xi(t))\eta^i(t)\eta^j(t).$$

The components of the same curve in the system $(\widetilde{x}, \widetilde{v})$ are $\widetilde{\xi}^a(t) = F^a(\xi(t))$ and $\widetilde{\eta}^a(t) = \frac{\partial F^a}{\partial x^i}(\xi(t))\eta^i(t)$. By the chain rule,

$$\frac{d\widetilde{\xi}^a}{dt}(t) = \widetilde{\eta}^a(t).$$

Moreover,

$$\frac{d\widetilde{\eta}^a}{dt}(t) = \frac{\partial^2 F^a}{\partial x^i \partial x^j}(\xi(t))\eta^i(t)\eta^j(t) + \frac{\partial F^a}{\partial x^k}(\xi(t))\frac{d\eta^k}{dt}(t).$$

Substituting the equation for $\dfrac{d\eta^k}{dt}$ gives

$$\frac{d\widetilde{\eta}^a}{dt}(t) = \left(\frac{\partial^2 F^a}{\partial x^i \partial x^j} - \frac{\partial F^a}{\partial x^k}\Gamma_{ij}^k \right)(\xi(t))\eta^i(t)\eta^j(t).$$

By the transformation law for the Christoffel symbols (Lemma 2.4.12),

$$\widetilde{\Gamma}_{bc}^a(F(x))\frac{\partial F^b}{\partial x^i}(x)\frac{\partial F^c}{\partial x^j}(x) = \frac{\partial F^a}{\partial x^k}(x)\Gamma_{ij}^k(x) - \frac{\partial^2 F^a}{\partial x^i \partial x^j}(x).$$

Applying this identity in $x = \xi(t)$, we conclude that

$$\frac{d\widetilde{\eta}^a}{dt}(t) = -\widetilde{\Gamma}_{bc}^a(\widetilde{\xi}(t))\widetilde{\eta}^b(t)\widetilde{\eta}^c(t).$$

This shows that, in the induced coordinates associated with $(\widetilde{U}, \widetilde{\varphi})$, the curve ζ satisfies the differential system corresponding to the vector field $\mathbf{G}_{\widetilde{U}}$. Therefore, the local vector fields $\mathbf{G}_U$ and $\mathbf{G}_{\widetilde{U}}$ agree on overlaps and define a global smooth vector field $\mathbf{G} \in \mathfrak{X}(TM)$.

Let us now verify that this global vector field has the stated property. Let $\zeta\colon I \longrightarrow TM$ be a smooth curve

and write $\zeta(t) = \big(\gamma(t), \mathbf{V}(t)\big)$. First suppose that ζ is an integral curve of $\mathbf{G}$. For fixed $t_0 \in I$, there exist a chart (U, φ) of M and an open interval $J \subseteq I$ with $t_0 \in J$ such that $\zeta(J) \subseteq \pi^{-1}(U)$. Then $\zeta|_J$ is an integral curve of $\mathbf{G}_U$ and, by what we have proved, $\mathbf{V}(t) = \dot\gamma(t)$ and $\frac{D\mathbf{V}}{dt}(t) = 0$ for every $t \in J$. Since t_0 is arbitrary, we conclude that these equalities hold for every $t \in I$.
Conversely, suppose that $\mathbf{V}(t) = \dot\gamma(t)$ and $\frac{D\mathbf{V}}{dt}(t) = 0$ for every $t \in I$. Given $t_0 \in I$, choose again a chart (U, φ) and an open interval $J \subseteq I$ with $t_0 \in J$ such that $\zeta(J) \subseteq \pi^{-1}(U)$. By the local result already proved, the restriction $\zeta|_J$ is an integral curve of $\mathbf{G}_U$ and hence of $\mathbf{G}$. Since this holds for every $t_0 \in I$, it follows that ζ is an integral curve of $\mathbf{G}$ on all of I.
This proves the characterizing property of $\mathbf{G}$.
For uniqueness, let $\mathbf{H} \in \mathfrak{X}(TM)$ be another smooth vector field with the same property. Let (U, φ) be a smooth chart of M and let $q \in \pi^{-1}(U)$. Consider the integral curve ζ of $\mathbf{G}$ such that $\zeta(0) = q$. By the characterizing property, ζ satisfies $\mathbf{V}(t) = \dot\gamma(t)$ and $\frac{D\mathbf{V}}{dt}(t) = 0$ and is therefore also an integral curve of $\mathbf{H}$. Consequently, $\mathbf{G}_q = \zeta'(0) = \mathbf{H}_q$. Since q is arbitrary, we conclude that $\mathbf{G} = \mathbf{H}$.
The last assertion follows immediately: if $\zeta(t) = \big(\gamma(t), \dot\gamma(t)\big)$, then the condition $\mathbf{V}(t) = \dot\gamma(t)$ and $\frac{D\mathbf{V}}{dt}(t) = 0$ is equivalent to $\frac{D\dot\gamma}{dt}(t) = 0$, which is precisely the geodesic equation. □

A geodesic $\gamma\colon I \longrightarrow M$ that cannot be extended to a geodesic on a larger interval is called a ***maximal geodesic***. A ***geodesic segment*** is a geodesic whose domain is a compact interval. The existence of maximal geodesics is established in the following theorem:

Theorem 2.8.3. (Existence, uniqueness, and maximality of geodesics) Let M be a smooth manifold without boundary and let ∇ be a connection on TM. For each $p \in M$, $v \in T_pM$, and $t_0 \in \mathbb{R}$, there exists a unique maximal geodesic

$$\gamma_{(p,v,t_0)}\colon I_{(p,v,t_0)} \longrightarrow M$$

such that $t_0 \in I_{(p,v,t_0)}$ and $\gamma_{(p,v,t_0)}(t_0) = p$, $\dot\gamma_{(p,v,t_0)}(t_0) = v$.
Moreover, if $\gamma_1\colon I_1 \longrightarrow M$ and $\gamma_2\colon I_2 \longrightarrow M$ are geodesics such that $\gamma_1(t_0) = \gamma_2(t_0)$ and $\dot\gamma_1(t_0) = \dot\gamma_2(t_0)$, then $\gamma_1(t) = \gamma_2(t)$ for every $t \in I_1 \cap I_2$.

Proof. Let $\mathbf{G} \in \mathfrak{X}(TM)$ be the geodesic vector field given by Proposition 2.8.2. By Theorem 1.8.15, for each $(p, v) \in TM$ there exists a unique maximal integral curve $\zeta_{(p,v,t_0)}\colon I_{(p,v,t_0)} \longrightarrow TM$ such that $\zeta_{(p,v,t_0)}(t_0) = (p, v)$. Define $\gamma_{(p,v,t_0)} := \pi \circ \zeta_{(p,v,t_0)}$. Then $\gamma_{(p,v,t_0)}$ is a smooth curve in M and $\gamma_{(p,v,t_0)}(t_0) = \pi(\zeta_{(p,v,t_0)}(t_0)) = p$.
Write $\zeta_{(p,v,t_0)}(t) = \big(\gamma_{(p,v,t_0)}(t), \mathbf{V}(t)\big)$ for $t \in I_{(p,v,t_0)}$, where $\mathbf{V}(t) \in T_{\gamma_{(p,v,t_0)}(t)}M$. By Proposition 2.8.2, we have $\mathbf{V}(t) = \dot\gamma_{(p,v,t_0)}(t)$ for every $t \in I_{(p,v,t_0)}$, and moreover

$$\frac{D\dot\gamma_{(p,v,t_0)}}{dt}(t) = 0.$$

Therefore, $\gamma_{(p,v,t_0)}$ is a geodesic. Evaluating at $t = t_0$ gives $\mathbf{V}(t_0) = v$, that is, $\dot\gamma_{(p,v,t_0)}(t_0) = v$.
This proves existence.
We now prove uniqueness. Let $\widetilde\gamma\colon J \longrightarrow M$ be a geodesic such that $\widetilde\gamma(t_0) = p$ and $\dot{\widetilde\gamma}(t_0) = v$. Define $\widetilde\zeta\colon J \longrightarrow TM$ by $\widetilde\zeta(t) := \dot{\widetilde\gamma}(t)$. Since $\widetilde\gamma$ is a geodesic, Proposition 2.8.2 implies that $\widetilde\zeta$ is an integral curve of $\mathbf{G}$. Moreover, $\widetilde\zeta(t_0) = (p, v) = \zeta_{(p,v,t_0)}(t_0)$. Uniqueness of integral curves of the vector field $\mathbf{G}$ gives $\widetilde\zeta(t) = \zeta_{(p,v,t_0)}(t)$ for every $t \in J \cap I_{(p,v,t_0)}$. Applying the projection π gives $\widetilde\gamma(t) = \gamma_{(p,v,t_0)}(t)$ for every $t \in J \cap I_{(p,v,t_0)}$. This proves uniqueness.

Finally, let us verify maximality. Suppose that $\gamma_{(p,v,t_0)}$ is not maximal. Then there exists a geodesic $\overline{\gamma}\colon \widetilde{I} \longrightarrow M$ such that $I_{(p,v,t_0)} \subsetneq \widetilde{I}$ and $\overline{\gamma}(t) = \gamma_{(p,v,t_0)}(t)$ for every $t \in I_{(p,v,t_0)}$. Define $\overline{\zeta}\colon \widetilde{I} \longrightarrow TM$ by $\overline{\zeta}(t) := \dot{\overline{\gamma}}(t)$. Since $\overline{\gamma}$ is a geodesic, Proposition 2.8.2 implies that $\overline{\zeta}$ is an integral curve of $\mathbf{G}$. Moreover, $\overline{\zeta}(t) = \dot{\overline{\gamma}}(t) = \dot{\gamma}_{(p,v,t_0)}(t) = \zeta_{(p,v,t_0)}(t)$ for every $t \in I_{(p,v,t_0)}$. Therefore, $\overline{\zeta}$ is a proper extension of the integral curve $\zeta_{(p,v,t_0)}$, contradicting its maximality. We conclude that $\gamma_{(p,v,t_0)}$ is maximal. □

From now on, we denote this unique maximal geodesic by γ_v and assume $t_0 = 0$ to simplify the notation.

Remark 2.8.4. By Theorem 2.8.3, there exists a unique maximal flow Φ_t associated with the geodesic vector field $\mathbf{G}$, given by

$$\Phi_t(p,v) = \big(\gamma_v(t), \dot{\gamma}_v(t)\big).$$

By the definition of the vector field as the derivative of its flow, we have

$$\mathbf{G}_{(p,v)} = \frac{d}{dt}\Phi_t(p,v)\Big|_{t=0}.$$

Therefore, for every $f \in C^\infty(TM)$,

$$\mathbf{G}f(p,v) = df_{(p,v)}\big(\mathbf{G}_{(p,v)}\big) = \frac{d}{dt}\Big(f(\Phi_t(p,v))\Big)\Big|_{t=0}.$$

Substituting the expression for the flow gives

$$\mathbf{G}f(p,v) = \frac{d}{dt}\Big(f(\gamma_v(t), \dot{\gamma}_v(t))\Big)\Big|_{t=0}.$$

On the other hand, in induced coordinates $(x^1,\dots,x^n,v^1,\dots,v^n)$ on $\pi^{-1}(U)$, we have

$$\mathbf{G} = v^k\partial_k - v^i v^j \Gamma_{ij}^k(x)\partial_{v^k},$$

and consequently, for every $f \in C^\infty(\pi^{-1}(U))$,

$$\mathbf{G}f = v^k\frac{\partial f}{\partial x^k} - v^i v^j \Gamma_{ij}^k(x)\frac{\partial f}{\partial v^k}.$$

In particular, if $f \in C^\infty(M)$, then its lift $\pi^* f = f \circ \pi$ satisfies

$$\mathbf{G}(\pi^* f)(p,v) = \frac{d}{dt}\Big(f(\gamma_v(t))\Big)\Big|_{t=0} = df_p(v).$$

The exponential map compares a neighborhood of the origin in T_pM with a neighborhood of p in the manifold. Before constructing it, we should observe how a geodesic changes when its initial velocity is rescaled.

Lemma 2.8.5. (Rescaling lemma) Let M be a smooth manifold without boundary and let ∇ be a connection on TM. For every $p \in M$, $v \in T_pM$, and $c \in \mathbb{R}$, we have

$$\gamma_{cv}(t) = \gamma_v(ct)$$

for every t for which both sides are defined.

Proof. If $c = 0$, both curves are constant and equal to p, so the assertion is trivial. Suppose $c \neq 0$.
Let $I \subseteq \mathbb{R}$ be the maximal domain of γ_v and define

$$\widetilde{\gamma}_v \colon c^{-1}I \longrightarrow M, \qquad \widetilde{\gamma}_v(t) = \gamma_v(ct).$$

We will show that $\widetilde{\gamma}_v$ is a geodesic with initial point p and initial velocity cv. By uniqueness and maximality of γ_{cv}, it will follow that $\widetilde{\gamma}_v = \gamma_{cv}$.
Both curves start at p, since $\widetilde{\gamma}_v(0) = \gamma_v(0) = p$. Consider a chart (U, φ) and suppose that

$$(\varphi \circ \gamma_v)(t) = (x^1(t), \ldots, x^n(t)).$$

Then

$$(\varphi \circ \widetilde{\gamma}_v)(t) = (x^1(ct), \ldots, x^n(ct)).$$

By the chain rule,

$$\dot{\widetilde{\gamma}}_v^i(t) = \frac{d}{dt} x^i(ct) = c\, \dot{x}^i(ct).$$

In particular,

$$\dot{\widetilde{\gamma}}_v(0) = c\, \dot{\gamma}_v(0) = cv.$$

To see that $\widetilde{\gamma}_v$ is a geodesic, we compute its covariant derivative. Using the local expression,

$$\frac{D\dot{\widetilde{\gamma}}_v}{dt}(t) = \left(\frac{d}{dt} \dot{\widetilde{\gamma}}_v^k(t) + \Gamma_{ij}^k(\widetilde{\gamma}_v(t)) \dot{\widetilde{\gamma}}_v^i(t) \dot{\widetilde{\gamma}}_v^j(t) \right) \partial_k.$$

Substituting the preceding expression for $\dot{\widetilde{\gamma}}_v^i(t)$ gives

$$\frac{d}{dt} \dot{\widetilde{\gamma}}_v^k(t) = c^2 \ddot{x}^k(ct),$$

and

$$\dot{\widetilde{\gamma}}_v^i(t) \dot{\widetilde{\gamma}}_v^j(t) = c^2 \dot{x}^i(ct) \dot{x}^j(ct).$$

Therefore,

$$\frac{D\dot{\widetilde{\gamma}}_v}{dt}(t) = c^2 \left(\ddot{x}^k(ct) + \Gamma_{ij}^k(\gamma_v(ct)) \dot{x}^i(ct) \dot{x}^j(ct) \right) \partial_k.$$

Since γ_v is a geodesic, the term in parentheses is zero, and consequently

$$\frac{D\dot{\widetilde{\gamma}}_v}{dt}(t) = 0.$$

This shows that $\widetilde{\gamma}_v$ is a geodesic with initial conditions (p, cv), so $\widetilde{\gamma}_v = \gamma_{cv}$. □

2.8.1 The exponential map

The assignment $v \mapsto \gamma_v$ defines a map from TM to the set of geodesics of M. Moreover, by the rescaling lemma, we may define a function from a subset of TM to M that sends each line through the origin of T_pM to a geodesic:

Definition 2.8.6. Let M be a smooth manifold without boundary and let ∇ be a connection on TM. By Theorem 2.8.3, each $p \in M$ and $v \in T_pM$ determine a unique maximal geodesic γ_v, defining a map $v \mapsto \gamma_v$ from TM to the set of geodesics in M.
Let

$$\mathcal{E} = \{v \in TM \mid \gamma_v \text{ is defined on an interval containing } [0,1]\}.$$

Define the **exponential map** $\exp\colon \mathcal{E} \longrightarrow M$ by $\exp(v) = \gamma_v(1)$. For each $p \in M$, the **exponential map restricted to** p, denoted by $\exp_p$, is the restriction of the exponential map to the set $\mathcal{E}_p = \mathcal{E} \cap T_pM$.

Figure 2.4. Exponential map on a Riemannian manifold.

From this point onward, when $(M, \mathbf{g})$ is a Riemannian manifold, geodesics and the exponential map are understood to be associated with the Levi–Civita connection of $\mathbf{g}$, unless otherwise stated. The preceding results formulated for an arbitrary connection retain their original meaning.

The following proposition collects the basic properties of the exponential map that will be used to construct normal coordinates and study the local geometry.

Proposition 2.8.7. (Properties of the exponential map) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and let $\exp\colon \mathcal{E} \longrightarrow M$ be the exponential map of its Levi–Civita connection.

(a) $\mathcal{E}$ is an open subset of TM containing $0_p \in T_pM$ for every $p \in M$, and each $\mathcal{E}_p \subseteq T_pM$ is star-shaped with respect to 0.

(b) For each $v \in TM$, the geodesic γ_v is given by

$$\gamma_v(t) = \exp(tv)$$

for every t for which both sides are defined.

(c) exp is smooth.

(d) For each $p \in M$, the differential

$$d(\exp_p)_0 \colon T_0(T_pM) \cong T_pM \longrightarrow T_pM$$

is the identity under the usual identification of $T_0(T_pM)$ with T_pM.

Proof. By Lemma 2.8.5, for every $v \in TM$ and every $t \in \mathbb{R}$ for which both sides are defined, we have

$$\gamma_v(t) = \gamma_{tv}(1) = \exp(tv).$$

This proves (b).
Moreover, for each $p \in M$, the constant geodesic at p has initial velocity 0_p, so $0_p \in \mathcal{E}_p$. Now, if $v \in \mathcal{E}_p$, then γ_v is defined on $t = 1$. By Lemma 2.8.5, for every $t \in [0,1]$ we have

$$\exp_p(tv) = \gamma_{tv}(1) = \gamma_v(t),$$

and in particular $tv \in \mathcal{E}_p$. This shows that $\mathcal{E}_p$ is star-shaped with respect to 0.
We now show that $\mathcal{E}$ is open and exp is smooth. Let $\mathbf{G}$ be the geodesic vector field and let

$$\Phi \colon \mathcal{D}(\Phi) \longrightarrow TM$$

be its maximal flow. By Theorem 1.8.15, the domain $\mathcal{D}(\Phi) \subseteq \mathbb{R} \times TM$ is open and the map Φ is smooth. By Remark 2.8.4, we have

$$\Phi_t(v) = \big(\gamma_v(t), \dot{\gamma}_v(t)\big)$$

whenever both sides are defined.
By the definition of $\mathcal{E}$,

$$\mathcal{E} = \{v \in TM \mid \gamma_v(1) \text{ is defined}\}.$$

Since the maximal domain of γ_v contains 0, it follows that $\gamma_v(1)$ is defined if and only if $(1, v) \in \mathcal{D}(\Phi)$. Therefore,

$$\mathcal{E} = \{v \in TM \mid (1, v) \in \mathcal{D}(\Phi)\}.$$

If we define $\iota \colon TM \longrightarrow \mathbb{R} \times TM$ by $\iota(v) = (1, v)$, then

$$\mathcal{E} = \iota^{-1}(\mathcal{D}(\Phi)).$$

Since ι is continuous and $\mathcal{D}(\Phi)$ is open, we conclude that $\mathcal{E}$ is open.
Moreover, for every $v \in \mathcal{E}$,

$$\exp(v) = \gamma_v(1) = \pi\big(\Phi_1(v)\big).$$

Consequently,

$$\exp = \pi \circ \Phi_1\big|_{\mathcal{E}},$$

and since Φ and π are smooth, it follows that exp is smooth. This proves (c) and also completes the proof of (a).

Finally, fix $p \in M$ and let $v \in T_pM$. Consider the curve $\alpha(t) = tv \in T_pM$. By (b),

$$(\exp_p \circ \alpha)(t) = \exp_p(tv) = \gamma_v(t)$$

for every t in an open interval around 0 on which the expression is defined. Differentiating at $t = 0$ gives

$$d(\exp_p)_0(v) = \frac{d}{dt}\Big(\exp_p(tv)\Big)\Big|_{t=0} = \dot{\gamma}_v(0) = v.$$

Under the usual identification of $T_0(T_pM)$ with T_pM, this shows that $d(\exp_p)_0$ is the identity. This proves (d). □

Figure 2.5. $\mathcal{E}$ is open.

2.8.2 Geodesic normal coordinates

Among the properties of the exponential map, we proved that $d(\exp_p)_0$ is invertible, so the inverse function theorem for manifolds (Theorem 1.5.6) guarantees the existence of open sets $V \subseteq T_pM$ and $U \subseteq M$ such that $0 \in V$, $p \in U$, and

$$\exp_p : V \longrightarrow U$$

is a diffeomorphism.

If V is star-shaped with respect to the origin, we say that U is a ***normal neighborhood of*** p. Every orthonormal basis $\{\beta_1, \ldots, \beta_n\}$ of T_pM determines a canonical isomorphism $B : \mathbb{R}^n \longrightarrow T_pM$ by $B(x^1, \ldots, x^n) = x^i \beta_i$. If $U = \exp_p(V)$ is a normal neighborhood of p, we may combine this isomorphism with the exponential map to obtain a smooth chart (U, φ) of M containing p, where $\varphi = B^{-1} \circ (\exp_p |_V)^{-1} : U \longrightarrow \mathbb{R}^n$. These coordinates are called ***normal coordinates centered at*** p. They are unique in the following sense:

Proposition 2.8.8. Let $(M,\mathbf{g})$ be a Riemannian manifold of dimension n without boundary, let $p \in M$, and let U be a normal neighborhood of p. For each normal coordinate chart (U,φ) centered at p, the coordinate basis $\{\partial_1|_p,\dots,\partial_n|_p\} \subseteq T_pM$ is orthonormal. Conversely, for each orthonormal basis $\{\beta_1,\dots,\beta_n\}$ of T_pM, there exists a unique normal coordinate chart (x^i) on U such that $\partial_i|_p = \beta_i$ for every $i \in \{1,\dots,n\}$. Moreover, any two normal coordinate charts (x^i) and $(\widetilde{x}^i)$ are related by

$$\widetilde{x}^j = A^j_i x^i$$

for some matrix $(A^j_i) \in O(n)$.

Proof. Let (U,φ) be a normal coordinate chart centered at p, with coordinate functions $\varphi = (x^1,\dots,x^n)$. By definition,

$$\varphi = B^{-1} \circ \exp_p^{-1},$$

where $B\colon \mathbb{R}^n \longrightarrow T_pM$ is an isomorphism determined by an orthonormal basis $\{b_1,\dots,b_n\}$ of T_pM. Then

$$\varphi^{-1} = \exp_p \circ B,$$

and therefore

$$d(\varphi^{-1})_0 = d(\exp_p)_0 \circ dB_0 = B,$$

since $d(\exp_p)_0 = \mathrm{Id}_{T_pM}$ and B is linear. Consequently,

$$\partial_i|_p = d(\varphi^{-1})_0(\partial_i|_0) = B(\partial_i|_0) = b_i,$$

which shows that the basis $\{\partial_i|_p\}$ is orthonormal.
Conversely, an orthonormal basis $\{\beta_1,\dots,\beta_n\}$ of T_pM determines an isomorphism $B\colon \mathbb{R}^n \longrightarrow T_pM$ and hence a normal coordinate chart $\varphi = B^{-1} \circ \exp_p^{-1}$ satisfying $\partial_i|_p = \beta_i$.
If $\widetilde{\varphi} = \widetilde{B}^{-1} \circ \exp_p^{-1}$ is another normal coordinate chart centered at p, then the change of coordinates is given by

$$\widetilde{\varphi} \circ \varphi^{-1} = \widetilde{B}^{-1} \circ B,$$

which is a linear isometry of $\mathbb{R}^n$. Therefore, there exists a constant matrix $(A^j_i) \in O(n)$ such that

$$\widetilde{x}^j = A^j_i x^i.$$

This proves uniqueness. □

Other properties of normal coordinates include the following:

Proposition 2.8.9. (Properties of normal coordinates) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let (U,φ) be a normal coordinate chart centered at $p \in M$.

(a) The coordinates of p are $(0,\dots,0)$.

(b) The metric components at p are $g_{ij}(p) = \delta_{ij}$.

(c) For $v = v^i\partial_i|_p \in T_pM$, the geodesic γ_v starting at p with $\dot\gamma(0) = v$ is represented in normal coordinates

by

$$(\varphi \circ \gamma_v)(t) = (tv^1, \dots, tv^n)$$

if $t \in I$, where I is an interval such that $0 \in I$ and $\gamma_v(I) \subseteq U$.

(d) The Christoffel symbols in these coordinates vanish at p.

(e) The first derivatives of the metric components vanish at p:

$$\partial_k g_{ij}(p) = 0 \quad \text{for all } i, j, k.$$

Proof. Part (a) follows directly from the definition of normal coordinates, since $\varphi(p) = 0$.
For (b), Proposition 2.8.8 shows that the coordinate basis $\{\partial_i|_p\}$ is orthonormal, giving $g_{ij}(p) = \delta_{ij}$.
Part (c) follows from Proposition 2.8.7(b): since $\gamma_v(t) = \exp_p(tv)$, composing with $\varphi = B^{-1} \circ \exp_p^{-1}$ gives

$$(\varphi \circ \gamma_v)(t) = B^{-1}(tv) = (tv^1, \dots, tv^n).$$

To prove (d), let $v = v^i \partial_i|_p \in T_pM$. By (c), writing $x^i(t) = (\varphi \circ \gamma_v)^i(t)$ gives $x^i(t) = tv^i$, so $\dot{x}^i(t) = v^i$ and $\ddot{x}^k(t) = 0$. Substituting into the equation for the geodesic (2.69), we obtain

$$\Gamma_{ij}^k(x(t))\, v^i v^j = 0.$$

Evaluating at $t = 0$, that is, at p, we conclude that

$$\Gamma_{ij}^k(p)\, v^i v^j = 0$$

for every k and every $v \in T_pM$.
The Levi–Civita connection is torsion-free; therefore, in a coordinate frame,

$$\Gamma_{ab}^k = \Gamma_{ba}^k.$$

Taking $v = \partial_a|_p$ gives $\Gamma_{aa}^k(p) = 0$. If $a \neq b$, taking $v = \partial_a|_p + \partial_b|_p$ gives

$$0 = \Gamma_{aa}^k(p) + \Gamma_{ab}^k(p) + \Gamma_{ba}^k(p) + \Gamma_{bb}^k(p) = 2\Gamma_{ab}^k(p).$$

Thus, $\Gamma_{ab}^k(p) = 0$ for all a, b, k, proving (d).
Finally, the Levi–Civita connection is compatible with $\mathbf{g}$. Corollary 2.4.16, applied to $\mathbf{E}_k = \partial_k$ and evaluated at p, gives

$$\partial_k g_{ij}(p) = \Gamma_{ki}^a(p) g_{aj}(p) + \Gamma_{kj}^a(p) g_{ia}(p) = 0,$$

by (d). This proves (e). □

Continuity of the metric allows us to make the identity $g_{ij}(p) = \delta_{ij}$ quantitative on a sufficiently small ball. The following result specifies the type of normal coordinates we will use in approximation arguments.

Proposition 2.8.10. (Normal coordinate balls with Euclidean control) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $p \in \mathrm{Int}(M)$, and let $0 < \theta < 1$. There exist numbers $0 < r < R$ and a linear

isometry $B_p\colon \mathbb{R}^n \longrightarrow (T_pM, \mathbf{g}_p)$ such that $\exp_p$ is a diffeomorphism from $B_{\mathbf{g}_p}(0,R)$ onto an open set $U_p' \subseteq \mathrm{Int}(M)$ and, setting

$$U_p := \exp_p\big(B_{\mathbf{g}_p}(0,r)\big), \qquad \kappa_p := B_p^{-1} \circ \exp_p^{-1}\colon U_p \longrightarrow B_{\mathrm{euc}}(0,r),$$

the pair (U_p, κ_p) is a regular normal coordinate ball centered at p, with $\overline{U}_p \subseteq U_p'$, and satisfies

$$(1-\theta)\|w\| \le \left|d(\kappa_p^{-1})_z w\right|_{\mathbf{g}} \le (1+\theta)\|w\|$$

for all $z \in B_{\mathrm{euc}}(0,r)$ and $w \in \mathbb{R}^n$.

Proof. Since $d(\exp_p)_0 = \mathrm{Id}_{T_pM}$, the inverse function theorem gives an open neighborhood $W \subseteq T_pM$ of 0 on which $\exp_p$ is a diffeomorphism. Since p is an interior point, we may shrink W so that its image is contained in $\mathrm{Int}(M)$. Choose $R > 0$ so that $\overline{B}_{\mathbf{g}_p}(0,R) \subseteq W$ and fix a linear isometry $B_p\colon \mathbb{R}^n \longrightarrow (T_pM, \mathbf{g}_p)$. The normal chart

$$\kappa_p' := B_p^{-1} \circ \exp_p^{-1} : U_p' := \exp_p\big(B_{\mathbf{g}_p}(0,R)\big) \longrightarrow B_{\mathrm{euc}}(0,R)$$

is centered at p. If $G(z)$ denotes the matrix of the metric in these coordinates, Proposition 2.8.9 implies $G(0) = I_n$. Since $z \mapsto G(z)$ is also continuous in the operator norm, there exists $0 < r < R$ such that

$$(1-\theta)^2\|w\|^2 \le \langle G(z)w, w\rangle_{\mathbb{R}^n} \le (1+\theta)^2\|w\|^2$$

for every $z \in \overline{B}_{\mathrm{euc}}(0,r)$ and every $w \in \mathbb{R}^n$. Indeed, it suffices to make $\|G(z) - I_n\|_{\mathrm{op}}$ smaller than the minimum of $1-(1-\theta)^2$ and $(1+\theta)^2 - 1$.

The restriction of κ_p' to $U_p := \exp_p(B_{\mathbf{g}_p}(0,r))$ is the chart κ_p in the statement. Moreover, $\overline{U}_p = \exp_p(\overline{B}_{\mathbf{g}_p}(0,r))$ is compact and contained in U_p', so U_p is a regular normal coordinate ball in the sense of Definition 1.2.9. Finally,

$$\left|d(\kappa_p^{-1})_z w\right|_{\mathbf{g}}^2 = \langle G(z)w, w\rangle_{\mathbb{R}^n},$$

and taking square roots gives the required inequalities. □

2.9 The Riemannian distance function

The metric first acts infinitesimally, assigning a length to each tangent vector. Integrating these lengths along curves gives a global notion of distance between points. This step is more than a formality: the resulting distance reflects both the local geometry and the ways in which curves can travel through the manifold.

Definition 2.9.1. Let M be a Riemannian manifold with or without boundary.

(a) A **curve segment** is a smooth curve whose domain is a compact interval.

(b) A smooth curve $\gamma\colon I \longrightarrow M$ is called a **regular curve** if $\gamma'(t) \neq 0$ for every $t \in I$ (which implies that γ is an immersion).

(c) A continuous curve segment $\gamma\colon [a,b] \longrightarrow M$ is said to be **piecewise regular** if there exists a partition $\{t_0, \dots, t_k\}$ of $[a,b]$ such that $\gamma|_{[t_{i-1},t_i]}$ is a regular (smooth) curve segment for each $i \in \{1,\dots,k\}$. We also

call these **admissible curves**, and partitions satisfying this condition are called **admissible partitions for** γ. For convenience, we regard a curve $\gamma\colon \{a\} \longrightarrow M$ as an admissible curve.

(d) If $\gamma\colon I \longrightarrow M$ is a smooth curve, a **reparametrization of** γ is a curve of the form $\widetilde{\gamma} = \gamma \circ \varphi\colon I' \longrightarrow M$, where I' is an interval and $\varphi\colon I' \longrightarrow I$ is a diffeomorphism. If φ is strictly increasing, we say that $\widetilde{\gamma}$ is a **forward parametrization** or an **orientation-preserving parametrization**. If φ is strictly decreasing, we say that $\widetilde{\gamma}$ is a **backward parametrization** or an **orientation-reversing parametrization**.

(e) For an admissible curve $\gamma\colon [a,b] \longrightarrow M$, a **reparametrization of** γ is a curve of the form $\widetilde{\gamma} = \gamma \circ \varphi$, where $\varphi\colon [c,d] \longrightarrow [a,b]$ is a homeomorphism for which there exists a partition $\{c_0,\dots,c_k\}$ of $[c,d]$ such that the restriction $\varphi|_{[c_{i-1},c_i]}$ is a diffeomorphism onto its image for each $i \in \{1,\dots,k\}$.

(f) If $\gamma\colon [a,b] \longrightarrow M$ is an admissible curve, we define the **length of** γ to be

$$L_{\mathbf{g}}(\gamma) := \int_a^b \|\gamma'(t)\|_{\mathbf{g}}\, dt.$$

We may define the distance between two points on a connected Riemannian manifold as follows:

Definition 2.9.2. Let $(M,\mathbf{g})$ be a connected Riemannian manifold with or without boundary. For each pair of points $p,q \in M$, define the **Riemannian distance from** p **to** q, denoted by $d_{\mathbf{g}}(p,q)$, to be

$$d_{\mathbf{g}}(p,q) := \inf\{L_{\mathbf{g}}(\gamma) \mid \gamma \text{ is an admissible curve from } p \text{ to } q\}.$$

The infimum is finite on each connected component by the following result.

Proposition 2.9.3. If M is a connected smooth manifold (with or without boundary), then any two points of M can be joined by an admissible curve.

Proof. Fix $p \in M$ and let A be the set of points that can be joined to p by an admissible curve. The set A is nonempty. If $q \in A$, choose a chart around q whose image contains a Euclidean ball, or a relative ball in $\mathbb{H}^n$, centered at the image of q. After shrinking it, this set is convex. Straight segments in the chart, transported to M, join q to all the points in a neighborhood of it; concatenating them with a curve from p to q gives an admissible curve. Therefore, A is open. The same argument shows that $M \setminus A$ is open: if one of its points had a point of A in this neighborhood, the local segment would also join it to p. Since M is connected, it follows that $A = M$. □

Every Riemannian manifold is metrizable by its Riemannian distance.

Theorem 2.9.4. Let $(M,\mathbf{g})$ be a connected Riemannian manifold with or without boundary. With the distance function $d_{\mathbf{g}}$, M is a metric space whose metric topology agrees with its original topology as a smooth manifold.

Proof. The preceding proposition shows that $d_{\mathbf{g}}(p,q)$ is finite. Nonnegativity is immediate. Reversing the parameter of a curve proves that $d_{\mathbf{g}}(p,q) = d_{\mathbf{g}}(q,p)$, and concatenating admissible curves, then taking infima, gives

$$d_{\mathbf{g}}(p,r) \le d_{\mathbf{g}}(p,q) + d_{\mathbf{g}}(q,r).$$

It remains to prove that distinct points have positive distance and to compare the topologies. Fix $p \in M$. In a chart (U, x) around p, choose $r > 0$ so that the relative ball

$$Q := B_{\mathrm{euc}}(x(p), 2r) \cap \mathbb{H}^n$$

is contained in $x(U)$ and has closure contained in $x(U)$; in an interior chart, omit the intersection with $\mathbb{H}^n$. Continuity and positive definiteness of the metric give constants $0 < c \le C$ such that

$$c|v| \le \left| d(x^{-1})_z v \right|_{\mathbf{g}} \le C|v| \tag{2.70}$$

for $z \in \overline{Q}$ and $v \in \mathbb{R}^n$ tangent to the half-space. Set

$$V := x^{-1}\big(B_{\mathrm{euc}}(x(p), r) \cap \mathbb{H}^n\big).$$

If $q \in V$, the straight segment from $x(p)$ to $x(q)$ stays in the relative ball, and the second inequality in (2.70) shows that

$$d_{\mathbf{g}}(p, q) \le C|x(q) - x(p)|.$$

On the other hand, every admissible curve from p to a point outside V must first reach the coordinate sphere of radius r. On the portion before this first exit point, the first inequality in (2.70) gives a length of at least cr. If $q \in V$ and a curve from p to q does not leave V, the same inequality and the Euclidean inequality between length and displacement give a length of at least $c|x(q) - x(p)|$; if it leaves V, its length is at least cr and the same bound remains valid. Consequently,

$$c|x(q) - x(p)| \le d_{\mathbf{g}}(p, q) \le C|x(q) - x(p)|, \qquad q \in V. \tag{2.71}$$

These bounds first prove that $d_{\mathbf{g}}(p, q) > 0$ when $p \neq q$: if $q \notin V$, use the bound cr, and if $q \in V$, use the first inequality in (2.71). Therefore, $d_{\mathbf{g}}$ is a metric. The second inequality shows that convergence in the manifold topology implies convergence with respect to $d_{\mathbf{g}}$ near each point; the first, together with the barrier cr for leaving V, gives the converse. The two topologies agree. □

Lemma 2.9.5. (Gauss lemma) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, let $p \in M$, and let $v, w \in T_pM$ be such that $\exp_p$ is defined on a neighborhood of v. Then

$$\mathbf{g}_{\exp_p(v)}\big(d(\exp_p)_v(v), d(\exp_p)_v(w)\big) = \mathbf{g}_p(v, w).$$

Proof. For small s and $0 \le t \le 1$, consider the variation

$$\alpha(s, t) := \exp_p\big(t(v + sw)\big).$$

Along the curve $t \mapsto \alpha(0, t)$, set $\mathbf{T} = \partial_t \alpha$ and $\mathbf{J} = \partial_s \alpha|_{s=0}$. The Levi–Civita connection is torsion-free, so $D\mathbf{J}/dt = D\mathbf{T}/ds$, and each curve $t \mapsto \alpha(s, t)$ is a geodesic. Since this connection is also compatible with $\mathbf{g}$, we

can differentiate inner products along the variation. Therefore,

$$\begin{aligned}\frac{d}{dt}\langle \mathbf{J}, \mathbf{T}\rangle &= \left\langle \frac{D\mathbf{J}}{dt}, \mathbf{T}\right\rangle + \left\langle \mathbf{J}, \frac{D\mathbf{T}}{dt}\right\rangle \\ &= \left\langle \frac{D\mathbf{T}}{ds}, \mathbf{T}\right\rangle = \frac{1}{2}\frac{\partial}{\partial s}\Big|_{s=0} |\partial_t \alpha(s,t)|_{\mathbf{g}}^2.\end{aligned}$$

For each s, metric compatibility and the geodesic equation give

$$\frac{d}{dt}|\partial_t \alpha(s,t)|_{\mathbf{g}}^2 = 2\left\langle \frac{D}{dt}\partial_t \alpha(s,t), \partial_t \alpha(s,t)\right\rangle_{\mathbf{g}} = 0.$$

The speed of $t \mapsto \alpha(s,t)$ is therefore constant and equal to $|v + sw|_{\mathbf{g}}$. Thus the last member of the preceding equality is $\langle v, w\rangle_{\mathbf{g}}$. Since $\mathbf{J}(0) = 0$, integration between 0 and 1 gives

$$\langle \mathbf{J}(1), \mathbf{T}(1)\rangle = \langle v, w\rangle_{\mathbf{g}}.$$

Finally, $\mathbf{J}(1) = d(\exp_p)_v(w)$ and $\mathbf{T}(1) = d(\exp_p)_v(v)$. □

Proposition 2.9.6. (Radial minimization in a normal neighborhood) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and let $p \in M$. There exists $\varepsilon > 0$ such that, for every $v \in B_{T_pM}(0, \varepsilon)$, the radial geodesic

$$\gamma_v(t) = \exp_p(tv), \qquad 0 \le t \le 1,$$

realizes the distance between p and $\exp_p(v)$. Up to monotone reparametrizations, it is the unique minimizing curve between these points that stays in the normal neighborhood.

Proof. Choose $\varepsilon > 0$ so that $\exp_p$ is a diffeomorphism on the tangent ball of radius ε. In the corresponding normal neighborhood, define

$$\rho(\exp_p z) := |z|_{\mathbf{g}}.$$

The Gauss lemma shows that the radial unit vector is the gradient of ρ. Indeed, if $z \neq 0$, decompose any $w \in T_pM$ as $w = az + w^{\perp}$, and the lemma gives

$$d\rho_{\exp_p z}\big(d(\exp_p)_z w\big) = \left\langle d(\exp_p)_z w, \frac{d(\exp_p)_z z}{|z|_{\mathbf{g}}}\right\rangle = a|z|_{\mathbf{g}}.$$

In particular, $|\operatorname{grad}\rho|_{\mathbf{g}} = 1$. For every admissible curve c contained in the normal neighborhood,

$$\left|\frac{d}{dt}(\rho \circ c)\right| \le |\dot{c}|_{\mathbf{g}}$$

on each smooth portion. If it joins p to $\exp_p(v)$, integration gives $L_{\mathbf{g}}(c) \ge |v|_{\mathbf{g}}$. The radial curve has constant speed $|v|_{\mathbf{g}}$ and attains equality.

If a curve c leaves the normal neighborhood before reaching $\exp_p(v)$, let t_* be its first exit time. For $t < t_*$, we may write $c(t) = \exp_p z(t)$, with $|z(t)|_{\mathbf{g}} = \rho(c(t)) < \varepsilon$. As t approaches t_*, necessarily $|z(t)|_{\mathbf{g}} \to \varepsilon$: otherwise, a subsequence of $z(t)$ would converge to a point in the interior of the tangent ball, and $c(t_*)$ would still belong to the normal neighborhood. Consequently, for each ε' with $|v|_{\mathbf{g}} < \varepsilon' < \varepsilon$, continuity gives a first time before

t_* at which $\rho = \varepsilon'$. The preceding inequality, applied up to this time, shows that the length is already at least $\varepsilon' > |v|_{\mathbf{g}}$. This proves minimization among all curves.
Now suppose equality is attained. In the chain

$$L_{\mathbf{g}}(c) = \int |\dot{c}| \geq \int |(\rho \circ c)'| \geq \left| \int (\rho \circ c)' \right| = |v|_{\mathbf{g}}$$

both inequalities are equalities. Hence, $|(\rho \circ c)'| = |\dot{c}|$ and $(\rho \circ c)' \geq 0$ almost everywhere. Equality in Cauchy–Schwarz implies that $\dot{c}$ is a nonnegative multiple of the radial gradient; it has no component tangent to the spheres $\rho = \text{const}$. Therefore, up to a monotone choice of parameter, the image of c is the radial geodesic. □

Corollary 2.9.7. Every minimizing admissible curve parametrized with constant speed is a geodesic.

Proof. Every subarc of a minimizing curve is again minimizing; otherwise, replacing it by a shorter curve would reduce the total length. Fix an interior parameter t_0 and choose a normal neighborhood centered at $c(t_0)$. For sufficiently small $\delta > 0$, the subarcs $c|_{[t_0, t_0+\delta]}$ and $c|_{[t_0-\delta, t_0]}$ stay in this neighborhood. The preceding proposition shows that both are radial segments, up to monotone reparametrization. Since c has constant speed, these reparametrizations are affine.
The entire subarc $c|_{[t_0-\delta, t_0+\delta]}$ is also minimizing. If the two radial segments formed a corner at $c(t_0)$, their concatenation could not be the unique minimizing radial curve between $c(t_0 - \delta)$ and $c(t_0 + \delta)$ in a sufficiently small normal neighborhood of the first of these points. Therefore, the one-sided velocities agree. Uniqueness for the geodesic equation shows that both segments are restrictions of a single geodesic. Since t_0 was arbitrary, c is a geodesic on its entire domain. □

Riemannian distance and geodesics are closely related: curves realizing the distance between their endpoints must satisfy the geodesic equation. The following notion allows us to formulate this global property.

Definition 2.9.8. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary. An admissible curve $\gamma : [a, b] \longrightarrow M$ in M is called a **minimizing curve** if $L_{\mathbf{g}}(\gamma) \leq L_{\mathbf{g}}(\widetilde{\gamma})$ for every admissible curve $\widetilde{\gamma}$ with the same endpoints ($\gamma(a) = \widetilde{\gamma}(a)$ and $\gamma(b) = \widetilde{\gamma}(b)$).

Recall that a Riemannian manifold is *geodesically complete* if every maximal geodesic is defined on $\mathbb{R}$.

Theorem 2.9.9. (Hopf–Rinow) Let $(M, \mathbf{g})$ be a connected Riemannian manifold without boundary. The following are equivalent:

(a) $(M, d_{\mathbf{g}})$ is a complete metric space;

(b) every closed bounded subset of $(M, d_{\mathbf{g}})$ is compact;

(c) M is geodesically complete;

(d) for every $p \in M$, $\exp_p$ is defined on all of T_pM;

(e) there exists $p_0 \in M$ such that $\exp_{p_0}$ is defined on all of $T_{p_0}M$.

If any of these conditions holds, any two points of M are joined by a geodesic segment that realizes their distance.

Figure 2.6. Although every minimizing curve is a geodesic, a geodesic minimizes distance only locally between sufficiently close points.

The proof follows Lee's strategy [95].

Proof. Conditions (c) and (d) are equivalent by the definition of $\exp_p(v) = \gamma_v(1)$ and affine changes of parameter for geodesics; moreover, (d) implies (e).
Assume (e), fix $q \in M$, and set $r = d_{\mathbf{g}}(p_0, q)$. If $r = 0$, there is nothing to prove. If $r > 0$, consider

$$A := \big\{ s \in [0,r] \;\big|\; \text{there exists } v_s \in T_{p_0}M, |v_s|_{\mathbf{g}} = 1, \text{ such that} \\ x_s := \exp_{p_0}(sv_s), \quad d_{\mathbf{g}}(p_0, x_s) = s, \quad d_{\mathbf{g}}(x_s, q) = r - s \big\}.$$

We have $0 \in A$. The set A is closed: if $s_j \to s$ and $s_j \in A$, the unit sphere of $T_{p_0}M$ is compact, so a subsequence of v_{s_j} converges to a unit vector v. Continuity of $\exp_{p_0}$ and of the distance preserves the three equalities defining A.
Let $s \in A$ with $s < r$ and write $x = x_s$. First choose a normal neighborhood V of x with compact closure. This is possible by local compactness and because normal neighborhoods form a basis at x. Since the Riemannian distance induces the manifold topology, there exists $\delta > 0$, smaller than $r - s$, such that $\overline{B}_{\mathbf{g}}(x, \delta) \subseteq V$. This ball is closed in M and contained in the compact set $\overline{V}$; therefore, it is compact. By the definition of distance, there exist curves c_j from x to q, parametrized by arc length, with

$$L_{\mathbf{g}}(c_j) \longrightarrow d_{\mathbf{g}}(x, q) = r - s.$$

Let $y_j = c_j(\delta)$. Then

$$d_{\mathbf{g}}(x, y_j) \le \delta, \qquad d_{\mathbf{g}}(y_j, q) \le L_{\mathbf{g}}(c_j) - \delta.$$

By compactness, we may assume that $y_j \to y$. Passing to the limit in the triangle inequality

$$r - s = d_{\mathbf{g}}(x, q) \le d_{\mathbf{g}}(x, y_j) + d_{\mathbf{g}}(y_j, q) \le d_{\mathbf{g}}(x, y_j) + L_{\mathbf{g}}(c_j) - \delta$$

gives

$$d_{\mathbf{g}}(x,y)=\delta, \qquad d_{\mathbf{g}}(y,q)=r-s-\delta.$$

Proposition 2.9.6 gives a minimizing geodesic from x to y. Concatenating it with the minimizing radial segment from p_0 to x gives a curve of length $s+\delta$. Moreover,

$$r \le d_{\mathbf{g}}(p_0,y)+d_{\mathbf{g}}(y,q) \le s+\delta+r-s-\delta=r,$$

so the concatenation is minimizing. If $s=0$, choose v_0 to be the initial unit velocity of the segment from $p_0=x$ to y; the preceding equalities give $\delta\in A$ directly. If $s>0$, Corollary 2.9.7 shows that it has no corner at x; by uniqueness for the geodesic equation, it is the extension of $t\mapsto \exp_{p_0}(tv_s)$. Therefore, $s+\delta\in A$.
Since A is closed, it contains its supremum. The preceding extension property prevents this supremum from being less than r, so $r\in A$. Thus there exists a vector $v\in T_{p_0}M$ with

$$\exp_{p_0}(v)=q, \qquad |v|_{\mathbf{g}}=r,$$

and the corresponding radial geodesic is minimizing.
Now let (q_j) be a Cauchy sequence. It is bounded, so $d_{\mathbf{g}}(p_0,q_j)\le R$ for some R. By the preceding argument, we may write $q_j=\exp_{p_0}(v_j)$ with $|v_j|_{\mathbf{g}}\le R$. The closed ball of radius R in the finite-dimensional space $T_{p_0}M$ is compact; a subsequence v_{j_ℓ} converges to v, and then $q_{j_\ell}\to\exp_{p_0}(v)$. Since the original sequence is Cauchy, the entire sequence converges to the same point. This proves $(e)\Rightarrow(a)$.
Now assume (a). If a maximal geodesic $\gamma\colon[0,b)\to M$ had $b<\infty$, its speed would be constant and

$$d_{\mathbf{g}}(\gamma(s),\gamma(t))\le L_{\mathbf{g}}(\gamma\restriction_{[s,t]})=|t-s|\,|\dot\gamma(0)|_{\mathbf{g}}.$$

Thus, $\gamma(t)$ would have a limit $p\in M$ as $t\to b^-$. Choose a chart around p and a smaller neighborhood whose compact closure is contained in that chart. A tail of γ stays in the smaller neighborhood. On its closure, the metric is uniformly equivalent to the Euclidean metric and the Christoffel symbols are bounded. If $x^i(t)$ are the coordinates of $\gamma(t)$ and $v^i(t)=\dot x^i(t)$, the constant Riemannian speed bounds all the components $v^i(t)$. The geodesic equation

$$\dot v^k(t)=-\Gamma^k_{ij}(x(t))v^i(t)v^j(t)$$

then bounds their derivatives. Hence, $v(t)$ is uniformly Lipschitz on this tail and has a limit v_b as $t\to b^-$. Extend $(x(t),v(t))$ continuously to the data $(x(p),v_b)$. The integral equation for the geodesic system passes to the limit at b; local existence and uniqueness for this system, with these initial data, extend the solution beyond b, a contradiction. The same argument at the left endpoint proves (c). We now also have (d); applying the radial argument of the preceding paragraph with any point as center gives a minimizing geodesic segment between two arbitrary points.
Under these conditions, for $p\in M$ and $R>0$, the existence of minimizers gives

$$\overline{B}_{\mathbf{g}}(p,R)=\exp_p\big(\overline{B}_{\mathbf{g}_p}(0,R)\big).$$

The right-hand side is the continuous image of a compact finite-dimensional set, so every closed ball is compact. Every closed bounded set is contained as a closed subset in one of these balls, giving (b). Finally, (b) implies (a): a Cauchy sequence is bounded, has a convergent subsequence in a compact closed ball, and,

being Cauchy, converges to the same limit. This proves all the equivalences and consequences. □

We record separately three consequences that will be used later:

Corollary 2.9.10. If $(M, \mathbf{g})$ is a connected Riemannian manifold without boundary and there exists $p \in M$ such that $\exp_p$ is defined on all of T_pM, then M is complete.

Proof. This is implication $(e) \Rightarrow (a)$ of Theorem 2.9.9, taking $p_0 = p$. □

Corollary 2.9.11. If M is a connected complete Riemannian manifold without boundary, then any two points of M can be joined by a minimizing geodesic segment.

Proof. Metric completeness is condition (a) of Hopf–Rinow; the last assertion of the theorem gives the minimizing segment. □

Corollary 2.9.12. If M is a connected complete Riemannian manifold without boundary, then every maximal geodesic in M is defined on all of $\mathbb{R}$.

Proof. By Hopf–Rinow, metric completeness is equivalent to geodesic completeness, which is precisely the assertion. □

2.10 Curvature

Curvature is the central notion in the study of Riemannian geometry. Intuitively, it measures the failure of covariant derivatives to commute: transporting a vector in different directions and then comparing the resulting vectors reveals the presence of curvature.

Definition 2.10.1. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. The $(1,3)$-***Riemann curvature tensor*** of M is the tensor field $\mathbf{R} \in \Gamma(T^{(1,3)}(TM))$ of type $(1,3)$ given by

$$\mathbf{R}(\mathbf{X}, \mathbf{Y})(\mathbf{Z}) := \nabla_{\mathbf{X}} \nabla_{\mathbf{Y}} \mathbf{Z} - \nabla_{\mathbf{Y}} \nabla_{\mathbf{X}} \mathbf{Z} - \nabla_{[\mathbf{X},\mathbf{Y}]} \mathbf{Z}.$$

Proposition 2.10.2. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. The $(1,3)$-Riemann curvature tensor $\mathbf{R}$ defines a tensor field of type $(1,3)$ on M.

Proof. By Lemma 1.10.18, it suffices to verify that $\mathbf{R}$ is $C^\infty(M)$-multilinear in each argument. Additivity in all three arguments follows from the linearity of the connection and the bracket; it remains to check compatibility with multiplication by a function. Take $f \in C^\infty(M)$ and $\mathbf{X}, \mathbf{Y}, \mathbf{Z} \in \mathfrak{X}(M)$.
Let us verify this for the first argument:

$$\begin{aligned}
\mathbf{R}(f\mathbf{X}, \mathbf{Y})\mathbf{Z} &= \nabla_{f\mathbf{X}} \nabla_{\mathbf{Y}} \mathbf{Z} - \nabla_{\mathbf{Y}} \nabla_{f\mathbf{X}} \mathbf{Z} - \nabla_{[f\mathbf{X},\mathbf{Y}]} \mathbf{Z} \\
&= f \nabla_{\mathbf{X}} \nabla_{\mathbf{Y}} \mathbf{Z} - \nabla_{\mathbf{Y}} (f \nabla_{\mathbf{X}} \mathbf{Z}) - \nabla_{f[\mathbf{X},\mathbf{Y}] - (\mathbf{Y}f)\mathbf{X}} \mathbf{Z} \\
&= f \nabla_{\mathbf{X}} \nabla_{\mathbf{Y}} \mathbf{Z} - (\mathbf{Y}f) \nabla_{\mathbf{X}} \mathbf{Z} - f \nabla_{\mathbf{Y}} \nabla_{\mathbf{X}} \mathbf{Z} - f \nabla_{[\mathbf{X},\mathbf{Y}]} \mathbf{Z} + (\mathbf{Y}f) \nabla_{\mathbf{X}} \mathbf{Z} \\
&= f \mathbf{R}(\mathbf{X}, \mathbf{Y})\mathbf{Z}.
\end{aligned}$$

For the second argument:

$$\begin{aligned}\mathbf{R}(\mathbf{X}, f\mathbf{Y})\mathbf{Z} &= \nabla_{\mathbf{X}}\nabla_{f\mathbf{Y}}\mathbf{Z} - \nabla_{f\mathbf{Y}}\nabla_{\mathbf{X}}\mathbf{Z} - \nabla_{[\mathbf{X},f\mathbf{Y}]}\mathbf{Z}\\ &= \nabla_{\mathbf{X}}(f\nabla_{\mathbf{Y}}\mathbf{Z}) - f\nabla_{\mathbf{Y}}\nabla_{\mathbf{X}}\mathbf{Z} - \nabla_{f[\mathbf{X},\mathbf{Y}]+(\mathbf{X}f)\mathbf{Y}}\mathbf{Z}\\ &= (\mathbf{X}f)\nabla_{\mathbf{Y}}\mathbf{Z} + f\nabla_{\mathbf{X}}\nabla_{\mathbf{Y}}\mathbf{Z} - f\nabla_{\mathbf{Y}}\nabla_{\mathbf{X}}\mathbf{Z} - f\nabla_{[\mathbf{X},\mathbf{Y}]}\mathbf{Z} - (\mathbf{X}f)\nabla_{\mathbf{Y}}\mathbf{Z}\\ &= f\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z}.\end{aligned}$$

Finally, for the third and last argument:

$$\begin{aligned}\mathbf{R}(\mathbf{X},\mathbf{Y})(f\mathbf{Z}) &= \nabla_{\mathbf{X}}\nabla_{\mathbf{Y}}(f\mathbf{Z}) - \nabla_{\mathbf{Y}}\nabla_{\mathbf{X}}(f\mathbf{Z}) - \nabla_{[\mathbf{X},\mathbf{Y}]}(f\mathbf{Z})\\ &= \nabla_{\mathbf{X}}\big((\mathbf{Y}f)\mathbf{Z} + f\nabla_{\mathbf{Y}}\mathbf{Z}\big) - \nabla_{\mathbf{Y}}\big((\mathbf{X}f)\mathbf{Z} + f\nabla_{\mathbf{X}}\mathbf{Z}\big) - ([\mathbf{X},\mathbf{Y}]f)\mathbf{Z} - f\nabla_{[\mathbf{X},\mathbf{Y}]}\mathbf{Z}\\ &= (\mathbf{X}(\mathbf{Y}f))\mathbf{Z} + (\mathbf{Y}f)\nabla_{\mathbf{X}}\mathbf{Z} + (\mathbf{X}f)\nabla_{\mathbf{Y}}\mathbf{Z} + f\nabla_{\mathbf{X}}\nabla_{\mathbf{Y}}\mathbf{Z}\\ &\quad - (\mathbf{Y}(\mathbf{X}f))\mathbf{Z} - (\mathbf{X}f)\nabla_{\mathbf{Y}}\mathbf{Z} - (\mathbf{Y}f)\nabla_{\mathbf{X}}\mathbf{Z} - f\nabla_{\mathbf{Y}}\nabla_{\mathbf{X}}\mathbf{Z}\\ &\quad - ([\mathbf{X},\mathbf{Y}]f)\mathbf{Z} - f\nabla_{[\mathbf{X},\mathbf{Y}]}\mathbf{Z}.\end{aligned}$$

The terms containing first derivatives of f cancel. Moreover,

$$\mathbf{X}(\mathbf{Y}f) - \mathbf{Y}(\mathbf{X}f) - [\mathbf{X},\mathbf{Y}]f = 0,$$

by the definition of the Lie bracket acting on functions. Consequently,

$$\mathbf{R}(\mathbf{X},\mathbf{Y})(f\mathbf{Z}) = f\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z}.$$

We have verified multilinearity in all three arguments. Therefore, $\mathbf{R}$ is a tensor field of type $(1,3)$ on M. □

Since $\mathbf{R}$ is a tensor field of type $(1,3)$, we may write it in local coordinates (x^i) as

$$\mathbf{R} = R_{ijk}{}^{l}\,\mathbf{d}x^i \otimes \mathbf{d}x^j \otimes \mathbf{d}x^k \otimes \partial_l.$$

The small space before the index l visually separates the three covariant indices from the contravariant index.

The coefficients satisfy the relation

$$\mathbf{R}(\partial_i, \partial_j)\partial_k = R_{ijk}{}^{l}\partial_l.$$

The following proposition shows how to compute the components of R in coordinates:

Proposition 2.10.3. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. The components of the $(1,3)$-curvature tensor in coordinates (x^i) are given by

$$R_{ijk}{}^{l} = \partial_i\Gamma^l_{jk} - \partial_j\Gamma^l_{ik} + \Gamma^m_{jk}\Gamma^l_{im} - \Gamma^m_{ik}\Gamma^l_{jm}.$$

Proof. Let (x^i) be local coordinates on M and let $\{\partial_i\}$ be the associated coordinate frame. By the definition of the Christoffel symbols,

$$\nabla_{\partial_i}\partial_j = \Gamma^m_{ij}\partial_m.$$

Using the linearity and Leibniz rule of the connection, we have

$$\nabla_{\partial_i}\nabla_{\partial_j}\partial_k = \nabla_{\partial_i}\left(\Gamma^l_{jk}\partial_l\right) = \partial_i\Gamma^l_{jk}\partial_l + \Gamma^l_{jk}\nabla_{\partial_i}\partial_l = \partial_i\Gamma^l_{jk}\partial_l + \Gamma^l_{jk}\Gamma^m_{il}\partial_m.$$

Interchanging the indices i and j in the preceding calculation gives

$$\nabla_{\partial_j}\nabla_{\partial_i}\partial_k = \partial_j\Gamma^l_{ik}\partial_l + \Gamma^l_{ik}\Gamma^m_{jl}\partial_m.$$

Since $[\partial_i, \partial_j] = 0$ in our coordinate frame, the third term in the definition vanishes:

$$\nabla_{[\partial_i,\partial_j]}\partial_k = 0.$$

Therefore, recalling that $\mathbf{R}(\partial_i,\partial_j)\partial_k = \nabla_{\partial_i}\nabla_{\partial_j}\partial_k - \nabla_{\partial_j}\nabla_{\partial_i}\partial_k - \nabla_{[\partial_i,\partial_j]}\partial_k$ and interchanging l and m in $\Gamma^l_{jk}\Gamma^m_{il}\partial_m - \Gamma^l_{ik}\Gamma^m_{jl}\partial_m$,

$$\mathbf{R}(\partial_i,\partial_j)\partial_k = \left(\partial_i\Gamma^l_{jk} - \partial_j\Gamma^l_{ik} + \Gamma^m_{jk}\Gamma^l_{im} - \Gamma^m_{ik}\Gamma^l_{jm}\right)\partial_l.$$

Comparing coefficients in the basis $\{\partial_l\}$, we conclude that

$$R_{ijk}{}^l = \partial_i\Gamma^l_{jk} - \partial_j\Gamma^l_{ik} + \Gamma^m_{jk}\Gamma^l_{im} - \Gamma^m_{ik}\Gamma^l_{jm},$$

which is the desired formula. □

For any vector fields $\mathbf{X}, \mathbf{Y} \in \mathfrak{X}(M)$, the map $\mathbf{R}(\mathbf{X},\mathbf{Y})\colon \mathfrak{X}(M) \longrightarrow \mathfrak{X}(M)$ given by $\mathbf{Z} \mapsto \mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z}$ is a smooth homomorphism of the tangent bundle; in particular, $\mathbf{R}(\mathbf{X},\mathbf{Y})$ is $C^\infty(M)$-linear. It is called the ***curvature endomorphism determined by*** $\mathbf{X}$ ***and*** $\mathbf{Y}$. Lowering the contravariant index with the metric gives the covariant tensor field defined next.

Definition 2.10.4. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. Define the ***Riemann curvature tensor*** to be the tensor field of type $(0,4)$ given by

$$\mathbf{Rm}(\mathbf{X},\mathbf{Y},\mathbf{Z},\mathbf{W}) = \langle \mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z}, \mathbf{W}\rangle_{\mathbf{g}}.$$

As a corollary of Proposition 2.10.3, we obtain a local expression for the Riemann curvature tensor:

Corollary 2.10.5. If $(M, \mathbf{g})$ is a Riemannian manifold with or without boundary and

$$\mathbf{Rm} = R_{ijkl}\,\mathbf{d}x^i \otimes \mathbf{d}x^j \otimes \mathbf{d}x^k \otimes \mathbf{d}x^l,$$

then

$$R_{ijkl} = g_{lm}\left(\partial_i\Gamma^m_{jk} - \partial_j\Gamma^m_{ik} + \Gamma^p_{jk}\Gamma^m_{ip} - \Gamma^p_{ik}\Gamma^m_{jp}\right).$$

Proof. By the definition of $\mathbf{Rm}$ and the formula in Proposition 2.10.3,

$$R_{ijkl} = \mathbf{Rm}(\partial_i,\partial_j,\partial_k,\partial_l) = g_{lm}R^m{}_{ijk}.$$

Substituting

$$R^m{}_{ijk} = \partial_i\Gamma^m_{jk} - \partial_j\Gamma^m_{ik} + \Gamma^p_{jk}\Gamma^m_{ip} - \Gamma^p_{ik}\Gamma^m_{jp}$$

gives the stated expression. □

The symmetries and antisymmetries of the Riemann curvature tensor relate its components and simplify calculations involving it.

Proposition 2.10.6. (Symmetries of the curvature tensor) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. The Riemann curvature tensor has the following properties for all $\mathbf{X}, \mathbf{Y}, \mathbf{Z}, \mathbf{W} \in \mathfrak{X}(M)$.

(a) $\mathbf{Rm}(\mathbf{W}, \mathbf{X}, \mathbf{Y}, \mathbf{Z}) = -\mathbf{Rm}(\mathbf{X}, \mathbf{W}, \mathbf{Y}, \mathbf{Z})$.

(b) $\mathbf{Rm}(\mathbf{W}, \mathbf{X}, \mathbf{Y}, \mathbf{Z}) = -\mathbf{Rm}(\mathbf{W}, \mathbf{X}, \mathbf{Z}, \mathbf{Y})$.

(c) $\mathbf{Rm}(\mathbf{W}, \mathbf{X}, \mathbf{Y}, \mathbf{Z}) = \mathbf{Rm}(\mathbf{Y}, \mathbf{Z}, \mathbf{W}, \mathbf{X})$.

(d) $\mathbf{Rm}(\mathbf{W}, \mathbf{X}, \mathbf{Y}, \mathbf{Z}) + \mathbf{Rm}(\mathbf{X}, \mathbf{Y}, \mathbf{W}, \mathbf{Z}) + \mathbf{Rm}(\mathbf{Y}, \mathbf{W}, \mathbf{X}, \mathbf{Z}) = 0$. This identity is known as the ***Bianchi identity***.

Proof. Write

$$R(\mathbf{X}, \mathbf{Y}, \mathbf{Z}, \mathbf{W}) := \langle \mathbf{R}(\mathbf{X}, \mathbf{Y})\mathbf{Z}, \mathbf{W} \rangle.$$

The definition of $\mathbf{R}$ immediately gives $\mathbf{R}(\mathbf{X}, \mathbf{Y}) = -\mathbf{R}(\mathbf{Y}, \mathbf{X})$, proving (1).
Metric compatibility of the connection implies

$$\begin{aligned} &R(\mathbf{X}, \mathbf{Y}, \mathbf{Z}, \mathbf{W}) + R(\mathbf{X}, \mathbf{Y}, \mathbf{W}, \mathbf{Z}) \\ &\quad = \mathbf{X}\mathbf{Y}\langle \mathbf{Z}, \mathbf{W} \rangle - \mathbf{Y}\mathbf{X}\langle \mathbf{Z}, \mathbf{W} \rangle - [\mathbf{X}, \mathbf{Y}]\langle \mathbf{Z}, \mathbf{W} \rangle = 0. \end{aligned}$$

In the first equality, the three covariant derivatives in each curvature term are expanded and grouped using the compatibility rule; the last equality is the definition of the bracket acting on functions. This proves (2).
Since the connection is torsion-free, expanding the cyclic sum gives

$$\begin{aligned} &\mathbf{R}(\mathbf{X}, \mathbf{Y})\mathbf{Z} + \mathbf{R}(\mathbf{Y}, \mathbf{Z})\mathbf{X} + \mathbf{R}(\mathbf{Z}, \mathbf{X})\mathbf{Y} \\ &= \nabla_{\mathbf{X}}(\nabla_{\mathbf{Y}}\mathbf{Z} - \nabla_{\mathbf{Z}}\mathbf{Y}) + \nabla_{\mathbf{Y}}(\nabla_{\mathbf{Z}}\mathbf{X} - \nabla_{\mathbf{X}}\mathbf{Z}) + \nabla_{\mathbf{Z}}(\nabla_{\mathbf{X}}\mathbf{Y} - \nabla_{\mathbf{Y}}\mathbf{X}) \\ &\quad - \nabla_{[\mathbf{X},\mathbf{Y}]}\mathbf{Z} - \nabla_{[\mathbf{Y},\mathbf{Z}]}\mathbf{X} - \nabla_{[\mathbf{Z},\mathbf{X}]}\mathbf{Y} \\ &= \nabla_{\mathbf{X}}[\mathbf{Y}, \mathbf{Z}] + \nabla_{\mathbf{Y}}[\mathbf{Z}, \mathbf{X}] + \nabla_{\mathbf{Z}}[\mathbf{X}, \mathbf{Y}] \\ &\quad - \nabla_{[\mathbf{X},\mathbf{Y}]}\mathbf{Z} - \nabla_{[\mathbf{Y},\mathbf{Z}]}\mathbf{X} - \nabla_{[\mathbf{Z},\mathbf{X}]}\mathbf{Y} = 0. \end{aligned}$$

In the last equality, terms are grouped, for example, as $\nabla_{\mathbf{X}}[\mathbf{Y}, \mathbf{Z}] - \nabla_{[\mathbf{Y},\mathbf{Z}]}\mathbf{X} = [\mathbf{X}, [\mathbf{Y}, \mathbf{Z}]]$, and the three resulting expressions sum to zero by the Jacobi identity. Pairing with $\mathbf{W}$ gives (4).
It remains to prove (3). Fix four vector fields and abbreviate their names by a, b, c, d. Using only the antisymmetries already proved, the Bianchi identities corresponding to the relevant permutations can be written as

$$\begin{aligned} R_{bcad} &= R_{acbd} - R_{abcd}, \\ R_{bdac} &= R_{abcd} + R_{adbc}, \\ R_{cdab} &= R_{acbd} - R_{adbc}, \\ R_{bcad} &= R_{bdac} - R_{cdab}, \end{aligned}$$

where $R_{abcd} := R(a,b,c,d)$. Substituting the first three equalities into the fourth gives

$$R_{abcd} = R_{acbd} - R_{adbc} = R_{cdab}.$$

This is the pair-interchange symmetry in (3). □

We may express the symmetries of the curvature tensor in coordinates as follows:

Corollary 2.10.7. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary. In any local coordinates, the components of $\mathbf{Rm}$ satisfy:

(a) $R_{ijkl} = -R_{jikl}$.

(b) $R_{ijkl} = -R_{ijlk}$.

(c) $R_{ijkl} = R_{klij}$.

(d) $R_{ijkl} + R_{jkil} + R_{kijl} = 0$.

Proof. Apply the four parts of the preceding proposition to the coordinate vector fields $\partial_i, \partial_j, \partial_k, \partial_l$. □

Definition 2.10.8. (Ricci tensor and Ricci endomorphism) Let $(M,\mathbf{g})$ be a Riemannian manifold of dimension n with or without boundary. For $X, Y \in T_pM$, define

$$\mathbf{Ric}_p(X,Y) := \sum_{i=1}^{n} \mathbf{g}_p\big(\mathbf{R}(\mathbf{e}_i, X)Y, \mathbf{e}_i\big), \tag{2.72}$$

where $(\mathbf{e}_1,\dots,\mathbf{e}_n)$ is an orthonormal basis of T_pM. This expression is independent of the chosen orthonormal basis and defines a symmetric tensor field of type $(0,2)$, called the *Ricci tensor*.
The *Ricci endomorphism* is the field $\mathbf{Ric}^\sharp \in \Gamma(\mathrm{End}(TM))$ determined by

$$\mathbf{g}(\mathbf{Ric}^\sharp X, Y) = \mathbf{Ric}(X,Y). \tag{2.73}$$

Proposition 2.10.9. (Curvature contraction and the Ricci endomorphism) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary of dimension n. For every $p \in M$, every orthonormal basis $(\mathbf{e}_1,\dots,\mathbf{e}_n)$ of T_pM, and every $X \in T_pM$,

$$-\sum_{i=1}^{n} \mathbf{R}(\mathbf{e}_i, X)\mathbf{e}_i = \mathbf{Ric}^\sharp X. \tag{2.74}$$

In particular, $\mathbf{Ric}^\sharp$ is self-adjoint with respect to $\mathbf{g}$.

Proof. Independence of the basis in (2.72) follows from basis independence of the trace of an endomorphism. Let us verify symmetry. If $X, Y \in T_pM$, the pair symmetries and antisymmetries of the curvature

tensor give

$$\begin{aligned}\mathbf{Ric}(Y,X) &= \sum_{i=1}^{n} \mathbf{Rm}(\mathbf{e}_i, Y, X, \mathbf{e}_i)\\ &= \sum_{i=1}^{n} \mathbf{Rm}(X, \mathbf{e}_i, \mathbf{e}_i, Y)\\ &= -\sum_{i=1}^{n} \mathbf{Rm}(\mathbf{e}_i, X, \mathbf{e}_i, Y)\\ &= \sum_{i=1}^{n} \mathbf{Rm}(\mathbf{e}_i, X, Y, \mathbf{e}_i) = \mathbf{Ric}(X,Y).\end{aligned}$$

To prove (2.74), take $Y \in T_pM$ and use the antisymmetry of $\mathbf{Rm}$ in its last two arguments:

$$\begin{aligned}\mathbf{g}\left(-\sum_{i=1}^{n} \mathbf{R}(\mathbf{e}_i, X)\mathbf{e}_i, Y\right) &= -\sum_{i=1}^{n} \mathbf{Rm}(\mathbf{e}_i, X, \mathbf{e}_i, Y)\\ &= \sum_{i=1}^{n} \mathbf{Rm}(\mathbf{e}_i, X, Y, \mathbf{e}_i) = \mathbf{Ric}(X,Y).\end{aligned}$$

Nondegeneracy of $\mathbf{g}$ gives the identity. Finally, symmetry of $\mathbf{Ric}$ implies

$$\mathbf{g}(\mathbf{Ric}^\sharp X, Y) = \mathbf{Ric}(X,Y) = \mathbf{Ric}(Y,X) = \mathbf{g}(X, \mathbf{Ric}^\sharp Y),$$

so $\mathbf{Ric}^\sharp$ is self-adjoint. □

Definition 2.10.10. (Scalar curvature) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. The *scalar curvature* is the smooth function

$$R_{\mathbf{g}} := \operatorname{tr}_{\mathbf{g}}(\mathbf{Ric}_{\mathbf{g}}).$$

If $(\mathbf{e}_1, \dots, \mathbf{e}_n)$ is a local orthonormal frame, then

$$R_{\mathbf{g}} = \sum_{i=1}^{n} \mathbf{Ric}_{\mathbf{g}}(\mathbf{e}_i, \mathbf{e}_i),$$

and in coordinates, $R_{\mathbf{g}} = g^{ij}\,\mathrm{Ric}_{ij}$. In the analytic chapters, we retain the notation $R_{\mathbf{g}}$ to distinguish the scalar from the curvature tensor or endomorphism.

Definition 2.10.11. (Sectional curvature) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary and let $p \in M$. Given a two-dimensional plane $\Pi \subseteq T_pM$ spanned by two linearly independent vectors $u, v \in T_pM$, the *sectional curvature* of Π is defined by

$$K(\Pi) = \frac{\mathbf{g}(\mathbf{R}(u,v)v, u)}{\mathbf{g}(u,u)\mathbf{g}(v,v) - \mathbf{g}(u,v)^2},$$

where $\mathbf{R}$ is the Riemann curvature tensor. This value depends only on the plane Π and is independent of the basis $\{u, v\}$ chosen to span it.

Theorem 2.10.12. (Curvature tensor for spaces of constant curvature) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. If $(M, \mathbf{g})$ has constant sectional curvature K, then, for every $p \in M$ and all $u, v, w \in T_pM$, we have

$$\mathbf{R}(u,v)w = K\big(\mathbf{g}(v,w)u - \mathbf{g}(u,w)v\big).$$

Proof. By hypothesis, the sectional curvature is a constant K. From the definition of sectional curvature, we rewrite the equation to obtain

$$\mathbf{g}(\mathbf{R}(u,v)v,u) = K\big(\mathbf{g}(u,u)\mathbf{g}(v,v) - \mathbf{g}(u,v)^2\big).$$

This equality holds for every pair of linearly independent vectors u, v and extends trivially to the case in which they are linearly dependent (since both sides vanish).
Given arbitrary u, v, w, we compute the expression $\mathbf{g}(\mathbf{R}(u+w,v)v,u+w)$ in two different ways.
First, applying the preceding formula directly to the pair $(u+w, v)$, we obtain:

$$\begin{aligned}\mathbf{g}(\mathbf{R}(u+w,v)v,u+w) &= K\big(\mathbf{g}(v,v)\mathbf{g}(u+w,u+w) - \mathbf{g}(u+w,v)^2\big)\\ &= K\big(\mathbf{g}(v,v)[\mathbf{g}(u,u)+\mathbf{g}(w,w)+2\mathbf{g}(u,w)]\\ &\qquad - [\mathbf{g}(u,v)^2+\mathbf{g}(w,v)^2+2\mathbf{g}(u,v)\mathbf{g}(w,v)]\big).\end{aligned}$$

Second, using multilinearity of the Riemann tensor on the left-hand side:

$$\begin{aligned}\mathbf{g}(\mathbf{R}(u+w,v)v,u+w) &= \mathbf{g}(\mathbf{R}(u,v)v+\mathbf{R}(w,v)v,u+w)\\ &= \mathbf{g}(\mathbf{R}(u,v)v,u)+\mathbf{g}(\mathbf{R}(w,v)v,w)+\mathbf{g}(\mathbf{R}(u,v)v,w)+\mathbf{g}(\mathbf{R}(w,v)v,u).\end{aligned}$$

By Proposition 2.10.6 (parts 1, 2, and 3), we know that $\mathbf{Rm}(u,v,v,w) = \mathbf{Rm}(w,v,v,u)$, which is equivalent to $\mathbf{g}(\mathbf{R}(u,v)v,w) = \mathbf{g}(\mathbf{R}(w,v)v,u)$. Moreover, applying our basic formula to the first two terms simplifies the expression to

$$K\big(\mathbf{g}(u,u)\mathbf{g}(v,v) - \mathbf{g}(u,v)^2\big) + K\big(\mathbf{g}(w,w)\mathbf{g}(v,v) - \mathbf{g}(w,v)^2\big) + 2\mathbf{g}(\mathbf{R}(u,v)v,w).$$

Equating the two expansions of $\mathbf{g}(\mathbf{R}(u+w,v)v,u+w)$ and canceling the common terms gives

$$2\mathbf{g}(\mathbf{R}(u,v)v,w) = 2K\big(\mathbf{g}(v,v)\mathbf{g}(u,w) - \mathbf{g}(u,v)\mathbf{g}(w,v)\big).$$

After division by 2, this equality can be written as

$$\mathbf{g}\big(\mathbf{R}(u,v)v - K(\mathbf{g}(v,v)u - \mathbf{g}(u,v)v), w\big) = 0 \qquad \text{for every } w \in T_pM.$$

Nondegeneracy of $\mathbf{g}_p$ forces the first argument to be zero. Therefore,

$$\mathbf{R}(u,v)v = K\big(\mathbf{g}(v,v)u - \mathbf{g}(u,v)v\big). \tag{2.75}$$

We now polarize in the second and third arguments. Take arbitrary u, v, w and compute $\mathbf{R}(u, v+w)(v+w)$

in two ways. First, using (2.75):

$$\begin{aligned}\mathbf{R}(u,v+w)(v+w) &= K\big(\mathbf{g}(v+w,v+w)u-\mathbf{g}(u,v+w)(v+w)\big)\\ &= K\big([\mathbf{g}(v,v)+\mathbf{g}(w,w)+2\mathbf{g}(v,w)]u\\ &\qquad -\mathbf{g}(u,v)v-\mathbf{g}(u,w)v-\mathbf{g}(u,v)w-\mathbf{g}(u,w)w\big).\end{aligned}$$

Second, by multilinearity of $\mathbf{R}$:

$$\mathbf{R}(u,v+w)(v+w)=\mathbf{R}(u,v)v+\mathbf{R}(u,w)w+\mathbf{R}(u,v)w+\mathbf{R}(u,w)v.$$

Applying (2.75) to the first two terms of this sum:

$$K\big(\mathbf{g}(v,v)u-\mathbf{g}(u,v)v\big)+K\big(\mathbf{g}(w,w)u-\mathbf{g}(u,w)w\big)+\mathbf{R}(u,v)w+\mathbf{R}(u,w)v.$$

Equating these two new expansions and canceling corresponding terms, we arrive at:

$$\mathbf{R}(u,v)w+\mathbf{R}(u,w)v=K\big(2\mathbf{g}(v,w)u-\mathbf{g}(u,w)v-\mathbf{g}(u,v)w\big). \tag{2.76}$$

The final step uses the Bianchi identity, which states that $\mathbf{R}(v,u)w+\mathbf{R}(u,w)v+\mathbf{R}(w,v)u=0$. Interchanging the roles of u and v in equation (2.76), we obtain:

$$\mathbf{R}(v,u)w+\mathbf{R}(v,w)u=K\big(2\mathbf{g}(u,w)v-\mathbf{g}(v,w)u-\mathbf{g}(u,v)w\big).$$

By the Bianchi identity and antisymmetry in the first two arguments, $\mathbf{R}(v,w)u=-\mathbf{R}(w,v)u=\mathbf{R}(v,u)w+\mathbf{R}(u,w)v$. Substituting gives

$$\mathbf{R}(v,u)w+\big(\mathbf{R}(v,u)w+\mathbf{R}(u,w)v\big)=2\mathbf{R}(v,u)w+\mathbf{R}(u,w)v.$$

Using $\mathbf{R}(v,u)w=-\mathbf{R}(u,v)w$, this is equivalent to $-2\mathbf{R}(u,v)w+\mathbf{R}(u,w)v$. Therefore,

$$-2\mathbf{R}(u,v)w+\mathbf{R}(u,w)v=K\big(2\mathbf{g}(u,w)v-\mathbf{g}(v,w)u-\mathbf{g}(u,v)w\big). \tag{2.77}$$

Finally, subtract equation (2.77) from equation (2.76):

$$\begin{aligned}&\big(\mathbf{R}(u,v)w+\mathbf{R}(u,w)v\big)-\big(-2\mathbf{R}(u,v)w+\mathbf{R}(u,w)v\big)=\\ &K\big(2\mathbf{g}(v,w)u-\mathbf{g}(u,w)v-\mathbf{g}(u,v)w\big)-K\big(2\mathbf{g}(u,w)v-\mathbf{g}(v,w)u-\mathbf{g}(u,v)w\big).\end{aligned}$$

Simplifying both sides, the terms involving $\mathbf{R}(u,w)v$ and $\mathbf{g}(u,v)w$ cancel, leaving

$$3\mathbf{R}(u,v)w=K\big(3\mathbf{g}(v,w)u-3\mathbf{g}(u,w)v\big).$$

Dividing by 3 gives the desired formula:

$$\mathbf{R}(u,v)w=K\big(\mathbf{g}(v,w)u-\mathbf{g}(u,w)v\big).$$

□

2.11 Riemannian submanifolds

Trace conditions and many variational problems are formulated on a submanifold. To compare intrinsic derivatives with derivatives in M, we must separate the tangential and normal components of the Levi–Civita connection.

Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $N \subseteq M$ be an embedded submanifold without boundary. The induced metric is $\mathbf{g}_N = \mathbf{g}\restriction_{TN}$, and

$$T_xM = T_xN \oplus T_x^{\perp}N, \qquad T_x^{\perp}N = \{v \in T_xM \mid \mathbf{g}(v,w) = 0 \text{ for every } w \in T_xN\}.$$

The spaces $T_x^{\perp}N$ form the normal bundle $T^{\perp}N$. For a section $\mathbf{V}$ of $TM|_N$, we write $\mathbf{V}^{\top}$ and $\mathbf{V}^{\perp}$ for its orthogonal projections.

Lemma 2.11.1. (Ambient connection along a submanifold) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $N \subseteq M$ be an embedded submanifold without boundary. Let $\iota\colon N \hookrightarrow M$ be the inclusion. There exists a unique connection $\overline{\nabla}$ on the restricted bundle $\iota^*TM \to N$ such that, if $\mathbf{X} \in \mathfrak{X}(N)$ and $\mathbf{V} \in \Gamma(\iota^*TM)$ admit local extensions $\widetilde{\mathbf{X}}, \widetilde{\mathbf{V}} \in \mathfrak{X}(M)$, then

$$\overline{\nabla}_{\mathbf{X}}\mathbf{V} = (\nabla^M_{\widetilde{\mathbf{X}}}\widetilde{\mathbf{V}})\restriction_N .$$

This expression does not depend on the extensions. Moreover,

$$\mathbf{X}\mathbf{g}(\mathbf{V},\mathbf{W}) = \mathbf{g}(\overline{\nabla}_{\mathbf{X}}\mathbf{V},\mathbf{W}) + \mathbf{g}(\mathbf{V},\overline{\nabla}_{\mathbf{X}}\mathbf{W})$$

for $\mathbf{V},\mathbf{W} \in \Gamma(\iota^*TM)$ and, if $\mathbf{X},\mathbf{Y} \in \mathfrak{X}(N)$, then

$$\overline{\nabla}_{\mathbf{X}}\mathbf{Y} - \overline{\nabla}_{\mathbf{Y}}\mathbf{X} = [\mathbf{X},\mathbf{Y}].$$

Proof. In coordinates $(x^1,\dots,x^m)$ on M, if $\mathbf{V} = V^j\partial_j\restriction_N$ and $d\iota(\mathbf{X}) = X^i\partial_i\restriction_N$, necessarily

$$\overline{\nabla}_{\mathbf{X}}\mathbf{V} = \Big(\mathbf{X}(V^k) + X^iV^j\Gamma^k_{ij}\restriction_N\Big)\partial_k\restriction_N .$$

The right-hand side contains only the values of $\mathbf{X}$, $\mathbf{V}$, and the tangential derivatives $\mathbf{X}(V^k)$ on N; it therefore does not depend on any extension. The transformation rule for the Christoffel symbols shows that the local expressions glue together, and the connection rules are verified directly from the formula. The last two identities are the restrictions, respectively, of metric compatibility in Theorem 2.4.14 and of the torsion-free property of the Levi–Civita connection. □

Definition 2.11.2. (Second fundamental form and normal connection) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $N \subseteq M$ be an embedded submanifold without boundary. For $\mathbf{X},\mathbf{Y} \in \mathfrak{X}(N)$ and $\eta \in \Gamma(T^{\perp}N)$, define

$$\mathbf{II}(\mathbf{X},\mathbf{Y}) = (\overline{\nabla}_{\mathbf{X}}\mathbf{Y})^{\perp}, \qquad \nabla^{\perp}_{\mathbf{X}}\eta = (\overline{\nabla}_{\mathbf{X}}\eta)^{\perp}.$$

For $\eta \in \Gamma(T^{\perp}N)$, the *Weingarten map* or *shape operator* $\mathbf{A}_\eta\colon TN \longrightarrow TN$ is the unique endomorphism satis-

fying

$$\mathbf{g}_N(\mathbf{A}_\eta \mathbf{X}, \mathbf{Y}) = \mathbf{g}(\mathbf{II}(\mathbf{X}, \mathbf{Y}), \eta)$$

for all $\mathbf{X}, \mathbf{Y} \in \mathfrak{X}(N)$.

Proposition 2.11.3. (Gauss and Weingarten formulas) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and let $N \subseteq M$ be an embedded submanifold without boundary. The second fundamental form $\mathbf{II}$ is a symmetric tensor, and $\nabla^\perp$ is a metric connection on the normal bundle. We have

$$\overline{\nabla}_{\mathbf{X}} \mathbf{Y} = \nabla^N_{\mathbf{X}} \mathbf{Y} + \mathbf{II}(\mathbf{X}, \mathbf{Y}), \tag{2.78}$$

$$\overline{\nabla}_{\mathbf{X}} \eta = -\mathbf{A}_\eta \mathbf{X} + \nabla^\perp_{\mathbf{X}} \eta. \tag{2.79}$$

The Weingarten map depends $C^\infty(N)$–linearly on η and is self-adjoint with respect to $\mathbf{g}_N$.

Proof. Lemma 2.11.1 eliminates all dependence on extensions. Linearity of a connection in its first argument gives $\mathbf{II}(f\mathbf{X}, \mathbf{Y}) = f\,\mathbf{II}(\mathbf{X}, \mathbf{Y})$. In the second argument,

$$\overline{\nabla}_{\mathbf{X}}(f\mathbf{Y}) = \mathbf{X}(f)\mathbf{Y} + f\overline{\nabla}_{\mathbf{X}}\mathbf{Y};$$

the first summand is tangent, so $\mathbf{II}(\mathbf{X}, f\mathbf{Y}) = f\,\mathbf{II}(\mathbf{X}, \mathbf{Y})$. Thus, $\mathbf{II}$ is tensorial. Since $\overline{\nabla}$ is torsion-free on tangent vector fields,

$$\mathbf{II}(\mathbf{X}, \mathbf{Y}) - \mathbf{II}(\mathbf{Y}, \mathbf{X}) = [\mathbf{X}, \mathbf{Y}]^\perp = 0.$$

Define $\mathbf{D}_{\mathbf{X}}\mathbf{Y} := (\overline{\nabla}_{\mathbf{X}}\mathbf{Y})^\top$. Metric compatibility of $\overline{\nabla}$ and orthogonality of the decomposition show that $\mathbf{D}$ is metric; the preceding torsion identity shows that it is torsion-free. By uniqueness of the Levi–Civita connection, $\mathbf{D} = \nabla^N$, and the tangential–normal decomposition gives the Gauss formula (2.78).
Differentiating the identity $\mathbf{g}(\eta, \mathbf{Y}) = 0$ gives

$$\mathbf{g}((\overline{\nabla}_{\mathbf{X}}\eta)^\top, \mathbf{Y}) = -\mathbf{g}(\eta, \mathbf{II}(\mathbf{X}, \mathbf{Y})) = -\mathbf{g}_N(\mathbf{A}_\eta \mathbf{X}, \mathbf{Y}).$$

Nondegeneracy of $\mathbf{g}_N$ gives $(\overline{\nabla}_{\mathbf{X}}\eta)^\top = -\mathbf{A}_\eta \mathbf{X}$, proving (2.79). The connection rules and metric compatibility of $\nabla^\perp$ follow by projecting those of $\overline{\nabla}$. Finally, symmetry of $\mathbf{II}$ implies

$$\mathbf{g}_N(\mathbf{A}_\eta \mathbf{X}, \mathbf{Y}) = \mathbf{g}_N(\mathbf{X}, \mathbf{A}_\eta \mathbf{Y}),$$

and linearity in η follows from the identity defining $\mathbf{A}_\eta$. □

Corollary 2.11.4. (Weingarten map of a Euclidean hypersurface) Let $N \subseteq \mathbb{R}^{n+1}$ be a smooth oriented hypersurface without boundary, of dimension n, and let $\boldsymbol{\nu} \colon N \longrightarrow \mathbb{S}^n$ be its unit normal field. Then

$$\mathbf{A}_{\boldsymbol{\nu}} \mathbf{X} = -d\boldsymbol{\nu}(\mathbf{X}), \qquad \mathbf{X} \in \mathfrak{X}(N).$$

In particular, $d\boldsymbol{\nu}$ is self-adjoint with the opposite sign; the eigenvalues of $\mathbf{A}_{\boldsymbol{\nu}}$ are the principal curvatures, and $H := \frac{1}{n}\operatorname{tr}(\mathbf{A}_{\boldsymbol{\nu}})$ is the scalar mean curvature with this convention.

Proof. Identify $T_{\boldsymbol{\nu}(x)}\mathbb{S}^n$ with the subspace $\boldsymbol{\nu}(x)^\perp \subseteq \mathbb{R}^{n+1}$. Since $\|\boldsymbol{\nu}\| = 1$, we have $\mathbf{g}(d\boldsymbol{\nu}(\mathbf{X}), \boldsymbol{\nu}) = \frac{1}{2}\mathbf{X}\mathbf{g}(\boldsymbol{\nu}, \boldsymbol{\nu}) = 0$, so $d\boldsymbol{\nu}(\mathbf{X})$ is tangent. The Euclidean connection along N satisfies $\overline{\nabla}_{\mathbf{X}}\boldsymbol{\nu} = d\boldsymbol{\nu}(\mathbf{X})$. The Weingarten formula (2.79) and vanishing of the normal component give $d\boldsymbol{\nu}(\mathbf{X}) = -\mathbf{A}_{\boldsymbol{\nu}}\mathbf{X}$. The remaining assertions are the corresponding spectral definitions; reality of the eigenvalues follows from self-adjointness proved in Proposition 2.11.3. □

Definition 2.11.5. (Covariant derivatives of the second fundamental form) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and let $N \subseteq M$ be an embedded submanifold without boundary. The connections ∇^N on TN and $\nabla^\perp$ on $T^\perp N$ induce a connection, denoted by $\nabla^{\mathbf{II}}$, on the bundle

$$T^*N \otimes T^*N \otimes T^\perp N.$$

Explicitly, if $\mathbf{B} \in \Gamma(T^*N \otimes T^*N \otimes T^\perp N)$ and $\mathbf{X}, \mathbf{Y}, \mathbf{Z} \in \mathfrak{X}(N)$, then

$$(\nabla^{\mathbf{II}}_{\mathbf{X}}\mathbf{B})(\mathbf{Y}, \mathbf{Z}) = \nabla^\perp_{\mathbf{X}}(\mathbf{B}(\mathbf{Y}, \mathbf{Z})) - \mathbf{B}(\nabla^N_{\mathbf{X}}\mathbf{Y}, \mathbf{Z}) - \mathbf{B}(\mathbf{Y}, \nabla^N_{\mathbf{X}}\mathbf{Z}).$$

Define recursively

$$(\nabla^{\mathbf{II}})^0\mathbf{II} := \mathbf{II}, \qquad (\nabla^{\mathbf{II}})^{m+1}\mathbf{II} := \nabla^{\mathbf{II}}\big((\nabla^{\mathbf{II}})^m\mathbf{II}\big), \qquad m \in \mathbb{N}_0,$$

where the right-hand side uses the induced connection on each additional covariant factor. In particular,

$$(\nabla^{\mathbf{II}})^m\mathbf{II} \in \Gamma\big((T^*N)^{\otimes(m+2)} \otimes T^\perp N\big).$$

The dual metric of $\mathbf{g}_N$ on the factors T^*N and the restriction of $\mathbf{g}$ to the normal bundle induce the pointwise norm $|(\nabla^{\mathbf{II}})^m\mathbf{II}|_{\mathbf{g}}$. We say that this derivative is uniformly bounded if

$$\sup_{x \in N} \big|(\nabla^{\mathbf{II}})^m\mathbf{II}(x)\big|_{\mathbf{g}} < \infty.$$

Definition 2.11.6. (Normal curvature) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and let $N \subseteq M$ be an embedded submanifold without boundary. The curvature of the normal connection is the field $\mathbf{R}^\perp$ defined by

$$\mathbf{R}^\perp(\mathbf{X}, \mathbf{Y})\boldsymbol{\eta} := \nabla^\perp_{\mathbf{X}}\nabla^\perp_{\mathbf{Y}}\boldsymbol{\eta} - \nabla^\perp_{\mathbf{Y}}\nabla^\perp_{\mathbf{X}}\boldsymbol{\eta} - \nabla^\perp_{[\mathbf{X},\mathbf{Y}]}\boldsymbol{\eta}.$$

Theorem 2.11.7. (Gauss, Codazzi, and Ricci equations) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and let $N \subseteq M$ be an embedded submanifold without boundary. For tangent vector fields $\mathbf{X}, \mathbf{Y}, \mathbf{Z}, \mathbf{W}$ and normal fields $\boldsymbol{\eta}, \boldsymbol{\zeta}$, we have

$$\mathbf{g}(\mathbf{R}^N(\mathbf{X}, \mathbf{Y})\mathbf{Z}, \mathbf{W}) = \mathbf{g}(\mathbf{R}^M(\mathbf{X}, \mathbf{Y})\mathbf{Z}, \mathbf{W}) + \mathbf{g}(\mathbf{II}(\mathbf{X}, \mathbf{W}), \mathbf{II}(\mathbf{Y}, \mathbf{Z})) - \mathbf{g}(\mathbf{II}(\mathbf{X}, \mathbf{Z}), \mathbf{II}(\mathbf{Y}, \mathbf{W})), \tag{2.80}$$

$$(\mathbf{R}^M(\mathbf{X}, \mathbf{Y})\mathbf{Z})^\perp = (\nabla^{\mathbf{II}}_{\mathbf{X}}\mathbf{II})(\mathbf{Y}, \mathbf{Z}) - (\nabla^{\mathbf{II}}_{\mathbf{Y}}\mathbf{II})(\mathbf{X}, \mathbf{Z}), \tag{2.81}$$

$$\mathbf{g}(\mathbf{R}^\perp(\mathbf{X}, \mathbf{Y})\boldsymbol{\eta}, \boldsymbol{\zeta}) = \mathbf{g}(\mathbf{R}^M(\mathbf{X}, \mathbf{Y})\boldsymbol{\eta}, \boldsymbol{\zeta}) + \mathbf{g}_N([\mathbf{A}_{\boldsymbol{\eta}}, \mathbf{A}_{\boldsymbol{\zeta}}]\mathbf{X}, \mathbf{Y}). \tag{2.82}$$

We use the convention $\mathbf{R}(\mathbf{X}, \mathbf{Y})\mathbf{Z} = \nabla_{\mathbf{X}}\nabla_{\mathbf{Y}}\mathbf{Z} - \nabla_{\mathbf{Y}}\nabla_{\mathbf{X}}\mathbf{Z} - \nabla_{[\mathbf{X},\mathbf{Y}]}\mathbf{Z}$ from Definition 2.10.1.

Proof. Lemma 2.11.1 allows us to compute $\mathbf{R}^M(\mathbf{X},\mathbf{Y})$ using fields along N. Substituting the Gauss and Weingarten formulas into each of the three terms in the definition of $\mathbf{R}^M$ gives

$$(\mathbf{R}^M(\mathbf{X},\mathbf{Y})\mathbf{Z})^{\top} = \mathbf{R}^N(\mathbf{X},\mathbf{Y})\mathbf{Z} - \mathbf{A}_{\mathbf{II}(\mathbf{Y},\mathbf{Z})}\mathbf{X} + \mathbf{A}_{\mathbf{II}(\mathbf{X},\mathbf{Z})}\mathbf{Y}.$$

Pairing with $\mathbf{W}$ and using $\mathbf{g}_N(\mathbf{A}_\eta\mathbf{X},\mathbf{W}) = \mathbf{g}(\mathbf{II}(\mathbf{X},\mathbf{W}),\eta)$ proves the Gauss equation. The normal component is

$$(\mathbf{R}^M(\mathbf{X},\mathbf{Y})\mathbf{Z})^{\perp} = (\nabla^{\mathbf{II}}_{\mathbf{X}}\mathbf{II})(\mathbf{Y},\mathbf{Z}) - (\nabla^{\mathbf{II}}_{\mathbf{Y}}\mathbf{II})(\mathbf{X},\mathbf{Z}),$$

because the terms containing $\nabla^N_{\mathbf{X}}\mathbf{Y} - \nabla^N_{\mathbf{Y}}\mathbf{X} - [\mathbf{X},\mathbf{Y}]$ vanish by the torsion-free property. This proves Codazzi. Expanding $\mathbf{R}^M(\mathbf{X},\mathbf{Y})\eta$ gives

$$(\mathbf{R}^M(\mathbf{X},\mathbf{Y})\eta)^{\perp} = \mathbf{R}^{\perp}(\mathbf{X},\mathbf{Y})\eta - \mathbf{II}(\mathbf{X},\mathbf{A}_\eta\mathbf{Y}) + \mathbf{II}(\mathbf{Y},\mathbf{A}_\eta\mathbf{X}),$$

and pairing with ζ proves Ricci. □

2.12 Tubular neighborhoods and Fermi coordinates

The exponential map applied to the normal bundle turns the preceding tangential–normal decomposition into coordinates adapted to N.

We may adapt the exponential map to obtain information about the normal bundle as follows, defining what is known as the *normal exponential map*.

Definition 2.12.1. Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $N \subseteq M$ be an embedded submanifold without boundary. Define the normal exponential map $\exp^{\perp}\colon \mathcal{E}_N \longrightarrow M$, with $\mathcal{E}_N := \mathcal{E} \cap T^{\perp}N$, by $\exp^{\perp} = \exp|_{\mathcal{E}_N}$.

We will be interested in "normal neighborhoods around N," which we call *tubular neighborhoods*, as in the following figure:

Figure 2.7. Tubular neighborhood around the embedded submanifold N.

Definition 2.12.2. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and let $N \subseteq M$ be an embedded submanifold without boundary. We say that $U \subseteq M$ is a *normal neighborhood* of N in M if there exists an open set $V \subseteq \mathcal{E}_N$ such that:

(a) V intersects each fiber $T_x^\perp N$ in a set star-shaped with respect to 0,

(b) the restriction

$$\exp^\perp \restriction_V : V \longrightarrow U$$

is a diffeomorphism.

We say that U is a *tubular neighborhood* if it is a normal neighborhood and, in addition, V can be chosen in the form

$$V := \{(x, v) \in T^\perp N \mid |v|_{\mathbf{g}} < \delta(x)\},$$

for some continuous function $\delta : N \longrightarrow (0, \infty)$.
If V can be chosen with $\delta(x) \equiv \varepsilon$, we say that U is a *uniform tubular neighborhood* of radius ε, or an ε-tubular neighborhood.

Every embedded submanifold admits a tubular neighborhood, and if the submanifold is compact, this tubular

neighborhood can be chosen to be uniform:

Theorem 2.12.3. (Existence of tubular neighborhoods) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and let $N \subseteq M$ be an embedded submanifold without boundary. Then N has a tubular neighborhood in M. If N is compact, it has a uniform tubular neighborhood.

Proof. Let $N_0 := \{(x,0) \mid x \in N\} \subseteq T^\perp N$. At a point of the zero section, there is a canonical decomposition

$$T_{(x,0)}(T^\perp N) = T_{(x,0)}N_0 \oplus T_{(x,0)}(T^\perp_x N) \cong T_x N \oplus T^\perp_x N. \tag{2.83}$$

The restriction of $\exp^\perp$ to N_0 is the inclusion $N \hookrightarrow M$; its differential maps the first summand onto $T_x N$. On the fiber $T^\perp_x N$, the normal exponential map equals $\exp_x$, and $d(\exp_x)_0 = I$ by Proposition 2.8.7. Therefore, $d(\exp^\perp)_{(x,0)}$ is the isomorphism

$$T_x N \oplus T^\perp_x N \longrightarrow T_x M, \qquad (X, V) \longmapsto X + V.$$

The inverse function theorem, Theorem 1.5.6, shows that $\exp^\perp$ is a local diffeomorphism near each point of N_0.

To obtain a single neighborhood of the entire zero section, we must prevent normal geodesics with different initial points from intersecting. Denote the ambient distance restricted to $N \times N$ by $d_{\mathbf{g}}$ and set

$$V_\delta(x) := \{(y, v) \in T^\perp N \mid d_{\mathbf{g}}(x, y) < \delta,\ |v|_{\mathbf{g}} < \delta\}, \qquad 0 < \delta \leq 1.$$

For each x, the preceding local result allows us to choose $\delta > 0$ so that $\exp^\perp$ is a diffeomorphism from $V_\delta(x)$ onto its image. Define

$$\rho(x) := \sup\{0 < \delta \leq 1 \mid \exp^\perp \restriction_{V_\delta(x)} \text{ is a diffeomorphism onto its image}\}. \tag{2.84}$$

Then $\rho(x) > 0$. The property defining the supremum is monotone with respect to δ. Hence, given two points of $V_{\rho(x)}(x)$, there exist $\delta < \rho(x)$ containing both and an δ', with $\delta < \delta' < \rho(x)$, for which the restriction is a diffeomorphism. Thus, $\exp^\perp$ is injective and a local diffeomorphism on $V_{\rho(x)}(x)$, and therefore is a diffeomorphism from this set onto its image.

The function ρ is continuous. If $d_{\mathbf{g}}(x, x') < \rho(x)$, the triangle inequality gives

$$V_{\rho(x) - d_{\mathbf{g}}(x,x')}(x') \subseteq V_{\rho(x)}(x),$$

and hence $\rho(x') \geq \rho(x) - d_{\mathbf{g}}(x, x')$. If $d_{\mathbf{g}}(x, x') \geq \rho(x)$, this same inequality is trivial. Interchanging x and x' gives

$$|\rho(x) - \rho(x')| \leq d_{\mathbf{g}}(x, x'). \tag{2.85}$$

The ambient distance induces the topology of the embedded submanifold, so ρ is continuous.

Consider the open set

$$V := \{(x, v) \in T^\perp N \mid |v|_{\mathbf{g}} < \tfrac{1}{2}\rho(x)\}. \tag{2.86}$$

Let us prove that $\exp^\perp$ is injective on V. Suppose that $\exp_x(v) = \exp_{x'}(v')$ and, without loss of generality, $\rho(x') \leq \rho(x)$. The two radial geodesics, the second traversed in reverse, form an admissible curve from x to

x' of length $|v|_{\mathbf{g}} + |v'|_{\mathbf{g}}$. Consequently,

$$d_{\mathbf{g}}(x,x') \leq |v|_{\mathbf{g}} + |v'|_{\mathbf{g}} < \tfrac{1}{2}\rho(x) + \tfrac{1}{2}\rho(x') \leq \rho(x).$$

Both (x,v) and (x',v') then belong to $V_{\rho(x)}(x)$, where $\exp^\perp$ is injective; the two points are equal.
Every point of V belongs to an open set on which $\exp^\perp$ is a local diffeomorphism. Consequently, $\exp^\perp \restriction_V$ is an injective local diffeomorphism, hence a diffeomorphism onto the open set $U := \exp^\perp(V)$. The formulas (2.86) and continuity of $\frac{\rho}{2}$ show that U is a tubular neighborhood. If N is compact, $\frac{\rho}{2}$ attains a positive minimum ε, and restriction to $\{|v|_{\mathbf{g}} < \varepsilon\}$ gives the uniform tubular neighborhood. □

2.12.1 Fermi coordinates

The tubular neighborhood identifies a neighborhood of N with a neighborhood of the zero section of its normal bundle. Local trivializations of this bundle give coordinates adapted simultaneously to the tangential and normal directions.

Definition 2.12.4. (Fermi coordinates) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary of dimension n, let $N \subseteq M$ be an embedded submanifold without boundary of dimension k, and let $U = \exp^\perp(V)$ be a normal neighborhood of N. Let $\theta = (y^1,\dots,y^k)\colon W \longrightarrow \theta(W) \subseteq \mathbb{R}^k$ be a chart of N and let $(\mathbf{E}_1,\dots,\mathbf{E}_c)$, $c = n-k$, be a local orthonormal frame of $T^\perp N$ over W. On any open product $W' \times Z \subseteq \theta(W) \times \mathbb{R}^c$ on which the following expression takes values in V, define

$$\Phi(u,z) := \exp^\perp_{\theta^{-1}(u)} \left(\sum_{\alpha=1}^{c} z^\alpha \mathbf{E}_\alpha \big|_{\theta^{-1}(u)} \right). \tag{2.87}$$

The inverse chart of Φ is called a *Fermi chart*; its coordinates are denoted by $(y^1,\dots,y^k,z^1,\dots,z^c)$.

The parametrization (2.87) is a diffeomorphism onto its image: it is the composition of the local trivialization of the normal bundle with $\exp^\perp \restriction_V$. Thus the definition presupposes no additional property of the coordinates.

Proposition 2.12.5. (Local properties of Fermi coordinates) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary of dimension n, let $N \subseteq M$ be an embedded submanifold without boundary of dimension k, and let $(y^1,\dots,y^k,z^1,\dots,z^c)$ be a Fermi chart associated with the local normal frame $(\mathbf{E}_1,\dots,\mathbf{E}_c)$. With indices $1 \leq a,b \leq k$ and $1 \leq \alpha,\beta,\gamma \leq c$, the following hold:

(a) N is described by $z^1 = \cdots = z^c = 0$.

(b) On N,

$$g_{a,k+\alpha} = 0, \qquad g_{k+\alpha,k+\beta} = \delta_{\alpha\beta}. \tag{2.88}$$

(c) For $q \in W$ and $v = z^\alpha \mathbf{E}_\alpha|_q$, the geodesic with initial data (q,v) has the expression

$$t \longmapsto (y^1(q),\dots,y^k(q),tz^1,\dots,tz^c). \tag{2.89}$$

(d) On N,

$$\Gamma^i_{k+\alpha,k+\beta} = 0 \quad (1 \leq i \leq n,\ 1 \leq \alpha,\beta \leq c). \tag{2.90}$$

(e) On N,

$$\partial_{z^\alpha} g_{k+\beta,k+\gamma} = 0. \tag{2.91}$$

The local identities agree with Proposition 5.26 in [95].

Proof. Part (a) follows from $\exp_q(0) = q$ and injectivity of the normal exponential map on the chosen neighborhood. At $(q,0)$, the differential of Φ sends ∂_{y^a} to a vector in T_qN and ∂_{z^α} to $\mathbf{E}_\alpha|_q \in T_q^\perp N$. Orthogonality and orthonormality of the frame prove (2.88).
The rescaling lemma for geodesics, Lemma 2.8.5, gives $\exp_q(tv) = \gamma_v(t)$ and proves (2.89). Substituting this curve into the geodesic equation and evaluating at $t = 0$ gives, for each i,

$$\Gamma^i_{k+\alpha,k+\beta}(q,0) z^\alpha z^\beta = 0 \quad \text{for every } z \in \mathbb{R}^c.$$

The Levi–Civita connection is torsion-free, so the two lower indices of Γ are symmetric. Polarizing the preceding quadratic form proves (2.90). Finally, metric compatibility in coordinates, Corollary 2.4.16, gives

$$\partial_{z^\alpha} g_{k+\beta,k+\gamma} = \Gamma^m_{k+\alpha,k+\beta} g_{m,k+\gamma} + \Gamma^m_{k+\alpha,k+\gamma} g_{k+\beta,m},$$

and both terms vanish by (2.90). This proves (2.91). □

Proposition 2.12.6. (Boundary normal coordinates) Let $(M,\mathbf{g})$ be a smooth Riemannian manifold of dimension n with nonempty boundary and let $p \in \partial M$. There exist a chart $\theta = (y^1,\dots,y^{n-1})\colon W \longrightarrow \theta(W)$ of ∂M around p, an $\varepsilon > 0$, and a chart of M

$$\Phi(u,t) = \exp_{\theta^{-1}(u)}\big(t\boldsymbol{\nu}_{\theta^{-1}(u)}\big), \qquad 0 \le t < \varepsilon, \tag{2.92}$$

where $\boldsymbol{\nu}$ is the inward unit normal. Throughout the chart,

$$\mathbf{g} = dt^2 + \mathbf{g}_t, \qquad g_{tt} = 1, \qquad g_{at} = 0. \tag{2.93}$$

If $\mathbf{II}^{\boldsymbol{\nu}}(\mathbf{X},\mathbf{Y}) := \mathbf{g}(\mathbf{II}(\mathbf{X},\mathbf{Y}),\boldsymbol{\nu})$ and we use the convention $\nabla_{\mathbf{X}}\boldsymbol{\nu} = -\mathbf{A}_{\boldsymbol{\nu}}\mathbf{X}$, then

$$\partial_t g_{ab}|_{t=0} = -2\mathbf{II}^{\boldsymbol{\nu}}_{ab}. \tag{2.94}$$

These semigeodesic coordinates are also described in [95, Example 6.44].

Proof. By Corollary 1.6.13, a smooth manifold with boundary is included as one half of its double, and the metric $\mathbf{g}$ extends to a Riemannian metric on a neighborhood of this half. There, apply Theorem 2.12.3 to the hypersurface ∂M and choose the sign of the normal coordinate to point inward. This gives (2.92).
Let $\mathbf{T} = \partial_t$ and let $\mathbf{J}_a = \partial_{y^a}$ be the variational field obtained by varying the initial point of the normal geodesics. Each curve $t \mapsto \Phi(y,t)$ is a unit-speed geodesic, so $\mathbf{g}(\mathbf{T},\mathbf{T}) = 1$. The coordinate vector fields commute and the connection is torsion-free; therefore,

$$\frac{d}{dt}\mathbf{g}(\mathbf{J}_a,\mathbf{T}) = \mathbf{g}(\nabla_{\mathbf{T}}\mathbf{J}_a,\mathbf{T}) + \mathbf{g}(\mathbf{J}_a,\nabla_{\mathbf{T}}\mathbf{T}) = \mathbf{g}(\nabla_{\mathbf{J}_a}\mathbf{T},\mathbf{T}) = \frac{1}{2}\mathbf{J}_a\mathbf{g}(\mathbf{T},\mathbf{T}) = 0.$$

At $t = 0$, $\mathbf{J}_a$ is tangent to ∂M and $\mathbf{T} = \boldsymbol{\nu}$, so $\mathbf{g}(\mathbf{J}_a,\mathbf{T}) = 0$. This proves (2.93) throughout the collar.

Using $[\mathbf{T}, \mathbf{J}_a] = 0$ and metric compatibility again,

$$\partial_t g_{ab} = \mathbf{g}(\nabla_{\mathbf{T}} \mathbf{J}_a, \mathbf{J}_b) + \mathbf{g}(\mathbf{J}_a, \nabla_{\mathbf{T}} \mathbf{J}_b) = 2\mathbf{g}(\nabla_{\mathbf{J}_a} \mathbf{T}, \mathbf{J}_b).$$

At $t = 0$, the Weingarten identity $\nabla_{\mathbf{J}_a} \boldsymbol{\nu} = -\mathbf{A}_{\boldsymbol{\nu}} \mathbf{J}_a$ gives (2.94). □

2.13 Jacobi fields and comparison theory

Jacobi fields describe the differential of the exponential map and therefore the infinitesimal separation of nearby geodesics.

Definition 2.13.1. (Variation and variational field) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary. A **smooth variation** of a curve $\gamma \colon I \to M$ is a smooth map

$$\alpha \colon (-\varepsilon, \varepsilon) \times I \longrightarrow M, \qquad \alpha(0, t) = \gamma(t).$$

We write

$$\mathbf{S} := d\alpha(\partial_s), \qquad \mathbf{T} := d\alpha(\partial_t),$$

and call $\mathbf{J}(t) := \mathbf{S}(0, t)$ the variational field along γ. The variation is **through geodesics** if $t \mapsto \alpha(s, t)$ is a geodesic for each s.

Proposition 2.13.2. (Commutation in a variation) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, let α be a smooth variation, and let $\mathbf{Z}$ be a vector field along α. Then

$$D_s \mathbf{T} = D_t \mathbf{S}, \qquad (D_s D_t - D_t D_s)\mathbf{Z} = \mathbf{R}(\mathbf{S}, \mathbf{T})\mathbf{Z}.$$

Proof. The coordinate vector fields ∂_s and ∂_t commute. The first identity is the torsion formula applied to $\mathbf{S}$ and $\mathbf{T}$, since the Levi–Civita connection is torsion-free. The second is directly the definition of $\mathbf{R}$ applied to the coordinate vector fields of the parametrized surface; the term corresponding to $[\partial_s, \partial_t]$ is zero. □

Theorem 2.13.3. (Jacobi equation) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary. The variational field $\mathbf{J}$ of a variation through geodesics satisfies

$$\frac{D^2 \mathbf{J}}{dt^2} + \mathbf{R}(\mathbf{J}, \dot\gamma)\dot\gamma = 0. \tag{2.95}$$

A smooth field along a geodesic satisfying (2.95) is called a **Jacobi field**.

Proof. For each s, $D_t \mathbf{T} = 0$. Differentiating with respect to s and using the preceding proposition,

$$0 = D_s D_t \mathbf{T} = D_t D_s \mathbf{T} + \mathbf{R}(\mathbf{S}, \mathbf{T})\mathbf{T} = D_t^2 \mathbf{S} + \mathbf{R}(\mathbf{S}, \mathbf{T})\mathbf{T}.$$

Restriction to $s = 0$ gives the stated equation. The sign agrees with the convention $\mathbf{R}(\mathbf{X}, \mathbf{Y})\mathbf{Z} = \nabla_{\mathbf{X}}\nabla_{\mathbf{Y}}\mathbf{Z} - \nabla_{\mathbf{Y}}\nabla_{\mathbf{X}}\mathbf{Z} - \nabla_{[\mathbf{X},\mathbf{Y}]}\mathbf{Z}$ fixed in Definition 2.10.1. □

Proposition 2.13.4. (Existence and uniqueness) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, let $\gamma\colon I \to M$ be a geodesic, and let $t_0 \in I$ and $a, b \in T_{\gamma(t_0)}M$. There exists a unique Jacobi field $\mathbf{J}$ along γ such that

$$\mathbf{J}(t_0) = a, \qquad \frac{D\mathbf{J}}{dt}(t_0) = b.$$

In particular, the space of Jacobi fields along γ has dimension $2\dim M$.

Proof. Choose a parallel frame along γ. In this frame, (2.95) is a homogeneous second-order linear system whose coefficients are the smooth components of the curvature. The existence and uniqueness theorem for linear systems gives a unique solution with the prescribed data on all of I. The map $\mathbf{J} \mapsto (\mathbf{J}(t_0), D_t\mathbf{J}(t_0))$ is then an isomorphism with $T_{\gamma(t_0)}M \oplus T_{\gamma(t_0)}M$. □

Proposition 2.13.5. (Representation by geodesic variations) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, let $\gamma\colon I \to M$ be a geodesic, and let $\mathbf{J}$ be a Jacobi field along γ. Locally in the parameter, $\mathbf{J}$ is the variational field of a variation through geodesics. More precisely, this representation can be realized simultaneously on any compact subinterval contained in the domain of γ.

Proof. Fix t_0 and set $a = \mathbf{J}(t_0)$ and $b = D_t\mathbf{J}(t_0)$. Choose a curve $\sigma(s)$ with $\sigma(0) = \gamma(t_0)$ and $\sigma'(0) = a$, and a field $\mathbf{V}(s) \in T_{\sigma(s)}M$ such that

$$\mathbf{V}(0) = \dot\gamma(t_0), \qquad D_s\mathbf{V}(0) = b.$$

Smooth dependence of solutions of the geodesic equation on their initial data allows us to define, for small s,

$$\alpha(s,t) = \exp_{\sigma(s)}\big((t - t_0)\mathbf{V}(s)\big).$$

Each curve with s fixed is a geodesic. Its variational field has the same initial data a, b at t_0 as $\mathbf{J}$; the preceding uniqueness result shows that it equals $\mathbf{J}$. Smooth dependence of the geodesic flow allows us to choose a single interval of values of s on any compact subinterval of I. □

Proposition 2.13.6. (Differential of the exponential map) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, let $p \in M$, let v be a vector in the domain of $\exp_p$, and let $w \in T_pM$. Along $\gamma_v(t) = \exp_p(tv)$, define

$$\mathbf{J}_w(t) := d(\exp_p)_{tv}(tw).$$

Then $\mathbf{J}_w$ is the unique Jacobi field with

$$\mathbf{J}_w(0) = 0, \qquad \frac{D\mathbf{J}_w}{dt}(0) = w,$$

and, in particular,

$$d(\exp_p)_v(w) = \mathbf{J}_w(1).$$

Proof. The family $\alpha(s,t) = \exp_p(t(v+sw))$ is a variation through geodesics and its variational field is precisely $\mathbf{J}_w(t)$. At $t = 0$, all the curves start at p, so $\mathbf{J}_w(0) = 0$; the initial derivative is w. The last equality follows by taking $t = 1$. □

Definition 2.13.7. (Conjugate points) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, let $\gamma\colon I\to M$ be a geodesic, and let $t_0,t_1\in I$ be distinct. The points $\gamma(t_0)$ and $\gamma(t_1)$ are **conjugate along** γ if there exists a nonzero Jacobi field $\mathbf{J}$ such that $\mathbf{J}(t_0)=\mathbf{J}(t_1)=0$. Their multiplicity is the dimension of the space of such fields.

Proposition 2.13.8. (Conjugacy and critical values of the exponential map) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, let $p\in M$, and let $v\neq 0$ be a vector in the domain of $\exp_p$. Then $\exp_p(v)$ is conjugate to p along $t\mapsto\exp_p(tv)$ if and only if v is a critical point of $\exp_p$. The multiplicity of the conjugate point is $\dim\ker d(\exp_p)_v$.

Proof. By the preceding proposition, the map $w\mapsto \mathbf{J}_w$ identifies $\ker d(\exp_p)_v$ with the Jacobi fields that vanish at $t=0$ and $t=1$. Since the domain and codomain of $d(\exp_p)_v$ have the same dimension, it is singular exactly when its kernel is nontrivial. □

To formulate the constant-curvature models, define

$$s_c(t):=\begin{cases}\dfrac{\sin(\sqrt{c}\,t)}{\sqrt{c}}, & c>0,\\[2mm] t, & c=0,\\[2mm] \dfrac{\sinh(\sqrt{-c}\,t)}{\sqrt{-c}}, & c<0,\end{cases}\qquad c_c(t):=s_c'(t).$$

These functions satisfy $s_c''+cs_c=0$, $s_c(0)=0$, and $s_c'(0)=1$.

Proposition 2.13.9. (Jacobi fields in constant curvature) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary of constant sectional curvature c, let γ be a unit-speed geodesic, and let $\mathbf{J}$ be a Jacobi field along γ. Let P_t be parallel transport from $\gamma(0)$ to $\gamma(t)$. If $a=\mathbf{J}(0)$ and $b=D_t\mathbf{J}(0)$, decompose $a=a^\top+a^\perp$ and $b=b^\top+b^\perp$ with respect to $\mathbb{R}\dot\gamma(0)\oplus\dot\gamma(0)^\perp$. Then

$$\mathbf{J}(t)=P_t\big(a^\top+tb^\top+c_c(t)a^\perp+s_c(t)b^\perp\big).$$

In particular, if $\mathbf{J}(0)=0$ and $D_t\mathbf{J}(0)=w\perp\dot\gamma(0)$, then $\mathbf{J}(t)=s_c(t)P_tw$.

Proof. In constant curvature, $\mathbf{R}(\mathbf{X},\dot\gamma)\dot\gamma=c\mathbf{X}$ for $\mathbf{X}\perp\dot\gamma$, while the curvature term vanishes in the direction of $\dot\gamma$. In a parallel frame, the Jacobi equation thus splits into $u''=0$ for the tangential component and $u''+cu=0$ for each normal component. The solutions with the given initial data are exactly those in the formula. □

To formulate the variational argument underlying comparison, we introduce the index form. A partition $a=t_0<t_1<\cdots<t_N=b$ is *admissible* for a field $\mathbf{V}$ along γ if $\mathbf{V}$ is continuous on $[a,b]$ and its restriction to each $[t_{r-1},t_r]$ is smooth up to the endpoints. Denote the space of these piecewise smooth fields by $\mathcal{V}_{\mathrm{ps}}(\gamma)$ and write

$$\mathcal{V}_0(\gamma):=\{\mathbf{V}\in\mathcal{V}_{\mathrm{ps}}(\gamma)\mid \mathbf{V}(a)=\mathbf{V}(b)=0\}.$$

Definition 2.13.10. (Index form) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $\gamma\colon [a,b]\longrightarrow M$ be a geodesic. For $\mathbf{V},\mathbf{W}\in\mathcal{V}_{\mathrm{ps}}(\gamma)$, define

$$I_\gamma(\mathbf{V},\mathbf{W}) := \int_a^b \left[\left\langle \frac{D\mathbf{V}}{dt},\frac{D\mathbf{W}}{dt}\right\rangle_{\mathbf{g}} - \left\langle \mathbf{R}(\mathbf{V},\dot\gamma)\dot\gamma,\mathbf{W}\right\rangle_{\mathbf{g}}\right] dt.$$

Covariant derivatives are taken on each subinterval of an admissible partition.

Proposition 2.13.11. (Properties and integration by parts for the index form) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $\gamma\colon [a,b]\to M$ be a geodesic. The form I_γ is well-defined, bilinear, and symmetric. If $a=t_0<\cdots<t_N=b$ is a common admissible partition for $\mathbf{V}$ and $\mathbf{W}$, and

$$\left[\frac{D\mathbf{V}}{dt}\right]_{t_r} := \frac{D\mathbf{V}}{dt}(t_r^+) - \frac{D\mathbf{V}}{dt}(t_r^-), \qquad 1\le r\le N-1,$$

then

$$\begin{aligned} I_\gamma(\mathbf{V},\mathbf{W}) = &\left[\left\langle \frac{D\mathbf{V}}{dt},\mathbf{W}\right\rangle_{\mathbf{g}}\right]_a^b - \sum_{r=1}^{N-1}\left\langle \left[\frac{D\mathbf{V}}{dt}\right]_{t_r},\mathbf{W}(t_r)\right\rangle_{\mathbf{g}} \\ &- \int_a^b \left\langle \frac{D^2\mathbf{V}}{dt^2}+\mathbf{R}(\mathbf{V},\dot\gamma)\dot\gamma,\mathbf{W}\right\rangle_{\mathbf{g}} dt. \end{aligned} \tag{2.96}$$

The values at a and b are the limits from the interior. In particular, if $\mathbf{J}$ is a smooth Jacobi field, then

$$I_\gamma(\mathbf{J},\mathbf{W}) = \left[\left\langle \frac{D\mathbf{J}}{dt},\mathbf{W}\right\rangle_{\mathbf{g}}\right]_a^b. \tag{2.97}$$

Proof. On a common admissible partition, the integrand is continuous in the interior of each subinterval and has one-sided limits at its endpoints. Refining the partition merely subdivides existing integrals, and the partition points have measure zero; the value is therefore independent of the partition. Bilinearity is immediate. The symmetries of the curvature tensor imply

$$\langle \mathbf{R}(\mathbf{V},\dot\gamma)\dot\gamma,\mathbf{W}\rangle_{\mathbf{g}} = \langle \mathbf{R}(\mathbf{W},\dot\gamma)\dot\gamma,\mathbf{V}\rangle_{\mathbf{g}},$$

so I_γ is symmetric.
On each interval $[t_{r-1},t_r]$, we have

$$\frac{d}{dt}\left\langle \frac{D\mathbf{V}}{dt},\mathbf{W}\right\rangle_{\mathbf{g}} = \left\langle \frac{D^2\mathbf{V}}{dt^2},\mathbf{W}\right\rangle_{\mathbf{g}} + \left\langle \frac{D\mathbf{V}}{dt},\frac{D\mathbf{W}}{dt}\right\rangle_{\mathbf{g}}.$$

Integrate this equality and sum over r. At an interior point t_r, the boundary terms contribute

$$\left\langle \frac{D\mathbf{V}}{dt}(t_r^-),\mathbf{W}(t_r)\right\rangle_{\mathbf{g}} - \left\langle \frac{D\mathbf{V}}{dt}(t_r^+),\mathbf{W}(t_r)\right\rangle_{\mathbf{g}} = -\left\langle \left[\frac{D\mathbf{V}}{dt}\right]_{t_r},\mathbf{W}(t_r)\right\rangle_{\mathbf{g}},$$

because $\mathbf{W}$ is continuous. Including the curvature term gives (2.96). If $\mathbf{J}$ is a Jacobi field, it has no jumps and the integrand in the second line vanishes, giving (2.97). □

The index form is the second variation of energy at a geodesic with fixed endpoints.

Proposition 2.13.12. (Second variation of energy) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and let $\alpha\colon (-\varepsilon,\varepsilon)\times[a,b]\to M$ be a smooth variation of a geodesic $\gamma = \alpha(0,\cdot)$ with fixed endpoints, and let $\mathbf{V}$ be its variational field. If

$$E(\alpha_s) := \frac{1}{2}\int_a^b \left|d\alpha_{(s,t)}(\partial_t)\right|_{\mathbf{g}}^2 dt,$$

then

$$\left.\frac{d^2}{ds^2}\right|_{s=0} E(\alpha_s) = I_\gamma(\mathbf{V},\mathbf{V}).$$

Without the fixed-endpoint hypothesis, the formula also contains the boundary term

$$\Big[\langle D_s\mathbf{S},\mathbf{T}\rangle_{\mathbf{g}}\Big]_a^b\Big|_{s=0}, \qquad \mathbf{S} = d\alpha(\partial_s),\quad \mathbf{T} = d\alpha(\partial_t).$$

Proof. Write $\mathbf{S} = d\alpha(\partial_s)$ and $\mathbf{T} = d\alpha(\partial_t)$. Metric compatibility and the identity $D_s\mathbf{T} = D_t\mathbf{S}$ give

$$\frac{d}{ds}E(\alpha_s) = \int_a^b \langle D_t\mathbf{S},\mathbf{T}\rangle_{\mathbf{g}}\,dt.$$

Differentiating again and restricting to $s=0$, use $D_sD_t\mathbf{S} = D_tD_s\mathbf{S} + \mathbf{R}(\mathbf{S},\mathbf{T})\mathbf{S}$ and $D_s\mathbf{T} = D_t\mathbf{S}$ to obtain

$$\left.\frac{d^2}{ds^2}\right|_{s=0} E(\alpha_s) = \int_a^b \left[\langle D_tD_s\mathbf{S},\dot\gamma\rangle_{\mathbf{g}} + \langle \mathbf{R}(\mathbf{V},\dot\gamma)\mathbf{V},\dot\gamma\rangle_{\mathbf{g}} + \left|\frac{D\mathbf{V}}{dt}\right|_{\mathbf{g}}^2\right] dt.$$

After integration by parts, the first integral reduces to the boundary term in the statement, since the geodesic satisfies $D_t\dot\gamma = 0$. Because the endpoints of the variation are fixed, $D_s\mathbf{S} = 0$ there, and this term vanishes. Finally,

$$\langle \mathbf{R}(\mathbf{V},\dot\gamma)\mathbf{V},\dot\gamma\rangle_{\mathbf{g}} = -\langle \mathbf{R}(\mathbf{V},\dot\gamma)\dot\gamma,\mathbf{V}\rangle_{\mathbf{g}},$$

which gives the asserted formula. □

Lemma 2.13.13. (Index lemma) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, let $\gamma\colon[a,b]\to M$ be a geodesic, and suppose that $\gamma(a)$ is not conjugate to $\gamma(t)$ along γ for any $t\in(a,b]$. Let $\mathbf{J}$ be a Jacobi field along γ with $\mathbf{J}(a) = 0$. If $\mathbf{V}\in\mathcal{V}_{\mathrm{ps}}(\gamma)$ satisfies

$$\mathbf{V}(a) = 0, \qquad \mathbf{V}(b) = \mathbf{J}(b),$$

then

$$I_\gamma(\mathbf{J},\mathbf{J}) \le I_\gamma(\mathbf{V},\mathbf{V}).$$

Equality holds if and only if $\mathbf{V} = \mathbf{J}$.

Proof. Choose an orthonormal basis $(\mathbf{e}_1,\dots,\mathbf{e}_n)$ of $T_{\gamma(a)}M$ and extend it to a parallel frame along γ. For each i, let $\mathbf{J}_i$ be the unique Jacobi field determined by

$$\mathbf{J}_i(a) = 0, \qquad \frac{D\mathbf{J}_i}{dt}(a) = \mathbf{e}_i.$$

For $t > a$, the vectors $\mathbf{J}_1(t),\dots,\mathbf{J}_n(t)$ form a basis of $T_{\gamma(t)}M$. Indeed, a linear combination vanishing at t would give a Jacobi field vanishing at a and t; by the absence of conjugate points, it would have to be the zero field, and its initial data would force all the coefficients to vanish.

We first prove that

$$I_\gamma(\mathbf{W},\mathbf{W}) \geq 0 \qquad \text{for every } \mathbf{W} \in \mathcal{V}_0(\gamma), \tag{2.98}$$

and determine the equality case. For $t > a$, write uniquely

$$\mathbf{W}(t) = f^i(t)\mathbf{J}_i(t).$$

The functions f^i are piecewise smooth. They also extend smoothly from the right to a on the first admissible subinterval. To see this, express the fields in the parallel frame and denote by $A(t)$ the matrix whose columns are the components of the $\mathbf{J}_i(t)$. Since $A(a) = 0$ and $A'(a) = I$, the integral formula

$$A(t) = (t-a)B(t), \qquad B(t) := \int_0^1 A'\big(a + s(t-a)\big)\,ds,$$

defines a smooth matrix with $B(a) = I$. Similarly, $\mathbf{W}(a) = 0$ allows us to write $\mathbf{W}(t) = (t-a)w(t)$ with w smooth on the first subinterval. For t close to a, $B(t)$ is invertible and

$$(f^1(t),\dots,f^n(t))^{\mathsf{T}} = B(t)^{-1}w(t),$$

which proves the extension and controls the endpoint where all the $\mathbf{J}_i$ vanish.

For each pair i, j, the function

$$\left\langle \frac{D\mathbf{J}_i}{dt}, \mathbf{J}_j \right\rangle_{\mathbf{g}} - \left\langle \mathbf{J}_i, \frac{D\mathbf{J}_j}{dt} \right\rangle_{\mathbf{g}}$$

is constant. Its derivative vanishes by the Jacobi equation and symmetry of the endomorphism $\mathbf{Z} \mapsto \mathbf{R}(\mathbf{Z},\dot\gamma)\dot\gamma$; its value at a is zero. Therefore,

$$\left\langle \frac{D\mathbf{J}_i}{dt}, \mathbf{J}_j \right\rangle_{\mathbf{g}} = \left\langle \mathbf{J}_i, \frac{D\mathbf{J}_j}{dt} \right\rangle_{\mathbf{g}}. \tag{2.99}$$

On each subinterval where $\mathbf{W}$ is smooth, set

$$\mathbf{X} := f^i \frac{D\mathbf{J}_i}{dt}, \qquad \mathbf{Y} := \frac{df^i}{dt}\mathbf{J}_i.$$

Then $\frac{D\mathbf{W}}{dt} = \mathbf{X} + \mathbf{Y}$. The Jacobi equation and (2.99) give

$$\frac{D\mathbf{X}}{dt} = \frac{df^i}{dt}\frac{D\mathbf{J}_i}{dt} - \mathbf{R}(\mathbf{W},\dot\gamma)\dot\gamma, \qquad \left\langle \mathbf{W}, \frac{df^i}{dt}\frac{D\mathbf{J}_i}{dt} \right\rangle_{\mathbf{g}} = \langle \mathbf{Y}, \mathbf{X}\rangle_{\mathbf{g}}.$$

Consequently,

$$\left|\frac{D\mathbf{W}}{dt}\right|^2_{\mathbf{g}} - \langle \mathbf{R}(\mathbf{W},\dot\gamma)\dot\gamma, \mathbf{W}\rangle_{\mathbf{g}} = \frac{d}{dt}\langle \mathbf{W}, \mathbf{X}\rangle_{\mathbf{g}} + |\mathbf{Y}|^2_{\mathbf{g}}. \tag{2.100}$$

The coefficients f^i are continuous at the partition points because $\mathbf{W}$ is continuous and $(\mathbf{J}_i(t))$ is a basis;

therefore, $\mathbf{X}$ is also continuous there. Integrating (2.100) over all the subintervals, the interior boundary terms cancel. At a, they vanish because $\mathbf{W}(a) = 0$ and $\mathbf{X}$ has a limit, and at b they vanish because $\mathbf{W}(b) = 0$. Thus,

$$I_\gamma(\mathbf{W}, \mathbf{W}) = \int_a^b |\mathbf{Y}|_{\mathbf{g}}^2 dt \geq 0.$$

If equality holds, $\mathbf{Y} = 0$ on each subinterval. Since the $\mathbf{J}_i(t)$ are linearly independent for $t > a$, all the functions f^i are constant on each subinterval; their continuity shows that they are constant on all of $[a, b]$. Then $\mathbf{W}$ is a Jacobi field. Since $\mathbf{W}(a) = \mathbf{W}(b) = 0$ and the endpoints are not conjugate, it follows that $\mathbf{W} = 0$. Conversely, $\mathbf{W} = 0$ gives equality. This proves (2.98) and its equality case.

Return to the fields in the statement and set $\mathbf{W} := \mathbf{V} - \mathbf{J}$. Then $\mathbf{W} \in \mathcal{V}_0(\gamma)$. The integration-by-parts formula and the Jacobi equation imply

$$I_\gamma(\mathbf{J}, \mathbf{W}) = \left[\left\langle \frac{D\mathbf{J}}{dt}, \mathbf{W} \right\rangle_{\mathbf{g}} \right]_a^b = 0.$$

By symmetry and bilinearity,

$$I_\gamma(\mathbf{V}, \mathbf{V}) = I_\gamma(\mathbf{J}, \mathbf{J}) + 2I_\gamma(\mathbf{J}, \mathbf{W}) + I_\gamma(\mathbf{W}, \mathbf{W}) = I_\gamma(\mathbf{J}, \mathbf{J}) + I_\gamma(\mathbf{W}, \mathbf{W}).$$

The inequality already proved gives the conclusion, and equality holds exactly when $\mathbf{W} = 0$, that is, when $\mathbf{V} = \mathbf{J}$. □

Theorem 2.13.14. (Comparison of Jacobi fields) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary of dimension at least two, let $\gamma\colon [0, b] \to M$ be a unit-speed geodesic, and let $\mathbf{J}$ be a normal Jacobi field, that is, $\langle \mathbf{J}, \dot{\gamma} \rangle_{\mathbf{g}} = 0$, with $\mathbf{J}(0) = 0$. Define

$$\rho_c := \begin{cases} +\infty, & c \leq 0, \\ \dfrac{\pi}{\sqrt{c}}, & c > 0, \end{cases}$$

and let τ be the first time conjugate to 0 along γ, with the convention $\tau = +\infty$ if there is none.

(a) If every sectional curvature of M is less than or equal to c, then

$$|\mathbf{J}(t)|_{\mathbf{g}} \geq s_c(t) \left| \frac{D\mathbf{J}}{dt}(0) \right|_{\mathbf{g}}.$$

The inequality holds for $0 \leq t \leq \min\{b, \rho_c\}$. Moreover, $\gamma(0)$ has no conjugate points along γ as long as $0 < t < \min\{b, \rho_c\}$.

(b) If every sectional curvature of M is greater than or equal to c, then

$$|\mathbf{J}(t)|_{\mathbf{g}} \leq s_c(t) \left| \frac{D\mathbf{J}}{dt}(0) \right|_{\mathbf{g}}$$

for $0 \leq t \leq \min\{b, \tau, \rho_c\}$. If $c > 0$ and $b \geq \rho_c$, then $\tau \leq \rho_c$.

If $\mathbf{J}$ is not the zero field and $0 < t_0 < \min\{b, \tau, \rho_c\}$ in the case involving τ, or $0 < t_0 < \min\{b, \rho_c\}$ in the other

case, equality in the corresponding comparison at t_0 holds if and only if

$$\mathbf{J}(t) = s_c(t)P_t\left(\frac{D\mathbf{J}}{dt}(0)\right) \quad \text{and} \quad \mathbf{R}(P_t w, \dot\gamma(t))\dot\gamma(t) = cP_t w$$

for $0 < t \le t_0$, where $w = \frac{D\mathbf{J}}{dt}(0)$ and P_t is parallel transport from $\gamma(0)$ to $\gamma(t)$.

Proof. Set $w = \frac{D\mathbf{J}}{dt}(0)$. If $w = 0$, uniqueness for the Jacobi equation implies $\mathbf{J} = 0$, and both inequalities are immediate. Thus, suppose that $w \neq 0$. Choose a parallel orthonormal frame $(\mathbf{E}_2, \dots, \mathbf{E}_n)$ of the orthogonal complement of $\dot\gamma$ and write

$$\mathbf{J}(t) = u^\alpha(t)\mathbf{E}_\alpha(t), \qquad u(t) = (u^2(t), \dots, u^n(t)) \in \mathbb{R}^{n-1}.$$

In particular, $|\mathbf{J}|_{\mathbf{g}} = |u|$, $\left|\frac{D\mathbf{J}}{dt}\right|_{\mathbf{g}} = |u'|$, and $u'(0)$ represents w.
For $t < \rho_c$, consider on $[0, t]$ the model index form

$$I_c(v, v) := \int_0^t \left(|v'(s)|^2 - c|v(s)|^2\right) ds$$

on fields with values in $\mathbb{R}^{n-1}$. The model Jacobi equation is $v'' + cv = 0$. Since $s_c(s) > 0$ for $0 < s < \rho_c$, this equation has no nonzero solution vanishing at 0 and t. The field

$$\overline{u}_t(s) := \frac{s_c(s)}{s_c(t)}u(t)$$

minimizes I_c among fields taking the value 0 at $s = 0$ and $u(t)$ at $s = t$. Indeed, for such a field, write $v(s) = s_c(s)f(s)$ on $(0, t]$. The factorization at the initial endpoint used in the proof of Lemma 2.13.13 shows that f extends regularly to 0. Since $s_c'' = -cs_c$,

$$|v'|^2 - c|v|^2 = \frac{d}{ds}\left(s_c c_c |f|^2\right) + s_c^2|f'|^2.$$

The boundary term at 0 vanishes. The value at t is fixed and the remaining integral is nonnegative, with equality exactly when f is constant. This proves the minimizing property and, for $v = \overline{u}_t$, gives

$$I_c(\overline{u}_t, \overline{u}_t) = \frac{c_c(t)}{s_c(t)}|u(t)|^2. \tag{2.101}$$

First suppose that $K \le c$. Since $\mathbf{J}$ is normal and γ has unit speed,

$$\langle \mathbf{R}(\mathbf{J}, \dot\gamma)\dot\gamma, \mathbf{J}\rangle_{\mathbf{g}} \le c|\mathbf{J}|_{\mathbf{g}}^2.$$

The index lemma for the model and this inequality imply

$$\begin{aligned}\frac{c_c(t)}{s_c(t)}|\mathbf{J}(t)|_{\mathbf{g}}^2 &= I_c(\overline{u}_t, \overline{u}_t)\\ &\le I_c(u, u)\\ &\le I_{\gamma|_{[0,t]}}(\mathbf{J}, \mathbf{J})\end{aligned}$$

$$= \left\langle \frac{D\mathbf{J}}{dt}(t), \mathbf{J}(t) \right\rangle_{\mathbf{g}}.$$

The last equality is (2.97), since $\mathbf{J}(0) = 0$. On every interval where $\mathbf{J}(t) \neq 0$, it follows that

$$\frac{d}{dt} \log \left(\frac{|\mathbf{J}(t)|_{\mathbf{g}}}{s_c(t)} \right) = \frac{\left\langle \frac{D\mathbf{J}}{dt}, \mathbf{J} \right\rangle_{\mathbf{g}}}{|\mathbf{J}|^2_{\mathbf{g}}} - \frac{c_c}{s_c} \geq 0.$$

In the parallel frame, $u(0) = 0$ and $u'(0) = w$; hence,

$$\lim_{t \to 0^+} \frac{|\mathbf{J}(t)|_{\mathbf{g}}}{s_c(t)} = \lim_{t \to 0^+} \frac{\left| \frac{u(t)}{t} \right|}{\frac{s_c(t)}{t}} = |w|_{\mathbf{g}}.$$

The quotient is nondecreasing, giving

$$|\mathbf{J}(t)|_{\mathbf{g}} \geq s_c(t)|w|_{\mathbf{g}}$$

as long as $s_c(t) > 0$. In particular, $\mathbf{J}$ cannot vanish there. If an arbitrary Jacobi field vanishes at 0 and at some $t > 0$, its tangential component has the form $at\dot{\gamma}$ and must vanish; the field is therefore normal. The preceding inequality excludes such a nonzero field for $t < \rho_c$. The comparison extends to the endpoint $t = \min\{b, \rho_c\}$ by continuity. This proves (a).

Now suppose that $K \geq c$ and fix $0 < t < \min\{b, \tau, \rho_c\}$. Along $\gamma|_{[0,t]}$, define the field

$$\mathbf{V}_t(s) := \frac{s_c(s)}{s_c(t)} P_{t,s} \mathbf{J}(t),$$

where $P_{t,s}$ is parallel transport from $\gamma(t)$ to $\gamma(s)$. The fields $\mathbf{V}_t$ and $\mathbf{J}$ have the same values at the endpoints. Since there are no conjugate points before t, Lemma 2.13.13 and the lower curvature bound give

$$\begin{aligned} \left\langle \frac{D\mathbf{J}}{dt}(t), \mathbf{J}(t) \right\rangle_{\mathbf{g}} &= I_{\gamma|_{[0,t]}}(\mathbf{J}, \mathbf{J}) \\ &\leq I_{\gamma|_{[0,t]}}(\mathbf{V}_t, \mathbf{V}_t) \\ &\leq I_c(\overline{u}_t, \overline{u}_t) \\ &= \frac{c_c(t)}{s_c(t)} |\mathbf{J}(t)|^2_{\mathbf{g}}. \end{aligned}$$

Therefore,

$$\frac{d}{dt} \log \left(\frac{|\mathbf{J}(t)|_{\mathbf{g}}}{s_c(t)} \right) \leq 0,$$

and the same limit at 0 shows that

$$|\mathbf{J}(t)|_{\mathbf{g}} \leq s_c(t)|w|_{\mathbf{g}}.$$

Continuity allows us to include the first conjugate time and the endpoint of the indicated interval. If $c > 0$, $b \geq \rho_c$, and there were no conjugate point before ρ_c, the inequality, applied for $t < \rho_c$, would give $\mathbf{J}(\rho_c) = 0$ for every normal Jacobi field with $\mathbf{J}(0) = 0$. Taking $w \neq 0$ would produce a conjugate point at ρ_c. Consequently, $\tau \leq \rho_c$, completing (b).

It remains to study equality. In either case, the quotient $\frac{|\mathbf{J}|_{\mathbf{g}}}{s_c}$ is monotone and its limit at zero is $|w|_{\mathbf{g}}$. If

equality holds at t_0, this quotient is constant on $[0, t_0]$. In the preceding chains of inequalities, equality must hold both in the comparison of the index forms and in the curvature estimate. The equality condition for the model identity in the first case and that of Lemma 2.13.13 in the second give

$$\mathbf{J}(t) = s_c(t) P_t w.$$

Moreover, the self-adjoint endomorphism $\mathbf{Z} \mapsto \mathbf{R}(\mathbf{Z}, \dot\gamma)\dot\gamma$ is bounded above by cI in the first case and bounded below by cI in the second. Equality of their quadratic forms along $P_t w$ implies

$$\mathbf{R}(P_t w, \dot\gamma)\dot\gamma = c P_t w.$$

Conversely, these two identities turn all the preceding steps into equalities and yield equality in the comparison. □

Proposition 2.13.15. (Continuity of the injectivity radius) Let $(M, \mathbf{g})$ be a complete connected Riemannian manifold without boundary. Then

$$\operatorname{inj} \colon M \longrightarrow (0, \infty]$$

is continuous, where $(0, \infty]$ carries the extended order topology.

We use continuity of the cut time on the unit tangent bundle, proved by Lee [95].

Proof. For $v \in SM$, let

$$c(v) := \sup\{t > 0 \mid d_{\mathbf{g}}(\pi(v), \exp_{\pi(v)}(tv)) = t\}$$

be the cut time of the unit-speed geodesic determined by v. On a complete manifold, the cut time is a continuous function $c \colon SM \to (0, \infty]$. Moreover,

$$\operatorname{inj}(p) = \inf_{v \in S_pM} c(v).$$

In a local trivialization of SM, the fibers S_pM are identified with the compact sphere $\mathbb{S}^{n-1}$. Continuity of c and compactness of this sphere imply that the infimum depends continuously on p (including when its value is infinite). The assertion follows. □

2.14 Integration on Riemannian manifolds

Integration on a manifold requires replacing the Euclidean volume element by an object that transforms correctly under changes of coordinates. On an oriented manifold, differential forms of top degree provide such an object; the Riemannian metric will later select a canonical volume form. We begin with orientation and integration of forms in charts.

Definition 2.14.1. Let V be a finite-dimensional vector space. We say that two ordered bases $(E_1, \dots, E_n)$ and $(\widetilde E_1, \dots, \widetilde E_n)$ are **consistently oriented** if the change-of-basis matrix (B_i^j) satisfying $E_i = B_i^j \widetilde E_j$ has positive determinant.

One can show that consistent orientation is an equivalence relation on the set of ordered bases of a finite-

dimensional vector space. Moreover, this equivalence relation has exactly two classes, allowing us to give the following definition:

Definition 2.14.2. Let V be a finite-dimensional vector space. An **orientation of** V is an equivalence class of ordered bases. Given an ordered basis $(E_1,\dots,E_n)$, denote the orientation it determines by $[E_1,\dots,E_n]$. An **oriented vector space** is a vector space V together with an orientation determined by an ordered basis $[E_1,\dots,E_n]$. Once we fix an orientation of V, a basis with this orientation is said to be **positively oriented**. An ordered basis that is not positively oriented is said to be **negatively oriented**.

Definition 2.14.3. Let M be a smooth manifold with or without boundary. A **pointwise orientation** on M is a choice of orientation on each tangent space. If $(\mathbf{E}_i)$ is a local frame of TM, we say that $(\mathbf{E}_i)$ **is positively oriented** if $(\mathbf{E}_1|_p,\dots,\mathbf{E}_n|_p)$ is a positively oriented ordered basis of T_pM for each $p \in U$, where U is the domain of the local frame $(\mathbf{E}_i)$. If $(\mathbf{E}_1|_p,\dots,\mathbf{E}_n|_p)$ is negatively oriented for each $p \in U$, we say that the local frame is **negatively oriented**.

A **continuous orientation of** M is a pointwise orientation such that, for each $p \in M$, there exists an open set $U \subseteq M$ such that U is the domain of a positively oriented local frame. We say that M is **orientable** if it has a continuous pointwise orientation. We denote this orientation by $\mathscr{O}$ and say that $(M,\mathscr{O})$ is an **oriented smooth manifold**.

Finally, if (U,φ) is a smooth chart of an oriented manifold M, with $\varphi = (x^1,\dots,x^n)$, we say that it is a **positively oriented chart** (or simply an **oriented chart**) if the coordinate frame $\left(\partial_i\right)$ is positively oriented. If this coordinate frame is negatively oriented, we say that the chart is a **negatively oriented chart**.

Proposition 2.14.4. (The Riemannian volume form) Let $(M,\mathbf{g})$ be an oriented Riemannian manifold of dimension n with or without boundary. There exists a unique n-form $dV_{\mathbf{g}} \in \Omega^n(M)$, called the **Riemannian volume form**, characterized by any of the following properties:

(a) If $(\varepsilon^1,\dots,\varepsilon^n)$ is any positively oriented orthonormal local coframe of T^*M, then

$$dV_{\mathbf{g}} = \varepsilon^1 \wedge \cdots \wedge \varepsilon^n.$$

(b) If $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ is any positively oriented orthonormal local frame of TM, then

$$dV_{\mathbf{g}}(\mathbf{E}_1,\dots,\mathbf{E}_n) = 1.$$

(c) If (U,φ), $\varphi = (x^1,\dots,x^n)$ is an oriented chart of M, then

$$dV_{\mathbf{g}} = \sqrt{\det(\mathbf{g})}\,\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n.$$

Proof. Let $(U,x^1,\dots,x^n)$ be a positively oriented chart. The matrix $G_x = (g_{ij})$ is symmetric and positive definite, so $\det G_x > 0$. On U, define

$$\omega_x := \sqrt{\det G_x}\,\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n. \tag{2.102}$$

This form is smooth. We will show that the forms obtained in this way agree on overlaps.

Let $(x^1,\dots,x^n)$ and $(y^1,\dots,y^n)$ be two positively oriented coordinate systems and write $G_y = (\widetilde{g}_{ab})$ for the matrix of the metric in the coordinates y. On the overlap,

$$\widetilde{g}_{ab} = g_{ij}\frac{\partial x^i}{\partial y^a}\frac{\partial x^j}{\partial y^b},$$

that is,

$$G_y = \left(\frac{\partial x}{\partial y}\right)^T G_x \left(\frac{\partial x}{\partial y}\right).$$

Taking determinants gives

$$\det G_y = \det\left(\frac{\partial x}{\partial y}\right)^2 \det G_x. \tag{2.103}$$

Both coordinate systems induce the fixed orientation; therefore,

$$\det\left(\frac{\partial x}{\partial y}\right) > 0.$$

The transformation law for the wedge product, in turn, gives

$$\mathbf{d}y^1 \wedge \cdots \wedge \mathbf{d}y^n = \det\left(\frac{\partial y}{\partial x}\right)\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n.$$

Combining this equality with (2.103), we conclude that

$$\begin{aligned}\sqrt{\det G_y}\,\mathbf{d}y^1 \wedge \cdots \wedge \mathbf{d}y^n &= \det\left(\frac{\partial x}{\partial y}\right)\sqrt{\det G_x}\det\left(\frac{\partial y}{\partial x}\right)\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n \\ &= \sqrt{\det G_x}\,\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n.\end{aligned}$$

Thus the local forms glue together to define a smooth global form $dV_{\mathbf{g}}$. Property (c) holds by construction. Now let $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ be a positively oriented orthonormal local frame. In an oriented chart, write

$$\mathbf{E}_a = B_a^i \partial_i$$

and denote by B the matrix whose columns are the components of the $\mathbf{E}_a$. Orthonormality is equivalent to

$$B^T G_x B = I.$$

Therefore, $(\det B)^2 \det G_x = 1$. Since the frame and the chart have the same orientation, $\det B > 0$, and hence

$$\det B = \frac{1}{\sqrt{\det G_x}}.$$

It follows from (2.102) that

$$dV_{\mathbf{g}}(\mathbf{E}_1,\dots,\mathbf{E}_n) = \sqrt{\det G_x}\,\det B = 1.$$

This proves (b). If $(\varepsilon^1,\dots,\varepsilon^n)$ is the dual coframe, then $(\varepsilon^1 \wedge \cdots \wedge \varepsilon^n)(\mathbf{E}_1,\dots,\mathbf{E}_n) = 1$. Since the space of n-covectors at each point is one-dimensional, (b) implies

$$dV_{\mathbf{g}} = \varepsilon^1 \wedge \cdots \wedge \varepsilon^n,$$

which is (a). Conversely, (a) immediately implies (b), and the calculation with the coordinate frame shows that (b) implies (c). Thus the three characterizations are equivalent.
The construction does not depend on the orthonormal frame. Two positively oriented orthonormal frames are related by a matrix with values in $SO(n)$, whose determinant is one; the wedge products of their dual coframes agree. If another n-form satisfies any of the characterizations, its value on each positively oriented orthonormal frame is one, so it agrees pointwise with $dV_{\mathbf{g}}$. This proves uniqueness.

□

Remark 2.14.5. The notation $dV_{\mathbf{g}}$ here denotes an n-form and requires a fixed orientation. The Riemannian density $\boldsymbol{\mu}_{\mathbf{g}}$, defined later, exists even when M is not orientable and transforms with the absolute value of the Jacobian. The Riemann–Lebesgue measure $\lambda_{\mathbf{g}}$ will be constructed by integrating this density; the notation $d\lambda_{\mathbf{g}}$ indicates only integration with respect to the measure $\lambda_{\mathbf{g}}$ and does not represent a differential form or an exterior derivative.

The volume form has the important property of compatibility with the Levi–Civita connection. To prove this, we first recall an important result from differential calculus:

Proposition 2.14.6. (Jacobi's formula) If $A\colon I \subseteq \mathbb{R} \longrightarrow GL(n,\mathbb{R})$ is differentiable, then

$$\frac{d}{dt}\det\big(A(t)\big) = \det\big(A(t)\big)\,\operatorname{tr}\left(A(t)^{-1}\frac{d}{dt}A(t)\right).$$

Proof. Fix $t \in I$ and denote the columns of $A(t)$ by $\mathbf{a}_1(t),\dots,\mathbf{a}_n(t)$. Multilinearity of the determinant gives

$$\frac{d}{dt}\det A(t) = \sum_{j=1}^{n}\det\big(\mathbf{a}_1(t),\dots,\mathbf{a}_j'(t),\dots,\mathbf{a}_n(t)\big).$$

Set $B(t) := A(t)^{-1}A'(t)$. Then $A' = AB$, and

$$\mathbf{a}_j' = \sum_{i=1}^{n} B_{ij}\mathbf{a}_i.$$

Substituting this sum into the determinant indexed by j, all the terms with $i \neq j$ vanish because they contain two equal columns. The remaining term is $B_{jj}\det A$. Therefore,

$$\frac{d}{dt}\det A(t) = \det A(t)\sum_{j=1}^{n} B_{jj}(t) = \det A(t)\operatorname{tr}\big(A(t)^{-1}A'(t)\big).$$

□

Remark 2.14.7. Proposition 2.14.6 allows us to compute the partial derivatives of $\sqrt{\det(\mathbf{g})}$ and relate them to the Christoffel symbols. Consider a chart (U,φ) with induced coordinates

$$\varphi = (x^1,\dots,x^n)\colon U \longrightarrow \mathbb{R}^n.$$

Denote by $G = (g_{ij})$ the matrix of metric components, where

$$g_{ij}(p) = \mathbf{g}_p\left(\partial_i\big|_p, \partial_j\big|_p\right), \qquad p \in U.$$

Fix a point $p \in U$ and a coordinate x^a. Define a curve in U by

$$\gamma(t) = \varphi^{-1}(x^1(p), \ldots, x^a(p) + t, \ldots, x^n(p)).$$

In coordinates, we have

$$(\varphi \circ \gamma)(t) = (x^1(p), \ldots, x^a(p) + t, \ldots, x^n(p)).$$

Let $f : U \longrightarrow \mathbb{R}$ be a smooth function and write $F = f \circ \varphi^{-1} : \varphi(U) \subseteq \mathbb{R}^n \longrightarrow \mathbb{R}$. Then

$$f(\gamma(t)) = F((\varphi \circ \gamma)(t)).$$

Applying the chain rule,

$$\frac{d}{dt}\bigg|_{t=0} f(\gamma(t)) = dF_{\varphi(p)}\left(\frac{d}{dt}\bigg|_{t=0} (\varphi \circ \gamma)(t)\right).$$

Since

$$\frac{d}{dt}\bigg|_{t=0} (\varphi \circ \gamma)(t) = (0, \ldots, 1, \ldots, 0) = e_a \in \mathbb{R}^n,$$

it follows that

$$\frac{d}{dt}\bigg|_{t=0} f(\gamma(t)) = dF_{\varphi(p)}(e_a) = \frac{\partial F}{\partial u^a}(\varphi(p)),$$

where $(u^1, \ldots, u^n)$ are the standard coordinates of $\mathbb{R}^n$. By definition, this agrees with the action of $\partial_a|_p$ on f. Consequently,

$$\gamma'(0) = \partial_a\big|_p.$$

Applying this to each coordinate component of the metric, which is a smooth function $g_{ij} : U \longrightarrow \mathbb{R}$, we conclude that

$$\frac{d}{dt}\bigg|_{t=0} g_{ij}(\gamma(t)) = \partial_a g_{ij}(p).$$

Defining the curve of matrices

$$A(t) = (g_{ij}(\gamma(t))),$$

and applying Proposition 2.14.6 gives

$$\frac{d}{dt}\det\left(A(t)\right) = \det\left(A(t)\right)\operatorname{tr}\left(A(t)^{-1}\frac{d}{dt}A(t)\right).$$

Evaluating at $t = 0$ and using $\gamma(0) = p$ together with the preceding calculation, we conclude that

$$\partial_a(\det G)(p) = (\det G(p))g^{ij}(p)\partial_a g_{ij}(p).$$

Thus Jacobi's formula in one real variable becomes, in local coordinates on the manifold, the identity

$$\partial_a(\det G) = (\det G)g^{ij}\partial_a g_{ij}.$$

It follows that

$$\partial_a \sqrt{\det G} = \frac{1}{2\sqrt{\det G}} \partial_a (\det G).$$

Substituting the preceding identity gives

$$\partial_a \sqrt{\det G} = \frac{1}{2\sqrt{\det G}} \left((\det G) g^{ij} \partial_a g_{ij} \right),$$

and therefore

$$\partial_a \sqrt{\det G} = \frac{1}{2} \sqrt{\det G}\, g^{ij} \partial_a g_{ij}.$$

In particular, using Corollary 2.4.11, this formula gives the identity

$$\Gamma^i_{ik} = \frac{1}{\sqrt{\det G}} \partial_k \left(\sqrt{\det G} \right),$$

where Γ^i_{jk} denote the Christoffel symbols of the Levi–Civita connection.

Proposition 2.14.8. Let $(M, \mathbf{g})$ be an oriented Riemannian manifold with or without boundary and with Levi–Civita connection ∇. Then the Riemannian volume form is parallel with respect to the connection, that is,

$$\nabla dV_{\mathbf{g}} = 0.$$

Proof. In an oriented chart $(x^1, \dots, x^n)$, we have

$$dV_{\mathbf{g}} = \sqrt{\det G}\, \mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n.$$

Using Proposition 2.4.22 and linearity of the connection gives

$$\nabla_a dV_{\mathbf{g}} = \nabla_a (\sqrt{\det G})\, \mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n + \sqrt{\det G}\, \nabla_a (\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n).$$

For the first term, since $\sqrt{\det G}$ is a function, we have

$$\nabla_a (\sqrt{\det G}) = \partial_a (\sqrt{\det G}).$$

For the second term, applying Proposition 2.4.22 again,

$$\nabla_a (\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n) = \sum_{s=1}^{n} \mathbf{d}x^1 \wedge \cdots \wedge \nabla_a \mathbf{d}x^s \wedge \cdots \wedge \mathbf{d}x^n.$$

In coordinates,

$$\nabla_a \mathbf{d}x^s = -\Gamma^s_{ar} \mathbf{d}x^r.$$

If $r \neq s$, the term

$$\mathbf{d}x^1 \wedge \cdots \wedge (-\Gamma^s_{ar} \mathbf{d}x^r) \wedge \cdots \wedge \mathbf{d}x^n$$

contains two equal factors ($\mathbf{d}x^r$ appears twice), so it vanishes. The only nontrivial contribution occurs when

$r = s$, giving

$$\nabla_a(\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n) = -\left(\Gamma^1_{a1} + \cdots + \Gamma^n_{an}\right)\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n.$$

Combining both results,

$$\nabla_a dV_{\mathbf{g}} = \left(\partial_a(\sqrt{\det G}) - \sqrt{\det G}(\Gamma^1_{a1} + \cdots + \Gamma^n_{an})\right)\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n.$$

By Remark 2.14.7,

$$\partial_a(\sqrt{\det G}) = \frac{1}{2}\sqrt{\det G}\, g^{ij}\partial_a g_{ij}.$$

Since the Levi–Civita connection is compatible with $\mathbf{g}$, we have

$$\Gamma^r_{ra} = \frac{1}{2} g^{ij}\partial_a g_{ij}.$$

Moreover, symmetry in the lower indices implies $\Gamma^r_{ar} = \Gamma^r_{ra}$, so

$$\Gamma^1_{a1} + \cdots + \Gamma^n_{an} = \Gamma^r_{ra}.$$

Substituting these identities,

$$\nabla_a dV_{\mathbf{g}} = \left(\Gamma^r_{ra}\sqrt{\det G} - \Gamma^r_{ra}\sqrt{\det G}\right)\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n = 0.$$

Thus, $dV_{\mathbf{g}}$ is parallel with respect to the Levi–Civita connection. □

We now have the ingredients needed to define integrals of n-forms on smooth manifolds. To do so, we use Theorem 1.3.5.

Definition 2.14.9. Let $D \subseteq \mathbb{H}^n$ be a Jordan-measurable set and let ω be a continuous n-form defined on $\overline{D}$. We have $\omega = f\,\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n$ for some continuous function $f : \overline{D} \longrightarrow \mathbb{R}$. Define the **integral of ω over D** to be

$$\int_D \omega = \int_D f\, dx^1 \cdots dx^n$$

where the integral on the right is the usual Riemann integral. More generally, if $U \subseteq \mathbb{H}^n$ is open and ω is a continuous n-form with compact support contained in U, define

$$\int_U \omega = \int_D \omega$$

where D is a Jordan-measurable set such that $\operatorname{supp}(\omega) \subseteq D \subseteq U$, regarding ω as extended by zero outside its support. One can show that such a Jordan-measurable set always exists and that the definition is independent of the chosen set D.

Definition 2.14.10. Let M be an oriented smooth manifold with or without boundary and let ω be a continuous n-form on M with compact support contained in the domain of a smooth chart (U, φ) that is

positively or negatively oriented. Define the integral of ω over M to be

$$\int_M \omega = \pm \int_{\varphi(U)} (\varphi^{-1})^* \omega,$$

where the sign is positive if the chart is positively oriented and negative if it is negatively oriented.

Definition 2.14.11. Let M be an oriented smooth manifold with or without boundary and let ω be a continuous n-form with compact support. Let $\{U_i\}_{i=1}^k$ be an open cover of $\operatorname{supp}(\omega)$ by domains of positively or negatively oriented smooth charts. Let $(\psi_i)_{i=1}^k$ be a partition of unity subordinate to this open cover. Define the integral of ω over M to be

$$\int_M \omega = \sum_{i=1}^k \int_M \psi_i \omega.$$

It is proved in [94] that this definition is independent of the choice of oriented charts and partition of unity.

We extend this definition to Riemannian manifolds as follows:

Definition 2.14.12. Let $(M, \mathbf{g})$ be an oriented Riemannian manifold with or without boundary and let $f : M \longrightarrow \mathbb{R}$ be continuous with compact support. Define the integral of f over M to be

$$\int_M f = \int_M f \, dV_{\mathbf{g}}.$$

The nonorientable case is handled by densities, which incorporate the absolute value of the Jacobian and require no choice of orientation.

Definition 2.14.13. (Density of weight w on a vector space) Let V be a vector space of dimension n and let $w \in \mathbb{R}$. Write

$$\operatorname{Fr}(V) := \{(v_1, \ldots, v_n) \in V^n \mid (v_1, \ldots, v_n) \text{ is an ordered basis of } V\}.$$

A **density of weight w on** V is a function

$$\mu : \operatorname{Fr}(V) \longrightarrow \mathbb{R}$$

such that, for every invertible linear operator $T : V \longrightarrow V$ and every $(v_1, \ldots, v_n) \in \operatorname{Fr}(V)$,

$$\mu(T(v_1), \ldots, T(v_n)) = |\det(T)|^w \mu(v_1, \ldots, v_n).$$

A density μ is called **positive** if $\mu(v_1, \ldots, v_n) > 0$ for every ordered basis $(v_1, \ldots, v_n)$ of V.
Denote the set of densities of weight w on V by $\mathcal{D}_w(V)$.

With pointwise operations, $\mathcal{D}_w(V)$ is a one-dimensional vector space. Indeed, fixing an ordered basis $\mathcal{E} = (e_1, \ldots, e_n)$, every ordered basis $\mathcal{V} = (v_1, \ldots, v_n)$ can be written uniquely as $\mathcal{V} = T\mathcal{E}$ with $T \in \mathrm{GL}(V)$. Therefore,

$$\mu(\mathcal{V}) = |\det T|^w \mu(\mathcal{E}).$$

Thus the value of μ at $\mathcal{E}$ determines all its values. Conversely, for each $c \in \mathbb{R}$, the formula $\mu_c(T\mathcal{E}) := |\det T|^w c$ is well-defined and determines a density. The map $\mu \mapsto \mu(\mathcal{E})$ is consequently a linear isomorphism from $\mathcal{D}_w(V)$ onto

$\mathbb{R}$.

Definition 2.14.14. (Bundle of densities of weight w on a manifold) Let M be a smooth manifold with or without boundary. The **bundle of densities of weight w on M**, denoted by $\boldsymbol{\mathcal{D}}_w(M)$, is the set

$$\boldsymbol{\mathcal{D}}_w(M) := \coprod_{p\in M} \mathcal{D}_w(T_pM).$$

$\boldsymbol{\mathcal{D}}_w(M)$ is a smooth vector bundle of rank 1. Over any coordinate chart (U, x^i), a local basis for this bundle is given by $|\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n|^w$.
A **density of weight w on M** is a smooth section of $\boldsymbol{\mathcal{D}}_w(M)$.

We will define the integral of a density on a smooth manifold. For this, we use a construction analogous to the one for differential forms.

Definition 2.14.15. If $D \subseteq \mathbb{H}^n$ is a Jordan-measurable set and $\boldsymbol{\mu}$ is a continuous density of weight one on $\overline{D}$, we may write $\boldsymbol{\mu} = f|\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n|$ for a unique continuous function $f : \overline{D} \longrightarrow \mathbb{R}$. Define the integral of $\boldsymbol{\mu}$ over D by

$$\int_D \boldsymbol{\mu} = \int_D f\, dx^1 \cdots dx^n.$$

Similarly, if $U \subseteq \mathbb{H}^n$ is open and $\boldsymbol{\mu}$ is a continuous density with compact support contained in U, define

$$\int_U \boldsymbol{\mu} = \int_D \boldsymbol{\mu}$$

where D is a Jordan-measurable set such that

$$\operatorname{supp}(\boldsymbol{\mu}) \subseteq D \quad \text{and} \quad \overline{D} \subseteq U.$$

Such a set exists: cover the support by finitely many sufficiently small closed rectangular boxes contained in U and take their union.

Definition 2.14.16. Let M be a smooth manifold with or without boundary (not necessarily orientable). If $\boldsymbol{\mu}$ is a compactly supported density on M whose support is contained in the domain of a smooth chart (U, φ), define the integral of $\boldsymbol{\mu}$ over M to be

$$\int_M \boldsymbol{\mu} = \int_{\varphi(U)} (\varphi^{-1})^* \boldsymbol{\mu}.$$

We may extend this definition to arbitrary compactly supported densities by defining the **integral of $\boldsymbol{\mu}$ over M** by

$$\int_M \boldsymbol{\mu} = \sum_{i=1}^{k} \int_M \psi_i \boldsymbol{\mu},$$

where the chart domains $U_1, \ldots, U_k$ cover $\operatorname{supp}(\boldsymbol{\mu})$, each $\operatorname{supp}(\psi_i)$ is contained in U_i, and $\sum_{i=1}^{k} \psi_i = 1$ on a neighborhood of $\operatorname{supp}(\boldsymbol{\mu})$. These functions are obtained by applying a partition of unity to the cover

$U_1, \dots, U_k, M \setminus \operatorname{supp}(\boldsymbol{\mu})$.

Proposition 2.14.17. (Well-definedness of the integral of densities) The preceding integral is independent of the chosen Jordan-measurable set, chart, finite cover, and partition of unity.

Proof. Begin with an open set $U \subseteq \mathbb{H}^n$ and a continuous density $\boldsymbol{\mu} = f\,|\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n|$ whose support K is compact and contained in U. The extension of f by zero outside U is continuous on a neighborhood of any Jordan-measurable set D such that $K \subseteq D$ and $\overline{D} \subseteq U$. If D_1 and D_2 are two such sets, the extended function vanishes on both $(D_1 \cup D_2) \setminus D_1$ and $(D_1 \cup D_2) \setminus D_2$. Since $D_1 \cup D_2$ is Jordan-measurable, additivity of the Riemann integral gives

$$\int_{D_1} f \, d\lambda_n = \int_{D_1 \cup D_2} f \, d\lambda_n = \int_{D_2} f \, d\lambda_n.$$

This proves independence of D.

Now let (U, φ) and (V, ψ) be two charts whose domains contain $\operatorname{supp}(\boldsymbol{\mu})$, and set $\Theta := \psi \circ \varphi^{-1}$ on $\varphi(U \cap V)$. If

$$(\varphi^{-1})^* \boldsymbol{\mu} = f_\varphi \, |\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n|, \qquad (\psi^{-1})^* \boldsymbol{\mu} = f_\psi \, |\mathbf{d}y^1 \wedge \cdots \wedge \mathbf{d}y^n|,$$

the transformation law for densities gives

$$f_\varphi(x) = f_\psi(\Theta(x)) \, |\det D\Theta(x)|.$$

The change-of-variables theorem B.6.15, applied on $\varphi(U \cap V)$, then implies

$$\int_{\varphi(U)} f_\varphi \, d\lambda_n = \int_{\psi(V)} f_\psi \, d\lambda_n,$$

since both integrands vanish outside the image of the support. Thus the local integral is independent of the chart.

Finally, let $(\psi_i)_{i=1}^k$ and $(\eta_j)_{j=1}^\ell$ be two partitions of unity subordinate to respective finite covers of the support of $\boldsymbol{\mu}$ by chart domains. Additivity of the local integral and the chart independence already proved allow us to integrate each $\psi_i \eta_j \boldsymbol{\mu}$ in either of the two charts containing its support. Since the sums are finite,

$$\begin{aligned} \sum_{i=1}^{k} \int_M \psi_i \boldsymbol{\mu} &= \sum_{i=1}^{k} \sum_{j=1}^{\ell} \int_M \psi_i \eta_j \boldsymbol{\mu} \\ &= \sum_{j=1}^{\ell} \int_M \eta_j \boldsymbol{\mu}. \end{aligned}$$

This proves independence of both the partition and the cover. □

Proposition 2.14.18. (The Riemannian density) If $(M, \mathbf{g})$ is a Riemannian manifold with or without boundary, then there exists a unique smooth positive density $\boldsymbol{\mu}_{\mathbf{g}}$ defined on M, called the **Riemannian density**, with the property that $\boldsymbol{\mu}_{\mathbf{g}}(\mathbf{E}_1, \dots, \mathbf{E}_n) = 1$ for every local orthonormal frame $(\mathbf{E}_i)$.

Proof. In a chart $(U, x^1, \dots, x^n)$, set

$$\boldsymbol{\mu}_{\mathbf{g}} = \sqrt{\det(\mathbf{g})}\,|\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n|.$$

We have the identity

$$\det \widetilde{G} = \det\left(\frac{\partial x}{\partial y}\right)^2 \det G,$$

where $G = (g_{ij})$ and $\widetilde{G} = (\widetilde{g}_{ij})$ are the matrices of components in the coordinates x and y, respectively. This identity, together with the transformation law for a density, shows that these expressions agree on overlaps, regardless of the sign of the Jacobian. Therefore, they define a global smooth positive density. If $(\mathbf{E}_1, \dots, \mathbf{E}_n)$ is an orthonormal frame and B is its matrix of components in the coordinate frame, then $B^T(g_{ij})B = I$ and $|\det B| = (\det(\mathbf{g}))^{-\frac{1}{2}}$; this gives $\boldsymbol{\mu}_{\mathbf{g}}(\mathbf{E}_1, \dots, \mathbf{E}_n) = 1$. Every density with this property agrees with $\boldsymbol{\mu}_{\mathbf{g}}$ on each frame and consequently equals it. □

We define the integral of a compactly supported function on a Riemannian manifold, not necessarily orientable, as follows:

Definition 2.14.19. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. If $f : M \longrightarrow \mathbb{R}$ is a continuous compactly supported function, define the **integral of f over M** to be

$$\int_M f = \int_M f\,\boldsymbol{\mu}_{\mathbf{g}}.$$

We now state the most important integration theorems on manifolds, whose proofs can be found in [94].

Theorem 2.14.20. (Stokes' theorem) Let M be an oriented smooth manifold of dimension n with or without boundary, and let ω be a smooth $(n-1)$-form on M with compact support. Equip ∂M with the orientation induced by the outward-normal-first convention. Then

$$\int_M d\omega = \int_{\partial M} \omega.$$

If $\partial M = \varnothing$, the right-hand side is interpreted as zero.

Theorem 2.14.21. (Divergence theorem) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, not necessarily orientable, and let $\mathbf{X} \in \mathfrak{X}(M)$ be a smooth vector field with compact support. If $\partial M \neq \varnothing$, denote by $\boldsymbol{\nu}$ the outward unit normal field and by $\widetilde{\mathbf{g}}$ the induced metric on ∂M. Then

$$\int_M \operatorname{div}(\mathbf{X})\, d\lambda_{\mathbf{g}} = \int_{\partial M} \langle \mathbf{X}, \boldsymbol{\nu} \rangle_{\mathbf{g}}\, d\lambda_{\widetilde{\mathbf{g}}}.$$

If $\partial M = \varnothing$, the right-hand side is zero.

Proof. First suppose that M is oriented and let $dV_{\mathbf{g}}$ be the positive volume form. In an oriented chart, write $\mathbf{X} = X^i \partial_i$ and

$$dV_{\mathbf{g}} = \sqrt{\det(\mathbf{g})}\,\mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n.$$

Then

$$\iota_{\mathbf{X}} dV_{\mathbf{g}} = \sqrt{\det(\mathbf{g})} \sum_{i=1}^{n} (-1)^{i-1} X^i \, \mathbf{d}x^1 \wedge \cdots \wedge \widehat{\mathbf{d}x^i} \wedge \cdots \wedge \mathbf{d}x^n.$$

Differentiating each summand, the components of $\mathbf{d}(\sqrt{\det(\mathbf{g})} X^i)$ other than $\mathbf{d}x^i$ vanish when taking the exterior product, because the corresponding differential already occurs in the $(n-1)$-form. The remaining component produces the sign $(-1)^{i-1}$ twice, once from contraction and once from ordering the differentials. Hence

$$d\left(\iota_{\mathbf{X}} dV_{\mathbf{g}}\right) = \sum_{i=1}^{n} \partial_i \left(\sqrt{\det(\mathbf{g})} \, X^i \right) \mathbf{d}x^1 \wedge \cdots \wedge \mathbf{d}x^n = \operatorname{div}(\mathbf{X}) \, dV_{\mathbf{g}}.$$

Apply Stokes' theorem to the compactly supported form $\iota_{\mathbf{X}} dV_{\mathbf{g}}$. If $(\mathbf{e}_1, \ldots, \mathbf{e}_{n-1})$ is a positively oriented orthonormal frame of $T(\partial M)$, the boundary orientation convention makes $(\boldsymbol{\nu}, \mathbf{e}_1, \ldots, \mathbf{e}_{n-1})$ positively oriented, and

$$\begin{aligned} \left(\iota_{\mathbf{X}} dV_{\mathbf{g}}\right)(\mathbf{e}_1, \ldots, \mathbf{e}_{n-1}) &= dV_{\mathbf{g}}(\mathbf{X}, \mathbf{e}_1, \ldots, \mathbf{e}_{n-1}) \\ &= \mathbf{g}(\mathbf{X}, \boldsymbol{\nu}). \end{aligned}$$

Therefore,

$$\int_M \operatorname{div}(\mathbf{X}) \, d\lambda_{\mathbf{g}} = \int_{\partial M} \mathbf{g}(\mathbf{X}, \boldsymbol{\nu}) \, d\lambda_{\tilde{\mathbf{g}}}$$

in the orientable case.

Now consider an arbitrary M. The compact set $K := \operatorname{supp}(\mathbf{X})$ admits a finite cover by chart domains $U_1, \ldots, U_N$, each of which is orientable. Add $M \setminus K$ to the cover and choose a subordinate smooth partition of unity. Denote the functions corresponding to U_i by χ_i. The function corresponding to $M \setminus K$ has zero product with $\mathbf{X}$, and

$$\sum_{i=1}^{N} \chi_i = 1, \qquad \sum_{i=1}^{N} \mathbf{d}\chi_i = 0$$

on a neighborhood of K. Each field $\chi_i \mathbf{X}$ has compact support contained in U_i. Since U_i is open in a manifold with boundary, its boundary as a manifold is $U_i \cap \partial M$; no artificial boundary appears inside M. The orientable case, applied to U_i with either of its two orientations, gives

$$\int_{U_i} \operatorname{div}(\chi_i \mathbf{X}) \, d\lambda_{\mathbf{g}} = \int_{\partial M \cap U_i} \chi_i \mathbf{g}(\mathbf{X}, \boldsymbol{\nu}) \, d\lambda_{\tilde{\mathbf{g}}}.$$

The Leibniz rule for divergence implies

$$\sum_{i=1}^{N} \operatorname{div}(\chi_i \mathbf{X}) = \left(\sum_{i=1}^{N} \chi_i \right) \operatorname{div}(\mathbf{X}) + \left\langle \sum_{i=1}^{N} \operatorname{grad} \chi_i, \mathbf{X} \right\rangle_{\mathbf{g}} = \operatorname{div}(\mathbf{X}).$$

Summing the local identities and again using $\sum_{i=1}^{N} \chi_i = 1$ on $K \cap \partial M$ gives the global formula. The assertion for empty boundary is the same equality with an integral over the empty set. $\square$

2.15 The Riemann–Lebesgue measure

Integration of smooth forms suffices for elementary differential geometry, but analysis requires integrating measurable functions and working with convergence, L^p spaces, and weak derivatives. The Riemann–Lebesgue measure extends geometric integration to this setting while retaining, in each chart, the density determined by the metric. It allows us to handle much less regular functions while preserving the intrinsic structure of the manifold.

Definition 2.15.1. Let M be a smooth manifold with or without boundary. A set $A \subseteq M$ is **Lebesgue measurable** if, for every smooth chart (U, φ) of M, the set $\varphi(A \cap U)$ is Lebesgue measurable in $\mathbb{R}^n$. Write

$$\mathcal{L}_M := \{A \subseteq M \mid A \text{ is Lebesgue measurable}\}.$$

Proposition 2.15.2. Let M be a smooth manifold with or without boundary. Then $\mathcal{L}_M$ is a σ-algebra on M containing the Borel sets.

Proof. Let (U, φ) be a chart of M. If $A \in \mathcal{L}_M$, then $\varphi(A \cap U) \in \mathcal{L}(n)$. Since $\mathcal{L}(n)$ is a σ-algebra, we have $\varphi((M \setminus A) \cap U) = \varphi(U) \setminus \varphi(A \cap U) \in \mathcal{L}(n)$, and thus $M \setminus A \in \mathcal{L}_M$. If $(A_k)_{k\in\mathbb{N}} \subseteq \mathcal{L}_M$, then $\varphi(A_k \cap U) \in \mathcal{L}(n)$, so

$$\varphi\left(\left(\bigcup_{k\in\mathbb{N}} A_k\right) \cap U\right) = \varphi\left(\bigcup_{k\in\mathbb{N}} (A_k \cap U)\right) = \bigcup_{k\in\mathbb{N}} \varphi(A_k \cap U) \in \mathcal{L}(n),$$

which implies $\bigcup_{k\in\mathbb{N}} A_k \in \mathcal{L}_M$. Now $\varphi(M \cap U) = \varphi(U) \in \mathcal{L}(n)$ because it is open, so $M \in \mathcal{L}_M$, and we conclude that $\mathcal{L}_M$ is a σ-algebra on M.
Finally, if $O \subseteq M$ is open, then $\varphi(O \cap U) \in \mathcal{L}(n)$ because it is open in $\mathbb{H}^n$. Therefore, $\mathcal{B}(M) \subseteq \mathcal{L}_M$. □

Definition 2.15.3. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary and let (U, φ) be a chart of M. If $A \in \mathcal{L}_M$ and $A \subseteq U$, define $\lambda_{\mathbf{g},U}(A) := \displaystyle\int_{\varphi(A)} \varphi_*\left(\sqrt{\det(\mathbf{g})}\right) d\lambda_n$, where $\varphi_*\left(\sqrt{\det(\mathbf{g})}\right) = \left(\sqrt{\det(\mathbf{g})}\right) \circ \varphi^{-1}$.

Proposition 2.15.4. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary and let $A \in \mathcal{L}_M$.

(a) The definition of $\lambda_{\mathbf{g},U}$ is independent of the chart (U, φ) when $A \subseteq U$.

(b) $\lambda_{\mathbf{g},U}$ defines a measure on the measurable space $(U, (\mathcal{L}_M)\restriction_U)$.

Proof. Let (U, φ) be a chart and write

$$G_\varphi = (g_{ij}), \qquad \rho_\varphi := \sqrt{\det G_\varphi} \circ \varphi^{-1}.$$

The function ρ_φ is continuous and strictly positive on $\varphi(U)$.

(a) Let (U, φ) and (V, ψ) be two charts with $A \subseteq U \cap V$, and let

$$f := \psi \circ \varphi^{-1} \colon \varphi(U \cap V) \longrightarrow \psi(U \cap V)$$

be the change of coordinates. If $G_\psi = (\widetilde{g}_{ab})$ is the matrix of components of $\mathbf{g}$ in the chart ψ, the transformation law for a covariant tensor of order two gives

$$G_\psi(f(x)) = Df(x)^{-\mathsf{T}} G_\varphi(x) Df(x)^{-1}.$$

Taking determinants and square roots gives

$$\rho_\varphi(x) = \rho_\psi(f(x))\,|\det Df(x)|. \tag{2.104}$$

The change-of-variables formula applied to the nonnegative function $\rho_\psi \mathbf{1}_{\psi(A)}$ implies

$$\begin{aligned}\lambda_{\mathbf{g},V}(A) &= \int_{\psi(A)} \rho_\psi(y)\, d\lambda_n(y) \\ &= \int_{\varphi(A)} \rho_\psi(f(x))|\det Df(x)|\, d\lambda_n(x) \\ &= \int_{\varphi(A)} \rho_\varphi(x)\, d\lambda_n(x) = \lambda_{\mathbf{g},U}(A),\end{aligned}$$

where the last equality uses (2.104). Thus the local measure is independent of the chart.

(b) For every Lebesgue measurable set $B \subseteq \varphi(U)$, define

$$\nu_\varphi(B) := \int_B \rho_\varphi\, d\lambda_n.$$

Since $\rho_\varphi \geq 0$ is measurable, ν_φ is a measure: σ-additivity follows by applying the monotone convergence theorem to sums of indicator functions of pairwise disjoint sets. Moreover,

$$\lambda_{\mathbf{g},U}(A) = \nu_\varphi(\varphi(A)), \qquad A \in (\mathcal{L}_M)\restriction_U .$$

Since φ is a measurable bijection with measurable inverse, this identity transfers σ-additivity from ν_φ to $\lambda_{\mathbf{g},U}$. Thus, $\lambda_{\mathbf{g},U}$ is a measure on $(U, (\mathcal{L}_M)\restriction_U)$.

□

Definition 2.15.5. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary. For each $A \in \mathcal{L}_M$, choose a countable atlas $\mathcal{A} = \{(U_k, \varphi_k) \mid k \in \mathbb{N}\}$ of M and define

$$A_0 := A \cap U_0, \qquad A_{k+1} := (A \cap U_{k+1}) \setminus \bigcup_{j=0}^{k} A_j.$$

The sets A_k are measurable, pairwise disjoint, satisfy $A_k \subseteq U_k$, and cover A. Define

$$\lambda_{\mathbf{g}}(A) := \sum_{k=0}^{\infty} \lambda_{\mathbf{g},U_k}(A_k).$$

This function is called the **Riemann–Lebesgue measure** associated with $\mathbf{g}$.

Figure 2.8. The definition does not depend on the orientability of the manifold.

Proposition 2.15.6. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. The definition of $\lambda_{\mathbf{g}}$ is independent of the choice of countable atlas.

Proof. Let $\widetilde{\mathcal{A}}$ be another countable atlas of M. Let $\widetilde{A}_0 := A \cap \widetilde{U}_0$; for each $i \in \mathbb{N}$ with $i \geq 0$, define $\widetilde{A}_{i+1} := (A \cap \widetilde{U}_{i+1}) \setminus \bigcup_{j=0}^{i} \widetilde{A}_j$. By Proposition 2.15.4, $\lambda_{\mathbf{g},U_k}$ and $\lambda_{\mathbf{g},\widetilde{U}_i}$ are measures on U_k and $\widetilde{U}_i$, respectively, so they are σ-additive, and using $\bigcup_{k\in\mathbb{N}} A_k = \bigcup_{i\in\mathbb{N}} \widetilde{A}_i = A$,

$$\lambda_{\mathbf{g},U_k}(A_k) = \lambda_{\mathbf{g},U_k}(A_k \cap A) = \lambda_{\mathbf{g},U_k}\left(A_k \cap \bigcup_{i\in\mathbb{N}} \widetilde{A}_i\right) = \lambda_{\mathbf{g},U_k}\left(\bigcup_{i\in\mathbb{N}} (A_k \cap \widetilde{A}_i)\right) = \sum_{i\in\mathbb{N}} \lambda_{\mathbf{g},U_k}(A_k \cap \widetilde{A}_i).$$

Apply the same decomposition to $\lambda_{\mathbf{g},\widetilde{U}_i}(\widetilde{A}_i) = \sum_{k\in\mathbb{N}} \lambda_{\mathbf{g},\widetilde{U}_i}(\widetilde{A}_i \cap A_k)$. By Proposition 2.15.4, we know that $\lambda_{\mathbf{g},U_k}(A_k \cap \widetilde{A}_i) = \lambda_{\mathbf{g},\widetilde{U}_i}(\widetilde{A}_i \cap A_k)$ since $A_k \cap \widetilde{A}_i \subseteq U_k \cap \widetilde{U}_i$.
Therefore,

$$\sum_{k=0}^{\infty} \lambda_{\mathbf{g},U_k}(A_k) = \sum_{k=0}^{\infty}\sum_{i=0}^{\infty} \lambda_{\mathbf{g},U_k}(A_k \cap \widetilde{A}_i)$$

$$= \sum_{k=0}^{\infty}\sum_{i=0}^{\infty} \lambda_{\mathbf{g},\widetilde{U}_i}(\widetilde{A}_i \cap A_k) = \sum_{i=0}^{\infty}\sum_{k=0}^{\infty} \lambda_{\mathbf{g},\widetilde{U}_i}(\widetilde{A}_i \cap A_k) = \sum_{i=0}^{\infty} \lambda_{\mathbf{g},\widetilde{U}_i}(\widetilde{A}_i).$$

□

The measure $\lambda_{\mathbf{g}}$ agrees with $\lambda_{\mathbf{g},U}$ on measurable sets contained in U:

Proposition 2.15.7. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary and let (U,φ) be a smooth chart. If $A \in \mathcal{L}_M$ and $A \subseteq U$, then $\lambda_{\mathbf{g}}(A) = \lambda_{\mathbf{g},U}(A)$.

Proof. Let $(U_k,\varphi_k)_{k\in\mathbb{N}}$ be a countable atlas of M such that $U_0 = U$. Consider $A_0 = A \cap U_0 = A \cap U = A$ and $A_{k+1} = (A \cap U_{k+1}) \setminus \bigcup_{j=0}^{k} A_j$. We know that $(A_k)_{k\in\mathbb{N}}$ is a sequence of pairwise disjoint measurable sets whose union is A. Since $A_0 = A$, observe that this implies $A_k = \varnothing$ for every $k \geq 1$. Therefore,

$$\lambda_{\mathbf{g}}(A) = \sum_{k=0}^{\infty} \lambda_{\mathbf{g},U_k}(A_k) = \lambda_{\mathbf{g},U_0}(A_0) = \lambda_{\mathbf{g},U}(A).$$

□

Theorem 2.15.8. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary. Then $\lambda_{\mathbf{g}}$ is a complete Radon measure on $(M,\mathcal{L}_M)$.

Proof. Fix a countable atlas $\{(U_j,\varphi_j) \mid j \in \mathbb{N}\}$. For each $B \in \mathcal{L}_M$, set

$$B^{(0)} = B \cap U_0, \qquad B^{(j+1)} = (B \cap U_{j+1}) \setminus \bigcup_{l=0}^{j} B^{(l)}.$$

These pieces are measurable, pairwise disjoint, cover B, and satisfy $B^{(j)} \subseteq U_j$. If (A_k) is a countable family of pairwise disjoint measurable sets and $A = \bigcup_k A_k$, then, for each j,

$$A^{(j)} = \bigcup_k A_k^{(j)},$$

and the union on the right is also disjoint. Countable additivity of the local measures and interchange of two series of nonnegative terms give

$$\begin{aligned}\lambda_{\mathbf{g}}(A) &= \sum_{j=1}^{\infty} \lambda_{\mathbf{g},U_j}(A^{(j)}) = \sum_{j=1}^{\infty}\sum_{k=1}^{\infty} \lambda_{\mathbf{g},U_j}(A_k^{(j)}) \\ &= \sum_{k=1}^{\infty}\sum_{j=1}^{\infty} \lambda_{\mathbf{g},U_j}(A_k^{(j)}) = \sum_{k=1}^{\infty} \lambda_{\mathbf{g}}(A_k).\end{aligned}$$

Moreover, $\lambda_{\mathbf{g}}(\varnothing) = 0$; therefore, $\lambda_{\mathbf{g}}$ is a measure.
We first establish local regularity. In a chart (U,φ), the local measure is the transport by φ of the measure

$$\nu(B) = \int_B w \, d\lambda_n, \qquad w = \varphi_* \sqrt{\det(\mathbf{g})},$$

on the relatively open set $\varphi(U) \subseteq \mathbb{H}^n$. The function w is continuous and strictly positive. Take an increasing sequence of relatively compact open sets W_m whose union is $\varphi(U)$. On each $\overline{W}_m$, the function w has a finite upper bound and a positive lower bound. Regularity of Lebesgue measure, applied on each W_m, then shows

that for every measurable set $B \subseteq \varphi(U)$,

$$\nu(B) = \sup\{\nu(K) \mid K \subseteq B, K \text{ compact}\} = \inf\{\nu(O) \mid B \subseteq O, O \text{ open in } \varphi(U)\}.$$

Indeed, for inner approximation, first choose m so that $\nu(B \setminus W_m)$ is small and then a compact set $K \subseteq B \cap W_m$ whose complement has small Lebesgue measure; the upper bound for w turns this last estimate into an estimate for ν. If $\nu(B) = \infty$, the same argument applied to $B \cap W_m$ gives compact sets of arbitrarily large measure. For outer approximation, decompose B into the measurable sets $B \cap (W_m \setminus W_{m-1})$ and, again using the upper bound for w on $\overline{W}_m$, choose for the mth piece an open set whose excess has measure less than $\frac{\varepsilon}{2^{m+1}}$. The union of these open sets contains B and its total excess has measure less than ε.

We may choose the countable atlas so that each U_j is a precompact coordinate domain with bounded image and $\lambda_{\mathbf{g}}(U_j) < \infty$. For $A \in \mathcal{L}_M$, let (A_j) be the disjoint pieces associated with this atlas. If $\lambda_{\mathbf{g}}(A) < \infty$ and $\varepsilon > 0$, choose N so that

$$\sum_{j>N} \lambda_{\mathbf{g}}(A_j) < \frac{\varepsilon}{2}.$$

Local regularity gives compact sets $K_j \subseteq A_j$, for $0 \le j \le N$, such that

$$\sum_{j=0}^{N} \lambda_{\mathbf{g}}(A_j \setminus K_j) < \frac{\varepsilon}{2}.$$

The finite union $K = \bigcup_{j=0}^{N} K_j$ is compact, is contained in A, and satisfies $\lambda_{\mathbf{g}}(A \setminus K) < \varepsilon$. If $\lambda_{\mathbf{g}}(A) = \infty$, first take a partial sum greater than a given number and approximate its terms from within; this gives compact sets contained in A of arbitrarily large measure. This proves inner regularity.

For outer regularity, we need only consider $\lambda_{\mathbf{g}}(A) < \infty$. For each j, use local regularity to choose an open subset O_j of M such that

$$A_j \subseteq O_j \subseteq U_j, \qquad \lambda_{\mathbf{g}}(O_j \setminus A_j) < \frac{\varepsilon}{2^{j+1}}.$$

Then $O = \bigcup_j O_j$ is open, contains A, and

$$\lambda_{\mathbf{g}}(O \setminus A) \le \sum_{j=1}^{\infty} \lambda_{\mathbf{g}}(O_j \setminus A_j) < \varepsilon.$$

If $\lambda_{\mathbf{g}}(A) = \infty$, every open set containing A has infinite measure. This proves outer regularity.

Finally, every point has a coordinate domain V with compact closure contained in another coordinate domain. The function w is bounded on the image of this closure, and $\varphi(V)$ can be chosen bounded; therefore, $\lambda_{\mathbf{g}}(V) < \infty$. The measure is locally finite. It is also complete: if $N \subseteq Z$ and $\lambda_{\mathbf{g}}(Z) = 0$, positivity of w and its lower bounds on compact sets imply that $\varphi(Z \cap U)$ has Lebesgue measure zero in every chart. Every subset of this set is Lebesgue measurable and has local measure zero, so $N \in \mathcal{L}_M$ and $\lambda_{\mathbf{g}}(N) = 0$. We conclude that $\lambda_{\mathbf{g}}$ is a Radon measure on the indicated measurable space. □

Remark 2.15.9. The expression $\int_M f \, d\lambda_{\mathbf{g}}$ denotes the Lebesgue integral with respect to the measure $\lambda_{\mathbf{g}}$. For every continuous compactly supported function,

$$\int_M f \, d\lambda_{\mathbf{g}} = \int_M f \, \boldsymbol{\mu}_{\mathbf{g}}.$$

If M is oriented and $dV_{\mathbf{g}}$ corresponds to the chosen orientation, $\boldsymbol{\mu}_{\mathbf{g}}$ is the density associated with $dV_{\mathbf{g}}$, and therefore

$$\int_M f \, d\lambda_{\mathbf{g}} = \int_M f \, dV_{\mathbf{g}}.$$

Thus, $dV_{\mathbf{g}}$, $\boldsymbol{\mu}_{\mathbf{g}}$, and $d\lambda_{\mathbf{g}}$ denote, respectively, a form, a density, and the differential notation for a measure.

Local finiteness of the Riemann–Lebesgue measure has the following consequence:

Remark 2.15.10. Let $(M, \mathbf{g})$ be a compact Riemannian manifold with or without boundary. Then $\lambda_{\mathbf{g}}(M) < \infty$.

Proof. Since M is compact and $\lambda_{\mathbf{g}}$ is locally finite, we can find a finite open cover of M, say $M = \bigcup_{j=0}^{N} U_j$, such that $\lambda_{\mathbf{g}}(U_j) < \infty$ for every $j \in \{0, \dots, N\}$.
Then

$$\lambda_{\mathbf{g}}(M) \leq \sum_{j=0}^{N} \lambda_{\mathbf{g}}(U_j) < \infty.$$

□

For later analytic applications, we will explicitly need the Borel completion and σ-finiteness of the Riemann–Lebesgue measure.

Lemma 2.15.11. (Borel completion and σ-finiteness of the Riemann–Lebesgue measure) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary and let $\lambda_{\mathbf{g}}$ be the associated Riemann–Lebesgue measure. Then

$$\mathcal{L}_M = \overline{\mathcal{B}(M)}^{\lambda_{\mathbf{g}}},$$

where the right-hand side denotes the completion of the Borel σ-algebra with respect to $\lambda_{\mathbf{g}}$. Moreover, $(M, \mathcal{L}_M, \lambda_{\mathbf{g}})$ is σ-finite.

Proof. By Proposition 1.2.11, we may choose a countable cover $(U_j, \varphi_j)_{j \in \mathbb{N}}$ by regular coordinate balls and, in the boundary case, by the corresponding regular coordinate half-balls, so that $\overline{U_j}$ is compact for every j.
We first prove equality of the σ-algebras. The inclusion $\overline{\mathcal{B}(M)}^{\lambda_{\mathbf{g}}} \subseteq \mathcal{L}_M$ follows from Theorem 2.15.8: $\mathcal{B}(M) \subseteq \mathcal{L}_M$ and $\lambda_{\mathbf{g}}$ is complete on $\mathcal{L}_M$.
For the reverse inclusion, take $A \in \mathcal{L}_M$ and form the disjoint decomposition

$$A_0 := A \cap U_0, \qquad A_j := (A \cap U_j) \setminus \bigcup_{i=0}^{j-1} A_i, \qquad j \geq 1.$$

Then $A = \bigcup_{j=0}^{\infty} A_j$, each A_j belongs to $\mathcal{L}_M$, and $A_j \subseteq U_j$. By the definition of $\mathcal{L}_M$, $\varphi_j(A_j)$ is Lebesgue measurable in $\varphi_j(U_j)$. Since the Lebesgue σ-algebra of a Euclidean open set or a relatively open subset of the half-space is the completion of its Borel σ-algebra, there exist a Borel set $B_j \subseteq \varphi_j(U_j)$ and a set of Lebesgue measure zero $N_j \subseteq \varphi_j(U_j)$ such that

$$\varphi_j(A_j) \triangle B_j \subseteq N_j.$$

Since $\overline{U_j}$ is compact, the coordinate density $\sqrt{\det(\mathbf{g})} \circ \varphi_j^{-1}$ is bounded above and, on the compact sets exhausting $\varphi_j(U_j)$, is also bounded away from zero. In particular, every set of Lebesgue measure zero in $\varphi_j(U_j)$ has preimage of $\lambda_{\mathbf{g}}$-measure zero. Therefore,

$$Z_j := \varphi_j^{-1}(N_j)$$

is $\lambda_{\mathbf{g}}$-null. Moreover, $C_j := \varphi_j^{-1}(B_j)$ is Borel in U_j and, since U_j is open, it is Borel in M. Defining

$$C := \bigcup_{j=0}^{\infty} C_j, \qquad Z := \bigcup_{j=0}^{\infty} Z_j,$$

gives $C \in \mathcal{B}(M)$, $\lambda_{\mathbf{g}}(Z) = 0$, and

$$A \triangle C \subseteq Z.$$

Thus, A belongs to the completion of $\mathcal{B}(M)$, proving

$$\mathcal{L}_M \subseteq \overline{\mathcal{B}(M)}^{\lambda_{\mathbf{g}}}.$$

It remains to prove σ-finiteness. For each j, compactness of $\overline{U_j}$ and local finiteness of $\lambda_{\mathbf{g}}$ imply

$$\lambda_{\mathbf{g}}(U_j) \leq \lambda_{\mathbf{g}}(\overline{U_j}) < \infty.$$

Since $M = \bigcup_{j=0}^{\infty} U_j$, the measure $\lambda_{\mathbf{g}}$ is σ-finite. □

The remaining properties of the Riemann–Lebesgue measure are left as an exercise:

Exercise 2.15.12. (Basic properties of the Riemann–Lebesgue measure) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary and let $\lambda_{\mathbf{g}}$ be the associated Riemann–Lebesgue measure.

(a) Prove that $\lambda_{\mathbf{g}}$ is complete, that is, if $A \subset M$ is measurable and $\lambda_{\mathbf{g}}(A) = 0$, then every subset of A is measurable.

(b) Let (U, φ) be a coordinate chart. Prove that if $A \subset U$ satisfies $\lambda_{\mathbf{g}}(A) = 0$, then $\lambda_n\big(\varphi(A)\big) = 0$ in $\mathbb{R}^n$, where λ_n denotes Lebesgue measure on $\mathbb{R}^n$.

(c) Prove that a function $f : M \longrightarrow \mathbb{R}$ is $\mathcal{L}_M$-measurable if and only if, for every chart (U, φ), the function

$$f \circ \varphi^{-1} : \varphi(U) \longrightarrow \mathbb{R}$$

is λ_n-measurable on $\varphi(U) \subset \mathbb{R}^n$.

(d) Prove that if $U \subset M$ is nonempty and open, then $\lambda_{\mathbf{g}}(U) > 0$.

(e) Let $(M, \mathbf{g})$ be orientable and let $dV_{\mathbf{g}}$ be the Riemannian volume form associated with an orientation. Prove that, for every continuous compactly supported function,

$$\int_M f \, d\lambda_{\mathbf{g}} = \int_M f \, dV_{\mathbf{g}}.$$

2.16 Gradient, divergence, and the Laplace–Beltrami operator

The gradient, divergence, and Laplace–Beltrami operator form the basic differential vocabulary of Riemannian analysis. They generalize familiar Euclidean operations, but their intrinsic definitions show exactly where the metric, connection, and measure enter. In Chapter 8, after defining the general notion of a differential operator on bundles, we will verify that these constructions are examples of it. These operations will be used to formulate the elliptic equations, energy identities, and geometric flows of later chapters.

We first define the gradient of a scalar function $f : M \longrightarrow \mathbb{R}$.

The covariant derivative of f equals the covector df. To obtain a vector field, we must raise this index with the metric. In the Euclidean case, this identification is expressed by

$$\langle \operatorname{grad} f, \mathbf{X} \rangle_{\mathbf{g}} = \mathbf{X}(f),$$

and leads to the following intrinsic definition.

Definition 2.16.1. Let $(M, \mathbf{g})$ be a Riemannian manifold (with or without boundary). For a function $f : M \longrightarrow \mathbb{R}$ of class C^1, the *gradient* of f is the unique continuous vector field $\operatorname{grad}(f) \in \Gamma^0(TM)$ such that

$$\langle \operatorname{grad}(f), \mathbf{X} \rangle_{\mathbf{g}} = df(\mathbf{X}) \quad \text{for every } \mathbf{X} \in \mathfrak{X}(M).$$

That is, $\operatorname{grad}(f) = (df)^\sharp$, where $^\sharp : T^*M \longrightarrow TM$ is the musical isomorphism induced by $\mathbf{g}$ given in Definition 2.1.10.

Remark 2.16.2. (Local expression for the gradient) Let (U, φ) be a chart with coordinates $(x^1, \ldots, x^n)$. In this chart, the differential of f is written as

$$df = \partial_j f \, \mathbf{d}x^j, \qquad \partial_j f = \frac{\partial (f \circ \varphi^{-1})}{\partial x^j}.$$

Applying the musical isomorphism $^\sharp : T^*M \longrightarrow TM$ gives

$$(df)^\sharp = g^{ij} \partial_j f \, \partial_i.$$

The gradient satisfies the Leibniz rule, just as the differential of a function does:

Proposition 2.16.3. (Leibniz rule for the gradient) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary. If $f,g\in C^1(M)$, then

$$\operatorname{grad}(fg)=f\operatorname{grad}(g)+g\operatorname{grad}(f).$$

Proof. For every smooth vector field $\mathbf{X}$,

$$\begin{aligned}\langle\operatorname{grad}(fg),\mathbf{X}\rangle &= d(fg)(\mathbf{X})=f\,dg(\mathbf{X})+g\,df(\mathbf{X})\\ &=\langle f\operatorname{grad}g+g\operatorname{grad}f,\mathbf{X}\rangle.\end{aligned}$$

Nondegeneracy of the metric gives equality of the fields. □

Divergence of a vector field is a central notion in vector calculus. We introduce its analogue on Riemannian manifolds:

Definition 2.16.4. Let $(M,\mathbf{g})$ be a Riemannian manifold (with or without boundary) and let $\mathbf{X}$ be a vector field of class C^1. Define the *divergence* of $\mathbf{X}$ by

$$\operatorname{div}(\mathbf{X})=\operatorname{tr}(\nabla\mathbf{X}),$$

where tr denotes the natural contraction of a tensor of type $(1,1)$ in its two indices. In a local orthonormal frame $(\mathbf{e}_1,\dots,\mathbf{e}_n)$, we recover the classical expression

$$\operatorname{div}(\mathbf{X})=\sum_{i=1}^{n}\mathbf{g}(\nabla_{\mathbf{e}_i}\mathbf{X},\mathbf{e}_i).$$

In local coordinates, we have the following:

Proposition 2.16.5. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary and let $\mathbf{X}=X^i\partial_i$ be a vector field of class C^1. In local coordinates $(x^1,\dots,x^n)$, we have

$$\operatorname{div}(\mathbf{X})=\frac{1}{\sqrt{\det(\mathbf{g})}}\partial_i\left(\sqrt{\det(\mathbf{g})}X^i\right).$$

Proof. By definition, divergence is the trace of $\nabla\mathbf{X}$:

$$\operatorname{div}(\mathbf{X})=\operatorname{tr}(\nabla\mathbf{X}).$$

In local coordinates $(x^1,\dots,x^n)$ with coordinate frame $\partial_j=\partial_j$, we have

$$\nabla_{\partial_j}\mathbf{X}=(\partial_jX^i+\Gamma^i_{jk}X^k)\partial_i,\quad\text{that is}\quad(\nabla_j\mathbf{X})^i=\partial_jX^i+\Gamma^i_{jk}X^k.$$

Taking the trace of $\nabla\mathbf{X}$ means contracting the covariant differentiation index j with the contravariant index i, which in index notation is written as

$$\operatorname{div}(\mathbf{X})=\nabla_iX^i.$$

Substituting the expression for $(\nabla_j \mathbf{X})^i$ gives

$$\operatorname{div}(\mathbf{X}) = \partial_i X^i + \Gamma^i_{ik} X^k.$$

We now use the identity

$$\Gamma^i_{ik} = \frac{1}{\sqrt{\det(\mathbf{g})}} \partial_k \big(\sqrt{\det(\mathbf{g})}\big),$$

obtained in Remark 2.14.7.
Substituting into the expression for $\operatorname{div}(\mathbf{X})$ gives

$$\operatorname{div}(\mathbf{X}) = \partial_i X^i + \frac{1}{\sqrt{\det(\mathbf{g})}} \partial_k \big(\sqrt{\det(\mathbf{g})}\big) X^k.$$

Applying the Leibniz rule to the product $\sqrt{\det(\mathbf{g})} X^i$,

$$\partial_i \big(\sqrt{\det(\mathbf{g})} X^i\big) = \sqrt{\det(\mathbf{g})} \partial_i X^i + X^i \partial_i \sqrt{\det(\mathbf{g})},$$

and dividing by $\sqrt{\det(\mathbf{g})}$ gives

$$\frac{1}{\sqrt{\det(\mathbf{g})}} \partial_i \big(\sqrt{\det(\mathbf{g})} X^i\big) = \partial_i X^i + \frac{1}{\sqrt{\det(\mathbf{g})}} \partial_i \big(\sqrt{\det(\mathbf{g})}\big) X^i.$$

Comparing with the preceding expression yields the compact formula

$$\operatorname{div}(\mathbf{X}) = \frac{1}{\sqrt{\det(\mathbf{g})}} \partial_i \big(\sqrt{\det(\mathbf{g})} X^i\big),$$

as desired. □

Divergence satisfies the following Leibniz rule:

Proposition 2.16.6. (Leibniz rule for divergence) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. Then, for every $\mathbf{X} \in \mathfrak{X}(M)$ and every $f \in C^\infty(M)$,

$$\operatorname{div}(f\mathbf{X}) = f \operatorname{div}(\mathbf{X}) + \langle \operatorname{grad}(f), \mathbf{X} \rangle_{\mathbf{g}}.$$

Proof. In an orthonormal frame $(\mathbf{e}_i)$,

$$\begin{aligned} \operatorname{div}(f\mathbf{X}) &= \sum_{i=1}^n \langle \nabla_{\mathbf{e}_i}(f\mathbf{X}), \mathbf{e}_i \rangle \\ &= \sum_{i=1}^n \mathbf{e}_i(f) \langle \mathbf{X}, \mathbf{e}_i \rangle + f \sum_{i=1}^n \langle \nabla_{\mathbf{e}_i} \mathbf{X}, \mathbf{e}_i \rangle \\ &= \langle \operatorname{grad} f, \mathbf{X} \rangle + f \operatorname{div} \mathbf{X}. \end{aligned}$$

□

The definition extends naturally to tensor fields of type (k, l):

Definition 2.16.7. Let $(M,\mathbf{g})$ be a Riemannian manifold (with or without boundary) and let $\mathbf{F} \in \Gamma(T^{(k,l)}(TM))$ with $k \geq 1$. Define

$$\operatorname{div}(\mathbf{F}) \in \Gamma(T^{(k-1,l)}(TM))$$

to be the contraction of the differentiation index of $\nabla\mathbf{F}$ with the first contravariant index of $\mathbf{F}$. In index notation,

$$(\operatorname{div}\mathbf{F})^{i_2\ldots i_k}_{j_1\ldots j_l} = \nabla_a F^{ai_2\ldots i_k}_{j_1\ldots j_l}.$$

Proposition 2.16.8. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary. In local coordinates $(x^1,\ldots,x^n)$, if

$$\mathbf{F} = F^{i_1\ldots i_k}_{j_1\ldots j_l}\partial_{i_1}\otimes\cdots\otimes\partial_{i_k}\otimes \mathbf{d}x^{j_1}\otimes\cdots\otimes\mathbf{d}x^{j_l},$$

then its divergence is given by

$$(\operatorname{div}\mathbf{F})^{i_2\ldots i_k}_{j_1\ldots j_l} = \partial_a F^{ai_2\ldots i_k}_{j_1\ldots j_l} + \sum_{r=2}^{k}\Gamma^{i_r}_{am}F^{ai_2\ldots m\ldots i_k}_{j_1\ldots j_l} - \sum_{s=1}^{l}\Gamma^{m}_{aj_s}F^{ai_2\ldots i_k}_{j_1\ldots m\ldots j_l} + \Gamma^{a}_{am}F^{mi_2\ldots i_k}_{j_1\ldots j_l}.$$

Proof. The expression follows by applying the definition

$$(\operatorname{div}\mathbf{F})^{i_2\ldots i_k}_{j_1\ldots j_l} = \nabla_a F^{ai_2\ldots i_k}_{j_1\ldots j_l}.$$

By Corollary 2.4.20, in local coordinates,

$$(\nabla_a\mathbf{F})^{i_1\ldots i_k}_{j_1\ldots j_l} = \partial_a F^{i_1\ldots i_k}_{j_1\ldots j_l} + \sum_{r=1}^{k}\Gamma^{i_r}_{am}F^{i_1\ldots m\ldots i_k}_{j_1\ldots j_l} - \sum_{s=1}^{l}\Gamma^{m}_{aj_s}F^{i_1\ldots i_k}_{j_1\ldots m\ldots j_l}.$$

Contracting the differentiation index a with the first contravariant index i_1 gives

$$(\operatorname{div}\mathbf{F})^{i_2\ldots i_k}_{j_1\ldots j_l} = \nabla_a F^{ai_2\ldots i_k}_{j_1\ldots j_l}.$$

Substituting into the preceding expression gives

$$(\operatorname{div}\mathbf{F})^{i_2\ldots i_k}_{j_1\ldots j_l} = \partial_a F^{ai_2\ldots i_k}_{j_1\ldots j_l} + \sum_{r=1}^{k}\Gamma^{i_r}_{am}F^{ai_2\ldots m\ldots i_k}_{j_1\ldots j_l} - \sum_{s=1}^{l}\Gamma^{m}_{aj_s}F^{ai_2\ldots i_k}_{j_1\ldots m\ldots j_l}.$$

In the summand with $r=1$, we have

$$\Gamma^{i_1}_{am}F^{mi_2\ldots i_k}_{j_1\ldots j_l} = \Gamma^{a}_{am}F^{mi_2\ldots i_k}_{j_1\ldots j_l},$$

which produces the last term. Rearranging, we finally obtain

$$(\operatorname{div}\mathbf{F})^{i_2\ldots i_k}_{j_1\ldots j_l} = \partial_a F^{ai_2\ldots i_k}_{j_1\ldots j_l} + \sum_{r=2}^{k}\Gamma^{i_r}_{am}F^{ai_2\ldots m\ldots i_k}_{j_1\ldots j_l} - \sum_{s=1}^{l}\Gamma^{m}_{aj_s}F^{ai_2\ldots i_k}_{j_1\ldots m\ldots j_l} + \Gamma^{a}_{am}F^{mi_2\ldots i_k}_{j_1\ldots j_l}.$$

□

The Laplacian is defined by the property that characterizes it in Euclidean space: it is the divergence of the gradient of a function.

Definition 2.16.9. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary and let $f : M \longrightarrow \mathbb{R}$ be a function of class C^2. The *Laplace–Beltrami operator* is defined by

$$\Delta_{\mathbf{g}} f := \operatorname{div}(\operatorname{grad} f).$$

Remark 2.16.10. First recall that the gradient of f is the vector field characterized by

$$\mathbf{g}(\operatorname{grad} f, \mathbf{X}) = df(\mathbf{X}), \qquad \mathbf{X} \in \mathfrak{X}(M).$$

In local coordinates $(x^1,\dots,x^n)$, this becomes

$$\operatorname{grad} f = g^{ij}\partial_j f\, \partial_i,$$

where (g^{ij}) are the entries of the inverse metric matrix.
Applying the definition of divergence now gives, in coordinates,

$$\operatorname{div}(\mathbf{X}) = \frac{1}{\sqrt{\det(\mathbf{g})}}\partial_i\big(\sqrt{\det(\mathbf{g})}X^i\big).$$

Substituting $\mathbf{X} = \operatorname{grad} f$ with components $X^i = g^{ij}\partial_j f$, we obtain

$$\Delta_{\mathbf{g}} f = \operatorname{div}(\operatorname{grad} f) = \frac{1}{\sqrt{\det(\mathbf{g})}}\partial_i\big(\sqrt{\det(\mathbf{g})}g^{ij}\partial_j f\big).$$

Thus the local coordinate expression for the Laplace–Beltrami operator is

$$\Delta_{\mathbf{g}} f = \frac{1}{\sqrt{\det(\mathbf{g})}}\partial_i\left(\sqrt{\det(\mathbf{g})}g^{ij}\partial_j f\right).$$

Combining the Leibniz rules for the gradient and divergence gives the following rule for the Laplacian of the product of two functions:

Proposition 2.16.11. (Leibniz rule for the Laplacian) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary. If $f, g \in C^\infty(M)$, then

$$\Delta_{\mathbf{g}}(fg) = f\Delta_{\mathbf{g}} g + 2\langle \operatorname{grad}(f), \operatorname{grad}(g)\rangle_{\mathbf{g}} + g\Delta_{\mathbf{g}} f.$$

Proof. By the two preceding Leibniz rules,

$$\begin{aligned}\Delta_{\mathbf{g}}(fg) &= \operatorname{div}\big(f\operatorname{grad} g + g\operatorname{grad} f\big)\\ &= f\Delta_{\mathbf{g}} g + \langle \operatorname{grad} f, \operatorname{grad} g\rangle + g\Delta_{\mathbf{g}} f + \langle \operatorname{grad} g, \operatorname{grad} f\rangle.\end{aligned}$$

Symmetry of $\mathbf{g}$ combines the two cross terms. □

2.17 Clifford geometry and spin structures

At this point, we have developed Lie groups and Lie algebras, vector bundles, principal bundles, associated bundles, and principal connections. These are precisely the geometric ingredients needed to construct spinor bundles and their connection. We will not yet define an operator associated with these data: contraction of a Clifford connection will be studied after developing the general theory of differential operators; its symbol will be computed only after symbols have been defined, and its pseudodifferential interpretation is reserved for the corresponding chapter.

Throughout this section, we use the convention

$$vw + wv = -2\mathbf{g}(v,w)1.$$

The constructions and conventions may be compared with [92, Chapter I, §§1–6; Chapter II, §§1 and 3–5] and [21, Chapter 17].

Clifford and spinors

In the nineteenth century, William Kingdon Clifford introduced an algebra combining the metric with exterior multiplication. Representations of this algebra give rise to spinors, objects that encode the geometry of the spin group linearly. On a Riemannian manifold, a spin structure allows these representations to be globalized and the Levi–Civita connection to be lifted to the spinor bundle. This geometric construction will underlie the operators appearing in later chapters.

2.17.1 Clifford algebras

Definition 2.17.1. (Clifford algebra) Let $(V,\mathbf{g})$ be a real Euclidean space of dimension n. Its *real Clifford algebra* is the unital quotient

$$\mathrm{Cl}(V,\mathbf{g}) := T(V)\big/\langle v\otimes v + \mathbf{g}(v,v)1 \mid v\in V\rangle.$$

Identify V with its image in the quotient. The complexification is

$$\mathrm{Cl}_{\mathbb{C}}(V,\mathbf{g}) := \mathrm{Cl}(V,\mathbf{g})\otimes_{\mathbb{R}}\mathbb{C}.$$

For the standard Euclidean space, we write Cl_n and $\mathrm{Cl}_n^{\mathbb{C}}$.

Polarization of $v^2 = -|v|_{\mathbf{g}}^2 1$ gives

$$vw + wv = -2\mathbf{g}(v,w)1, \qquad v^2 = -|v|_{\mathbf{g}}^2 1. \tag{2.105}$$

Proposition 2.17.2. (Universal property) Let A be a real unital associative algebra and let $q\colon V\to A$ be a linear map such that

$$q(v)^2 = -|v|_{\mathbf{g}}^2 1_A \qquad (v\in V).$$

There exists a unique unital algebra homomorphism $\widehat{q}\colon \mathrm{Cl}(V,\mathbf{g})\to A$ whose restriction to V is q.

Proof. The universal property of the tensor algebra extends q uniquely to a unital homomorphism $T(V) \to A$. Every generator $v \otimes v + |v|^2 1$ of the defining ideal belongs to its kernel. The homomorphism therefore factors through the quotient. Since $\mathrm{Cl}(V, \mathbf{g})$ is generated by V and the unit, this factorization is unique. □

Proposition 2.17.3. (Basis, grading, and reversion) If $(e_1, \dots, e_n)$ is an orthonormal basis of V, then

$$1, \qquad e_{i_1} \cdots e_{i_k}, \qquad 1 \le i_1 < \cdots < i_k \le n,$$

form a basis of $\mathrm{Cl}(V, \mathbf{g})$. In particular, $\dim_{\mathbb{R}} \mathrm{Cl}(V, \mathbf{g}) = 2^n$. Moreover:

(a) the automorphism α determined by $\alpha(v) = -v$ induces the intrinsic grading

$$\mathrm{Cl}(V, \mathbf{g}) = \mathrm{Cl}^0(V, \mathbf{g}) \oplus \mathrm{Cl}^1(V, \mathbf{g}),$$

given by the eigenspaces of α with eigenvalues 1 and -1;

(b) there exists a unique antiautomorphism τ, called *reversion*, such that $\tau(v) = v$ for every $v \in V$, and

$$\tau(v_1 \cdots v_k) = v_k \cdots v_1.$$

Proof. The relations $e_i^2 = -1$ and $e_i e_j = -e_j e_i$ for $i \neq j$ allow us to order any word and show that the indicated monomials span the algebra. To prove their independence, define on $\Lambda^\bullet V$

$$c_\Lambda(v) := \varepsilon(v) - \iota_v,$$

where $\varepsilon(v)$ is exterior multiplication and ι_v is contraction using $\mathbf{g}$. The identities between contraction and exterior product give $c_\Lambda(v)^2 = -|v|^2 I$; the universal property yields a Clifford representation. If $I = (i_1 < \cdots < i_k)$, then

$$c_\Lambda(e_{i_1}) \cdots c_\Lambda(e_{i_k}) 1 = e_{i_1} \wedge \cdots \wedge e_{i_k}.$$

The forms on the right constitute a basis of $\Lambda^\bullet V$, so the Clifford monomials are linearly independent.
The automorphism of $T(V)$ multiplying a tensor of degree k by $(-1)^k$ preserves the defining ideal and descends to α. Its two eigenspaces give the stated direct sum. Similarly, reversing the order of factors in $T(V)$ preserves the ideal and descends to the antiautomorphism τ. In both cases, uniqueness follows because V generates the algebra. □

2.17.2 The groups $\mathrm{Pin}(n)$ and $\mathrm{Spin}(n)$

Definition 2.17.4. (Pin and spin groups) Let $S(V) = \{v \in V : |v|_{\mathbf{g}} = 1\}$. Define

$$\mathrm{Pin}(V, \mathbf{g}) := \{v_1 \cdots v_k : k \ge 0,\ v_j \in S(V)\} \subseteq \mathrm{Cl}(V, \mathbf{g})^\times$$

and

$$\mathrm{Spin}(V, \mathbf{g}) := \mathrm{Pin}(V, \mathbf{g}) \cap \mathrm{Cl}^0(V, \mathbf{g}).$$

The empty product is 1. For $V = \mathbb{R}^n$, write $\mathrm{Pin}(n)$ and $\mathrm{Spin}(n)$.

Every unit vector satisfies $v^{-1} = -v$. In particular, the preceding sets are groups. The parity of a product of unit vectors is well-defined because the Clifford grading is a direct sum.

Theorem 2.17.5. (Cartan–Dieudonné) Every transformation $A \in \mathrm{O}(V, \mathbf{g})$ is a composition of at most n reflections in hyperplanes through the origin. The parity of the number of reflections agrees with the sign of $\det A$.

Proof. Proceed by induction on n. The result is immediate if $n = 0$. Let x be a unit vector. If $Ax = x$, then A preserves $x^{\perp}$ and the induction hypothesis applies to $A|_{x^{\perp}}$. If $Ax \neq x$, set

$$u := \frac{Ax - x}{|Ax - x|}.$$

For the reflection $r_u(y) = y - 2\mathbf{g}(y, u)u$, one verifies directly that $r_u(Ax) = x$. Hence $r_u A$ preserves $x^{\perp}$ and is a product of at most $n - 1$ reflections in that subspace. Since $r_u^2 = I$, this gives a factorization of A with at most n reflections. Finally, each reflection has determinant -1, which determines the parity. □

For a homogeneous element a of the Clifford algebra, define its twisted adjoint action on V by

$$\widetilde{\rho}(a)w := \alpha(a) w a^{-1}.$$

If v is a unit vector, the Clifford relations give

$$\widetilde{\rho}(v)w = (-v)w(-v) = w - 2\mathbf{g}(v, w)v = r_v(w).$$

Lemma 2.17.6. (Group of units of a finite-dimensional algebra) If A is a finite-dimensional real unital associative algebra, its group of units $A^{\times}$ is open in A and, with this manifold structure, is a Lie group.

Proof. For $a \in A$, let $L_a \in \mathrm{End}_{\mathbb{R}}(A)$ be left multiplication. The element a is a unit if and only if L_a is invertible. Indeed, if L_a is bijective, there exists b with $ab = 1$; moreover, $L_a(ba - 1) = (ab)a - a = 0$, and injectivity gives $ba = 1$. In a basis of A, the entries of L_a depend linearly on a, so

$$A^{\times} = \{a \in A : \det L_a \neq 0\}$$

is open. Multiplication is bilinear and, since $a^{-1} = L_a^{-1}(1)$, the matrix formula for the inverse proves that $a \mapsto a^{-1}$ is smooth. □

Proposition 2.17.7. (The pin group) For $n \geq 1$, the preceding formula defines a surjective homomorphism

$$\widetilde{\rho}\colon \mathrm{Pin}(n) \longrightarrow \mathrm{O}(n)$$

with kernel $\{\pm 1\}$. The group $\mathrm{Pin}(n)$ is a compact subgroup of $\mathrm{Cl}_n^{\times}$ and hence a Lie group. $\mathrm{Spin}(n)$ is a compact Lie subgroup.

Proof. Multiplicativity of α shows that $\widetilde{\rho}$ is a homomorphism. Its surjectivity follows from Theorem 2.17.5 and the calculation of reflections.

Let a be a homogeneous element of the kernel. If a is even, it commutes with every vector; if it is odd, it

anticommutes with every vector. Write a in the basis of Proposition 2.17.3. For a monomial e_I of degree k, we have

$$e_I e_j = (-1)^k e_j e_I \quad (j \notin I), \qquad e_I e_j = (-1)^{k-1} e_j e_I \quad (j \in I).$$

Comparing coefficients shows that the only even element commuting with all the e_j is a scalar, and that no nonzero odd element anticommutes with all of them. Thus, $a = \lambda 1$. Since an element of the kernel is even, it can be written as a product of an even number of unit vectors; consequently, $a^{-1} = \tau(a)$. Reversion fixes scalars, so $\lambda^{-1} = \lambda$ and $\lambda = \pm 1$.

If $a \in \mathrm{Pin}(n)$, Cartan–Dieudonné gives a product $b = v_1 \cdots v_k$, with $k \le n$, having the same orthogonal image. The kernel calculation gives $a = \pm b$. Consequently, $\mathrm{Pin}(n)$ is the finite union of the images of the compact sets

$$\{\pm 1\} \times S(\mathbb{R}^n)^k, \qquad 0 \le k \le n,$$

under Clifford multiplication. It is compact and, in particular, closed in the open Lie group $\mathrm{Cl}_n^\times$. The closed subgroup theorem gives it a Lie group structure. Finally, $\mathrm{Spin}(n) = \mathrm{Pin}(n) \cap \mathrm{Cl}_n^0$ is a closed subgroup of $\mathrm{Pin}(n)$ and is also a compact Lie group. □

On the even part, $\alpha(a) = a$, so the twisted adjoint action is ordinary conjugation.

Theorem 2.17.8. (Spin covering map) For $n \ge 1$, the formula

$$\rho\colon \mathrm{Spin}(n) \longrightarrow \mathrm{SO}(n), \qquad \rho(a)v = ava^{-1},$$

defines a surjective Lie group homomorphism with kernel $\{\pm 1\}$. Its Lie algebra is

$$\mathfrak{spin}(n) = \mathrm{span}_{\mathbb{R}} \left\{ \frac{1}{2} e_i e_j : 1 \le i < j \le n \right\},$$

and

$$d\rho\left(\frac{1}{2} e_i e_j\right) e_i = e_j, \qquad d\rho\left(\frac{1}{2} e_i e_j\right) e_j = -e_i,$$

while the action vanishes on the remaining basis vectors. In particular, $d\rho\colon \mathfrak{spin}(n) \to \mathfrak{so}(n)$ is an isomorphism and ρ is a two-sheeted covering map:

$$1 \longrightarrow \{\pm 1\} \longrightarrow \mathrm{Spin}(n) \xrightarrow{\rho} \mathrm{SO}(n) \longrightarrow 1.$$

Proof. Proposition 2.17.7 shows that the restriction to the even part takes values in $\mathrm{SO}(n)$, is surjective, and has kernel $\{\pm 1\}$. For $i < j$, the curve

$$\gamma_{ij}(t) = \exp\left(\frac{t}{2} e_i e_j\right) = \cos\frac{t}{2} + \sin\frac{t}{2}\, e_i e_j$$

belongs to $\mathrm{Spin}(n)$; indeed,

$$\cos\frac{t}{2} + \sin\frac{t}{2}\, e_i e_j = (-e_i)\left(\cos\frac{t}{2}\, e_i - \sin\frac{t}{2}\, e_j\right)$$

is a product of two unit vectors. Differentiating $\rho(\gamma_{ij}(t))v = \gamma_{ij}(t)v\gamma_{ij}(t)^{-1}$ at $t=0$ gives

$$d\rho\left(\frac{1}{2}e_ie_j\right)v = \left[\frac{1}{2}e_ie_j, v\right],$$

from which the stated formulas follow. Their images form the usual basis of $\mathfrak{so}(n)$.
On the other hand, $d\rho$ is injective: if X is in its kernel, then $\rho(\exp(tX)) = \exp(t\,d\rho(X)) = I$ for every t, and discreteness of $\{\pm 1\}$ forces $X = 0$. Thus the preceding bivectors span all of $\mathfrak{spin}(n)$, and $d\rho$ is an isomorphism. The inverse function theorem gives a neighborhood W of 1 in $\mathrm{Spin}(n)$ on which ρ is a diffeomorphism onto a neighborhood U of I. Shrinking W if necessary, W and $-W$ are disjoint. Since each fiber is a coset of $\{\pm 1\}$, $\rho^{-1}(U) = W \sqcup (-W)$, and both restrictions are diffeomorphisms onto U. Translations give the same description around every point of $\mathrm{SO}(n)$. This is precisely the property of being a two-sheeted covering map. □

2.17.3 Complex spinor modules

The following classification is included to fix the dimensions, grading, and Hermitian conventions.

Proposition 2.17.9. (Classification of complex Clifford algebras) For $m \geq 0$, there exist complex algebra isomorphisms

$$\mathrm{Cl}^{\mathbb{C}}_{2m} \cong \mathrm{End}(\mathbb{C}^{2^m}), \qquad \mathrm{Cl}^{\mathbb{C}}_{2m+1} \cong \mathrm{End}(\mathbb{C}^{2^m}) \oplus \mathrm{End}(\mathbb{C}^{2^m}).$$

Proof. The base cases are $\mathrm{Cl}^{\mathbb{C}}_0 = \mathbb{C}$ and

$$\mathrm{Cl}^{\mathbb{C}}_1 \cong \mathbb{C}[t]/(t^2+1) \cong \mathbb{C} \oplus \mathbb{C}.$$

For the induction step, consider

$$J = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \qquad A = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad B = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}.$$

We have $A^2 = B^2 = -I$, $J^2 = I$, and every pair of distinct matrices anticommutes. If $e_1, \dots, e_n$ are the generators of $\mathrm{Cl}^{\mathbb{C}}_n$, the assignments

$$e_j \longmapsto e_j \otimes J, \qquad e_{n+1} \longmapsto 1 \otimes A, \qquad e_{n+2} \longmapsto 1 \otimes B$$

satisfy the Clifford relations and define a homomorphism

$$\mathrm{Cl}^{\mathbb{C}}_{n+2} \longrightarrow \mathrm{Cl}^{\mathbb{C}}_n \otimes M_2(\mathbb{C}).$$

The matrices I, A, B, J generate $M_2(\mathbb{C})$; moreover, once $1 \otimes J$ has been obtained, $e_j \otimes 1$ can be recovered. Thus the homomorphism is surjective. Both sides have complex dimension 2^{n+2} by Proposition 2.17.3, so it is an isomorphism. Induction gives the two formulas. □

Proposition 2.17.10. (Complex spinor modules) If $n = 2m$, there exists, up to equivalence, a unique irreducible module Σ_n over $\mathrm{Cl}_n^{\mathbb{C}}$, and $\dim_{\mathbb{C}} \Sigma_n = 2^m$. If $n = 2m+1$, there are two irreducible modules of dimension 2^m; their restrictions to $\mathrm{Spin}(n)$ are equivalent, and we fix one of the two Clifford extensions as Σ_n.

In even dimension, for an oriented orthonormal basis, define

$$\omega_{\mathbb{C}} := i^m c(e_1)\cdots c(e_{2m}). \tag{2.106}$$

This endomorphism is independent of the chosen basis, satisfies $\omega_{\mathbb{C}}^2 = I$, and determines the chiral decomposition

$$\Sigma_n = \Sigma_n^+ \oplus \Sigma_n^-, \qquad \Sigma_n^{\pm} = \ker(\omega_{\mathbb{C}} \mp I).$$

Multiplication by a vector interchanges the two summands. In every dimension, a Hermitian inner product can be chosen for which

$$c(v)^* = -c(v), \qquad v \in \mathbb{R}^n. \tag{2.107}$$

The spin representation is

$$\rho_\Sigma \colon \mathrm{Spin}(n) \longrightarrow \mathrm{U}(\Sigma_n), \qquad \rho_\Sigma(a) = c(a).$$

Proof. Proposition 2.17.9 and the elementary classification of irreducible modules over a matrix algebra prove the assertions on existence, uniqueness, and dimension. In odd dimension, the even algebra is identified with the complex Clifford algebra in dimension $2m$; this is why the two representations restricted to $\mathrm{Spin}(2m+1)$ are equivalent.

The Clifford relation allows us to reverse the order of the $2m$ factors in (2.106) and gives $\omega_{\mathbb{C}}^2 = I$. An oriented orthonormal change of basis multiplies the alternating product by its determinant, which is one; hence the element is independent of the basis. Moving a vector past the other $2m-1$ factors introduces a negative sign, so $\omega_{\mathbb{C}}$ anticommutes with $c(v)$, and the latter interchanges the two eigenspaces.

By Proposition 2.17.7, we may average any Hermitian inner product over $\mathrm{Pin}(n)$. For the resulting inner product, $c(v)$ is unitary when v is a unit vector. Since $c(v)^{-1} = -c(v)$, we obtain $c(v)^* = -c(v)$; homogeneity extends the identity to every vector. The restriction to $\mathrm{Spin}(n)$ is unitary and defines ρ_Σ. □

Conjugation in the algebra gives the fundamental equivariance identity

$$\rho_\Sigma(a)c(v)\rho_\Sigma(a)^{-1} = c(\rho(a)v), \qquad a \in \mathrm{Spin}(n),\ v \in \mathbb{R}^n. \tag{2.108}$$

2.17.4 The orthonormal frame bundle and spin structures

Let $(M^n, \mathbf{g})$ be a smooth oriented Riemannian manifold with or without boundary. Define

$$\mathbf{P}_{\mathrm{SO}}(M)_x := \{p \colon \mathbb{R}^n \to T_xM : p \text{ is an orientation-preserving linear isometry}\}.$$

The right action is $p \cdot A = p \circ A$. A local oriented orthonormal frame $(\mathbf{e}_1, \dots, \mathbf{e}_n)$ identifies p with the matrix $A \in \mathrm{SO}(n)$ determined by $p(e_j^{\mathrm{est}}) = \sum_{i=1}^{n} A_i{}^j \mathbf{e}_i$. These charts make $\mathbf{P}_{\mathrm{SO}}(M) \to M$ a principal bundle with group $\mathrm{SO}(n)$, called

the *oriented orthonormal frame bundle*. Evaluation induces a bundle isomorphism

$$\mathbf{P}_{\mathrm{SO}}(M)\times_{\mathrm{SO}(n)}\mathbb{R}^n \longrightarrow TM, \qquad [p,v]\longmapsto p(v). \tag{2.109}$$

Indeed, the relation $[pA,v]=[p,Av]$ proves that the map is well-defined, and on each fiber it is a bijective linear isometry.

Definition 2.17.11. (Spinorial structure, or spin structure) A *spinorial structure*, also called a *spin structure*, on $(M,\mathbf{g})$ consists of a right principal bundle $\mathbf{P}_{\mathrm{Spin}}(M)\to M$ with group $\mathrm{Spin}(n)$ and a smooth map

$$\Lambda\colon \mathbf{P}_{\mathrm{Spin}}(M)\longrightarrow \mathbf{P}_{\mathrm{SO}}(M)$$

covering id_M and satisfying

$$\Lambda(p\cdot a)=\Lambda(p)\cdot\rho(a). \tag{2.110}$$

Two structures are equivalent if there exists a principal bundle isomorphism commuting with their maps Λ. An oriented Riemannian manifold is called *spin* if it admits a spin structure; when speaking of its spinors, an equivalence class of such structures is assumed to have been chosen.

In principal trivializations, the identity (2.110) shows that Λ has the form $(x,a)\mapsto(x,b(x)\rho(a))$. By Theorem 2.17.8, Λ is a two-sheeted covering map restricting on each fiber to the spin map. Existence of these data is not automatic. Appendix A, after introducing the necessary characteristic classes, proves the topological existence criterion and classifies spin structures.

Definition 2.17.12. (Spinor bundle and Clifford multiplication) Let $(M,\mathbf{g})$ be a spin manifold with a chosen structure. Its *complex spinor bundle* is the associated bundle

$$\Sigma M := \mathbf{P}_{\mathrm{Spin}}(M)\times_{\rho_\Sigma}\Sigma_n.$$

For $\xi\in T^*_xM$, $p\in\mathbf{P}_{\mathrm{Spin}}(M)_x$, and $\psi\in\Sigma_n$, let $v=\Lambda(p)^{-1}(\xi^\sharp)\in\mathbb{R}^n$. *Clifford multiplication* is defined by

$$c(\xi)[p,\psi]:=[p,c(v)\psi]. \tag{2.111}$$

The definition is independent of the representative. Indeed, replacing p by pa changes the coordinates of $\xi^\sharp$ and the spinor to $\rho(a)^{-1}v$ and $\rho_\Sigma(a)^{-1}\psi$; the identity (2.108) gives the same class. Therefore, (2.111) defines a smooth bundle homomorphism

$$c\colon \mathrm{Cl}_{\mathbb{C}}(T^*M,\mathbf{g}^{-1})\longrightarrow \mathrm{End}(\Sigma M)$$

and, for real covectors,

$$c(\xi)c(\eta)+c(\eta)c(\xi)=-2\mathbf{g}^{-1}(\xi,\eta)I, \qquad c(\xi)^*=-c(\xi). \tag{2.112}$$

If $n=2m$, chirality is invariant under $\mathrm{Spin}(n)$ and gives

$$\Sigma M=\Sigma^+M\oplus\Sigma^-M;$$

multiplication by a covector is odd with respect to this grading.

2.17.5 The spin connection

Denote by ω^{SO} the Levi–Civita principal connection form on $\mathbf{P}_{\mathrm{SO}}(M)$. Since $d\rho$ is an isomorphism, we may define

$$\omega^{\mathrm{Spin}} := (d\rho)^{-1}\Lambda^{*}\omega^{\mathrm{SO}}. \tag{2.113}$$

Proposition 2.17.13. (Spin connection) The form (2.113) is the unique principal connection on $\mathbf{P}_{\mathrm{Spin}}(M)$ that projects to the Levi–Civita connection. The associated connection ∇^{Σ} is Hermitian, preserves the grading in even dimension, and satisfies

$$\nabla^{\Sigma}_{\mathbf{X}}\big(c(\xi)\psi\big) = c(\nabla_{\mathbf{X}}\xi)\psi + c(\xi)\nabla^{\Sigma}_{\mathbf{X}}\psi. \tag{2.114}$$

If $(\mathbf{e}_1,\dots,\mathbf{e}_n)$ is an oriented orthonormal frame admitting a local spin lift and

$$\omega_{ij}(\mathbf{X}) := \mathbf{g}(\nabla_{\mathbf{X}}\mathbf{e}_i,\mathbf{e}_j),$$

then, in this trivialization,

$$\big(\nabla^{\Sigma}_{\mathbf{X}}\psi\big)^{\wedge} = \mathbf{X}(\widehat{\psi}) + \frac{1}{4}\sum_{i,j=1}^{n}\omega_{ij}(\mathbf{X})c(e_i)c(e_j)\widehat{\psi}. \tag{2.115}$$

Proof. The pullback $\Lambda^{*}\omega^{\mathrm{SO}}$ reproduces vertical fields after applying $d\rho$ and is equivariant under the adjoint action. Since $d\rho$ intertwines the adjoint representations, its composition with $(d\rho)^{-1}$ satisfies the two axioms of a principal connection form. Any connection projecting to Levi–Civita must have this form, which proves uniqueness.

The calculation in Theorem 2.17.8 identifies the element of $\mathfrak{spin}(n)$ corresponding to the skew-symmetric matrix (ω_{ij}) with $\frac{1}{4}\sum_{i,j=1}^{n}\omega_{ij}e_ie_j$. The local formula for associated connections gives (2.115). Each $c(e_i)c(e_j)$, with $i \neq j$, is skew-adjoint, so the connection is Hermitian. The complex volume element is invariant under $\mathrm{Spin}(n)$ and parallel; hence the grading is preserved. Finally, differentiating the equivariance identity (2.108), or substituting the local formula directly, gives (2.114). □

2.17.6 Clifford modules and connections

The later analytic construction requires only the structure just obtained, without necessarily requiring a global spin structure.

Definition 2.17.14. (Hermitian Clifford module) A *Hermitian Clifford module* over $(M,\mathbf{g})$ is a complex Hermitian bundle $\mathbf{S} \to M$ with a smooth unital homomorphism of algebra bundles

$$c\colon \mathrm{Cl}_{\mathbb{C}}(T^{*}M,\mathbf{g}^{-1}) \longrightarrow \mathrm{End}(\mathbf{S})$$

such that $c(\xi)^{*} = -c(\xi)$ for every real covector ξ. Equivalently, it suffices to give a smooth linear map $c\colon T^{*}M \to \mathrm{End}(\mathbf{S})$ satisfying (2.112); the equivalence is the Clifford universal property applied fiberwise.

A Hermitian connection $\nabla^{\mathbf{S}}$ is a *Clifford connection* if

$$\nabla^{\mathbf{S}}_X(c(\xi)\mathbf{s}) = c(\nabla_X\xi)\mathbf{s} + c(\xi)\nabla^{\mathbf{S}}_X\mathbf{s}. \tag{2.116}$$

If $\mathbf{S} = \mathbf{S}^+ \oplus \mathbf{S}^-$ is graded, we also require the connection to preserve the grading and $c(\xi)$ to be odd.

The bundle ΣM with ∇^{Σ} is the fundamental spinorial example.

Example 2.17.15. (Differential forms) Every Riemannian manifold, whether spin or not, has the graded module

$$\mathbf{S} = \Lambda^\bullet T^*M \otimes \mathbb{C}, \qquad c(\xi) = \varepsilon(\xi) - \iota_{\xi^\sharp}.$$

The identities

$$\iota_{\xi^\sharp}\varepsilon(\eta) + \varepsilon(\eta)\iota_{\xi^\sharp} = \mathbf{g}^{-1}(\xi,\eta)I$$

prove the Clifford relation. For the Hermitian inner product induced by $\mathbf{g}$, we have $\varepsilon(\xi)^* = \iota_{\xi^\sharp}$, so $c(\xi)^* = -c(\xi)$. The connection induced by Levi–Civita commutes with exterior product and contraction in the sense of the Leibniz rule; it is therefore a Clifford connection. The grading is the parity of forms.

2.17.7 Spin^c structures

Definition 2.17.16. (The group $\mathrm{Spin}^c(n)$) Define the compact Lie group

$$\mathrm{Spin}^c(n) := \big(\mathrm{Spin}(n) \times \mathrm{U}(1)\big)/\{(1,1),(-1,-1)\}.$$

The homomorphisms

$$\rho_c[a,z] = \rho(a), \qquad \det_c[a,z] = z^2$$

take values in $\mathrm{SO}(n)$ and $\mathrm{U}(1)$, respectively. The complex spin representation is

$$\rho^c_\Sigma[a,z] = z\rho_\Sigma(a). \tag{2.117}$$

All three formulas are well-defined on the quotient: replacing (a,z) by $(-a,-z)$ changes none of them, since $\rho(-a) = \rho(a)$ and $\rho_\Sigma(-1) = -I$. The quotient by the finite central subgroup inherits a Lie group structure. Indeed, the action of $\{(1,1),(-1,-1)\}$ by translations is free and, since the group is finite, properly discontinuous. A sufficiently small neighborhood of each point is disjoint from its nontrivial translate; its projection to the quotient is a chart, and in these charts the induced multiplication and inversion are smooth.

Definition 2.17.17. (Spin^c structure) A Spin^c *structure* on $(M,\mathbf{g})$ consists of a principal bundle $\mathbf{P}_{\mathrm{Spin}^c}(M) \to M$ and a map

$$\Lambda_c : \mathbf{P}_{\mathrm{Spin}^c}(M) \longrightarrow \mathbf{P}_{\mathrm{SO}}(M)$$

covering the identity and satisfying $\Lambda_c(pa) = \Lambda_c(p)\rho_c(a)$. Its *determinant line* and *spinor bundle* are, respectively,

$$\mathbf{L} := \mathbf{P}_{\mathrm{Spin}^c}(M) \times_{\det_c} \mathbb{C}, \qquad \Sigma^c M := \mathbf{P}_{\mathrm{Spin}^c}(M) \times_{\rho^c_\Sigma} \Sigma_n.$$

The equivariance identity (2.108) proves, exactly as in the spin case, that

$$c(\xi)[p,\psi] := [p, c(\Lambda_c(p)^{-1}\xi^\sharp)\psi]$$

defines Clifford multiplication on $\Sigma^c M$. In even dimension, it gives the grading $\Sigma^{c,+}M \oplus \Sigma^{c,-}M$.

A unitary connection on $\mathbf{L}$, together with the Levi–Civita connection, uniquely determines a principal connection on $\mathbf{P}_{\mathrm{Spin}^c}(M)$. Indeed, the Lie algebra map

$$(d\rho_c, d\det_c)\colon \mathfrak{spin}^c(n) \longrightarrow \mathfrak{so}(n) \oplus i\mathbb{R}$$

is an isomorphism: on the first factor it is $d\rho$, and on the second, the differential of $z \mapsto z^2$ is multiplication by 2. The pullbacks of the two connection forms, followed by the inverse of this isomorphism, give the desired principal connection. The associated connection on $\Sigma^c M$ is Hermitian and Clifford by the same argument as in Proposition 2.17.13.

The topological existence criterion is stated and proved, after the required characteristic classes have been introduced, in Theorem A.8.3 of Appendix A.

We have thus constructed the purely geometric data: the spin group and its covering map, spin structures, spinor bundles, Clifford multiplication, and their connections. In Chapter 8, a Clifford connection will be contracted to obtain a differential operator. Its symbol will be studied in Chapter 11, and its pseudodifferential symbol, with the appropriate Fourier convention, only in Chapter 15.

Part II

Nonlinear analysis in Euclidean spaces

Introduction to Part II

When an estimate on a manifold is proved within a chart, we are ultimately using a result formulated on an open subset of $\mathbb{R}^n$. Before returning to geometry, it is therefore useful to develop the Euclidean model carefully and determine which tools depend on the linear structure of the space, which survive a change of coordinates, and which can later be localized using cutoff functions.

Sobolev spaces arise when derivatives are allowed to be understood in the weak sense. Distributions extend this idea further, making it possible to treat singularities and data that are not ordinary functions. The Fourier transform allows differentiation and regularity to be studied from the frequency viewpoint. Interpolation theory then provides a common language for comparing different levels of regularity and leads naturally to the Bessel, Slobodeckij, Besov, and Triebel–Lizorkin scales. Orders of regularity are thus no longer restricted to integers.

This part supplies many of the tools that will later be used with almost no change to their mathematical substance: Sobolev inequalities, Rellich–Kondrashov compactness, multipliers, changes of variables, extension operators, convolutions, and localization arguments. On returning to a manifold, what changes is how these tools are transported and how the constants are controlled. The Euclidean work in these chapters makes it possible to distinguish clearly what belongs to analysis from what geometry must provide.

From classical solutions to weak solutions

For a long time, solving a differential equation meant finding a sufficiently differentiable function that satisfied it pointwise. Twentieth-century analysis decisively broadened this idea. Sobolev incorporated weak derivatives into normed spaces; Schwartz constructed a stable theory of distributions; Calderón and Zygmund developed fundamental tools of harmonic analysis; Gagliardo and Slobodeckij studied noninteger regularity; and Lions, Peetre, and Triebel organized broad scales of function spaces. These theories did not replace classical solutions: they made it possible to begin with less regularity and understand the conditions under which it could later be recovered.

3

Sobolev spaces on open subsets of $\mathbb{R}^n$

Sobolev spaces arise naturally in the Dirichlet problem for the Poisson equation. Let $\Omega \subseteq \mathbb{R}^n$ be an open subset and consider

$$-\Delta u = f \quad \text{on } \Omega, \qquad u = 0 \quad \text{on } \partial\Omega.$$

Suppose for the moment that u and φ are smooth, that u satisfies the boundary condition, and that φ is a test function vanishing on the boundary. Integration by parts gives

$$\int_\Omega \nabla u \cdot \nabla \varphi \, dx = \int_\Omega f \varphi \, dx.$$

This identity does not require classical second derivatives of u: it is enough for u and its gradient to have suitable integrability. This leads to weak derivatives, to $W^{1,2}(\Omega)$, and to the subspace $W_0^{1,2}(\Omega)$ that encodes the Dirichlet condition. The trace provides an interpretation of boundary values, while the Poincaré inequality, embeddings, and compactness theorems provide the estimates needed to solve the problem.

The same equation is obtained as the critical point condition for the functional

$$\mathcal{E}(u) = \frac{1}{2} \int_\Omega |\nabla u|^2 \, dx - \int_\Omega f u \, dx.$$

Indeed, its Euler–Lagrange equation is precisely the preceding weak identity. This relationship between a PDE and an energy will serve as the model for the variational methods developed at the end of the book.

The nonlinear problem

$$-\operatorname{div}\left(|\nabla u|^{p-2} \nabla u\right) = f$$

is formally associated with

$$\mathcal{E}_p(u) = \frac{1}{p} \int_\Omega |\nabla u|^p \, dx - \int_\Omega f u \, dx.$$

This example leads to $W^{1,p}(\Omega)$ and shows why convexity and reflexivity matter in the study of minimizing sequences. The theory of the p-Laplacian will not be developed here; it will guide the definitions and estimates in this chapter.

Sobolev and the shift toward weak regularity

In the 1930s, Sergei Sobolev showed that the regularity useful for an equation need not coincide with classical pointwise differentiability. By incorporating weak derivatives into normed spaces, he made it possible to combine integration by parts, completeness, and regularity estimates within a single framework. His embedding theorems also explain a central phenomenon in analysis: a certain degree of integrability of the derivatives forces a function to gain integrability, continuity, or even Hölder regularity. This chapter develops these ideas in the Euclidean setting before transferring them to manifolds and vector bundles [136].

3.1 Weak derivatives

We begin with the elementary formula that motivates the definition.

Proposition 3.1.1. (Integration by parts) If $f \in C^1(\Omega)$ and $\varphi \in C_c^1(\Omega)$, then

$$\int_\Omega \frac{\partial f}{\partial x_i}\varphi + \int_\Omega f\frac{\partial \varphi}{\partial x_i} = 0$$

for every $i \in \{1,\dots,n\}$.

Proof. The extension of φ by zero belongs to $C_c^1(\mathbb{R}^n)$, since the support of φ is a compact subset of Ω. We may therefore work in $\mathbb{R}^n$. Choose $M > 0$ such that $\operatorname{supp}(\varphi) \subset (-M,M)^n$. For $i = 1$ and each $\widehat{x} = (x_2,\dots,x_n) \in \mathbb{R}^{n-1}$, Theorem B.6.5 gives

$$\int_{-M}^{M} \frac{\partial \varphi}{\partial x_1}(x_1,\widehat{x})\,dx_1 = \varphi(M,\widehat{x}) - \varphi(-M,\widehat{x}) = 0.$$

Theorem B.6.18 allows us to integrate with respect to the remaining variables and conclude that $\int_\Omega \frac{\partial \varphi}{\partial x_1} = 0$. The other indices are treated in the same way. Applying this identity to $f\varphi \in C_c^1(\Omega)$ and using the product rule, we obtain

$$0 = \int_\Omega \frac{\partial (f\varphi)}{\partial x_i} = \int_\Omega \frac{\partial f}{\partial x_i}\varphi + \int_\Omega f\frac{\partial \varphi}{\partial x_i}.$$

□

The preceding identity suggests the following definition.

Definition 3.1.2. Let $u \in L^1_{\mathrm{loc}}(\Omega)$. We say that u is **weakly differentiable on** Ω if there exist $v_1,\dots,v_n \in L^1_{\mathrm{loc}}(\Omega)$ such that

$$\int_\Omega u\frac{\partial \varphi}{\partial x_i} + \int_\Omega v_i\varphi = 0$$

for every $\varphi \in C_c^\infty(\Omega)$ and every $i \in \{1,\dots,n\}$. Each v_i is called the ***i*th weak derivative of** u **on** Ω and is denoted by $D_i u$.

Differential operators constructed from partial derivatives thus admit a weak version. In particular, one can define the weak gradient, the weak Laplacian, and, analogously, higher-order operators.

Remark 3.1.3. If $v, w \in L^1_{\mathrm{loc}}(\Omega)$ satisfy

$$\int_\Omega u \frac{\partial \varphi}{\partial x_i} = -\int_\Omega v\varphi \quad \text{and} \quad \int_\Omega u \frac{\partial \varphi}{\partial x_i} = -\int_\Omega w\varphi \qquad \forall \varphi \in C_c^\infty(\Omega),$$

then $v = w$ a.e. (by Proposition B.6.20).

The weak derivative agrees with the classical derivative whenever the latter exists. If $u \in C^1(\Omega)$, Proposition 3.1.1 gives

$$\int_\Omega \frac{\partial u}{\partial x_i}\varphi + \int_\Omega u \frac{\partial \varphi}{\partial x_i} = 0$$

so that u is weakly differentiable and

$$D_i u = \frac{\partial u}{\partial x_i} \ \forall i \in \{1, \dots, n\}.$$

Weak derivatives have the following elementary properties.

Proposition 3.1.4. (a) If $u, v \in L^1_{\mathrm{loc}}(\Omega)$ are weakly differentiable and $\lambda, \mu \in \mathbb{R}$, then $\lambda u + \mu v$ is weakly differentiable and

$$D_i(\lambda u + \mu v) = \lambda D_i u + \mu D_i v$$

for each $i \in \{1, \dots, n\}$.

(b) If $u \in L^1_{\mathrm{loc}}(\Omega)$ is weakly differentiable on Ω and $\zeta \in C_c^\infty(\Omega)$, then the extension of ζu by zero is weakly differentiable on $\mathbb{R}^n$ and

$$D_i(\zeta u) = \frac{\partial \zeta}{\partial x_i} u + \zeta D_i u$$

Proof. (a) For each $i \in \{1, \dots, n\}$ and $\varphi \in C_c^\infty(\Omega)$,

$$\int_\Omega \left[(\lambda u + \mu v) \frac{\partial \varphi}{\partial x_i} + (\lambda D_i u + \mu D_i v)\varphi \right] = \lambda \int_\Omega \left[u \frac{\partial \varphi}{\partial x_i} + (D_i u)\varphi \right] + \mu \int_\Omega \left[v \frac{\partial \varphi}{\partial x_i} + (D_i v)\varphi \right] = 0$$

where the second equality uses the weak differentiability of u and v. This proves that $\lambda u + \mu v$ is weakly differentiable and $D_i(\lambda u + \mu v) = \lambda D_i u + \mu D_i v$.

(b) Let $\varphi \in C_c^\infty(\mathbb{R}^n)$. Then $\zeta\varphi \in C_c^\infty(\Omega)$ and

$$\int_{\mathbb{R}^n} \zeta u \frac{\partial \varphi}{\partial x_i} + \int_{\mathbb{R}^n} \left(\zeta D_i u + u \frac{\partial \zeta}{\partial x_i} \right) \varphi = \int_\Omega u \frac{\partial (\zeta\varphi)}{\partial x_i} + \int_\Omega (D_i u)(\zeta\varphi) = 0.$$

□

A function whose weak derivatives vanish retains the constancy property of differentiable functions with zero differential.

Lemma 3.1.5. (Functions with vanishing weak derivatives) Let $\Omega \subseteq \mathbb{R}^n$ be an open subset and let $v \in L^1_{\mathrm{loc}}(\Omega)$ be weakly differentiable. If

$$D_j v = 0 \qquad \text{almost everywhere on } \Omega, \quad j \in \{1, \dots, n\}, \tag{3.1}$$

then v is constant almost everywhere on each connected component of Ω.

Proof. It suffices to consider the case in which Ω is connected and nonempty. Fix a ball $B = B_{\mathrm{euc}}(x_0, r)$ with $\overline{B} \subseteq \Omega$. Choose $R > r$ such that $\overline{B_{\mathrm{euc}}(x_0, R)} \subseteq \Omega$. Let ρ be the mollifier from Theorem B.9.1 and, for $0 < \varepsilon < R - r$, define

$$v_\varepsilon(x) := \int_\Omega v(y)\rho_\varepsilon(x-y)\,dy, \qquad x \in B.$$

For each $x \in B$, the function $y \mapsto \rho_\varepsilon(x-y)$ has compact support in $B_{\mathrm{euc}}(x_0, R)$. The local integrability of v and part (a) of that theorem allow differentiation under the integral. Applying the definition of weak derivative to this test function, we obtain

$$\begin{aligned}\partial_j v_\varepsilon(x) &= \int_\Omega v(y)\partial_{x_j}\rho_\varepsilon(x-y)\,dy \\ &= -\int_\Omega v(y)\partial_{y_j}\rho_\varepsilon(x-y)\,dy \\ &= \int_\Omega D_j v(y)\rho_\varepsilon(x-y)\,dy = 0.\end{aligned}$$

Therefore, v_ε is smooth and has zero differential on the connected ball B, so that $v_\varepsilon = c_\varepsilon$ on B for some constant $c_\varepsilon \in \mathbb{R}$.

Part (b) of Theorem B.9.1, applied with $p = 1$ and the compact set $\overline{B}$, gives $v_\varepsilon \to v$ in $L^1(B)$. Set

$$c_B := \frac{1}{\lambda_n(B)} \int_B v\,d\lambda_n.$$

Since $v_\varepsilon = c_\varepsilon$ on B,

$$|c_\varepsilon - c_B| \le \frac{1}{\lambda_n(B)} \|v_\varepsilon - v\|_{L^1(B)} \longrightarrow 0.$$

Consequently,

$$\|v - c_B\|_{L^1(B)} \le \|v - v_\varepsilon\|_{L^1(B)} + \lambda_n(B)|c_\varepsilon - c_B| \longrightarrow 0,$$

and $v = c_B$ almost everywhere on B.

If two relatively compact balls in Ω intersect, their intersection is a nonempty open set and has positive measure. The corresponding constants agree, since both equal v almost everywhere on that intersection. Thus, we can define $c(x) := c_B$ using any ball $B \Subset \Omega$ containing x. This function is well defined and locally constant. Since Ω is connected, it has a single value $c \in \mathbb{R}$.

Finally, second countability of Ω allows us to choose a countable cover by such balls. On each ball, $v = c$ outside a set of measure zero; the countable union of these sets also has measure zero. Therefore, $v = c$ almost everywhere on Ω. □

3.2 Sobolev spaces

The notion of weak derivative allows us to define Sobolev spaces on open subsets of $\mathbb{R}^n$.

Definition 3.2.1. Let $p \in [1, \infty]$. The **Sobolev space** $W^{1,p}(\Omega)$ is defined by

$$W^{1,p}(\Omega) := \{u \in L^p(\Omega) \mid u \text{ is weakly differentiable on } \Omega \text{ and } D_i u \in L^p(\Omega) \text{ for every } i \in \{1, \dots, n\}\}.$$

We introduce the normed structure as follows.

Definition 3.2.2. Let $p \in [1,\infty]$. For $u \in W^{1,p}(\Omega)$, define

$$\|u\|_{W^{1,p}(\Omega)} := \begin{cases} (\|u\|_{L^p(\Omega)}^p + \sum_{i=1}^n \|D_i u\|_{L^p(\Omega)}^p)^{\frac{1}{p}} & \text{if } p \in [1,\infty) \\ \max\{\|u\|_{L^\infty(\Omega)}, \|D_1 u\|_{L^\infty(\Omega)}, \dots, \|D_n u\|_{L^\infty(\Omega)}\} & \text{if } p = \infty \end{cases}$$

The preceding expression defines a norm on $W^{1,p}(\Omega)$.

Proposition 3.2.3. $W^{1,p}(\Omega)$ is a real vector space and $\|\cdot\|_{W^{1,p}(\Omega)}$ is a norm on $W^{1,p}(\Omega)$ for every $p \in [1,\infty]$.

Proof. By Proposition 3.1.4, $W^{1,p}(\Omega)$ is a vector subspace of $L^p(\Omega)$, and hence is a vector space. Now, given $u \in W^{1,p}(\Omega)$, if $u = 0$, then $D_i u = 0$ for every $i \in \{1,\dots,n\}$, so that $\|u\|_{W^{1,p}(\Omega)} = 0$. Conversely, if $\|u\|_{W^{1,p}(\Omega)} = 0$, since $\|u\|_{L^p(\Omega)} \le \|u\|_{W^{1,p}(\Omega)}$, we have $u = 0$ in $L^p(\Omega)$.
We have $\|\lambda u\|_{W^{1,p}(\Omega)} = |\lambda| \|u\|_{W^{1,p}(\Omega)}$ for any $u \in W^{1,p}(\Omega)$ and $\lambda \in \mathbb{R}$.
Finally, if $p \in [1,\infty)$, applying first Minkowski's inequality in $L^p(\Omega)$, given in Theorem B.7.3, and then the triangle inequality for the $\|\cdot\|_p$ norm on $\mathbb{R}^{n+1}$, we obtain, for any $u, v \in W^{1,p}(\Omega)$,

$$\begin{aligned} \|u+v\|_{W^{1,p}(\Omega)} &\le \left((\|u\|_{L^p(\Omega)} + \|v\|_{L^p(\Omega)})^p + \sum_{i=1}^n (\|D_i u\|_{L^p(\Omega)} + \|D_i v\|_{L^p(\Omega)})^p \right)^{\frac{1}{p}} \\ &\le \left(\|u\|_{L^p(\Omega)}^p + \sum_{i=1}^n \|D_i u\|_{L^p(\Omega)}^p \right)^{\frac{1}{p}} + \left(\|v\|_{L^p(\Omega)}^p + \sum_{i=1}^n \|D_i v\|_{L^p(\Omega)}^p \right)^{\frac{1}{p}} \\ &= \|u\|_{W^{1,p}(\Omega)} + \|v\|_{W^{1,p}(\Omega)}. \end{aligned}$$

If $p = \infty$, the triangle inequality follows in exactly the same way from the triangle inequality for the $\|\cdot\|_\infty$ norm on $L^\infty(\Omega)$ and that for the $\|\cdot\|_\infty$ norm on $\mathbb{R}^{n+1}$. □

The following lemma will be particularly useful for working with Sobolev spaces, both in Euclidean spaces and later on Riemannian manifolds.

Lemma 3.2.4. Let $p \in [1,\infty]$ and let (u_k) be a sequence in $W^{1,p}(\Omega)$ such that $u_k \to u$ in $L^p(\Omega)$ and $D_i u_k \to v_i$ in $L^p(\Omega)$ for each $i \in \{1,\dots,n\}$. Then u is weakly differentiable on Ω, $v_i = D_i u$ for every $i \in \{1,\dots,n\}$, and $u_k \to u$ in $W^{1,p}(\Omega)$.

Proof. Let $\varphi \in C_c^\infty(\Omega)$. Then $\varphi, \dfrac{\partial \varphi}{\partial x_i} \in L^q(\Omega)$ for every $q \in [1,\infty]$. Let $q > 1$ be such that $\dfrac{1}{p} + \dfrac{1}{q} = 1$ if $p \in (1,\infty)$, $q = 1$ if $p = \infty$, and $q = \infty$ if $p = 1$. By Hölder's inequality (Proposition B.7.9), we have

$$\left| \int_\Omega u \frac{\partial \varphi}{\partial x_i} - \int_\Omega u_k \frac{\partial \varphi}{\partial x_i} \right| \le \|u - u_k\|_{L^p(\Omega)} \left\| \frac{\partial \varphi}{\partial x_i} \right\|_{L^q(\Omega)} \to 0 \text{ as } k \to \infty,$$

$$\left| \int_\Omega v_i \varphi - \int_\Omega (D_i u_k) \varphi \right| \le \|v_i - D_i u_k\|_{L^p(\Omega)} \|\varphi\|_{L^q(\Omega)} \to 0 \text{ as } k \to \infty.$$

Consequently,

$$\int_\Omega u\frac{\partial\varphi}{\partial x_i}+\int_\Omega v_i\varphi=\lim_{k\to\infty}\left(\int_\Omega u_k\frac{\partial\varphi}{\partial x_i}+\int_\Omega (D_iu_k)\varphi\right)=0$$

for each $i\in\{1,\dots,n\}$. This proves that u is weakly differentiable on Ω and that $v_i=D_iu$. Consequently, $u\in W^{1,p}(\Omega)$. Moreover, if $p\in[1,\infty)$, we have

$$\lim_{k\to\infty}\|u_k-u\|^p_{W^{1,p}(\Omega)}=\lim_{k\to\infty}\|u_k-u\|^p_{L^p(\Omega)}+\sum_{i=1}^n\lim_{k\to\infty}\|D_iu_k-D_iu\|^p_{L^p(\Omega)}=0.$$

If $p=\infty$, we have

$$\begin{aligned}\lim_{k\to\infty}\|u_k-u\|_{W^{1,\infty}(\Omega)}&=\lim_{k\to\infty}\max\left\{\|u_k-u\|_{L^\infty(\Omega)},\|D_1u_k-D_1u\|_{L^\infty(\Omega)},\dots,\|D_nu_k-D_nu\|_{L^\infty(\Omega)}\right\}\\&=0,\end{aligned}$$

by continuity of the function max and the assumed convergences in $L^\infty(\Omega)$. □

The preceding lemma helps us prove the following theorem.

Theorem 3.2.5. The space $W^{1,p}(\Omega)$ is a Banach space for every $p\in[1,\infty]$.

Proof. Let (u_k) be a Cauchy sequence in $W^{1,p}(\Omega)$. Then the sequences (u_k) and (D_iu_k) are Cauchy in $L^p(\Omega)$. Since $L^p(\Omega)$ is complete, we have $u_k\to u$ in $L^p(\Omega)$ and $D_iu_k\to v_i$ in $L^p(\Omega)$ for each $i\in\{1,\dots,n\}$. Lemma 3.2.4 gives $u\in W^{1,p}(\Omega)$ and $u_k\to u$ in $W^{1,p}(\Omega)$. This proves that $W^{1,p}(\Omega)$ is complete; since Proposition 3.2.3 already shows that it is a normed space, we conclude that it is a Banach space. □

In addition to being a Banach space, for $p=2$, $W^{1,2}(\Omega)$ is a Hilbert space, for which we use the notation $H^1(\Omega):=W^{1,2}(\Omega)$. We record this as a proposition.

Proposition 3.2.6. If $p=2$, $W^{1,p}(\Omega)$ is a Hilbert space with the inner product

$$\langle u,v\rangle_{H^1(\Omega)}:=\int_\Omega uv+\sum_{i=1}^n\int_\Omega (D_iu)(D_iv)=\int_\Omega uv+\int_\Omega\nabla u\cdot\nabla v.$$

Proof. The expression $\langle\cdot,\cdot\rangle_{H^1(\Omega)}$ is bilinear by linearity of the integral, distributivity of the product of real-valued functions, and bilinearity of the inner product on R^n. It is symmetric because multiplication of real-valued functions is commutative and the dot product on $\mathbb{R}^n$ is symmetric. It remains to show that if $\langle v,v\rangle=0$, then $v=0$. Suppose that $\langle v,v\rangle=0$. Then

$$\int_\Omega v^2+\int_\Omega|\nabla v|^2=0.$$

Since both summands are nonnegative, both must equal 0, whence $\displaystyle\int_\Omega v^2=0$ and therefore $v=0$ almost everywhere; that is, $v=0$ in $L^2(\Omega)$, and hence $v=0$ in $W^{1,2}(\Omega)$. □

Remark 3.2.7. $C_c^\infty(\Omega) \subseteq W^{1,p}(\Omega)$ for every $p \in [1,\infty)$, since every function of class $C_c^\infty(\Omega)$ is weakly differentiable and its partial derivatives are continuous and compactly supported, and thus belong to $L^p(\Omega)$.

The space $C_c^\infty(\Omega)$ leads to a basic question in Sobolev analysis: under what conditions can a Sobolev function be approximated by smooth functions with compact support? We know that, in general, a Sobolev function need not be classically differentiable; nevertheless, under suitable assumptions on the domain, these functions can be approximated by elements of $C_c^\infty(\Omega)$. Questions of this kind are called *approximation problems* and provide an essential tool both in the abstract theory and in applications to partial differential equations. We therefore give the following definition.

Definition 3.2.8. Let $p \in [1,\infty)$. We define the Sobolev space $W_0^{1,p}(\Omega)$ as the closure of $C_c^\infty(\Omega)$ in $W^{1,p}(\Omega)$. We write

$$H_0^1(\Omega) := W_0^{1,2}(\Omega).$$

Remark 3.2.9. This notation makes sense because $W_0^{1,2}(\Omega) = \overline{C_c^\infty(\Omega)}^{W^{1,2}(\Omega)}$ is a closed vector subspace of $W^{1,2}(\Omega)$, which is a Hilbert space, and therefore $H_0^1(\Omega)$ is also a Hilbert space.

In the case $\Omega = \mathbb{R}^n$, there are no boundary obstructions. The argument combines cutoffs moving out toward infinity with regularization by mollifiers, and will serve as the model for the proof on complete Riemannian manifolds.

Proposition 3.2.10. $C_c^\infty(\mathbb{R}^n)$ is dense in $W^{1,p}(\mathbb{R}^n)$ for every $p \in [1,\infty)$.

Proof. Let $u \in W^{1,p}(\mathbb{R}^n)$. By Proposition 1.3.6, there exists $\chi \in C_c^\infty(\mathbb{R}^n)$ such that $0 \le \chi \le 1$, $\chi = 1$ on $B_{\mathrm{euc}}(0,1)$, and $\operatorname{supp}\chi \subseteq B_{\mathrm{euc}}(0,2)$. For $R \ge 1$, set

$$\chi_R(x) := \chi\left(\frac{x}{R}\right), \qquad u_R := \chi_R u.$$

The weak Leibniz rule gives

$$D_i u_R = \chi_R D_i u + u D_i \chi_R.$$

Indeed, if $\varphi \in C_c^\infty(\mathbb{R}^n)$, we apply the definition of the weak derivative of u to $\chi_R\varphi$ and expand $D_i(\chi_R\varphi)$. Thus, we do not assume an unproved product rule.
Since $\chi_R(x) \to 1$ for every $x \in \mathbb{R}^n$ and $|1-\chi_R| \le 1$, the dominated convergence theorem B.6.14, applied to $|u|^p$ and $|D_i u|^p$, shows that

$$\|(1-\chi_R)u\|_{L^p(\mathbb{R}^n)} + \|(1-\chi_R)D_i u\|_{L^p(\mathbb{R}^n)} \longrightarrow 0.$$

Moreover,

$$\|u D_i \chi_R\|_{L^p(\mathbb{R}^n)} \le \frac{\|D_i\chi\|_{L^\infty(\mathbb{R}^n)}}{R}\|u\|_{L^p(\mathbb{R}^n)} \longrightarrow 0.$$

Therefore, $u_R \to u$ in $W^{1,p}(\mathbb{R}^n)$.
Now fix R. Let ρ be the mollifier from Theorem B.9.1 and define $u_{R,\varepsilon} := \rho_\varepsilon * u_R$. Then $u_{R,\varepsilon} \in C_c^\infty(\mathbb{R}^n)$ and, by Fubini's theorem B.6.18 and the definition of weak derivative,

$$D_i u_{R,\varepsilon} = \rho_\varepsilon * D_i u_R.$$

Continuity of translations from Proposition B.8.17, Minkowski's integral inequality from Theorem B.8.2, and the dominated convergence theorem B.6.14 imply that, for every $v \in L^p(\mathbb{R}^n)$,

$$\|\rho_\varepsilon * v - v\|_{L^p(\mathbb{R}^n)} \leq \int_{\mathbb{R}^n} \rho(z)\|v(\cdot - \varepsilon z) - v\|_{L^p(\mathbb{R}^n)}\, dz \longrightarrow 0.$$

We apply this estimate to $v = u_R$ and $v = D_i u_R$ to conclude that $u_{R,\varepsilon} \to u_R$ in $W^{1,p}(\mathbb{R}^n)$. Choosing first $R \to \infty$ and then $\varepsilon \to 0^+$, or taking a diagonal sequence, completes the proof. □

3.3 Sobolev embeddings

By definition, the Sobolev spaces $W_0^{1,p}(\Omega)$ are contained in $L^p(\Omega)$. An interesting question is: for which other values q is $W_0^{1,p}(\Omega)$ continuously embedded in $L^q(\Omega)$?

The fundamental tool for answering this question consists of inequalities that estimate the $L^q(\mathbb{R}^n)$ norm of a function $\varphi \in C_c^\infty(\mathbb{R}^n)$ in terms of the $(L^p(\mathbb{R}^n))^n$ norm of its gradient. Such inequalities are usually called *Sobolev inequalities*.

We begin by giving a norm on the product space

$$(L^p(\mathbb{R}^n))^n := L^p(\mathbb{R}^n) \times \cdots \times L^p(\mathbb{R}^n)$$

with $p \in [1, \infty)$. This norm is given by

$$\|(f_1, \ldots, f_n)\|_{(L^p(\mathbb{R}^n))^n} := \left(\sum_{i=1}^n \|f_i\|_{L^p(\mathbb{R}^n)}^p \right)^{\frac{1}{p}}.$$

Now consider $\varphi \in C_c^\infty(\mathbb{R}^n)$. Since $C_c^\infty(\mathbb{R}^n) \subseteq L^p(\mathbb{R}^n)$,

$$\nabla\varphi = \left(\frac{\partial \varphi}{\partial x_1}, \ldots, \frac{\partial \varphi}{\partial x_n} \right) \in (L^p(\mathbb{R}^n))^n$$

for every $p \in [1, \infty)$.

We ask for which numbers $p, q \in [1, \infty)$ it is possible to bound $\|\varphi\|_{L^q(\mathbb{R}^n)}$ uniformly in terms of $\|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n}$. We first show that p and q cannot be arbitrary.

Proposition 3.3.1. Let $p, q \in [1, \infty)$. If there is a constant $C > 0$ depending only on n, p, and q such that

$$\|\varphi\|_{L^q(\mathbb{R}^n)} \leq C\|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n}$$

for every $\varphi \in C_c^\infty(\mathbb{R}^n)$, then $p < n$ and $q = \dfrac{np}{n-p}$.

Proof. For each $\lambda > 0$, $\psi(x) = \lambda x$ is a diffeomorphism of $\mathbb{R}^n$ onto itself of class C^∞ such that $|\det(D\psi)| = |\lambda^n| = \lambda^n$. By Theorem B.6.15,

$$\|\varphi_\lambda\|_{L^q(\mathbb{R}^n)}^q = \frac{1}{\lambda^n}\|\varphi\|_{L^q(\mathbb{R}^n)}^q,$$

and

$$\left\| \frac{\partial \varphi_\lambda}{\partial x_i} \right\|_{L^p(\mathbb{R}^n)}^p = \frac{\lambda^p}{\lambda^n} \left\| \frac{\partial \varphi}{\partial x_i} \right\|_{L^p(\mathbb{R}^n)}^p.$$

Applying the hypothesis to φ_λ gives

$$\frac{1}{\lambda^{\frac{n}{q}}} \|\varphi\|_{L^q(\mathbb{R}^n)} \leq C \frac{\lambda}{\lambda^{\frac{n}{p}}} \|\nabla \varphi\|_{(L^p(\mathbb{R}^n))^n},$$

that is,

$$\|\varphi\|_{L^q(\mathbb{R}^n)} \leq C \lambda^{1-\frac{n}{p}+\frac{n}{q}} \|\nabla \varphi\|_{(L^p(\mathbb{R}^n))^n}.$$

We may take the limit as $\lambda \to 0^+$ if $1 - \frac{n}{p} + \frac{n}{q} > 0$, or as $\lambda \to \infty$ if $1 - \frac{n}{p} + \frac{n}{q} < 0$, and observe that if $1 - \frac{n}{p} + \frac{n}{q} \neq 0$, the preceding inequality cannot hold for any $\varphi \neq 0$, since we would have $\|\varphi\|_{L^q(\mathbb{R}^n)} = 0$.
We must therefore have $1 - \frac{n}{p} + \frac{n}{q} = 0$, which implies $\frac{n}{p} > 1$ and $q = \frac{np}{n-p}$.

□

This value of q plays an important role in Sobolev space theory and thus receives a special name.

Definition 3.3.2. If $p \in [1, n)$, the critical Sobolev exponent is defined by

$$p^* := \frac{np}{n-p}.$$

Moreover, $p^* > p$.

In fact, the inequality involving the norm of the gradient holds for $p \in [1, n)$ and $q = p^*$, as we shall now prove. We first need a lemma.

Lemma 3.3.3. Let $n \geq 2$ and $f_1, \ldots, f_n \in L^{n-1}(\mathbb{R}^{n-1})$. If $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$, write $\hat{x}_i := (x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n) \in \mathbb{R}^{n-1}$ and define

$$f(x) := \prod_{i=1}^n f_i(\hat{x}_i)$$

Then $f \in L^1(\mathbb{R}^n)$ and

$$\|f\|_{L^1(\mathbb{R}^n)} \leq \prod_{i=1}^n \|f_i\|_{L^{n-1}(\mathbb{R}^{n-1})}.$$

Proof. We argue by induction on n. If $n = 2$, we have

$$\int_{\mathbb{R}^2} |f(x_1, x_2)| dx_1 dx_2 = \int_{\mathbb{R}^2} |f_1(x_2) f_2(x_1)| dx_1 dx_2 = \int_{\mathbb{R}^2} |f_1(x_2)| |f_2(x_1)| dx_1 dx_2$$

$$= \int_{\mathbb{R}} |f_1(x_2)| dx_2 \int_{\mathbb{R}} |f_2(x_1)| dx_1.$$

Suppose that the assertion holds for some $n \geq 2$; we show that it holds for $n+1$.

Let $f_1, \dots, f_{n+1} \in L^n(\mathbb{R}^n)$. Fix the value of x_{n+1} and define

$$g_i(z_1, \dots, z_{n-1}) := |f_i(z_1, \dots, z_{n-1}, x_{n+1})|^{\frac{n}{n-1}}, i \in \{1, \dots, n\}.$$

By Theorem B.6.18, we have $g_i \in L^{n-1}(\mathbb{R}^{n-1})$ for almost every x_{n+1} (by Fubini's theorem with $m = n-1$). The induction hypothesis therefore shows that the function

$$g(y) := \prod_{i=1}^{n} g_i(\hat{y}_i) = \prod_{i=1}^{n} |f_i(\hat{y}_i, x_{n+1})|^{\frac{n}{n-1}} = \left(\prod_{i=1}^{n} |f_i(\hat{y}_i, x_{n+1})| \right)^{\frac{n}{n-1}}$$

$y \in \mathbb{R}^n$ belongs to $L^1(\mathbb{R}^n)$ and that

$$\|g\|_{L^1(\mathbb{R}^n)} \leq \prod_{i=1}^{n} \|g_i\|_{L^{n-1}(\mathbb{R}^{n-1})} = \prod_{i=1}^{n} \left(\int_{\mathbb{R}^{n-1}} |f_i(z, x_{n+1})|^n dz \right)^{\frac{1}{n-1}}.$$

We have

$$|f(y, x_{n+1})| = \left(\prod_{i=1}^{n} |f_i(\hat{y}_i, x_{n+1})| \right) |f_{n+1}(y)| = |g(y)|^{\frac{n-1}{n}} |f_{n+1}(y)|.$$

Using Proposition B.7.9 (Hölder's inequality) and the preceding inequality for $\|g\|_{L^1(\mathbb{R}^n)}$, we obtain the following:

$$\int_{\mathbb{R}^n} |f(y, x_{n+1})| dy \leq \|g\|_{L^1(\mathbb{R}^n)}^{\frac{n-1}{n}} \|f_{n+1}\|_{L^n(\mathbb{R}^n)} \leq \prod_{i=1}^{n} \left(\int_{\mathbb{R}^{n-1}} |f_i(z, x_{n+1})|^n dz \right)^{\frac{1}{n}} \|f_{n+1}\|_{L^n(\mathbb{R}^n)}.$$

The preceding argument holds for almost every x_{n+1}, so the functions

$$h_i(x_{n+1}) := \left(\int_{\mathbb{R}^{n-1}} |f_i(z, x_{n+1})|^n \, dz \right)^{\frac{1}{n}}, \qquad i \in \{1, \dots, n\},$$

belong to $L^n(\mathbb{R})$. Indeed, by Tonelli's theorem,

$$\begin{aligned} \|h_i\|_{L^n(\mathbb{R})}^n &= \int_{\mathbb{R}} \int_{\mathbb{R}^{n-1}} |f_i(z, x_{n+1})|^n \, dz \, dx_{n+1} \\ &= \|f_i\|_{L^n(\mathbb{R}^n)}^n. \end{aligned}$$

Since each $h_i \in L^n(\mathbb{R})$, we may apply Proposition B.7.9 with n factors and all exponents equal to n. Thus,

$$\int_{\mathbb{R}} \prod_{i=1}^{n} |h_i(x_{n+1})| \, dx_{n+1} \leq \prod_{i=1}^{n} \|h_i\|_{L^n(\mathbb{R})}.$$

We previously showed that

$$\int_{\mathbb{R}^n} |f(y, x_{n+1})| dy \leq \prod_{i=1}^{n} \left(\int_{\mathbb{R}^{n-1}} |f_i(z, x_{n+1})|^n dz \right)^{\frac{1}{n}} \|f_{n+1}\|_{L^n(\mathbb{R}^n)}.$$

Integrating this inequality with respect to x_{n+1} and using the preceding inequality gives

$$\begin{aligned}\int_{\mathbb{R}^{n+1}} |f(x)|\,dx &\le \left(\int_{\mathbb{R}} \prod_{i=1}^{n} |h_i(x_{n+1})|\,dx_{n+1}\right) \|f_{n+1}\|_{L^n(\mathbb{R}^n)} \\ &\le \left(\prod_{i=1}^{n} \|h_i\|_{L^n(\mathbb{R})}\right) \|f_{n+1}\|_{L^n(\mathbb{R}^n)} \\ &= \prod_{i=1}^{n+1} \|f_i\|_{L^n(\mathbb{R}^n)},\end{aligned}$$

which is the desired conclusion. □

Theorem 3.3.4. There are constants $C > 0$, depending only on n and p, with the following properties:

(a) Gagliardo–Nirenberg–Sobolev inequality: If $p \in [1, n)$, then

$$\|\varphi\|_{L^{p^*}(\mathbb{R}^n)} \le C\|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n}$$

for every $\varphi \in C_c^\infty(\mathbb{R}^n)$.

(b) If $p \in (n, \infty)$, then

$$\|\varphi\|_{L^\infty(\mathbb{R}^n)} \le C(\lambda_n(\operatorname{supp}(\varphi)))^{\frac{1}{n}-\frac{1}{p}} \|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n}$$

for every $\varphi \in C_c^\infty(\mathbb{R}^n)$, where $\lambda_n(\operatorname{supp}(\varphi))$ denotes the Lebesgue measure of the support of φ.

Proof. We begin by assuming $n \ge 2$; the case $n = 1$ in part (b) is treated separately at the end of the proof. Let $\varphi \in C_c^1(\mathbb{R}^n)$. Since φ has compact support, Theorem B.6.5 gives

$$\varphi(x) = \int_{-\infty}^{x_i} \frac{\partial\varphi}{\partial x_i}(x_1, \dots, x_{i-1}, t, x_{i+1}, \dots, x_n)dt$$

for each $i \in \{1, \dots, n\}$, and consequently

$$|\varphi(x)| \le \int_{-\infty}^{\infty} \left|\frac{\partial\varphi}{\partial x_i}(x_1, \dots, x_{i-1}, t, x_{i+1}, \dots, x_n)\right| dt$$

Since $n \ge 2$, we can define

$$f_i(z_1, \dots, z_{n-1}) := \left(\int_{-\infty}^{\infty} \left|\frac{\partial\varphi}{\partial x_i}(z_1, \dots, z_{i-1}, t, z_i, \dots, z_{n-1})\right| dt\right)^{\frac{1}{n-1}}.$$

The function f_i is well defined because $\varphi \in C_c^1(\mathbb{R}^n)$.
Then $f_1, \dots, f_n \in L^{n-1}(\mathbb{R}^{n-1})$ because

$$\begin{aligned}\int_{\mathbb{R}^{n-1}} |f_i(z)|^{n-1} dz &= \int_{\mathbb{R}^{n-1}} \left|\left(\int_{-\infty}^{\infty} \left|\frac{\partial\varphi}{\partial x_i}(z_1, \dots, z_{i-1}, t, z_i, \dots, z_{n-1})\right| dt\right)^{\frac{1}{n-1}}\right|^{n-1} dz \\ &= \int_{\mathbb{R}^n} \left|\frac{\partial\varphi}{\partial x_i}(x)\right| dx < \infty\end{aligned}$$

because $\dfrac{\partial\varphi}{\partial x_i} \in C_c^0(\mathbb{R}^n) \subseteq L^1(\mathbb{R}^n)$.
Moreover, the preceding argument tells us that

$$\|f_i\|_{L^{n-1}(\mathbb{R}^{n-1})} = \left\| \frac{\partial\varphi}{\partial x_i} \right\|_{L^1(\mathbb{R}^n)}^{\frac{1}{n-1}}.$$

Raising the inequalities

$$|\varphi(x)| \leq \int_{-\infty}^{\infty} \left| \frac{\partial\varphi}{\partial x_i}(x_1,\dots,x_{i-1},t,x_{i+1},\dots,x_n) \right| dt$$

to the power $\dfrac{1}{n-1}$ and taking their product gives

$$|\varphi(x)|^{\frac{n}{n-1}} \leq \prod_{i=1}^{n} f_i(\hat{x}_i)$$

where $\hat{x}_i$ omits the ith entry of x. Applying Lemma 3.3.3 gives

$$\int_{\mathbb{R}^n} |\varphi|^{\frac{n}{n-1}} \leq \int_{\mathbb{R}^n} \left(\prod_{i=1}^{n} f_i(\hat{x}_i) \right) \leq \prod_{i=1}^{n} \|f_i\|_{L^{n-1}(\mathbb{R}^{n-1})} = \prod_{i=1}^{n} \left\| \frac{\partial\varphi}{\partial x_i} \right\|_{L^1(\mathbb{R}^n)}^{\frac{1}{n-1}}$$

Therefore,

$$\|\varphi\|_{L^{\frac{n}{n-1}}(\mathbb{R}^n)} \leq \prod_{i=1}^{n} \left\| \frac{\partial\varphi}{\partial x_i} \right\|_{L^1(\mathbb{R}^n)}^{\frac{1}{n}}$$

Now the arithmetic–geometric mean inequality gives

$$\|\varphi\|_{L^{\frac{n}{n-1}}(\mathbb{R}^n)} \leq \prod_{i=1}^{n} \left\| \frac{\partial\varphi}{\partial x_i} \right\|_{L^1(\mathbb{R}^n)}^{\frac{1}{n}} \leq \frac{1}{n} \sum_{i=1}^{n} \left\| \frac{\partial\varphi}{\partial x_i} \right\|_{L^1(\mathbb{R}^n)} = \frac{1}{n} \|\nabla\varphi\|_{(L^1(\mathbb{R}^n))^n}.$$

The preceding inequality also holds for compactly supported functions φ defined on $\mathbb{R}^n$ that are of class C^1 on a bounded open subset of $\mathbb{R}^n$.
On the other hand, for each $\gamma > 1$, consider the function $\widetilde{\varphi}(x) = |\varphi(x)|^{\gamma-1}\varphi(x)$. This function has compact support, is at least continuous, and is of class C^1 on $\{x \in \mathbb{R}^n \mid \varphi(x) \neq 0\}$, which is open because φ is continuous, and bounded because $\operatorname{supp}(\varphi)$ is compact.
Its partial derivatives on this open subset are

$$\frac{\partial(|\varphi|^{\gamma-1}\varphi)}{\partial x_i} = \frac{\partial(|\varphi|^{\gamma-1})}{\partial x_i}\varphi + |\varphi|^{\gamma-1}\frac{\partial\varphi}{\partial x_i} = (\gamma-1)|\varphi|^{\gamma-2}\frac{\varphi}{|\varphi|}\frac{\partial\varphi}{\partial x_i}\varphi + |\varphi|^{\gamma-1}\frac{\partial\varphi}{\partial x_i} = \gamma\frac{\partial\varphi}{\partial x_i}|\varphi|^{\gamma-1}$$

, which are continuous on $\{x \in \mathbb{R}^n \mid \varphi(x) \neq 0\}$, so that $\widetilde{\varphi}$ is of class C^1 at least on $\{x \in \mathbb{R}^n \mid \varphi(x) \neq 0\}$.
Outside $\operatorname{supp}(\varphi)$, $\widetilde{\varphi} \equiv 0$, so it is also of class C^1 there. It remains to examine the boundary points.
In fact, the function $\psi\colon \mathbb{R} \longrightarrow \mathbb{R}$ given by $\psi(x) = x|x|^{\gamma-1}$ is of class C^1, since for $x < 0$, $\psi'(x) = \gamma(-x)^{\gamma-1}$, and for $x > 0$, $\psi'(x) = \gamma x^{\gamma-1}$. By Proposition B.1.1, ψ is differentiable at 0 and $\psi'(0) = 0$. Moreover, since the derivatives of ψ are continuous except possibly at 0, the expression for the derivative at 0 gives $\psi \in C^1(\mathbb{R})$.
Therefore, $\widetilde{\varphi}$ is of class $C^1(\mathbb{R}^n)$ as a composition of functions of class C^1, and hence $\widetilde{\varphi} \in C_0^1(\mathbb{R}^n)$.

On the other hand, the absolute value of this partial derivative, where it differs from 0, is

$$\left|\frac{\partial(|\varphi|^{\gamma-1}\varphi)}{\partial x_i}\right| = \left|(\gamma-1)|\varphi|^{\gamma-2}\frac{\varphi}{|\varphi|}\frac{\partial\varphi}{\partial x_i}\varphi + |\varphi|^{\gamma-1}\frac{\partial\varphi}{\partial x_i}\right| =$$

$$\left|\frac{\partial\varphi}{\partial x_i}\right|\left|(\gamma-1)|\varphi|^{\gamma-1} + |\varphi|^{\gamma-1}\right| = \gamma|\varphi|^{\gamma-1}\left|\frac{\partial\varphi}{\partial x_i}\right|$$

Replacing φ by $|\varphi|^{\gamma-1}\varphi$ in the inequality

$$\|\varphi\|_{L^{\frac{n}{n-1}}(\mathbb{R}^n)} \le \prod_{i=1}^{n}\left\|\frac{\partial\varphi}{\partial x_i}\right\|_{L^1(\mathbb{R}^n)}^{\frac{1}{n}}$$

and, for $1 < p < \infty$, applying Hölder's inequality from Proposition B.7.9, we obtain

$$\left(\int_{\mathbb{R}^n}|\varphi|^{\frac{n\gamma}{n-1}}\right)^{\frac{n-1}{n}} \le \gamma\left(\int_{\mathbb{R}^n}|\varphi|^{\frac{p(\gamma-1)}{p-1}}\right)^{\frac{p-1}{p}}\prod_{i=1}^{n}\left\|\frac{\partial\varphi}{\partial x_i}\right\|_{L^p(\mathbb{R}^n)}^{\frac{1}{n}}.$$

The geometric–arithmetic mean inequality, followed by the equivalence of finite-dimensional norms in Proposition B.1.2, gives

$$\prod_{i=1}^{n}\left\|\frac{\partial\varphi}{\partial x_i}\right\|_{L^p(\mathbb{R}^n)}^{\frac{1}{n}} \le \left(\sum_{i=1}^{n}\left\|\frac{\partial\varphi}{\partial x_i}\right\|_{L^p(\mathbb{R}^n)}^{p}\right)^{\frac{1}{p}} = \|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n}.$$

We shall use these inequalities to prove the assertions of the theorem.

(a) Suppose that $p \in [1, n)$. If $p = 1$, then $p^* = \dfrac{n}{n-1}$, and the inequality

$$\|\varphi\|_{L^{\frac{n}{n-1}}(\mathbb{R}^n)} \le \frac{1}{n}\|\nabla\varphi\|_{(L^1(\mathbb{R}^n))^n}$$

already proved is the desired one.

If $p \neq 1$, take $\gamma := \dfrac{n-1}{n}p^* = \dfrac{n-1}{n}\dfrac{np}{n-p} = \dfrac{np-p}{n-p} > 1$, since $1 < p < n$ implies $n < np < n^2$, whence $n < np$; thus $np - p > n - p$, as required.

We may therefore apply the inequality previously derived for $\gamma > 1$. To do so, we first compute $\dfrac{p(\gamma-1)}{p-1} = \dfrac{p(\frac{np-p}{n-p} - \frac{n-p}{n-p})}{p-1} = \dfrac{p(\frac{n(p-1)}{n-p})}{p-1} = \dfrac{pn}{n-p} =: p^*$, $\dfrac{n\gamma}{n-1} = p^*$, and $\dfrac{n-1}{n} - \dfrac{p-1}{p} = \dfrac{pn-p-np+n}{np} = \dfrac{n-p}{np} = \dfrac{1}{p^*}$, so that the inequality for $\gamma > 1$ gives the following:

$$\left(\int_{\mathbb{R}^n}|\varphi|^{p^*}\right)^{\frac{1}{p^*}} \le \gamma\|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n}$$

which is the same as

$$\|\varphi\|_{L^{p^*}(\mathbb{R}^n)} \le \gamma\|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n}$$

, as desired.

(b) Suppose that $p \in (n, \infty)$. If $n = 1$, the inequality

$$|\varphi(x)| \leq \int_{-\infty}^{\infty} |\varphi'(t)|\, dt$$

together with Proposition B.7.12, with $X = \operatorname{supp}(\varphi)$, implies

$$\|\varphi\|_{L^\infty(\mathbb{R})} \leq \|\varphi'\|_{L^1(\mathbb{R})} \leq \lambda_1(\operatorname{supp}(\varphi))^{\frac{p-1}{p}} \|\varphi'\|_{L^p(\mathbb{R})}$$

. This is the desired inequality once we observe that $\frac{1}{n} - \frac{1}{p} = 1 - \frac{1}{p} = \frac{p-1}{p}$.

If $n \geq 2$, first consider the case in which $\lambda_n(\operatorname{supp}(\varphi)) = 1$ and $\|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n} = 1$. The inequality for $\gamma > 1$ and Hölder's inequality on the support of measure one, with exponents $\frac{\gamma}{\gamma - 1}$ and γ, give:

$$\|\varphi\|_{L^{\frac{n\gamma}{n-1}}(\mathbb{R}^n)} \leq \gamma^{\frac{1}{\gamma}} \left(\int_{\mathbb{R}^n} |\varphi|^{\frac{p(\gamma-1)}{p-1}} \right)^{\frac{p-1}{p\gamma}} \leq \gamma^{\frac{1}{\gamma}} (\|\varphi\|_{L^{\frac{p\gamma}{p-1}}(\mathbb{R}^n)})^{\frac{\gamma-1}{\gamma}}$$

for every $\gamma > 1$.

Take $\gamma := \frac{n}{n-1}\frac{p-1}{p}$. Since $p > n$ and $n \geq 2$, we have $p > p - 1 > n - 1 \geq 1$, because $p > n$ and $n \geq 2$. On the other hand, $p > n$ implies $-n > -p$; adding np to this inequality gives $np - n > np - p$, which is equivalent to $n(p-1) > p(n-1)$. Since $n - 1 > 0$ and $p > 0$, we may divide by $p(n-1)$ without reversing the inequality to obtain $\frac{n(p-1)}{p(n-1)} > 1$, that is, $\gamma > 1$.

Now, for $k \in \mathbb{N}$, we have $\gamma^k = (\frac{n}{n-1}\frac{p-1}{p})^k = (\frac{n}{n-1})^k (\frac{p-1}{p})^k$ and also $\gamma^{k-1} = (\frac{n}{n-1}\frac{p-1}{p})^{k-1} = (\frac{n}{n-1})^{k-1}(\frac{p-1}{p})^{k-1}$, whence $\frac{p}{p-1}\gamma^k = \frac{n}{n-1}\gamma^{k-1}$.

Substituting γ^k for γ in the preceding inequality then gives the following:

$$\|\varphi\|_{L^{\frac{n}{n-1}\gamma^k}(\mathbb{R}^n)} \leq \gamma^{\frac{k}{\gamma^k}} (\|\varphi\|_{L^{\frac{n}{n-1}\gamma^{k-1}}(\mathbb{R}^n)})^{\frac{\gamma^k - 1}{\gamma^k}}.$$

Proposition B.7.13 and the inequality

$$\|\varphi\|_{L^{\frac{n}{n-1}}(\mathbb{R}^n)} \leq \frac{1}{n}\|\nabla\varphi\|_{(L^1(\mathbb{R}^n))^n}$$

give

$$\|\varphi\|_{L^{\frac{n}{n-1}}(\mathbb{R}^n)} \leq \frac{1}{n}\|\nabla\varphi\|_{(L^1(\mathbb{R}^n))^n} \leq \frac{1}{n}(n\lambda_n(\operatorname{supp}(\varphi)))^{\frac{p-1}{p}} \|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n}$$

, where the last expression equals the following, using $\lambda_n(\operatorname{supp}(\varphi)) = 1$ and $\|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n} = 1$:

$$\frac{1}{n}(n\lambda_n(\operatorname{supp}(\varphi)))^{\frac{p-1}{p}} \|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n} = \frac{n^{\frac{p-1}{p}}}{n} = n^{-\frac{1}{p}} = \frac{1}{n^{\frac{1}{p}}} < 1.$$

Therefore,

$$\|\varphi\|_{L^{\frac{n}{n-1}}(\mathbb{R}^n)} \leq \frac{1}{n}\|\nabla\varphi\|_{(L^1(\mathbb{R}^n))^n}$$

gives

$$\|\varphi\|_{L^{\frac{n}{n-1}}(\mathbb{R}^n)} \leq \frac{1}{n}\|\nabla\varphi\|_{(L^1(\mathbb{R}^n))^n} \leq \frac{1}{n}(n\lambda_n(\operatorname{supp}(\varphi)))^{\frac{p-1}{p}}\|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n} < 1.$$

If $\|\varphi\|_{L^{\frac{n}{n-1}\gamma^k}(\mathbb{R}^n)} \leq 1$ for infinitely many $k \in \mathbb{N}$, Proposition B.7.14 tells us that $\|\varphi\|_{L^\infty(\mathbb{R}^n)} \leq 1$. If, on the contrary, there exists $k_0 \in \mathbb{N}_0$ such that $\|\varphi\|_{L^{\frac{n}{n-1}\gamma^{k_0}}(\mathbb{R}^n)} \leq 1$ and $\|\varphi\|_{L^{\frac{n}{n-1}\gamma^k}(\mathbb{R}^n)} > 1$ for every $k > k_0$, then for every $k > k_0 + 1$ we have $\|\varphi\|_{L^{\frac{n}{n-1}\gamma^{k-1}}(\mathbb{R}^n)} > 1$; using $0 < \dfrac{\gamma^k - 1}{\gamma^k} < 1$, we obtain

$$(\|\varphi\|_{L^{\frac{n}{n-1}\gamma^{k-1}}(\mathbb{R}^n)})^{\frac{\gamma^k-1}{\gamma^k}} \leq \|\varphi\|_{L^{\frac{n}{n-1}\gamma^{k-1}}(\mathbb{R}^n)}$$

for every $k > k_0 + 1$.

Iterating the inequality obtained earlier and combining it with the preceding inequality yields the following inequalities:

$$\|\varphi\|_{L^{\frac{n}{n-1}\gamma^k}(\mathbb{R}^n)} \leq \gamma^{\left(\frac{k}{\gamma^k}+\cdots+\frac{k_0+1}{\gamma^{k_0+1}}\right)}(\|\varphi\|_{L^{\frac{n}{n-1}\gamma^{k_0}}(\mathbb{R}^n)})^{\frac{\gamma^{k_0+1}-1}{\gamma^{k_0+1}}} \leq \gamma^\alpha$$

where $\alpha := \displaystyle\sum_{i=1}^{\infty}\frac{i}{\gamma^i} < \infty$, since for each $i \geq 1$, $\dfrac{\left|\dfrac{i+1}{\gamma^{i+1}}\right|}{\left|\dfrac{i}{\gamma^i}\right|} = \dfrac{i+1}{i\gamma} = \dfrac{1}{\gamma} + \dfrac{1}{i\gamma} \to \dfrac{1}{\gamma}$ if $i \to \infty$, and $\dfrac{1}{\gamma} < 1$ because $\gamma > 1$, so the ratio test shows that the series converges.

By Proposition B.7.14, we obtain $\|\varphi\|_{L^\infty(\mathbb{R}^n)} \leq \gamma^\alpha$. Thus, in either case,

$$\|\varphi\|_{L^\infty(\mathbb{R}^n)} \leq \gamma^\alpha = \gamma^\alpha(\lambda_n(\operatorname{supp}(\varphi)))^{\frac{p-n}{np}}\|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n}$$

provided that $\lambda_n(\operatorname{supp}(\varphi)) = 1$ and $\|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n} = 1$, where we have used $\gamma^\alpha > 1$.

We now obtain the desired inequality in the general case.

If $\lambda_n(\operatorname{supp}(\varphi)) = 0$ or $\|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n} = 0$, then $\varphi = 0$ almost everywhere and the inequality holds immediately.

If $\lambda_n(\operatorname{supp}(\varphi)) \neq 0$ and $\|\nabla\varphi\|_{(L^p(\mathbb{R}^n))^n} \neq 0$, we may consider the function $\theta := \dfrac{\psi}{\|\nabla\psi\|_{(L^p(\mathbb{R}^n))^n}}$, where $\psi(x) := \varphi(\lambda_n(\operatorname{supp}(\varphi))^{\frac{1}{n}}x)$. We have $\operatorname{supp}(\theta) = \operatorname{supp}(\psi)$ and $\operatorname{supp}(\psi) = \overline{\{x \in \mathbb{R}^n \mid \psi(x) \neq 0\}} = \overline{\{x \in \mathbb{R}^n \mid \varphi((\lambda_n(\operatorname{supp}(\varphi)))^{\frac{1}{n}}x) \neq 0\}} = \operatorname{supp}(\varphi \circ g)$, where $g\colon \mathbb{R}^n \longrightarrow \mathbb{R}^n$, given by $g(x) = (\lambda_n(\operatorname{supp}(\varphi)))^{\frac{1}{n}}x$, is a diffeomorphism of class $C^\infty(\mathbb{R}^n)$. Since g is a homeomorphism, $\operatorname{supp}(\varphi \circ g) = g^{-1}(\operatorname{supp}(\varphi))$; by Theorem B.6.15, taking $|\det Dg^{-1}| = \dfrac{1}{\lambda_n(\operatorname{supp}(\varphi))}$ into account, we obtain

$$\lambda_n(g^{-1}(\operatorname{supp}(\varphi))) = \int_{g^{-1}(\operatorname{supp}(\varphi))} 1 = \frac{1}{\lambda_n(\operatorname{supp}(\varphi))}\int_{\operatorname{supp}(\varphi)} 1 = 1$$

and therefore $\lambda_n(\operatorname{supp}(\theta)) = \lambda_n(\operatorname{supp}(\psi)) = 1$.

Moreover,

$$\nabla\psi(x) = \lambda_n(\operatorname{supp}(\varphi))^{\frac{1}{n}}\nabla\varphi(g(x)).$$

Theorem B.6.15 gives

$$\left\| \frac{\partial \varphi}{\partial x_i} \circ g \right\|_{L^p(\mathbb{R}^n)}^p = \lambda_n(\operatorname{supp}(\varphi))^{-1} \left\| \frac{\partial \varphi}{\partial x_i} \right\|_{L^p(\mathbb{R}^n)}^p.$$

Consequently,

$$\|\nabla \varphi \circ g\|_{(L^p(\mathbb{R}^n))^n} = \lambda_n(\operatorname{supp}(\varphi))^{-\frac{1}{p}} \|\nabla \varphi\|_{(L^p(\mathbb{R}^n))^n},$$

and therefore

$$\|\nabla \psi\|_{(L^p(\mathbb{R}^n))^n} = \lambda_n(\operatorname{supp}(\varphi))^{\frac{1}{n}-\frac{1}{p}} \|\nabla \varphi\|_{(L^p(\mathbb{R}^n))^n} = \lambda_n(\operatorname{supp}(\varphi))^{\frac{p-n}{np}} \|\nabla \varphi\|_{(L^p(\mathbb{R}^n))^n}.$$

On the other hand, $\|\varphi\|_{L^\infty(\mathbb{R}^n)} = \|\psi\|_{L^\infty(\mathbb{R}^n)}$, so we may apply the preceding argument to $\theta \in C_c^\infty(\mathbb{R}^n)$ to obtain:

$$\|\varphi\|_{L^\infty(\mathbb{R}^n)} = \|\psi\|_{L^\infty(\mathbb{R}^n)} \leq \gamma^\alpha \|\nabla \psi\|_{(L^p(\mathbb{R}^n))^n} = \gamma^\alpha (\lambda_n(\operatorname{supp}(\varphi)))^{\frac{p-n}{np}} \|\nabla \varphi\|_{(L^p(\mathbb{R}^n))^n}$$

as desired.

□

For $u \in W_0^{1,p}(\Omega)$, we shall write $\nabla u = (D_1 u, \ldots, D_n u)$ and

$$\|\nabla u\|_{(L^p(\Omega))^n} := \left(\sum_{i=1}^n \|D_i u\|_{L^p(\Omega)}^p \right)^{\frac{1}{p}}.$$

The extension of the preceding inequality to the completed space is recorded in the following corollary.

Corollary 3.3.5. If $\Omega \subseteq \mathbb{R}^n$ is open and $p \in [1, n)$, then $W_0^{1,p}(\Omega) \subseteq L^{p^*}(\Omega)$, and there is a constant $C > 0$, depending only on n and p, such that

$$\|u\|_{L^{p^*}(\Omega)} \leq C \|\nabla u\|_{(L^p(\Omega))^n}$$

for every $u \in W_0^{1,p}(\Omega)$.

Proof. The Gagliardo–Nirenberg–Sobolev inequality shows that the inclusion operator

$$I_0 \colon C_c^\infty(\Omega) \longrightarrow L^{p^*}(\Omega)$$

is linear and satisfies $\|I_0 \varphi\|_{L^{p^*}(\Omega)} \leq C \|\varphi\|_{W^{1,p}(\Omega)}$. Since $W_0^{1,p}(\Omega)$ is the closure of $C_c^\infty(\Omega)$ in $W^{1,p}(\Omega)$ and $L^{p^*}(\Omega)$ is a Banach space, Theorem B.2.36 provides a unique continuous extension $I \colon W_0^{1,p}(\Omega) \longrightarrow L^{p^*}(\Omega)$. It remains to identify Iu with the usual representative of u and retain the estimate in terms of the gradient. Let $(\varphi_k) \subseteq C_c^\infty(\Omega)$ be a sequence converging to u in $W^{1,p}(\Omega)$. Then $\varphi_k \to u$ in $L^p(\Omega)$ and $\varphi_k \to Iu$ in $L^{p^*}(\Omega)$. Theorem B.7.15, applied to subsequences, shows that both limits agree almost everywhere. Moreover,

$$\|Iu\|_{L^{p^*}(\Omega)} = \lim_{k \to \infty} \|\varphi_k\|_{L^{p^*}(\Omega)} \leq C \lim_{k \to \infty} \|\nabla \varphi_k\|_{(L^p(\Omega))^n} = C \|\nabla u\|_{(L^p(\Omega))^n}.$$

Consequently, $u \in L^{p^*}(\Omega)$, the extension agrees with the canonical inclusion, and we obtain the stated inequality. □

The preceding corollary, combined with interpolation between L^p and L^{p^*}, yields the first continuous Sobolev embedding of this chapter.

Theorem 3.3.6. (Sobolev embedding) If Ω is an open subset of $\mathbb{R}^n$ and $p \in [1, n)$, then

$$W_0^{1,p}(\Omega) \subseteq L^q(\Omega)$$

for every $q \in [p, p^*]$, and this inclusion is continuous.

Proof. Corollary 3.3.5 states that $W_0^{1,p}(\Omega) \subseteq L^{p^*}(\Omega)$ and that there is a constant $C > 0$ such that

$$\|u\|_{L^{p^*}(\Omega)} \leq C\|\nabla u\|_{(L^p(\Omega))^n} \leq C\|u\|_{W^{1,p}(\Omega)}$$

for every $u \in W_0^{1,p}(\Omega)$.
Since we also have $W_0^{1,p}(\Omega) \subseteq L^p(\Omega)$ and $\|u\|_{L^p(\Omega)} \leq \|u\|_{W^{1,p}(\Omega)}$, Theorem B.7.16 ensures that $u \in L^q(\Omega)$ for every $u \in W_0^{1,p}(\Omega)$ and $q \in [p, p^*]$, and that

$$\|u\|_{L^q(\Omega)} \leq \|u\|_{L^p(\Omega)}^{1-\alpha}\|u\|_{L^{p^*}(\Omega)}^{\alpha} \leq C^{\alpha}\|u\|_{W^{1,p}(\Omega)}^{1-\alpha}\|u\|_{W^{1,p}(\Omega)}^{\alpha} = C^{\alpha}\|u\|_{W^{1,p}(\Omega)}$$

, where $\alpha \in [0,1]$ satisfies $\dfrac{1}{q} = \dfrac{1-\alpha}{p} + \dfrac{\alpha}{p^*}$. This proves that $W_0^{1,p}(\Omega) \subseteq L^q(\Omega)$ and that this inclusion is continuous. □

When Ω is bounded, $\|u\|_{L^q(\Omega)}$ can be bounded in terms of $\|\nabla u\|_{(L^p(\Omega))^n}$ and the measure of Ω for a wider range of values of p and q. The following inequality is known as the Poincaré inequality.

Theorem 3.3.7. (Poincaré inequality) Let Ω be a bounded open subset of $\mathbb{R}^n$. There is a constant $C > 0$ depending only on n, p, and q such that

$$\|u\|_{L^q(\Omega)} \leq C(\lambda_n(\Omega))^{\frac{1}{q}+\frac{1}{n}-\frac{1}{p}}\|\nabla u\|_{(L^p(\Omega))^n}$$

for every $u \in W_0^{1,p}(\Omega)$ if any of the following three conditions holds:

(a) $p \in [1, n)$ and $q \in [1, p^*]$.

(b) $p = n$ and $q \in [1, \infty)$.

(c) $p \in (n, \infty)$ and $q \in [1, \infty]$.

Consequently:

- If $p \in [1, n)$, then $W_0^{1,p}(\Omega) \subseteq L^q(\Omega)$ for each $q \in [1, p^*]$, and the inclusion is continuous.
- $W_0^{1,n}(\Omega) \subseteq L^q(\Omega)$ for each $q \in [1, \infty)$, and the inclusion is continuous.
- Furthermore, if $p \in (n, \infty)$, then, after choosing a representative, $W_0^{1,p}(\Omega) \subseteq C^0(\overline{\Omega})$, and the inclusion is continuous.

Proof. (a) If $p \in [1,n)$ and $q \in [1,p^*]$, applying the inequality from Corollary 3.3.5 and Proposition B.7.17 gives

$$\|u\|_{L^q(\Omega)} \le (\lambda_n(\Omega))^{\frac{1}{q}-\frac{1}{p^*}} \|u\|_{L^{p^*}(\Omega)} \le C(\lambda_n(\Omega))^{\frac{1}{q}+\frac{1}{n}-\frac{1}{p}} \|\nabla u\|_{(L^p(\Omega))^n}$$

for every $u \in W_0^{1,p}(\Omega)$.

(b) If $n = 1$, then for $\varphi \in C_c^\infty(\Omega)$, extension by zero and the fundamental theorem of calculus give $\|\varphi\|_{L^\infty(\Omega)} \le \|\varphi'\|_{L^1(\Omega)}$. By Hölder's inequality,

$$\|\varphi\|_{L^q(\Omega)} \le \lambda_1(\Omega)^{\frac{1}{q}} \|\varphi'\|_{L^1(\Omega)}.$$

Approximation by test functions extends this estimate to $W_0^{1,1}(\Omega)$ and proves this part in dimension one. Now assume $n \ge 2$. Let $p = n$ and $q \in [1,\infty)$. If $n = 1$, the inequality

$$|\varphi(x)| \le \int_{-\infty}^{\infty} |\varphi'(t)|\, dt$$

gives

$$\|\varphi\|_{L^q(\Omega)} \le \lambda_1(\Omega)^{\frac{1}{q}} \|\varphi'\|_{L^1(\Omega)}$$

for every $\varphi \in C_c^\infty(\Omega)$. Arguing as in Corollary 3.3.5, we conclude that

$$\|u\|_{L^q(\Omega)} \le (\lambda_1(\Omega))^{\frac{1}{q}} \|Du\|_{L^1(\Omega)}$$

for every $u \in W_0^{1,1}(\Omega)$.

If $n \ge 2$, define $r := \max\{\frac{nq}{n+q}, 1\}$. The number r belongs to $[1,n)$ because $n^2 > 0$ implies $n^2 + nq > nq$, and hence $\frac{nq}{n+q} < n$. Moreover, $r^* = q$ if $r = \frac{nq}{n+q}$, and $q \le \frac{n}{n-1}$ if $r = 1$. Thus, by (a), Proposition B.7.17, and Proposition B.7.13, for every $u \in W_0^{1,p}(\Omega)$ we have

$$\|u\|_{L^q(\Omega)} \le C\|\nabla u\|_{(L^r(\Omega))^n} \le Cn^{\frac{1}{q}} (\lambda_n(\Omega))^{\frac{1}{q}} \|\nabla u\|_{(L^n(\Omega))^n}$$

if $r = \frac{nq}{n+q}$ and

$$\|u\|_{L^q(\Omega)} \le (\lambda_n(\Omega))^{\frac{1}{q}-\frac{n-1}{n}} \|u\|_{\frac{n}{n-1}} \le C(\lambda_n(\Omega))^{\frac{1}{q}-\frac{n-1}{n}} \|\nabla u\|_{(L^1(\Omega))^n} \le Cn^{\frac{n-1}{n}} (\lambda_n(\Omega))^{\frac{1}{q}} \|\nabla u\|_{(L^n(\Omega))^n}$$

if $r = 1$.

(c) Let $p \in (n,\infty)$ and $q \in [1,\infty]$. The second inequality in Theorem 3.3.4, applied to the extension by zero, gives

$$\|\varphi\|_{L^\infty(\Omega)} \le C(\lambda_n(\Omega))^{\frac{1}{n}-\frac{1}{p}} \|\nabla\varphi\|_{(L^p(\Omega))^n}$$

for every $\varphi \in C_c^\infty(\Omega)$.

Now recall that $(C^0(\overline{\Omega}), \|\cdot\|_{C^0(\overline{\Omega})})$ is a Banach space, since Ω is bounded and therefore $\overline{\Omega}$ is compact. Arguing as in Corollary 3.3.5 shows that each $u \in W_0^{1,p}(\Omega)$ agrees almost everywhere with a function belonging to $C^0(\overline{\Omega})$, and that the preceding inequality holds for every u. Combining that inequality

with Proposition B.7.17 gives

$$\|u\|_{L^q(\Omega)} \le (\lambda_n(\Omega))^{\frac{1}{q}} \|u\|_{C^0(\overline{\Omega})} \le C(\lambda_n(\Omega))^{\frac{1}{q}+\frac{1}{n}-\frac{1}{p}} \|\nabla u\|_{(L^p(\Omega))^n}$$

, which is the desired inequality.

□

Just as we defined the Sobolev spaces $W^{1,p}(\Omega)$, we can define the "higher-order Sobolev spaces" $W^{m,p}(\Omega)$:

Definition 3.3.8. Let $\Omega \subseteq \mathbb{R}^n$ be open, and let $m \in \mathbb{N}$, $m \ge 2$, and $p \in [1,\infty]$. Define recursively

$$W^{m,p}(\Omega) := \{u \in L^p(\Omega) \mid u \in W^{1,p}(\Omega) \text{ and } D_i u \in W^{m-1,p}(\Omega), \forall i \in \{1,\dots,n\}\}.$$

That is, $u \in W^{m,p}(\Omega)$ if its weak derivatives of order at most m, namely

$$D^\alpha u := D_1^{\alpha_1} \cdots D_n^{\alpha_n} u$$

with $\alpha = (\alpha_1,\dots,\alpha_n) \in (\mathbb{N} \cup \{0\})^n$, $|\alpha| := \alpha_1 + \cdots + \alpha_n \le m$, exist and belong to $L^p(\Omega)$, where $D_i^0 u := u$ and $D_i^{\alpha_i} u := \underbrace{D_i \cdots D_i}_{\alpha_i\text{−times}} u$ if $\alpha_i \ge 1$. Note that all weak derivatives of order at most m have this form.
Using this notation, define

$$\|u\|_{W^{m,p}(\Omega)} = \left(\sum_{|\alpha| \le m} \|D^\alpha u\|_{L^p(\Omega)}^p \right)^{\frac{1}{p}}, \quad \text{if } p < \infty,$$

and

$$\|u\|_{W^{m,\infty}(\Omega)} = \max_{|\alpha| \le m} \|D^\alpha u\|_{L^\infty(\Omega)}.$$

Finally, define $W_0^{m,p}(\Omega) = \overline{C_c^\infty(\Omega)}^{W^{m,p}(\Omega)}$.

We have that $(W^{m,p}(\Omega), \|\cdot\|_{W^{m,p}(\Omega)})$ is a real normed vector space; the proof is analogous to that of Proposition 3.2.3. We shall give results analogous to those for the spaces $W^{1,p}(\Omega)$ and use the latter to establish the corresponding proofs.

Lemma 3.3.9. Let $p \in [1,\infty]$ and $m \ge 1$, and let (u_k) be a sequence in $W^{m,p}(\Omega)$ such that $u_k \to u$ in $L^p(\Omega)$ and $D^\alpha u_k \to v_\alpha$ in $L^p(\Omega)$ for each multi-index α with $|\alpha| \le m$. Then $u \in W^{m,p}(\Omega)$, $v_\alpha = D^\alpha u$ for every multi-index α with $|\alpha| \le m$, and $u_k \to u$ in $W^{m,p}(\Omega)$.

Proof. We prove the assertion by induction on m. The case $m = 1$ is Lemma 3.2.4. Assume $m \ge 2$ and fix a multi-index β with $|\beta| \le m-1$. For each $i \in \{1,\dots,n\}$,

$$D^\beta u_k \longrightarrow v_\beta, \qquad D_i(D^\beta u_k) = D^{\beta+e_i} u_k \longrightarrow v_{\beta+e_i} \quad \text{on } L^p(\Omega).$$

Lemma 3.2.4, applied to the sequence $(D^\beta u_k)$, shows that $v_\beta \in W^{1,p}(\Omega)$ and $D_i v_\beta = v_{\beta+e_i}$. For $\beta = 0$, uniqueness of the limit in $L^p(\Omega)$ gives $v_0 = u$. Iterating these identities according to the length of β yields $v_\alpha = D^\alpha u$ for every $|\alpha| \le m$; in particular, $u \in W^{m,p}(\Omega)$.

If $p < \infty$, then

$$\|u_k - u\|_{W^{m,p}(\Omega)}^p = \sum_{|\alpha| \le m} \|D^\alpha u_k - D^\alpha u\|_{L^p(\Omega)}^p \longrightarrow 0.$$

If $p = \infty$, the family of multi-indices with $|\alpha| \le m$ is finite, and therefore

$$\|u_k - u\|_{W^{m,\infty}(\Omega)} = \max_{|\alpha| \le m} \|D^\alpha u_k - D^\alpha u\|_{L^\infty(\Omega)} \longrightarrow 0.$$

This completes the proof. □

Theorem 3.3.10. $W^{m,p}(\Omega)$ is a Banach space for every $p \in [1, \infty]$.

Proof. Let (u_k) be a Cauchy sequence in $W^{m,p}(\Omega)$. Then the sequences (u_k) and $(D^\alpha u_k)$ are Cauchy in $L^p(\Omega)$ for every multi-index α with $|\alpha| \le m$. Since $L^p(\Omega)$ is a Banach space by Theorem B.7.3, we have $u_k \to u$ in $L^p(\Omega)$ and $D^\alpha u_k \to v_\alpha$ in $L^p(\Omega)$ for each multi-index α with $|\alpha| \le m$. By Lemma 3.3.9, $u \in W^{m,p}(\Omega)$ and $u_k \to u$ in $W^{m,p}(\Omega)$. Thus $W^{m,p}(\Omega)$ is complete. □

3.3.1 Density and extension by zero

Approximation by cutoffs and mollifiers also controls all derivatives of integer order. The following local construction is the Meyers–Serrin theorem; see [97, Section 11.2].

Lemma 3.3.11. (Restriction and extension by zero with interior support) Let $U \subseteq V \subseteq \mathbb{R}^n$ be open, and let $m \in \mathbb{N}_0$ and $1 \le p < \infty$. The restriction of $w \in W^{m,p}(V)$ belongs to $W^{m,p}(U)$ and satisfies

$$D^\alpha(w \restriction_U) = (D^\alpha w) \restriction_U, \quad |\alpha| \le m, \qquad \|w \restriction_U\|_{W^{m,p}(U)} \le \|w\|_{W^{m,p}(V)}.$$

If $u \in W^{m,p}(U)$ vanishes almost everywhere outside a compact set $K \subset U$, its extension by zero $\widetilde{u}$ to V belongs to $W^{m,p}(V)$ and

$$D^\alpha \widetilde{u} = \widetilde{D^\alpha u}, \qquad |\alpha| \le m, \qquad \|\widetilde{u}\|_{W^{m,p}(V)} = \|u\|_{W^{m,p}(U)}.$$

Moreover, $u \in W_0^{m,p}(U)$.

Proof. If $\varphi \in C_c^\infty(U)$, its extension by zero to V is a smooth test function. For this test function, the identity defining $D^\alpha w$ on V reduces to the identity on U. This identifies the derivatives of the restriction. The norm inequality follows by restricting each integral to U; no regularity of its boundary is required.
For extension by zero, the case $K = \varnothing$ is immediate. Choose $\eta \in C_c^\infty(U)$ equal to one on a neighborhood of K. Locality of weak derivatives gives $D^\alpha u = 0$ almost everywhere on $U \setminus K$: it suffices to test the weak identity against functions in $C_c^\infty(U \setminus K)$ and use uniqueness of the function representing the zero distribution. If

$\varphi \in C_c^\infty(V)$, then $\eta\varphi \restriction_U$ is an admissible test function and

$$\begin{aligned}\int_V \widetilde{u}\, D^\alpha \varphi \, dx &= \int_U u\, D^\alpha(\eta\varphi)\, dx \\ &= (-1)^{|\alpha|} \int_U D^\alpha u\, \eta\varphi \, dx \\ &= (-1)^{|\alpha|} \int_V \widetilde{D^\alpha u}\, \varphi \, dx.\end{aligned}$$

The first equality uses $\eta = 1$ near K and $u = 0$ outside K; the last uses the same property for $D^\alpha u$. Each extension preserves the L^p norm, and therefore also the Sobolev norm.
To prove the final assertion, apply the preceding argument with $V = \mathbb{R}^n$. If ρ_ε is a mollifier with support contained in $\overline{B}_{\mathrm{euc}}(0,\varepsilon)$, Fubini's theorem and the weak identity give

$$D^\alpha(\rho_\varepsilon * \widetilde{u}) = \rho_\varepsilon * \widetilde{D^\alpha u}.$$

Approximation by mollifiers in L^p implies convergence of each derivative in $L^p(\mathbb{R}^n)$. For sufficiently small ε, the support of the convolution is contained in $K + \overline{B}_{\mathrm{euc}}(0,\varepsilon) \Subset U$. Their restrictions belong to $C_c^\infty(U)$ and converge to u in $W^{m,p}(U)$, proving membership in $W_0^{m,p}(U)$. □

Proposition 3.3.12. (Density of smooth functions) Let $m \in \mathbb{N}_0$ and $1 \le p < \infty$. For every open subset $\Omega \subseteq \mathbb{R}^n$, the space $C^\infty(\Omega) \cap W^{m,p}(\Omega)$ is dense in $W^{m,p}(\Omega)$. Moreover,

$$W_0^{m,p}(\mathbb{R}^n) = W^{m,p}(\mathbb{R}^n).$$

Here $W^{0,p}(\Omega) := L^p(\Omega)$ and $W_0^{0,p}(\Omega) = L^p(\Omega)$, by Proposition B.7.18.

Proof. Successive applications of the weak Leibniz rule in Proposition 3.1.4 give, for $|\alpha| \le m$,

$$D^\alpha(\chi u) = \sum_{\beta \le \alpha} \binom{\alpha}{\beta} (D^\beta \chi) D^{\alpha-\beta} u,$$

where $\alpha, \beta \in \mathbb{N}_0^n$ and $\beta \le \alpha$ means $\beta_i \le \alpha_i$ for every $i \in \{1,\dots,n\}$. The induction producing this formula uses the first-order rule on each summand and Pascal's identity to combine the coefficients.
On $\mathbb{R}^n$, take the cutoffs χ_R from Proposition 3.2.10. The summand with $\beta = 0$ converges to $D^\alpha u$ in L^p by dominated convergence. If $\beta \neq 0$, then

$$\|(D^\beta \chi_R) D^{\alpha-\beta} u\|_{L^p(\mathbb{R}^n)} \le R^{-|\beta|} \|D^\beta \chi\|_{L^\infty(\mathbb{R}^n)} \|D^{\alpha-\beta} u\|_{L^p(\mathbb{R}^n)} \longrightarrow 0.$$

Thus, $\chi_R u \to u$ in $W^{m,p}(\mathbb{R}^n)$. For fixed R, Fubini's theorem and the definition of weak derivative give

$$D^\alpha(\rho_\varepsilon * (\chi_R u)) = \rho_\varepsilon * D^\alpha(\chi_R u).$$

Continuity of translations and the mollification estimate used in Proposition 3.2.10 prove convergence in L^p for each of the finitely many multi-indices. These mollifications are smooth and compactly supported, proving the stated equality.

For a general open subset, choose an exhaustion $\Omega_j \Subset \Omega_{j+1} \Subset \Omega$ with union Ω, and a smooth partition of unity $(\eta_j)_{j\in\mathbb{N}}$ whose supports are compact and contained in the open sets $V_j := \Omega_{j+1} \setminus \overline{\Omega_{j-1}}$; we may take $\Omega_0 = \Omega_{-1} = \varnothing$ and adjust the first two members. The existence of this partition follows from Theorem 1.3.5 by grouping the functions subordinate to each V_j. The family $(V_j)_{j\in\mathbb{N}}$ is locally finite. The Leibniz formula shows that $\eta_j u \in W^{m,p}(V_j)$, and its support is contained in the compact set $\operatorname{supp}\eta_j \Subset V_j$. Lemma 3.3.11 allows its extension by zero to $\mathbb{R}^n$ without changing either its norm or its weak derivatives.
Given $\delta > 0$, for each j choose $\varepsilon_j > 0$ sufficiently small that

$$v_j := \rho_{\varepsilon_j} * (\eta_j u) \in C_c^\infty(V_j), \qquad \|v_j - \eta_j u\|_{W^{m,p}(\mathbb{R}^n)} < \delta 2^{-j}.$$

The sum $v := \sum_{j=1}^{\infty} v_j$ is locally finite and therefore smooth on Ω. The series of errors $\sum_{j=1}^{\infty}(v_j - \eta_j u)$ converges absolutely in the Banach space $W^{m,p}(\mathbb{R}^n)$. Its limit, restricted to Ω, agrees with $v - u$: on each Ω_N, only finitely many terms occur, by local finiteness of the supports. In particular, $v - u \in W^{m,p}(\Omega)$ before we take its norm, and the triangle inequality gives

$$\|v - u\|_{W^{m,p}(\Omega)} \le \sum_{j=1}^{\infty} \|v_j - \eta_j u\|_{W^{m,p}(\mathbb{R}^n)} \le \delta.$$

This proves that $v \in W^{m,p}(\Omega)$ and establishes density. □

Proposition 3.3.13. (Extension by zero and derivatives of $W_0^{m,p}$) Let $\Omega \subseteq \mathbb{R}^n$ be open, and let $m \in \mathbb{N}_0$ and $1 \le p < \infty$. Extension by zero Z_Ω is an isometry

$$Z_\Omega \colon W_0^{m,p}(\Omega) \longrightarrow W^{m,p}(\mathbb{R}^n)$$

and, for every multi-index $\alpha \in \mathbb{N}_0^n$ with $|\alpha| \le m$,

$$D^\alpha(Z_\Omega u) = Z_\Omega(D^\alpha u), \qquad D^\alpha u \in W_0^{m-|\alpha|,p}(\Omega).$$

If $v \in W^{m,p}(\mathbb{R}^n)$ has support contained in a compact set $K \subseteq \Omega$, then $v \restriction_\Omega \in W_0^{m,p}(\Omega)$.

Proof. Choose $u_j \in C_c^\infty(\Omega)$ with $u_j \to u$ in $W^{m,p}(\Omega)$. For these functions, $D^\alpha(Z_\Omega u_j) = Z_\Omega(D^\alpha u_j)$ and

$$\|Z_\Omega u_j - Z_\Omega u_\ell\|_{W^{m,p}(\mathbb{R}^n)} = \|u_j - u_\ell\|_{W^{m,p}(\Omega)}.$$

Completeness and Lemma 3.3.9 identify the limit with $Z_\Omega u$ and all its derivatives with the corresponding extensions by zero. Equality of norms passes to the limit. Moreover, $D^\alpha u_j \to D^\alpha u$ in $W^{m-|\alpha|,p}(\Omega)$; since each $D^\alpha u_j \in C_c^\infty(\Omega)$, membership in the indicated closed subspace follows.
For the final assertion, the mollifications of v have support in $K + \overline{B}_{\mathrm{euc}}(0,\varepsilon) \Subset \Omega$ if ε is sufficiently small, and converge in $W^{m,p}$ by the proof of Proposition 3.3.12. Their restrictions approximate $v \restriction_\Omega$ by functions in $C_c^\infty(\Omega)$. □

The definition by closure requires no regularity of $\partial\Omega$. In particular, the preceding proposition does not identify $W_0^{m,p}(\Omega)$ with the kernel of a trace on an arbitrary open subset. For $W^{m,p}(\Omega)$, one must distinguish

smooth approximation in the interior from extension across the boundary.

Definition 3.3.14. (Sobolev extension domain) We say that an open subset Ω is an extension domain for $W^{m,p}$ if there is a continuous linear operator $\mathcal{E}\colon W^{m,p}(\Omega) \longrightarrow W^{m,p}(\mathbb{R}^n)$ such that $(\mathcal{E}u)\restriction_\Omega = u$ almost everywhere.

If $p < \infty$ and such an operator exists, approximation of $\mathcal{E}u$ by functions in $C_c^\infty(\mathbb{R}^n)$ shows that their restrictions are dense in $W^{m,p}(\Omega)$. These restrictions need not vanish on the boundary; their density does not assert that $W_0^{m,p}(\Omega) = W^{m,p}(\Omega)$. The restriction to finite exponents in the equality on $\mathbb{R}^n$ is necessary: the constant function one belongs to $W^{m,\infty}(\mathbb{R}^n)$ and cannot be approximated uniformly by compactly supported functions.

Definition 3.3.15. If $m < n$ and $p \in [1, \frac{n}{m})$, the mth critical Sobolev exponent is defined by

$$p_m^* := \frac{np}{n - mp}.$$

Note that $p_1^* = p^*$.

The following formulation gathers the higher-order embeddings for finite exponents.

Theorem 3.3.16. (Sobolev embedding with finite orders and exponents) Let $\Omega \subseteq \mathbb{R}^n$ be open and bounded. Let $m > k \geq 0$ be integers and $1 \leq p, q < \infty$ satisfy

$$m - \frac{n}{p} \geq k - \frac{n}{q}.$$

Then $W_0^{m,p}(\Omega) \hookrightarrow W_0^{k,q}(\Omega)$ continuously. If Ω is an extension domain for $W^{m,p}$, then also $W^{m,p}(\Omega) \hookrightarrow W^{k,q}(\Omega)$ continuously.

Proof. For $q \leq p$, Hölder's inequality gives, for $|\alpha| \leq k$,

$$\|D^\alpha u\|_{L^q(\Omega)} \leq \lambda_n(\Omega)^{\frac{1}{q} - \frac{1}{p}} \|D^\alpha u\|_{L^p(\Omega)}.$$

Summing over the finitely many multi-indices gives $\|u\|_{W^{k,q}(\Omega)} \leq C\|u\|_{W^{m,p}(\Omega)}$. If $u \in W_0^{m,p}(\Omega)$, applying this inequality to approximations of $C_c^\infty(\Omega)$ also shows that $u \in W_0^{k,q}(\Omega)$. Assume $q > p$ and set $d := m - k$ and

$$\frac{1}{r_i} := \frac{1}{p} - \frac{i}{d}\left(\frac{1}{p} - \frac{1}{q}\right), \qquad i \in \{0, \dots, d\}.$$

The exponents are finite, $r_0 = p$, $r_d = q$, and

$$\frac{1}{r_{i+1}} \geq \frac{1}{r_i} - \frac{1}{n} \qquad (0 \leq i < d).$$

If $r_i < n$, this means $r_{i+1} \leq r_i^*$; if $r_i = n$ or $r_i > n$, the next exponent is still finite. In all three cases, the corresponding part of Theorem 3.3.7 gives $W_0^{1,r_i}(\Omega) \hookrightarrow L^{r_{i+1}}(\Omega)$. Applying it to $D^\alpha \varphi$, with $|\alpha| \leq m - i - 1$ and $\varphi \in C_c^\infty(\Omega)$, yields

$$\|D^\alpha \varphi\|_{L^{r_{i+1}}(\Omega)} \leq C_i \|D^\alpha \varphi\|_{W^{1,r_i}(\Omega)}.$$

Summing over the multi-indices and using the equivalence of norms in finite dimensions, Proposition B.1.2, gives

$$\|\varphi\|_{W^{m-i-1,r_{i+1}}(\Omega)} \le C_i \left(\sum_{|\alpha|\le m-i-1} \|D^\alpha \varphi\|^{r_{i+1}}_{W^{1,r_i}(\Omega)} \right)^{\frac{1}{r_{i+1}}} \le C_i' \|\varphi\|_{W^{m-i,r_i}(\Omega)}.$$

In the last inequality, each derivative of order at most $m-i$ appears a finite number of times, depending only on n, m, i.
If $u \in W_0^{m-i,r_i}(\Omega)$, choose $\varphi_\nu \in C_c^\infty(\Omega)$ converging to u in $W^{m-i,r_i}(\Omega)$. The preceding estimate, applied to $\varphi_\nu - \varphi_\mu$, shows that this sequence is Cauchy in $W^{m-i-1,r_{i+1}}(\Omega)$. By completeness, it converges to an element v of this space, and $v \in W_0^{m-i-1,r_{i+1}}(\Omega)$ by the definition of closure. Since Ω has finite measure, convergence in L^{r_i} and in $L^{r_{i+1}}$ implies convergence in L^1; uniqueness of this limit gives $v = u$ almost everywhere. Passing to the limit in the estimate yields a continuous embedding

$$W_0^{m-i,r_i}(\Omega) \hookrightarrow W_0^{m-i-1,r_{i+1}}(\Omega).$$

The composition of these d embeddings starts at $W_0^{m,p}(\Omega)$ and ends at $W_0^{m-d,r_d}(\Omega) = W_0^{k,q}(\Omega)$, as required.
If there is an extension operator $\mathcal{E}$, choose a ball B containing $\overline{\Omega}$ and $\chi \in C_c^\infty(B)$ equal to one on a neighborhood of $\overline{\Omega}$. Set $Tu := (\chi \mathcal{E} u) \restriction_B$. The Leibniz rule and Proposition 3.3.13 give $Tu \in W_0^{m,p}(B)$, $Tu \restriction_\Omega = u$, and

$$\|Tu\|_{W^{m,p}(B)} \le \|\chi \mathcal{E} u\|_{W^{m,p}(\mathbb{R}^n)} \le C_\chi \|\mathcal{E} u\|_{W^{m,p}(\mathbb{R}^n)} \le C_\chi \|\mathcal{E}\| \|u\|_{W^{m,p}(\Omega)}.$$

The assertion already proved on B and continuity of restriction from Lemma 3.3.11 yield

$$\|u\|_{W^{k,q}(\Omega)} \le \|Tu\|_{W^{k,q}(B)} \le C_B C_\chi \|\mathcal{E}\| \|u\|_{W^{m,p}(\Omega)}.$$

This proves the second embedding. We have not required u to vanish on $\partial\Omega$: the cutoff vanishes near the boundary of the larger ball B. □

When $(m-k)p < n$, the Sobolev index is expressed through the critical exponent p^*_{m-k}. The usual formulation is a direct consequence of the preceding theorem.

Corollary 3.3.17. (Sobolev embedding and critical exponent) Let $\Omega \subseteq \mathbb{R}^n$ be a bounded open subset. Let $j \ge 0$ and $d \ge 1$ be integers, and let $1 \le p < n/d$. Then

$$W_0^{j+d,p}(\Omega) \hookrightarrow W_0^{j,q}(\Omega) \qquad \text{for every } 1 \le q \le p^*_d := \frac{np}{n-dp},$$

and these inclusions are continuous. In particular, $W_0^{d,p}(\Omega) \hookrightarrow L^q(\Omega)$ for the same exponents. If Ω is an extension domain for $W^{j+d,p}$, then also $W^{j+d,p}(\Omega) \hookrightarrow W^{j,q}(\Omega)$ continuously.

Proof. The condition $q \le p^*_d$ is equivalent to

$$j + d - \frac{n}{p} \ge j - \frac{n}{q}.$$

Apply Theorem 3.3.16 with total orders $m = j + d$ and $k = j$. For $j = 0$, use $W_0^{0,q}(\Omega) = L^q(\Omega)$. □

3.4 The Rellich–Kondrashov theorem in Euclidean spaces

The Poincaré inequality provides continuous embeddings of $W_0^{1,p}(\Omega)$ into $L^q(\Omega)$ up to the critical exponent. Continuity, however, does not ensure that a bounded sequence has a convergent subsequence in the target space. The Rellich–Kondrashov theorem determines the exponents for which this gain in compactness occurs, a decisive feature in many existence arguments. The proof begins with an estimate for translations.

Lemma 3.4.1. (Translation estimate in L^p) Let $1 \le p < \infty$, $u \in W^{1,p}(\mathbb{R}^n)$, and $\xi \in \mathbb{R}^n$. If $T_\xi u(x) := u(x - \xi)$, then

$$\|T_\xi u - u\|_{L^p(\mathbb{R}^n)} \le \|\xi\| \sum_{i=1}^{n} \|D_i u\|_{L^p(\mathbb{R}^n)} \le n^{1-\frac{1}{p}} \|\xi\| \|\nabla u\|_{(L^p(\mathbb{R}^n))^n}.$$

Proof. For $\varphi \in C_c^\infty(\mathbb{R}^n)$, the fundamental theorem of calculus along the segment $t \mapsto x - t\xi$ gives

$$\varphi(x - \xi) - \varphi(x) = -\int_0^1 \nabla\varphi(x - t\xi) \cdot \xi \, dt.$$

Minkowski's integral inequality from Theorem B.8.2 and translation invariance of the measure imply

$$\begin{aligned} \|T_\xi \varphi - \varphi\|_{L^p(\mathbb{R}^n)} &\le \|\xi\| \int_0^1 \sum_{i=1}^{n} \|D_i \varphi(\cdot - t\xi)\|_{L^p(\mathbb{R}^n)} \, dt \\ &= \|\xi\| \sum_{i=1}^{n} \|D_i \varphi\|_{L^p(\mathbb{R}^n)}. \end{aligned}$$

For $p = 1$, this also follows directly by applying Tonelli's theorem to the pointwise estimate. For $u \in W^{1,p}(\mathbb{R}^n)$, choose $\varphi_j \to u$ in $W^{1,p}$ by Proposition 3.2.10. Since translations are isometries,

$$\|T_\xi u - u\|_{L^p(\mathbb{R}^n)} \le 2\|u - \varphi_j\|_{L^p(\mathbb{R}^n)} + \|T_\xi \varphi_j - \varphi_j\|_{L^p(\mathbb{R}^n)}.$$

Let $j \to \infty$. The second inequality in the statement is Hölder's inequality for the finite sum, with equality of the factors when $p = 1$. □

Theorem 3.4.2. (Rellich–Kondrashov with finite orders and exponents) Let $\Omega \subseteq \mathbb{R}^n$ be a bounded open subset. Let $m > k \ge 0$ be integers and $1 \le p, q < \infty$ satisfy

$$m - \frac{n}{p} > k - \frac{n}{q}. \tag{3.2}$$

Then the embedding

$$W_0^{m,p}(\Omega) \hookrightarrow W_0^{k,q}(\Omega)$$

is compact. If, in addition, Ω is an extension domain for $W^{m,p}$, the embedding

$$W^{m,p}(\Omega) \hookrightarrow W^{k,q}(\Omega)$$

is also compact. The continuity constants depend on n, m, k, p, q, Ω and, in the second assertion, on the norm of the chosen extension operator.

Proof. Let $(u_j)_{j\in\mathbb{N}}$ be a bounded sequence in $W_0^{m,p}(\Omega)$. We begin by proving convergence of a subsequence in $W^{m-1,p}$. Extend by zero and write $v_j := Z_\Omega u_j$. By Proposition 3.3.13, (v_j) is bounded in $W^{m,p}(\mathbb{R}^n)$ and, for each $|\alpha| \le m-1$,

$$D^\alpha v_j \in W^{1,p}(\mathbb{R}^n), \qquad \operatorname{supp}(D^\alpha v_j) \subseteq \overline{\Omega}.$$

If $M_0 := \sup_{j\in\mathbb{N}} \|u_j\|_{W^{m,p}(\Omega)} < \infty$, Lemma 3.4.1 gives

$$\sup_{j\in\mathbb{N}} \|T_\xi D^\alpha v_j - D^\alpha v_j\|_{L^p(\mathbb{R}^n)} \le C_{n,p} M_0 \|\xi\|, \qquad |\alpha| \le m-1.$$

Apply Proposition B.7.19 on the open subset $\mathbb{R}^n$. The translation condition holds on every relatively compact open subset by the global estimate; the tail condition holds with zero error upon choosing a ball containing $\overline{\Omega}$. Boundedness in L^p is already known. Therefore, $(D^\alpha v_j)_j$ has a subsequence converging in L^p.

Enumerate the finitely many multi-indices of order at most $m-1$, extract a subsequence for the first, then a subsequence of that one for the second, and so on. The last subsequence retains all the convergences. Restricting to Ω and applying Lemma 3.3.9 yields convergence in $W^{m-1,p}(\Omega)$; when $m = 1$, completeness of L^p suffices. Each term belongs to $W_0^{m-1,p}(\Omega)$ by its approximation in $W^{m,p}$ by test functions. This subspace is closed, so the limit belongs to it. The argument uses strong compactness in L^p and also works for $p = 1$.

If $q \le p$, the continuous inclusion $W^{m-1,p}(\Omega) \hookrightarrow W^{k,q}(\Omega)$, obtained from the finite measure of Ω and $k \le m-1$, proves the desired convergence. If $q > p$, the strict inequality (3.2) allows us to choose a finite exponent $r > q$ such that

$$m - \frac{n}{p} \ge k - \frac{n}{r}.$$

Theorem 3.3.16 shows that (u_j) is bounded in $W^{k,r}(\Omega)$. For each $|\alpha| \le k$, the interpolation inequality from Theorem B.7.16 gives

$$\|D^\alpha(u_j - u_\ell)\|_{L^q(\Omega)} \le \|D^\alpha(u_j - u_\ell)\|_{L^p(\Omega)}^{\theta} \|D^\alpha(u_j - u_\ell)\|_{L^r(\Omega)}^{1-\theta}, \quad \frac{1}{q} = \frac{\theta}{p} + \frac{1-\theta}{r},$$

with $0 < \theta < 1$. Along the preceding subsequence, the first factor tends to zero and the second remains bounded. Summing over the multi-indices, we obtain a Cauchy sequence in $W^{k,q}(\Omega)$, which converges by completeness. In both cases, Theorem 3.3.16 places each term in $W_0^{k,q}(\Omega)$; closedness ensures that the limit also belongs to this space.

For $W^{m,p}(\Omega)$, use the operator $Tu = (\chi \mathcal{E} u)\restriction_B \in W_0^{m,p}(B)$ constructed in the proof of Theorem 3.3.16. For a bounded sequence $(u_j)_{j\in\mathbb{N}}$, with the same operator and the same cutoff, we have

$$\sup_{j\in\mathbb{N}} \|Tu_j\|_{W^{m,p}(B)} \le C_\chi \|\mathcal{E}\| \sup_{j\in\mathbb{N}} \|u_j\|_{W^{m,p}(\Omega)} < \infty.$$

The first part provides a subsequence $Tu_{j_\nu} \to z$ in $W_0^{k,q}(B)$. Since $Tu_{j_\nu}\restriction_\Omega = u_{j_\nu}$,

$$\|u_{j_\nu} - z\restriction_\Omega\|_{W^{k,q}(\Omega)} \le \|Tu_{j_\nu} - z\|_{W^{k,q}(B)} \longrightarrow 0.$$

Compactness is applied on the fixed ball B, not on all of $\mathbb{R}^n$. □

Corollary 3.4.3. (Loss of one derivative with the same exponent) For every bounded open subset $\Omega \subseteq \mathbb{R}^n$, every integer $m \geq 1$, and every $1 \leq p < \infty$, the embedding

$$W_0^{m,p}(\Omega) \hookrightarrow W_0^{m-1,p}(\Omega)$$

is compact. If Ω is an extension domain for $W^{m,p}$, then $W^{m,p}(\Omega) \hookrightarrow W^{m-1,p}(\Omega)$ is also compact.

Proof. Take $k = m-1$ and $q = p$ in the preceding theorem. The difference between the Sobolev indices is exactly one, in every dimension. □

The subcritical embeddings follow by choosing the corresponding exponents in the general theorem.

Corollary 3.4.4. (First-order Rellich–Kondrashov) If $\Omega \subseteq \mathbb{R}^n$ is open and bounded, $p \in [1, n)$, and $q \in [1, p^*)$, then the inclusion $W_0^{1,p}(\Omega) \subseteq L^q(\Omega)$ is compact.

Proof. Take $m = 1$ and $k = 0$ in Theorem 3.4.2. Since $p < n$, the condition $1 - \dfrac{n}{p} > -\dfrac{n}{q}$ is equivalent to $q < p^*$. □

At higher orders, the finite critical exponent appears when the product of the increase in order and p is less than n.

Corollary 3.4.5. (Rellich–Kondrashov and critical exponent) Let $\Omega \subseteq \mathbb{R}^n$ be a bounded open subset, let $j \in \mathbb{N}_0$ and $m \in \{1, \dots, n-1\}$, and let $1 \leq p < \frac{n}{m}$. Then, for every $1 \leq q < p_m^*$, the inclusion

$$W_0^{j+m,p}(\Omega) \hookrightarrow W_0^{j,q}(\Omega)$$

is compact. At the endpoint $q = p_m^*$, the embedding is continuous by Theorem 3.3.16.

Proof. Since $mp < n$, we have

$$q < p_m^* \quad \Longleftrightarrow \quad j + m - \frac{n}{p} > j - \frac{n}{q}.$$

Apply Theorem 3.4.2 with total orders $j + m$ and j. Continuity at the endpoint is Corollary 3.3.17. □

Remark 3.4.6. (The critical endpoint and assumptions on the domain) The strict inequality cannot in general be replaced by equality. Let $m > k \geq 0$, $(m-k)p < n$, $q = \frac{np}{n-(m-k)p}$, and $B_{\mathrm{euc}}(x_0, r) \Subset \Omega$. Choose a nonzero $\varphi \in C_c^\infty(B_{\mathrm{euc}}(0,1))$ and set, for $0 < \varepsilon < r$,

$$u_\varepsilon(x) := \varepsilon^{m-\frac{n}{p}} \varphi\left(\frac{x - x_0}{\varepsilon}\right).$$

For each $|\alpha| \leq m$,

$$\|D^\alpha u_\varepsilon\|_{L^p(\Omega)} = \varepsilon^{m-|\alpha|} \|D^\alpha \varphi\|_{L^p(B_{\mathrm{euc}}(0,1))}.$$

Thus, the family is bounded in $W_0^{m,p}(\Omega)$. For some $|\beta| = k$, the function $D^\beta \varphi$ is nonzero and

$$\|D^\beta u_\varepsilon\|_{L^q(\Omega)} = \|D^\beta \varphi\|_{L^q(B_{\mathrm{euc}}(0,1))} > 0.$$

However, $D^\beta u_\varepsilon \to 0$ almost everywhere as $\varepsilon \to 0^+$. No subsequence can converge in L^q. This prevents compactness at the critical exponent, although continuity does hold.

Nor does boundedness of an open subset suffice for compactness on $W^{m,p}$ without the zero subscript. Let Ω be the union of disjoint open balls $(B_j)_{j\in\mathbb{N}}$ contained in a fixed ball and accumulating only at a point outside Ω. The functions

$$u_j := \lambda_n(B_j)^{-\frac{1}{p}} \mathbf{1}_{B_j}$$

are constant on each component of Ω, so all their positive-order weak derivatives vanish and $\|u_j\|_{W^{m,p}(\Omega)} = 1$. For $j \neq \ell$, we have $\|u_j - u_\ell\|_{L^p(\Omega)} = 2^{1/p}$. Thus, even the loss of one derivative at the same exponent does not yield compactness on this $W^{m,p}(\Omega)$.

The condition $m > k$ is also essential: on a ball of finite measure, the index inequality holds with $m = k = 0$ and $q < p$, but the inclusion $L^p \hookrightarrow L^q$ is not compact. On a cube, functions alternating between 1 and -1 on dyadic intervals of the first coordinate are bounded in L^p, and any two differ on a set whose measure is half that of the cube. Their distances in L^q are therefore bounded away from zero.

3.4.1 Global embeddings and localization in $\mathbb{R}^n$

Proposition 3.4.7. (Global continuous embeddings with finite exponents) Let $m > k \geq 0$ be integers and $1 \leq p \leq q < \infty$ satisfy $m - \frac{n}{p} \geq k - \frac{n}{q}$. Then

$$W^{m,p}(\mathbb{R}^n) \hookrightarrow W^{k,q}(\mathbb{R}^n)$$

continuously. The same conclusion holds on an extension domain for $W^{m,p}$ by restricting its extension operator.

Proof. Let $Q_a := a + (0,1)^n$, with $a \in \mathbb{Z}^n$, and $\chi_a(x) := \chi(x-a)$, where $\chi \in C_c^\infty((-1,2)^n)$ equals one on $[0,1]^n$. Proposition 3.3.13 and the Leibniz rule give $\chi_a u \in W_0^{m,p}(a + (-1,2)^n)$. Applying Theorem 3.3.16 on these translated cubes yields

$$\|u\|_{W^{k,q}(Q_a)} \leq C\|u\|_{W^{m,p}(a+(-1,2)^n)},$$

with the same constant for every a. The cubes Q_a cover $\mathbb{R}^n$ except for a null set, and the enlarged cubes have multiplicity at most 3^n. Since $p \leq q$, for every nonnegative family (b_a) we have $(\sum_{a\in\mathbb{Z}^n} b_a^q)^{1/q} \leq (\sum_{a\in\mathbb{Z}^n} b_a^p)^{1/p}$. Consequently,

$$\begin{aligned}\|u\|_{W^{k,q}(\mathbb{R}^n)} &\leq C\left(\sum_{a\in\mathbb{Z}^n} \|u\|^p_{W^{m,p}(a+(-1,2)^n)}\right)^{1/p} \\ &\leq C3^{n/p}\|u\|_{W^{m,p}(\mathbb{R}^n)}.\end{aligned}$$

Composition with an extension operator followed by restriction proves the final assertion. □

Corollary 3.4.8. (Compactness with common support and local compactness) Let $m > k \geq 0$, $1 \leq p, q < \infty$, and $m - \frac{n}{p} > k - \frac{n}{q}$. For each compact set $K \subseteq \mathbb{R}^n$, the inclusion into $W^{k,q}(\mathbb{R}^n)$ of the subspace

$$W^{m,p}_K(\mathbb{R}^n) := \{u \in W^{m,p}(\mathbb{R}^n) \mid \operatorname{supp} u \subseteq K\}$$

is compact. For any open subset Ω, every bounded sequence in $W^{m,p}(\Omega)$ has a subsequence converging in $W^{k,q}(U)$ for each open subset $U \Subset \Omega$.

Proof. If $K \Subset B$ for a ball B, Proposition 3.3.13 places the functions in $W^{m,p}_0(B)$. Theorem 3.4.2 provides a subsequence converging in $W^{k,q}_0(B)$, and extension by zero preserves this convergence in $\mathbb{R}^n$.
For the local assertion, take an exhaustion of Ω and cutoffs $\chi_j \in C^\infty_c(\Omega)$ equal to one on its successive members. The Leibniz rule and the first part apply to each localized sequence. Extract successive subsequences and then the diagonal subsequence. The limits agree on intersections by uniqueness of the local limit in measure. Every $U \Subset \Omega$ is contained in a member of the exhaustion, proving the stated convergence. □

Remark 3.4.9. (Translations toward infinity) The equality $W^{m,p}_0(\mathbb{R}^n) = W^{m,p}(\mathbb{R}^n)$ for $p < \infty$ does not make the global continuous embeddings compact. If $0 \neq \varphi \in C^\infty_c(\mathbb{R}^n)$ and we choose points x_j so that the supports of $u_j(x) := \varphi(x - x_j)$ are disjoint, the $W^{m,p}$ norms remain constant and

$$\|u_j - u_\ell\|_{L^q(\mathbb{R}^n)} = 2^{1/q}\|\varphi\|_{L^q(\mathbb{R}^n)} \qquad (j \neq \ell, 1 \leq q < \infty).$$

For $q = \infty$, the distance is $\|\varphi\|_{L^\infty(\mathbb{R}^n)} > 0$. Global compactness fails even with a strict gain in indices. Localization or a common compact support prevents this escape.
The condition $q \geq p$ in the global continuous embeddings must also be retained. If $1 \leq q < p < \infty$, choose a with $n/p < a \leq n/q$. The function $u(x) = (1 + |x|^2)^{-a/2}$ and all its derivatives of every order belong to $L^p(\mathbb{R}^n)$, whereas $u \notin L^q$. Inclusions based on finite measure apply to bounded domains or fixed supports, not to the whole Euclidean space.

3.5 Sobolev embeddings into Hölder spaces

The Sobolev embeddings studied so far improve the integrability of a weakly differentiable function. In the supercritical regime, the gain is stronger: when the number of derivatives and the integrability exponent satisfy $mp > n$, functions in $W^{m,p}$ admit representatives with Hölder continuous classical derivatives. This property is fundamental in regularity theory. The embedding does not itself produce new derivatives: one must first obtain a priori estimates placing the weak solution in a sufficiently high space $W^{m,p}$; Morrey's embedding then converts this Sobolev regularity into quantitative classical regularity. The development in this section follows Morrey's strategy as presented in [97, Section 12.3].

Definition 3.5.1. (Functions of class C^k and $C^{k,\alpha}$ on the closure of an open subset) Let $\Omega \subseteq \mathbb{R}^n$ be an open subset. We begin with the usual convention

$$C^0(\overline{\Omega}) := \left\{v : \overline{\Omega} \longrightarrow \mathbb{R} \,\middle|\, v \text{ is continuous}\right\}.$$

For $k \in \mathbb{N} \cup \{\infty\}$, write

$$C^k(\overline{\Omega}) := \left\{ v \in C^0(\overline{\Omega}) \;\middle|\; \begin{array}{l} \text{there are an open subset } V \subseteq \mathbb{R}^n, \text{ with } \overline{\Omega} \subseteq V, \text{ and a function} \\ \widetilde{v} \in C^k(V) \text{ such that } \widetilde{v} \restriction_{\overline{\Omega}} = v \end{array} \right\}.$$

Continuity shows that an extension initially defined on Ω determines, whenever it exists, a unique function on $\overline{\Omega}$. In applications, we shall therefore identify a function on Ω with its continuous representative on the closure. Moreover, for $k \in \mathbb{N}_0 \cup \{\infty\}$, define

$$C_c^k(\overline{\Omega}) := \left\{ v \in C^k(\overline{\Omega}) \middle| \operatorname{supp}_{\overline{\Omega}}(v) \text{ is compact} \right\},$$

where the support is taken in the topological space $\overline{\Omega}$. Thus, for $k \geq 1$, the notation $C^k(\overline{\Omega})$ does not merely mean that the derivatives have limits at the boundary. It requires the function to be the restriction of a function of class C^k defined on an open neighborhood of $\overline{\Omega}$. This is also the convention used in trace theory.

Now let $K \subseteq \mathbb{R}^n$ be nonempty and let $w \colon K \longrightarrow \mathbb{R}$ be a bounded function. For $0 < \alpha < 1$, set

$$[w]_{C^{0,\alpha}(K)} := \sup_{\substack{x,y \in K \\ x \neq y}} \frac{|w(x) - w(y)|}{|x - y|^\alpha}, \qquad \|w\|_{C^{0,\alpha}(K)} := \|w\|_{C^0(K)} + [w]_{C^{0,\alpha}(K)}, \qquad \|w\|_{C^0(K)} := \sup_{x \in K} |w(x)|,$$

with the convention that the supremum is zero when K consists of a single point. For orders $k \geq 1$, we also assume $K = \overline{\operatorname{Int}(K)}$. This condition ensures that derivatives on K are determined by the restriction of the function: two extensions agreeing on K have the same derivatives on its interior and, by continuity, on K. If $k \in \mathbb{N}$ and w is of class C^k on a neighborhood of K, define the intrinsic norm

$$\|w\|_{C^{k,\alpha}_{\mathrm{int}}(K)} := \sum_{|\beta| \leq k} \|D^\beta w\|_{C^0(K)} + \sum_{|\beta| = k} [D^\beta w]_{C^{0,\alpha}(K)}. \tag{3.3}$$

For $k = 0$, write $\|w\|_{C^{0,\alpha}_{\mathrm{int}}(K)} := \|w\|_{C^{0,\alpha}(K)}$. Denote by $C^{k,\alpha}_{\mathrm{int}}(K)$ the space of restrictions to K of functions of class C^k on a neighborhood of K for which this norm is finite. The subscript int recalls that the norm compares only the values of the function and its derivatives on K; it does not require an extension with global control.

Let $k \in \mathbb{N}_0$ and $0 < \alpha < 1$. For $v \in C^k(\mathbb{R}^n)$, define

$$[v]_{C^{k,\alpha}(\mathbb{R}^n)} := \sum_{|\beta| = k} [D^\beta v]_{C^{0,\alpha}(\mathbb{R}^n)}$$

and

$$\|v\|_{C^{k,\alpha}(\mathbb{R}^n)} := \sum_{|\beta| \leq k} \|D^\beta v\|_{L^\infty(\mathbb{R}^n)} + [v]_{C^{k,\alpha}(\mathbb{R}^n)}.$$

Denote by $C^{k,\alpha}(\mathbb{R}^n)$ the space of functions for which this norm is finite.

Finally, suppose that Ω is bounded. For $v \in C^k(\overline{\Omega})$, let

$$\mathcal{E}^{k,\alpha}_\Omega(v) := \left\{ \widetilde{v} \in C^{k,\alpha}(\mathbb{R}^n) \middle| \widetilde{v} \restriction_{\overline{\Omega}} = v \right\}.$$

Define

$$C^{k,\alpha}(\overline{\Omega}) := \left\{ v \in C^k(\overline{\Omega}) \,\middle|\, \mathcal{E}^{k,\alpha}_{\Omega}(v) \neq \varnothing \right\}$$

and equip this space with the extension norm

$$\|v\|_{C^{k,\alpha}(\overline{\Omega})} := \inf_{\widetilde{v} \in \mathcal{E}^{k,\alpha}_{\Omega}(v)} \|\widetilde{v}\|_{C^{k,\alpha}(\mathbb{R}^n)}. \tag{3.4}$$

In particular, $C^{k,\alpha}(\overline{\Omega}) \subseteq C^k(\overline{\Omega})$.

Remark 3.5.2. (Local and global formulations by extensions) The preceding definition admits a local formulation. Indeed, a function v belongs to $C^{k,\alpha}(\overline{\Omega})$ if and only if there are open sets

$$\overline{\Omega} \subseteq V_0 \Subset V_1 \Subset V$$

and an extension $\widehat{v} \in C^k(V)$ of v, that is, $\widehat{v}\,|_{\overline{\Omega}} = v$, such that

$$\|\widehat{v}\|_{C^{k,\alpha}_{\mathrm{int}}(\overline{V_1})} < \infty.$$

A global extension satisfies this condition immediately. Conversely, choose a cutoff function $\chi \in C^\infty_c(V_1)$ equal to one on a neighborhood of $\overline{V_0}$. The extension by zero of $\chi\widehat{v}$ outside V_1, denoted by $\widetilde{\chi\widehat{v}}$, belongs to $C^{k,\alpha}(\mathbb{R}^n)$ and agrees with v on $\overline{\Omega}$. The intermediate open set V_1 ensures that all derivatives involved in the Leibniz rule are controlled on a compact subset of the domain of $\widehat{v}$. For $k = \infty$, the part of this formulation concerning the existence of a smooth extension recovers exactly the convention used for $C^\infty(\overline{\Omega})$ in trace theory.

When $k = 0$, the class thus defined agrees with the usual class of Hölder continuous functions on the compact set $\overline{\Omega}$. Indeed, if $H = [v]_{C^{0,\alpha}(\overline{\Omega})}$, McShane's formula

$$\widehat{v}(x) := \inf_{y \in \overline{\Omega}} \bigl(v(y) + H|x-y|^\alpha \bigr)$$

extends v to a Hölder continuous function of exponent α on $\mathbb{R}^n$, since $(x,y) \mapsto |x-y|^\alpha$ is a metric for $0 < \alpha \leq 1$. Multiplication by a cutoff function equal to one near $\overline{\Omega}$ then produces a bounded extension. Therefore, when $k = 0$, the extension norm in (3.4) is equivalent to the usual intrinsic norm on $\overline{\Omega}$.

For $k \geq 1$, the extension condition is part of the convention. In the applications in this section, the functions come from $W^{m,p}_0(\Omega)$, and their extensions by zero provide the required extensions. In the geometric applications, the coordinate domains are balls and the localized functions vanish near the coordinate boundary.

Remark 3.5.3. (Changing the Hölder exponent) If $0 < \alpha \leq \beta < 1$ and Ω is bounded, then

$$C^{k,\beta}(\overline{\Omega}) \hookrightarrow C^{k,\alpha}(\overline{\Omega})$$

continuously. To see this, fix a cutoff function $\chi \in C^\infty_c(\mathbb{R}^n)$ equal to one on a neighborhood of $\overline{\Omega}$. If $\widetilde{v}$ is an extension of v, then $\chi\widetilde{v}$ is still an extension, and the Leibniz rule gives

$$\|\chi\widetilde{v}\|_{C^{k,\beta}(\mathbb{R}^n)} \leq C_\chi \|\widetilde{v}\|_{C^{k,\beta}(\mathbb{R}^n)}.$$

Since $\chi\widetilde{v}$ has support in a fixed compact set, each of its derivatives of order k satisfies

$$[w]_{C^{0,\alpha}(\mathbb{R}^n)} \le C_{\chi,\alpha,\beta}\big(\|w\|_{L^\infty(\mathbb{R}^n)} + [w]_{C^{0,\beta}(\mathbb{R}^n)}\big).$$

Taking the infimum over extensions $\widetilde{v}$ proves continuity of the embedding. We shall also use the fact that a function of class C^1 with bounded derivative is Lipschitz, and hence Hölder continuous with every exponent $0 < \alpha < 1$ on sets of bounded diameter.

The quantity defined in (3.4) is a norm. Homogeneity and the triangle inequality follow by taking extensions and adding them. Moreover,

$$\|v\|_{C^0(\overline{\Omega})} \le \|v\|_{C^{k,\alpha}(\overline{\Omega})},$$

since the same inequality holds for every extension. The norm therefore vanishes only when $v = 0$.

Proposition 3.5.4. (Completeness of Hölder spaces) For $k \in \mathbb{N}_0$ and $0 < \alpha < 1$, the space $C^{k,\alpha}(\mathbb{R}^n)$ is a Banach space. If $\Omega \subseteq \mathbb{R}^n$ is open and bounded, then $C^{k,\alpha}(\overline{\Omega})$, with the norm (3.4), is also a Banach space.

Proof. Let $(v_j)_{j\in\mathbb{N}}$ be a Cauchy sequence in $C^{k,\alpha}(\mathbb{R}^n)$. For each multi-index β with $|\beta| \le k$, the sequence $(D^\beta v_j)$ converges uniformly to a bounded continuous function v_β. If $|\beta| < k$, the fundamental theorem of calculus along segments allows passage to the limit in

$$D^\beta v_j(x + te_i) - D^\beta v_j(x) = \int_0^t D^{\beta+e_i} v_j(x + se_i)\, ds.$$

It follows that $v_0 \in C^k(\mathbb{R}^n)$ and $D^\beta v_0 = v_\beta$ for $|\beta| \le k$. If $|\beta| = k$, passing to the limit in the Hölder inequalities gives $v_\beta \in C^{0,\alpha}(\mathbb{R}^n)$. Finally, letting one index tend to infinity in the Cauchy condition yields $v_j \to v_0$ in $C^{k,\alpha}(\mathbb{R}^n)$.

Now let $(u_j)_{j\in\mathbb{N}}$ be a Cauchy sequence in $C^{k,\alpha}(\overline{\Omega})$. Extract a subsequence $(u_{j_\nu})_{\nu\in\mathbb{N}}$ such that

$$\|u_{j_{\nu+1}} - u_{j_\nu}\|_{C^{k,\alpha}(\overline{\Omega})} < 2^{-\nu-1}.$$

Choose $U_1 \in \mathcal{E}^{k,\alpha}_\Omega(u_{j_1})$. For each $\nu \in \mathbb{N}$, the definition of the infimum gives $G_\nu \in \mathcal{E}^{k,\alpha}_\Omega(u_{j_{\nu+1}} - u_{j_\nu})$ such that

$$\|G_\nu\|_{C^{k,\alpha}(\mathbb{R}^n)} < 2^{-\nu}.$$

The series

$$U_1 + \sum_{\nu=1}^{\infty} G_\nu$$

converges in $C^{k,\alpha}(\mathbb{R}^n)$ to a function U. Upon restriction to $\overline{\Omega}$, the partial sum of order N is $u_{j_{N+1}}$. Therefore, $u := U\restriction_{\overline{\Omega}}$ belongs to $C^{k,\alpha}(\overline{\Omega})$, and $u_{j_\nu} \to u$ in the extension norm. Since the original sequence is Cauchy, the whole sequence converges to u. □

The central analytic ingredient is the following local estimate. Its advantage is that the power of r is determined by the scaling of the problem.

Lemma 3.5.5. (Morrey's estimate on cubes) Let $n < p < \infty$ and let $Q \subseteq \mathbb{R}^n$ be a cube with sides parallel to the coordinate axes and side length $r > 0$. There is a constant $C = C(n,p) > 0$ such that

$$|v(x) - v(y)| \le C r^{1-\frac{n}{p}} \|\nabla v\|_{L^p(Q)} \tag{3.5}$$

for every $v \in C^1(\overline{Q})$ and all $x, y \in Q$.

Proof. Denote by

$$v_Q := \frac{1}{\lambda_n(Q)} \int_Q v(z)\, dz$$

the average of v on Q. Fix $x \in Q$. Since Q is convex, for every $y \in Q$ the segment joining x to y is contained in Q and

$$v(y) - v(x) = \int_0^1 \langle \nabla v(x + t(y-x)), y - x \rangle \, dt.$$

Averaging with respect to y and making, for each $t \in (0,1)$, the change of variables $z = x + t(y-x)$, we obtain

$$|v(x) - v_Q| \le \frac{1}{r^n} \int_0^1 \int_{x + t(Q-x)} |x - z|\, t^{-n-1} |\nabla v(z)|\, dz\, dt.$$

If $z \in x + t(Q-x)$, then $|z - x| \le \sqrt{n}\, r t$ and therefore $t \ge \frac{|z-x|}{\sqrt{n}\, r}$. Tonelli's theorem allows us to change the order of integration and gives

$$|v(x) - v_Q| \le C_n \int_Q \frac{|\nabla v(z)|}{|x - z|^{n-1}}\, dz.$$

Let $p' = \frac{p}{p-1}$. Hölder's inequality and the inclusion $Q \subseteq B_{\mathrm{euc}}(x, \sqrt{n}\, r)$ imply

$$|v(x) - v_Q| \le C_n \left(\int_{B_{\mathrm{euc}}(x, \sqrt{n} r)} |x - z|^{(1-n)p'}\, dz \right)^{\frac{1}{p'}} \|\nabla v\|_{L^p(Q)}.$$

The radial integral is finite precisely because $p > n$, and its power of r is $1 - \frac{n}{p}$. Consequently,

$$|v(x) - v_Q| \le C r^{1-\frac{n}{p}} \|\nabla v\|_{L^p(Q)}.$$

Applying the same inequality to y and using $|v(x) - v(y)| \le |v(x) - v_Q| + |v(y) - v_Q|$ gives (3.5). □

Theorem 3.5.6. (First-order Morrey embedding) Let $\Omega \subseteq \mathbb{R}^n$ be a bounded open subset and let $n < p < \infty$. If

$$\mu := 1 - \frac{n}{p},$$

then every element of $W_0^{1,p}(\Omega)$ has a unique representative in $C^{0,\mu}(\overline{\Omega})$, and there is a constant $C = C(n,p,\Omega) > 0$ such that

$$\|u\|_{C^{0,\mu}(\overline{\Omega})} \le C \|u\|_{W^{1,p}(\Omega)}. \tag{3.6}$$

Proof. First let $\varphi \in C_c^\infty(\Omega)$, and denote by $\widetilde{\varphi}$ its extension by zero to $\mathbb{R}^n$. Given $x, y \in \mathbb{R}^n$, choose a cube of side length $2|x-y|$ containing both points. Lemma 3.5.5, applied to $\widetilde{\varphi}$, gives

$$|\widetilde{\varphi}(x) - \widetilde{\varphi}(y)| \le C|x-y|^\mu \|\nabla \widetilde{\varphi}\|_{L^p(\mathbb{R}^n)}.$$

Therefore,

$$[\widetilde{\varphi}]_{C^{0,\mu}(\mathbb{R}^n)} \le C\|\nabla \varphi\|_{L^p(\Omega)}.$$

Take a fixed cube Q_0 containing $\overline{\Omega}$ in its interior and a point $y_0 \in Q_0 \setminus \overline{\Omega}$. Since $\widetilde{\varphi}(y_0) = 0$, the preceding estimate also gives

$$\|\widetilde{\varphi}\|_{L^\infty(\mathbb{R}^n)} \le C_\Omega \|\nabla \varphi\|_{L^p(\Omega)}.$$

Thus, (3.6) holds for every $\varphi \in C_c^\infty(\Omega)$.

Now let $u \in W_0^{1,p}(\Omega)$ and choose $(\varphi_j)_{j\in\mathbb{N}} \subseteq C_c^\infty(\Omega)$ such that $\varphi_j \to u$ in $W^{1,p}(\Omega)$. The global inequality already proved shows that the sequence of extensions by zero $(\widetilde{\varphi}_j)_{j\in\mathbb{N}}$ is Cauchy in $C^{0,\mu}(\mathbb{R}^n)$. By Proposition 3.5.4, it converges to a function $\widetilde{u} \in C^{0,\mu}(\mathbb{R}^n)$. At the same time, $\widetilde{\varphi}_j$ converges in $L^p(\mathbb{R}^n)$ to the extension by zero of u, so $\widetilde{u} = u$ almost everywhere on Ω. The restriction of $\widetilde{u}$ to $\overline{\Omega}$ is the desired representative and, by the definition of the extension norm, satisfies (3.6).

If two continuous representatives of the same class in $L^p(\Omega)$ agree almost everywhere, they agree throughout Ω, since the set on which they differ would otherwise be open and have positive measure. Continuity up to the boundary completes uniqueness on $\overline{\Omega}$. □

The higher-order result admits a uniform formulation in terms of the Sobolev regularity number

$$\sigma := m - \frac{n}{p}.$$

The restriction $0 < \alpha < 1$ avoids the Lipschitz endpoint, which requires separate treatment when σ is an integer and does not in general follow from the same argument.

Theorem 3.5.7. (Higher-order Sobolev–Morrey embedding) Let $\Omega \subseteq \mathbb{R}^n$ be a bounded open subset, let $m \in \mathbb{N}$ and $1 \le p < \infty$, and suppose that

$$\sigma := m - \frac{n}{p} > 0.$$

If $k \in \mathbb{N}_0$ and $0 < \alpha < 1$ satisfy

$$k + \alpha \le \sigma, \tag{3.7}$$

then every element of $W_0^{m,p}(\Omega)$ has a unique representative in $C^{k,\alpha}(\overline{\Omega})$, and there is a constant $C = C(n, m, p, k, \alpha, \Omega) > 0$ such that

$$\|u\|_{C^{k,\alpha}(\overline{\Omega})} \le C\|u\|_{W^{m,p}(\Omega)}. \tag{3.8}$$

More precisely, the following assertions hold.

(a) If $\sigma \notin \mathbb{N}$, $\ell := \lfloor \sigma \rfloor$, and $\theta := \sigma - \ell$, then

$$W_0^{m,p}(\Omega) \hookrightarrow C^{\ell,\theta}(\overline{\Omega})$$

continuously.

(b) If $\sigma = s \in \mathbb{N}$, then for every $0 < \theta < 1$,

$$W_0^{m,p}(\Omega) \hookrightarrow C^{s-1,\theta}(\overline{\Omega})$$

continuously.

Proof. We begin with functions in $C_c^\infty(\Omega)$ and identify them with their extensions by zero to $\mathbb{R}^n$.
First suppose that $\sigma \notin \mathbb{N}$. Set

$$\ell := \lfloor \sigma \rfloor, \qquad \theta := \sigma - \ell \in (0,1), \qquad d := m - \ell.$$

Then

$$(d-1)p < n < dp.$$

If $d = 1$, we have $p > n$. For every multi-index β with $|\beta| \le \ell$, the function $D^\beta u$ belongs to $W_0^{1,p}(\Omega)$, so Theorem 3.5.6 gives

$$\|D^\beta u\|_{C^{0,\theta}(\overline{\Omega})} \le C\|u\|_{W^{m,p}(\Omega)}, \qquad \theta = 1 - \frac{n}{p}.$$

Now suppose that $d \ge 2$ and define

$$q := p_{d-1}^* = \frac{np}{n-(d-1)p}.$$

Corollary 3.3.17, applied with $j = \ell + 1$ and a gain of $d-1$ derivatives, gives the continuous embedding

$$W_0^{m,p}(\Omega) = W_0^{\ell+1+(d-1),p}(\Omega) \hookrightarrow W_0^{\ell+1,q}(\Omega).$$

The inequality $dp > n$ implies $q > n$, and a direct computation shows that

$$1 - \frac{n}{q} = d - \frac{n}{p} = m - \ell - \frac{n}{p} = \theta.$$

For each $|\beta| \le \ell$, we have $D^\beta u \in W_0^{1,q}(\Omega)$. Theorem 3.5.6 yields

$$\|D^\beta u\|_{C^{0,\theta}(\overline{\Omega})} \le C\|u\|_{W^{m,p}(\Omega)}.$$

Summing over the finite family of multi-indices proves part (a) for smooth functions. Density of $C_c^\infty(\Omega)$ in $W_0^{m,p}(\Omega)$ and completeness of $C^{\ell,\theta}(\overline{\Omega})$ extend the map to the whole space. Simultaneous convergence in $W^{m,p}$ and in $C^{\ell,\theta}$ identifies the classical derivatives of the representative with the weak derivatives of the original class.
Now suppose that $\sigma = s \in \mathbb{N}$. Then

$$d := m - s = \frac{n}{p} \in \mathbb{N}.$$

If $d = 1$, we already have $W_0^{m,p}(\Omega) = W_0^{s+1,n}(\Omega)$. If $d \ge 2$, Corollary 3.3.17, applied with $j = s + 1$ and a gain of $d - 1$ derivatives, gives

$$W_0^{m,p}(\Omega) = W_0^{s+1+(d-1),p}(\Omega) \hookrightarrow W_0^{s+1,n}(\Omega),$$

since $p^*_{d-1} = n$. Let $0 < \theta < 1$ and choose $q > n$ sufficiently large that

$$1 - \frac{n}{q} > \theta.$$

For every $|\gamma| \le s$, the derivative $D^\gamma u$ belongs to $W^{1,n}_0(\Omega)$. The part of Theorem 3.3.7 corresponding to the critical case $p = n$ shows that $D^\gamma u \in L^q(\Omega)$ and

$$\|D^\gamma u\|_{L^q(\Omega)} \le C_q \|u\|_{W^{m,p}(\Omega)}.$$

In particular, for $|\beta| \le s-1$, we have $D^\beta u \in W^{1,q}_0(\Omega)$. To retain the zero subscript, apply the same estimates to differences of approximants of u in $C^\infty_c(\Omega)$; all their derivatives of order at most s converge in L^q, so the derivatives of order at most $s-1$ converge in $W^{1,q}$ to elements of its closed subspace $W^{1,q}_0(\Omega)$. Theorem 3.5.6 gives a representative of $D^\beta u$ that is Hölder continuous with exponent $1 - \frac{n}{q}$. Since Ω is bounded and $1 - \frac{n}{q} > \theta$, we obtain

$$\|D^\beta u\|_{C^{0,\theta}(\overline{\Omega})} \le C \|u\|_{W^{m,p}(\Omega)}.$$

This proves part (b), first for smooth functions and then for all of $W^{m,p}_0(\Omega)$ by density.
Finally, let (k, α) be a pair satisfying (3.7). If σ is not an integer, part (a) and the elementary inclusions between Hölder spaces give (3.8). If $\sigma = s$ is an integer, choose $\theta \in (\alpha, 1)$ and use part (b). When $k < s-1$, the derivatives of order k of the extensions by zero in $\mathbb{R}^n$ have bounded first derivatives, and are therefore Lipschitz; when $k = s-1$, it suffices to use the inclusion $C^{s-1,\theta} \hookrightarrow C^{s-1,\alpha}$. Uniqueness of representatives is proved as in Theorem 3.5.6: two functions of class C^k agreeing almost everywhere on Ω agree on Ω and, by continuity, on its closure. □

To prove compactness, we shall need an elementary inequality between Hölder seminorms.

Lemma 3.5.8. (Interpolation of Hölder seminorms) Let $K \subseteq \mathbb{R}^n$, $0 < \alpha < \beta < 1$, and $v \in C^{0,\beta}(K)$. Then

$$[v]_{C^{0,\alpha}(K)} \le 2^{1-\frac{\alpha}{\beta}} \|v\|^{1-\frac{\alpha}{\beta}}_{C^0(K)} [v]^{\frac{\alpha}{\beta}}_{C^{0,\beta}(K)}. \tag{3.9}$$

Proof. Set $M := \|v\|_{C^0(K)}$ and $H := [v]_{C^{0,\beta}(K)}$. For $x \neq y$, we have simultaneously

$$|v(x) - v(y)| \le 2M, \qquad |v(x) - v(y)| \le H|x-y|^\beta.$$

If $H = 0$, the assertion is immediate. If $H > 0$, separate the cases $|x-y| \le \left(\frac{2M}{H}\right)^{\frac{1}{\beta}}$ and $|x-y| > \left(\frac{2M}{H}\right)^{\frac{1}{\beta}}$. Both give

$$\frac{|v(x) - v(y)|}{|x-y|^\alpha} \le (2M)^{1-\frac{\alpha}{\beta}} H^{\frac{\alpha}{\beta}}.$$

Taking the supremum completes the proof. □

Lemma 3.5.9. (Arzelà–Ascoli on compact Euclidean subsets) Let $K \subseteq \mathbb{R}^n$ be compact and let $(v_j)_{j\in\mathbb{N}}$ be a sequence of continuous functions on K. Suppose that there is $C > 0$ such that

$$\|v_j\|_{C^0(K)} \le C \qquad \text{for every } j \in \mathbb{N},$$

and that the family is equicontinuous. Then there is a subsequence converging uniformly on K.

Proof. For each $m \in \mathbb{N}$, compactness of K provides a finite set $D_m \subseteq K$ such that the balls of radius $\frac{1}{m}$ centered at D_m cover K. The set $D := \bigcup_{m\in\mathbb{N}} D_m$ is countable and dense. Enumerate it as $D = \{x_1, x_2, \dots\}$. The numerical sequence $(v_j(x_1))_{j\in\mathbb{N}}$ is bounded. By Bolzano–Weierstrass, it has a convergent subsequence. Extract from this a subsequence converging at x_2 and continue inductively. The diagonal subsequence, again denoted by (v_j), converges at each point of D.
We show that it is uniformly Cauchy. Let $\varepsilon > 0$. By equicontinuity, there is $\delta > 0$ such that

$$|v_j(x) - v_j(y)| < \frac{\varepsilon}{3}$$

for every j and any $x, y \in K$ with $|x - y| < \delta$. Compactness of K allows us to choose $x_{i_1}, \dots, x_{i_N} \in D$ so that the balls of radius δ centered at these points cover K. Since the subsequence converges at each of these points, there is j_0 such that

$$|v_j(x_{i_\nu}) - v_\ell(x_{i_\nu})| < \frac{\varepsilon}{3}$$

for $j, \ell \geq j_0$ and $\nu \in \{1, \dots, N\}$. Given $x \in K$, choose ν with $|x - x_{i_\nu}| < \delta$. Then

$$|v_j(x) - v_\ell(x)| \leq |v_j(x) - v_j(x_{i_\nu})| + |v_j(x_{i_\nu}) - v_\ell(x_{i_\nu})| + |v_\ell(x_{i_\nu}) - v_\ell(x)| < \varepsilon.$$

Thus, the subsequence is Cauchy in $C^0(K)$ and converges uniformly, since this space is Banach. □

Theorem 3.5.10. (Rellich–Kondrashov into Hölder spaces) Let $\Omega \subseteq \mathbb{R}^n$ be a bounded open subset, let $m \in \mathbb{N}$ and $1 \leq p < \infty$, and suppose that

$$\sigma := m - \frac{n}{p} > 0.$$

If $k \in \mathbb{N}_0$ and $0 < \alpha < 1$ satisfy

$$k + \alpha < \sigma, \tag{3.10}$$

then the embedding

$$W_0^{m,p}(\Omega) \hookrightarrow C^{k,\alpha}(\overline{\Omega})$$

is compact.

Proof. Choose β such that

$$\alpha < \beta < 1, \qquad k + \beta \leq \sigma.$$

This choice is possible by (3.10). Theorem 3.5.7 shows that every bounded sequence $(u_j)_{j\in\mathbb{N}}$ in $W_0^{m,p}(\Omega)$, after choosing the representatives obtained by extension by zero, is bounded in $C^{k,\beta}(\mathbb{R}^n)$. These extensions vanish outside $\overline{\Omega}$. Fix a compact cube Q containing $\overline{\Omega}$ in its interior.
For each $|\gamma| = k$, the family $(D^\gamma u_j)$ is uniformly bounded and uniformly Hölder continuous on Q. If $|\gamma| < k$, the family is uniformly Lipschitz, since its first derivatives are uniformly bounded. Lemma 3.5.9 and a diagonal argument over the finite family of multi-indices allow us to extract a subsequence, which we do not relabel, such that

$$D^\gamma u_j \longrightarrow v_\gamma \qquad \text{uniformly on } Q$$

for every $|\gamma| \le k$. The identities obtained from the fundamental theorem of calculus pass to the limit, so there is $v \in C^k(Q)$ with $D^\gamma v = v_\gamma$.
For $|\gamma| = k$, apply Lemma 3.5.8 to $D^\gamma(u_j - u_\ell)$. The seminorms of order β are uniformly bounded, while the uniform norms tend to zero. Consequently,

$$[D^\gamma(u_j - u_\ell)]_{C^{0,\alpha}(Q)} \longrightarrow 0 \qquad \text{as } j, \ell \to \infty.$$

Thus, the subsequence is Cauchy in the $\|\cdot\|_{C^{k,\alpha}_{\mathrm{int}}(Q)}$ norm and converges to v in that norm. All extensions are supported in the fixed compact set $\overline{\Omega} \Subset \mathrm{Int}(Q)$. Hence convergence in the $C^{k,\alpha}_{\mathrm{int}}(Q)$ norm implies convergence of these same extensions in $C^{k,\alpha}(\mathbb{R}^n)$: outside Q the functions vanish, and pairs with one point outside Q are controlled using the positive distance between $\overline{\Omega}$ and ∂Q. Restricting to $\overline{\Omega}$ and using the extension norm, we obtain a subsequence converging in $C^{k,\alpha}(\overline{\Omega})$. □

Remark 3.5.11. (Optimal form of the exponents) Let $\sigma = m - \frac{n}{p} > 0$.

(a) If $\sigma = \ell + \theta$ with $\ell \in \mathbb{N}_0$ and $0 < \theta < 1$, the embedding

$$W^{m,p}_0(\Omega) \hookrightarrow C^{\ell,\theta}(\overline{\Omega})$$

is continuous, and becomes compact upon replacing θ by any $0 < \alpha < \theta$.

(b) If $\sigma = s \in \mathbb{N}$, then for every $0 < \alpha < 1$ the embedding

$$W^{m,p}_0(\Omega) \hookrightarrow C^{s-1,\alpha}(\overline{\Omega})$$

is compact and, in particular, continuous.

Corollary 3.5.12. (Infinite exponents) Let $\Omega \subseteq \mathbb{R}^n$ be open and bounded, and let $m > k \ge 0$ and $1 \le p < \infty$. If $m - \frac{n}{p} > k$, the embedding

$$W^{m,p}_0(\Omega) \hookrightarrow W^{k,\infty}(\Omega)$$

is compact. The same conclusion holds for $W^{m,p}(\Omega)$ if Ω is an extension domain for $W^{m,p}$. At the endpoint $p = 1$ and $m - k = n$, both embeddings into $W^{k,\infty}$ remain continuous, although they are not compact when Ω is nonempty.
If $p = \infty$, $m > k \ge 0$, and Ω is an extension domain for $W^{m,\infty}$, the embeddings $W^{m,\infty}(\Omega) \hookrightarrow W^{k,q}(\Omega)$ are compact for $1 \le q \le \infty$. They are also compact on $W^{m,\infty}_0(\Omega) := \overline{C^\infty_c(\Omega)}^{W^{m,\infty}(\Omega)}$ for any bounded open subset. On $\mathbb{R}^n$, for $1 \le p < \infty$ and $m - \frac{n}{p} > k$, and also for $p = 1$ and $m - k = n$, the embedding $W^{m,p}(\mathbb{R}^n) \hookrightarrow W^{k,\infty}(\mathbb{R}^n)$ is continuous. Restriction through an extension operator gives the same continuity on the half-space.

Proof. For $p < \infty$, choose $0 < \alpha < 1$ with $k + \alpha < m - \frac{n}{p}$. Theorem 3.5.10 gives compactness in $C^{k,\alpha}(\overline{\Omega})$, whose norm controls all derivatives of order at most k in L^∞. On an extension domain, apply the same argument to $Tu = \chi \mathcal{E} u$ on a ball, as in Theorem 3.4.2.
At the endpoint $p = 1$, for $\varphi \in C^\infty_c(\mathbb{R}^n)$, successive applications of the fundamental theorem of calculus in

the n coordinates give

$$\varphi(x) = \int_{-\infty}^{x_1} \cdots \int_{-\infty}^{x_n} D_1 \cdots D_n \varphi(t_1, \ldots, t_n)\, dt_n \cdots dt_1, \qquad \|\varphi\|_\infty \le \|D_1 \cdots D_n \varphi\|_{L^1(\mathbb{R}^n)}.$$

Apply this bound to each $D^\alpha \varphi$, $|\alpha| \le k$. All derivatives on the right-hand side have order at most $k + n = m$. Density shows that the extensions by zero of the approximants converge uniformly together with their derivatives of order at most k. The fundamental theorem of calculus along segments identifies the limit as a function of class C^k and gives continuity into $W^{k,\infty}$. Applying a cutoff to an extension treats $W^{m,1}(\Omega)$. To see that compactness fails, take $u_\varepsilon(x) = \varepsilon^k \varphi((x - x_0)/\varepsilon)$ with support in an interior ball: their $W^{m,1}$ norms are bounded, and some derivative of order k has a constant nonzero uniform norm, although it converges to zero almost everywhere.

For $p = \infty$, choose $1 \le r < \infty$ sufficiently large that $m - \frac{n}{r} > k$. The functions Tu have support in a fixed compact set and are bounded in $W^{m,r}$ by Hölder's inequality on that set. The first part gives compactness in $W^{k,\infty}$, which implies compactness in $W^{k,q}(\Omega)$ by finiteness of the measure. For $W_0^{m,\infty}$, the closure argument in Proposition 3.3.13 remains valid in the $W^{m,\infty}$ norm and provides extension by zero. Their test function approximants also converge in $W^{m,r}$ on a fixed ball. The first part applies again.

For global continuity, repeat the localization on the cubes Q_a from Proposition 3.4.7. The Sobolev–Morrey embedding, applied to $\chi_a u$, controls $\|u\|_{W^{k,\infty}(Q_a)}$ by $C\|u\|_{W^{m,p}(a+(-1,2)^n)}$, with C independent of a. Taking the supremum over $a \in \mathbb{Z}^n$ gives the global estimate. □

Equality of indices with an infinite exponent requires its own analysis. For example, in dimension one, $W_0^{1,1}(a,b) \hookrightarrow C^0([a,b])$ continuously: the estimate $\|\varphi\|_\infty \le \|\varphi'\|_{L^1((a,b))}$ and density give the continuous representative. This embedding is not compact. If $c \in (a,b)$ and $0 \le \varphi \in C_c^\infty((-1,1))$ satisfies $\varphi(0) = 1$, the functions $u_j(x) = \varphi(j(x-c))$, for sufficiently large j, are bounded in $W_0^{1,1}(a,b)$, have uniform norm one, and converge to zero at every point other than c. They have no uniformly convergent subsequence. The preceding assertions do not infer compactness at any equality endpoint solely from a comparison of indices.

3.6 Localized embeddings on the half-space

The upper half-space is the Euclidean model for boundary charts. Since it is unbounded, compactness cannot be formulated globally without a condition preventing functions from moving toward infinity. In applications to compact manifolds, each function localized by a partition of unity has support contained in a fixed compact set. This is exactly the situation recorded below.

Definition 3.6.1. (Uniformly Lipschitz continuous boundary) Let $\Omega \subseteq \mathbb{R}^n$ be an open subset. We say that its boundary $\partial\Omega$ is **uniformly Lipschitz continuous** if there exist $\varepsilon, L > 0$, $M \in \mathbb{N}$, and a countable locally finite open cover $(\Omega_j)_{j\in\mathbb{N}}$ of $\partial\Omega$ such that:

(a) for each $x \in \partial\Omega$, there is $j \in \mathbb{N}$ such that $B_{\mathrm{euc}}(x,\varepsilon) \subseteq \Omega_j$;

(b) no point of $\mathbb{R}^n$ belongs to more than M sets in the family $(\Omega_j)_{j\in\mathbb{N}}$;

(c) for each $j \in \mathbb{N}$, there exist a coordinate system $y = (y', y_n) \in \mathbb{R}^{n-1} \times \mathbb{R}$ and a Lipschitz function

$f_j\colon \mathbb{R}^{n-1} \longrightarrow \mathbb{R}$, both depending on j, such that $\mathrm{Lip}(f_j) \le L$ and

$$\Omega_j \cap \Omega = \Omega_j \cap V_j, \qquad V_j := \{(y', y_n) \in \mathbb{R}^{n-1} \times \mathbb{R} \mid y_n > f_j(y')\}.$$

The numbers ε, L, and M are called the **uniformity parameters** of the boundary.

Theorem 3.6.2. (Extension on open subsets with uniformly Lipschitz boundary) Let $\Omega \subseteq \mathbb{R}^n$ be an open subset whose boundary is uniformly Lipschitz continuous with parameters $\varepsilon, L > 0$ and $M \in \mathbb{N}$. Let $1 \le p \le \infty$ and $m \in \mathbb{N}$. Then there is a continuous linear operator

$$\mathcal{E}\colon W^{m,p}(\Omega) \longrightarrow W^{m,p}(\mathbb{R}^n)$$

such that, for every $u \in W^{m,p}(\Omega)$, we have $\mathcal{E}(u)(x) = u(x)$ for almost every $x \in \Omega$. Moreover, there is a constant $c = c(n, m, p) > 0$ for which

$$\|\mathcal{E}(u)\|_{L^p(\mathbb{R}^n)} \le c(1 + M)\|u\|_{L^p(\Omega)} \tag{3.11}$$

and, for each $k \in \{1, \dots, m\}$,

$$\|\nabla^k \mathcal{E}(u)\|_{L^p(T^{(0,k)}(\mathbb{R}^n))} \le c\big(1 + M(1 + L^k)\big) \sum_{i=0}^{k} \left(\frac{M}{\varepsilon}\right)^{k-i} \|\nabla^i u\|_{L^p(T^{(0,i)}(\Omega))}, \tag{3.12}$$

where $\nabla^0 u := u$ and the covariant derivatives are those induced by the Euclidean metric. In particular, there is a constant $C = C(n, m, p, \varepsilon, M, L) > 0$ such that

$$\|\mathcal{E}(u)\|_{W^{m,p}(\mathbb{R}^n)} \le C\|u\|_{W^{m,p}(\Omega)}.$$

The construction of the operator and the estimates (3.11) and (3.12) can be found in [97, Theorem 13.17].

Corollary 3.6.3. (Embeddings on a ball without boundary conditions) Let $B \subset \mathbb{R}^n$ be a bounded open ball. Let $\ell > k \ge 0$ be integers and $1 \le p, q < \infty$. If

$$\ell - \frac{n}{p} \ge k - \frac{n}{q},$$

then $W^{\ell,p}(B) \hookrightarrow W^{k,q}(B)$ continuously; if the inequality is strict, the embedding is compact.

Proof. The boundary of a ball is smooth. Near each point, after a translation and a rotation, it can be represented as the graph of a smooth function on a ball in $\mathbb{R}^{n-1}$. Shrinking this ball makes the derivative of the function bounded, and the mean value theorem then shows that the graph is Lipschitz. Multiplying the function by a cutoff equal to one on a smaller ball gives a Lipschitz function defined on all of $\mathbb{R}^{n-1}$ without changing this local representation. Compactness of ∂B allows us to choose finitely many representations on open sets V_i and smaller open sets U_i that still cover ∂B, with $\overline{U_i} \Subset V_i$. The minimum of the positive distances $\mathrm{dist}(\overline{U_i}, \mathbb{R}^n \setminus V_i)$, the maximum of the Lipschitz constants, and the number of charts give the parameters in Definition 3.6.1. For $n = 1$, the boundary consists of the two endpoints of an interval, and the same description reduces to half-lines.

By Theorem 3.6.2, B is an extension domain for $W^{\ell,p}$. Apply the second part of Theorem 3.3.16 and, under the strict inequality, of Theorem 3.4.2. Both results apply to the full space $W^{\ell,p}(B)$, without requiring interior support or membership in $W_0^{\ell,p}(B)$. □

Corollary 3.6.4. (Half-space extension operator) Let $k \in \mathbb{N}_0$ and $1 \le p \le \infty$. There is a continuous linear operator

$$\mathcal{E}_k \colon W^{k,p}(\mathbb{R}^n_+) \longrightarrow W^{k,p}(\mathbb{R}^n)$$

such that $(\mathcal{E}_k u) \restriction_{\mathbb{R}^n_+} = u$ at almost every point of $\mathbb{R}^n_+$. In particular, there is $C_{k,p,n} > 0$ such that

$$\|\mathcal{E}_k u\|_{W^{k,p}(\mathbb{R}^n)} \le C_{k,p,n} \|u\|_{W^{k,p}(\mathbb{R}^n_+)}$$

for every $u \in W^{k,p}(\mathbb{R}^n_+)$.

Proof. If $k = 0$, extension by zero suffices. If $k \ge 1$, the half-space $\mathbb{R}^n_+ := \{(x',t) \in \mathbb{R}^{n-1} \times \mathbb{R} \mid t > 0\}$ has uniformly Lipschitz boundary, and Theorem 3.6.2 gives the operator for every $1 \le p \le \infty$.
For finite exponents, one can see explicitly how higher-order derivatives are preserved. Choose $a_1, \dots, a_k \in \mathbb{R}$ solving

$$\sum_{j=1}^{k} a_j (-j)^r = 1, \qquad r \in \{0, \dots, k-1\}.$$

The matrix is a Vandermonde matrix at the distinct points $-1, \dots, -k$, and is therefore invertible. For a function smooth up to the boundary, define

$$(\mathcal{E}_k u)(x',t) := \begin{cases} u(x',t), & t > 0, \\ \displaystyle\sum_{j=1}^{k} a_j u(x',-jt), & t < 0. \end{cases}$$

The tangential and normal derivatives of total order at most $k-1$ agree on both sides of $t = 0$ by the preceding equations. Integration by parts on both half-spaces cancels the boundary terms. Applying this argument successively to each derivative of order at most $k-1$ shows that the weak derivatives of order at most k are the ordinary derivatives on each side. For $\alpha = (\alpha', r)$, $|\alpha| \le k$, the change of variable $s = -jt$ and Minkowski's inequality give

$$\|D^\alpha \mathcal{E}_k u\|_{L^p(\{t<0\})} \le \sum_{j=1}^{k} |a_j| j^{r-1/p} \|D^\alpha u\|_{L^p(\mathbb{R}^n_+)}.$$

The extension operator already obtained and Proposition 3.3.12 show that restrictions of $C_c^\infty(\mathbb{R}^n)$ are dense in $W^{k,p}(\mathbb{R}^n_+)$ for $p < \infty$. The estimate allows this formula to be extended by continuity and verifies all its derivatives. For $k = 1$, we obtain even reflection; for $k \ge 2$, the finite combination also ensures agreement of the necessary normal derivatives. □

Remark 3.6.5. (Density and boundary conditions on the half-space) Restrictions of $C_c^\infty(\mathbb{R}^n)$ are dense in $W^{m,p}(\mathbb{R}^n_+)$ for $m \ge 1$ and $1 \le p < \infty$. These functions need not vanish on the boundary. In contrast, $W_0^{m,p}(\mathbb{R}^n_+)$ is defined using approximants compactly supported in the open half-space. Theorem 3.7.1 will characterize

this latter space by the vanishing of traces of order less than m.

For a compact set $K \subseteq \overline{\mathbb{R}^n_+}$, we shall write

$$W^{k,p}_K(\mathbb{R}^n_+) := \left\{ u \in W^{k,p}(\mathbb{R}^n_+) \middle| \operatorname{supp} u \subseteq K \right\},$$

where support is understood in the essential sense within $\overline{\mathbb{R}^n_+}$.

Theorem 3.6.6. (Localized Sobolev and Rellich–Kondrashov embeddings on the half-space) Let $K \subseteq \overline{\mathbb{R}^n_+}$ be compact, let $m > k \geq 0$ be integers, and let $1 \leq p, q < \infty$. If

$$m - \frac{n}{p} \geq k - \frac{n}{q},$$

the inclusion $W^{m,p}_K(\mathbb{R}^n_+) \hookrightarrow W^{k,q}(\mathbb{R}^n_+)$ is continuous. If the inequality is strict, this inclusion is compact. In particular, $W^{m,p}_K(\mathbb{R}^n_+) \hookrightarrow W^{m-1,p}(\mathbb{R}^n_+)$ is compact for every $m \geq 1$ and $1 \leq p < \infty$.
If $q = \infty$ and $p < \infty$, the inclusion is compact when $m - \frac{n}{p} > k$; for $p = 1$ and $m - k = n$, it is continuous. If $p = \infty$, it is compact for every $1 \leq q \leq \infty$ and $m > k$. These assertions also hold for the subspace $W^{m,p}_K(\mathbb{R}^n_+) \cap W^{m,p}_0(\mathbb{R}^n_+)$; for finite exponents, its limit belongs to $W^{k,q}_0(\mathbb{R}^n_+)$.

Proof. Take $R > 0$ such that $K \subseteq B_{\text{euc}}(0, R) \cap \overline{\mathbb{R}^n_+}$, and $\chi \in C^\infty_c(B_{\text{euc}}(0, 2R))$ equal to one on a neighborhood of K. Define

$$Tu := \chi \mathcal{E}_m u.$$

The Leibniz rule and Corollary 3.6.4 give

$$\|Tu\|_{W^{m,p}(\mathbb{R}^n)} \leq C \|u\|_{W^{m,p}(\mathbb{R}^n_+)}.$$

Moreover, Tu has compact support contained in $B := B_{\text{euc}}(0, 2R)$, and $(Tu) \restriction_{\mathbb{R}^n_+} = u$, since u vanishes outside K. For $p < \infty$, Proposition 3.3.13 gives $Tu \in W^{m,p}_0(B)$. Continuity for finite exponents follows from Theorem 3.3.16 on B, and compactness from Theorem 3.4.2. In the compactness assertion, the resulting sequence converges to an element of $W^{k,q}_0(B)$, since this is the target space in Theorem 3.4.2. Extension by zero is continuous by Proposition 3.3.13. Hence this convergence is preserved in $W^{k,q}(\mathbb{R}^n)$ and, upon restriction, in $W^{k,q}(\mathbb{R}^n_+)$. The same cutoff and the same ball are used for the entire sequence.
For $p < \infty$ and $q = \infty$, use Corollary 3.5.12 on B. For $p = \infty$, the functions Tu are bounded in $W^{m,r}(\mathbb{R}^n)$ for each $r < \infty$ because their support is fixed. Choose $r > n/(m-k)$ and apply that corollary again; the finite exponents follow from the finite measure of the support.
If each u_j also belongs to $W^{m,p}_0(\mathbb{R}^n_+)$ and the exponents are finite, we may use $Z_{\mathbb{R}^n_+} u_j$ in place of $\mathcal{E}_m u_j$. To justify the zero condition in the target space, approximate each u_j in $W^{m,p}$ by test functions and multiply them by χ. Multiplication preserves the approximation and places all supports in B. The continuous embedding on B shows that the restrictions converge in $W^{k,q}$ to u_j, so $u_j \in W^{k,q}_0(\mathbb{R}^n_+)$. Closedness of this subspace preserves the condition in the limit supplied by compactness. □

Remark 3.6.7. (Support up to the boundary and local compactness) The compact set K in the theorem may meet $\{t = 0\}$. In this case, a function in $W^{m,p}_K(\mathbb{R}^n_+)$ may have nonzero trace, and its extension by zero

may fail to belong to $W^{m,p}(\mathbb{R}^n)$; this is why $\mathcal{E}_m$ is used. If $K \Subset \mathbb{R}^n_+$ is contained in the interior, choose a cutoff in $C_c^\infty(\mathbb{R}^n_+)$ equal to one near K. The weak Leibniz rule and interior mollification then show that $W_K^{m,p}(\mathbb{R}^n_+) \subseteq W_0^{m,p}(\mathbb{R}^n_+)$ for $p < \infty$.
For a bounded sequence in $W^{m,p}(\mathbb{R}^n_+)$, cutoffs on balls and a diagonal extraction give local compactness up to the boundary: convergence holds in $W^{k,q}(B_{\mathrm{euc}}(0,R) \cap \mathbb{R}^n_+)$ for every $R > 0$ in the strict finite range. Without a condition on the tails, the whole half-space lacks global compactness. In dimension $n \geq 2$, tangential translations of a nonzero test function have constant norms and may have disjoint supports. In dimension $n = 1$, translate that function toward $+\infty$. Both examples reproduce the separation of norms in Remark 3.4.9, even within $W_0^{m,p}(\mathbb{R}^n_+)$.

To apply the half-space embeddings to functions defined on a half-ball, we must first extend them across its spherical portion. Separation of the support from that portion prevents jumps; no vanishing on the flat boundary is required.

Lemma 3.6.8. (Extension by zero from a half-ball) Let $m \in \mathbb{N}_0$, $1 \leq p < \infty$, and $R > 0$. Let $B^+ = B_{\mathrm{euc}}(0,R) \cap \mathbb{R}^n_+$ and $B' = B_{\mathrm{euc}}(0,R) \cap \partial\mathbb{R}^n_+$. Suppose that $v \in W^{m,p}(B^+)$ and that there is a compact set $K \subset B_{\mathrm{euc}}(0,R) \cap \{x_n \geq 0\}$, lying at a positive distance from the spherical portion $\partial B_{\mathrm{euc}}(0,R) \cap \{x_n \geq 0\}$, such that $v = 0$ almost everywhere on $B^+ \setminus K$.
Define $\widetilde{v} \colon \mathbb{R}^n_+ \longrightarrow \mathbb{R}$ by

$$\widetilde{v}(x) = \begin{cases} v(x), & x \in B^+, \\ 0, & x \in \mathbb{R}^n_+ \setminus B^+. \end{cases}$$

Then $\widetilde{v} \in W^{m,p}(\mathbb{R}^n_+)$, and for every multi-index β with $|\beta| \leq m$, we have $D^\beta \widetilde{v} = \widetilde{D^\beta v}$ in the weak sense, where $\widetilde{D^\beta v}$ denotes the extension by zero of $D^\beta v$ to $\mathbb{R}^n_+$. In particular,

$$\|\widetilde{v}\|_{W^{m,p}(\mathbb{R}^n_+)} = \|v\|_{W^{m,p}(B^+)}.$$

Proof. If $m = 0$, the definition of extension by zero gives $\|\widetilde{v}\|_{L^p(\mathbb{R}^n_+)} = \|v\|_{L^p(B^+)}$, and the identity corresponding to $\beta = 0$ is immediate. Since $W^{0,p} = L^p$, this proves the result in that case. Henceforth assume $m \geq 1$.
Denote the spherical portion of the half-ball by $\Gamma_R := \partial B_{\mathrm{euc}}(0,R) \cap \{x_n \geq 0\}$. If $K = \varnothing$, then $v = 0$ almost everywhere on B^+, and the result is immediate. Thus assume $K \neq \varnothing$.
Since K lies at a positive distance from Γ_R, we may take $\delta := \operatorname{dist}(K, \Gamma_R) > 0$. First consider what this implies. For each $x \in K$, we have $\operatorname{dist}(x, \Gamma_R) = R - \|x\|$. If $x \neq 0$, the point $\dfrac{R}{\|x\|}x$ belongs to Γ_R, and hence $\operatorname{dist}(x, \Gamma_R) \leq \left\| x - \dfrac{R}{\|x\|}x \right\| = R - \|x\|$. The reverse inequality follows from $\|x - \mathbf{y}\| \geq \big|\|\mathbf{y}\| - \|x\|\big| = R - \|x\|$ for every $\mathbf{y} \in \Gamma_R$. If $x = 0$, the equality is also clear. Therefore, $R - \|x\| \geq \delta$ for every $x \in K$; that is, $\|x\| \leq R - \delta$ for every $x \in K$. In particular, $K \subset B_{\mathrm{euc}}(0, R - \dfrac{\delta}{2}) \cap \{x_n \geq 0\}$.
Define $U := B^+ \cap \left\{ x \in \mathbb{R}^n \mid \|x\| > R - \dfrac{\delta}{2} \right\}$. Then U is an interior strip adjacent to Γ_R, and moreover $U \cap K = \varnothing$. Since $v = 0$ almost everywhere on $B^+ \setminus K$, it follows that $v = 0$ almost everywhere on U.
By locality of weak derivatives, $D^\beta v = 0$ almost everywhere on U for every $|\beta| \leq m$. If $w \in W^{k,p}(B^+)$ vanishes almost everywhere on a relatively open subset $V \subset B^+$, then for every $\psi \in C_c^\infty(V)$, viewed as a test function

Figure 3.1. Outline of the proof of extension by zero. The essential support of v is contained in a compact set K separated from the spherical portion Γ_R by a positive distance δ. This separation allows us to construct a neighborhood U of Γ_R on which v and its weak derivatives vanish, as well as a cutoff function χ equal to 1 near K and vanishing before it reaches Γ_R. This prevents boundary terms from appearing on the spherical portion and gives $D^\beta \widetilde{v} = \widetilde{D^\beta v}$.

on B^+, we have

$$\int_V D^\beta w\, \psi\, dx = \int_{B^+} D^\beta w\, \psi\, dx = (-1)^{|\beta|} \int_{B^+} w\, D^\beta \psi\, dx = (-1)^{|\beta|} \int_V w\, D^\beta \psi\, dx = 0.$$

For each $|\beta| \le k$, since $D^\beta w \in L^p(V)$, it follows that $D^\beta w = 0$ almost everywhere on V.
We now prove that $D^\beta \widetilde{v} = \widetilde{D^\beta v}$ in the weak sense for every $|\beta| \le m$. Fix such an β and take $\varphi \in C_c^\infty(\mathbb{R}^n_+)$. Choose a function $\chi \in C_c^\infty(\mathbb{R}^n)$ such that $\chi \equiv 1$ on $B_{\mathrm{euc}}(0, R - \frac{\delta}{2})$ and $\mathrm{supp}\,\chi \subset B_{\mathrm{euc}}(0, R - \frac{\delta}{4})$. This choice is possible because $R - \frac{\delta}{2} < R - \frac{\delta}{4} < R$. In particular, $\chi \equiv 1$ on a neighborhood of K, and $(\chi|_{\mathbb{R}^n_+})\varphi \restriction_{B^+} \in C_c^\infty(B^+)$, since χ vanishes near the spherical portion and φ has compact support in $\mathbb{R}^n_+$.
Since $\widetilde{v} = 0$ on $\mathbb{R}^n_+ \setminus B^+$, we have

$$\int_{\mathbb{R}^n_+} \widetilde{v}\, D^\beta \varphi\, dx = \int_{B^+} v\, D^\beta \varphi\, dx.$$

Moreover, since $v = 0$ almost everywhere on $B^+ \setminus K$, it suffices to compare the integrands on a neighborhood of K. On that neighborhood, $\chi \equiv 1$, and therefore $D^\beta(\chi\varphi) = D^\beta \varphi$, where $\chi\varphi$ denotes $(\chi|_{\mathbb{R}^n_+})\varphi$. It follows that $v D^\beta \varphi = v D^\beta(\chi\varphi)$ almost everywhere on B^+. Thus,

$$\int_{B^+} v\, D^\beta \varphi\, dx = \int_{B^+} v\, D^\beta(\chi\varphi)\, dx.$$

Since $(\chi|_{\mathbb{R}^n_+})\varphi \restriction_{B^+} \in C_c^\infty(B^+)$, the definition of weak derivative gives

$$\int_{B^+} v\, D^\beta(\chi\varphi)\, dx = (-1)^{|\beta|} \int_{B^+} D^\beta v\, \chi\varphi\, dx.$$

Now observe that within B^+, the set where $\chi \neq 1$ is contained in U, except possibly on the sphere

$\left\{\|x\| = R - \frac{\delta}{2}\right\}$, which has measure zero. Since we already showed that $D^\beta v = 0$ almost everywhere on U, we obtain

$$\int_{B^+} D^\beta v\, \chi\varphi\, dx = \int_{B^+} D^\beta v\, \varphi\, dx = \int_{\mathbb{R}^n_+} \widetilde{D^\beta v}\, \varphi\, dx.$$

Combining the preceding equalities gives

$$\int_{\mathbb{R}^n_+} \widetilde{v}\, D^\beta \varphi\, dx = (-1)^{|\beta|} \int_{\mathbb{R}^n_+} \widetilde{D^\beta v}\, \varphi\, dx.$$

This proves that $D^\beta \widetilde{v} = \widetilde{D^\beta v}$ in the weak sense for every $|\beta| \le m$.
Since $\widetilde{D^\beta v} \in L^p(\mathbb{R}^n_+)$ for every $|\beta| \le m$, we conclude that $\widetilde{v} \in W^{m,p}(\mathbb{R}^n_+)$. Moreover,

$$\|\widetilde{v}\|^p_{W^{m,p}(\mathbb{R}^n_+)} = \sum_{|\beta|\le m} \int_{\mathbb{R}^n_+} |D^\beta \widetilde{v}|^p\, dx = \sum_{|\beta|\le m} \int_{\mathbb{R}^n_+} |\widetilde{D^\beta v}|^p\, dx = \sum_{|\beta|\le m} \int_{B^+} |D^\beta v|^p\, dx = \|v\|^p_{W^{m,p}(B^+)}.$$

Therefore, $\|\widetilde{v}\|_{W^{m,p}(\mathbb{R}^n_+)} = \|v\|_{W^{m,p}(B^+)}$. □

Corollary 3.6.9. (Approximation and localized embeddings on a half-ball) Let $B^+ = B_{\mathrm{euc}}(0,R) \cap \mathbb{R}^n_+$, $B' = B_{\mathrm{euc}}(0,R) \cap \{x_n = 0\}$, and let $K \subset B_{\mathrm{euc}}(0,R) \cap \{x_n \ge 0\}$ be compact.

(a) If $s \in \mathbb{N}_0$, $1 \le p < \infty$, and $v \in W^{s,p}(B^+)$ vanishes almost everywhere on $B^+ \setminus K$, there exist $f_\nu \in C^\infty_c(B_{\mathrm{euc}}(0,R))$ whose restrictions converge to v in $W^{s,p}(B^+)$. Their supports are contained in a common compact subset of $B_{\mathrm{euc}}(0,R)$.

(b) If $\ell > k \ge 0$ are integers, $1 \le p,q < \infty$, and $\ell - n/p \ge k - n/q$, there is $C > 0$ such that every $v \in W^{\ell,p}(B^+)$ with that support satisfies

$$\|v\|_{W^{k,q}(B^+)} \le C\|v\|_{W^{\ell,p}(B^+)}.$$

If the index inequality is strict, every bounded sequence of these functions, with the same K, has a subsequence converging in $W^{k,q}(B^+)$.

The restrictions in the first part are smooth up to B', but need not vanish there.

Proof. Extend v by zero within the half-space using Lemma 3.6.8. The function $\widetilde{v}$ has the same Sobolev norm as v and vanishes outside K. For the first part, restrictions of $C^\infty_c(\mathbb{R}^n)$ are dense in $W^{s,p}(\mathbb{R}^n_+)$: for $s \ge 1$, apply the operator from Corollary 3.6.4 and Proposition 3.3.12; for $s = 0$, approximate the extension by zero in $L^p(\mathbb{R}^n)$. Thus, there exist $h_\nu \in C^\infty_c(\mathbb{R}^n)$ with $h_\nu \restriction_{\mathbb{R}^n_+} \to \widetilde{v}$ in $W^{s,p}$.
Choose a fixed cutoff $\eta \in C^\infty_c(B_{\mathrm{euc}}(0,R))$ equal to one near K and set $f_\nu := \eta h_\nu$. Since $\eta\widetilde{v} = \widetilde{v}$, the Leibniz rule and restriction give

$$\begin{aligned}\|f_\nu \restriction_{B^+} - v\|_{W^{s,p}(B^+)} &\le \|\eta(h_\nu \restriction_{\mathbb{R}^n_+} - \widetilde{v})\|_{W^{s,p}(\mathbb{R}^n_+)} \\ &\le C_{s,p,\eta}\|h_\nu \restriction_{\mathbb{R}^n_+} - \widetilde{v}\|_{W^{s,p}(\mathbb{R}^n_+)} \longrightarrow 0.\end{aligned}$$

The support of each f_ν is contained in $\operatorname{supp}\eta \Subset B_{\mathrm{euc}}(0,R)$.
For the second part, let $B := B_{\mathrm{euc}}(0,2R)$ and define

$$z := (\mathcal{E}_\ell \widetilde{v}) \restriction_B .$$

Half-space extension and Lemma 3.3.11 imply $z\restriction_{B^+} = v$ and

$$\|z\|_{W^{\ell,p}(B)} \le \|\mathcal{E}_\ell \widetilde{v}\|_{W^{\ell,p}(\mathbb{R}^n)} \le C_{\mathcal{E}} \|v\|_{W^{\ell,p}(B^+)}.$$

By Corollary 3.6.3,

$$\|v\|_{W^{k,q}(B^+)} \le \|z\|_{W^{k,q}(B)} \le C_B C_{\mathcal{E}} \|v\|_{W^{\ell,p}(B^+)}.$$

In this application we do not need to apply a cutoff to $\mathcal{E}_\ell \widetilde{v}$: the embedding is applied to its restriction in the full space on the ball. The cutoff in the first part serves a different purpose, keeping the supports of the approximants within the chart.

If $(v_\nu)_{\nu\in\mathbb{N}}$ is bounded and the inequality is strict, use the same operator and the same ball to define z_ν. Then

$$\sup_{\nu\in\mathbb{N}} \|z_\nu\|_{W^{\ell,p}(B)} \le C_{\mathcal{E}} \sup_{\nu\in\mathbb{N}} \|v_\nu\|_{W^{\ell,p}(B^+)} < \infty.$$

The same corollary provides a subsequence $z_{\nu_h} \to z_\infty$ in $W^{k,q}(B)$. Finally,

$$\|v_{\nu_h} - z_\infty\restriction_{B^+}\|_{W^{k,q}(B^+)} \le \|z_{\nu_h} - z_\infty\|_{W^{k,q}(B)} \longrightarrow 0.$$

This proves compactness without imposing a zero boundary condition. □

3.6.1 Summary of domains and embeddings

In the table, $m > k \ge 0$ are integers, p, q are finite unless otherwise stated, and $\delta := (m - \frac{n}{p}) - (k - \frac{n}{q})$. The extension condition concerns the source space. On every open subset, $W_0^{m,p}$ is defined by closure; interior smooth density and the equality $W_0 = W$ on $\mathbb{R}^n$ are given in Proposition 3.3.12.

Domain and space	Assumptions and range	Conclusion	Reference
Ω bounded, $W_0^{m,p}$	$1 \le p, q < \infty$	Continuous if $\delta \ge 0$; compact if $\delta > 0$, into $W_0^{k,q}$	3.3.16, 3.4.2
Ω bounded, $W^{m,p}$	Extension domain; $1 \le p, q < \infty$	Continuous if $\delta \ge 0$; compact if $\delta > 0$	3.3.16, 3.4.2
$\mathbb{R}^n$, $W^{m,p} = W_0^{m,p}$	$1 \le p \le q < \infty$	Globally continuous if $\delta \ge 0$	3.4.7
$\mathbb{R}^n$, support in compact K	$1 \le p, q < \infty$; $\delta > 0$	Compact with common support; locally compact	3.4.8
$\mathbb{R}^n_+$, $W_K^{m,p}$; also $W_K^{m,p} \cap W_0^{m,p}$	$K \subseteq \overline{\mathbb{R}^n_+}$ compact; $1 \le p, q < \infty$	Continuous if $\delta \ge 0$; compact if $\delta > 0$	3.6.6
Ω bounded; $W_0^{m,p}$ or $W^{m,p}$ with extension	$p < \infty$, $q = \infty$, $m - n/p > k$; or $p = \infty$	Compact into $W^{k,q}$ in the indicated ranges	3.5.12

3.7 The trace theorem on the half-space

The trace assigns boundary values to a Sobolev function through smooth approximation. On the half-space, an estimate in the normal direction allows its construction for every $1 \le p < \infty$; applying it to derivatives will also give the characterization of $W_0^{m,p}(\mathbb{R}^n_+)$.

We shall use the convention in Definition 3.5.1: a function belongs to $C^\infty(\overline{\Omega})$ if it is the restriction to $\overline{\Omega}$ of a

smooth function defined on an open neighborhood of $\overline{\Omega}$. Moreover,

$$C_c^\infty(\overline{\Omega}) = \left\{ f \in C^\infty(\overline{\Omega}) \middle| \operatorname{supp}_{\overline{\Omega}}(f) \text{ is compact} \right\}.$$

In particular, on the half-space we shall work with $C_c^\infty(\overline{\mathbb{R}^n_+})$. For each $m \in \mathbb{N}$ and $1 \le p < \infty$, this space is dense in $W^{m,p}(\mathbb{R}^n_+)$, and ordinary restriction to the flat boundary initially defines an operator on these functions. The trace theorem states that this operator extends uniquely and continuously to all of $W^{m,p}(\mathbb{R}^n_+)$.

Theorem 3.7.1. (Trace theorem on the half-space) Let $\mathbb{R}^n_+ = \{x \in \mathbb{R}^n \mid x_n > 0\}$, let $\partial\mathbb{R}^n_+ = \{x_n = 0\} \cong \mathbb{R}^{n-1}$, and let $m \ge 1$ and $1 \le p < \infty$. Then, for each multi-index β with $|\beta| \le m-1$, the operator

$$f \longmapsto (D^\beta f) \restriction_{\partial\mathbb{R}^n_+}, \qquad f \in C_c^\infty(\overline{\mathbb{R}^n_+}),$$

admits a unique continuous linear extension

$$\gamma_0 D^\beta \colon W^{m,p}(\mathbb{R}^n_+) \longrightarrow W^{m-1-|\beta|,p}(\mathbb{R}^{n-1}).$$

Moreover,

$$W_0^{m,p}(\mathbb{R}^n_+) = \left\{ f \in W^{m,p}(\mathbb{R}^n_+) \middle| \gamma_0 D^\beta f = 0 \text{ for every } |\beta| \le m-1 \right\},$$

where $W_0^{m,p}(\mathbb{R}^n_+)$ denotes the closure of $C_c^\infty(\mathbb{R}^n_+)$ in $W^{m,p}(\mathbb{R}^n_+)$.

Proof. Write $x = (x', t) \in \mathbb{R}^{n-1} \times (0, \infty)$. When $n = 1$, interpret $\mathbb{R}^0$ as a single point equipped with counting measure; the tangential derivatives appearing below then reduce to the derivative of order zero. By Corollary 3.6.4 and density of $C_c^\infty(\mathbb{R}^n)$ in $W^{m,p}(\mathbb{R}^n)$, restriction of smooth approximations of an extension of f proves density of $C_c^\infty(\overline{\mathbb{R}^n_+})$ in $W^{m,p}(\mathbb{R}^n_+)$.
Begin with $m = 1$. If $f \in C_c^\infty(\overline{\mathbb{R}^n_+})$, the fundamental theorem of calculus gives, for $p = 1$,

$$|f(x', 0)| \le \int_0^\infty |\partial_n f(x', t)| \, dt.$$

Integrating with respect to x' gives

$$\| f \restriction_{\partial\mathbb{R}^n_+} \|_{L^1(\mathbb{R}^{n-1})} \le \| \partial_n f \|_{L^1(\mathbb{R}^n_+)}.$$

For $1 < p < \infty$, apply the same argument to $|f|^p$ and integrate. Hölder's and Young's inequalities yield

$$\begin{aligned} \| f \restriction_{\partial\mathbb{R}^n_+} \|^p_{L^p(\mathbb{R}^{n-1})} &\le p \int_{\mathbb{R}^n_+} |f|^{p-1} |\partial_n f| \, dx \\ &\le p \| f \|^{p-1}_{L^p(\mathbb{R}^n_+)} \| \partial_n f \|_{L^p(\mathbb{R}^n_+)} \\ &\le (p-1) \| f \|^p_{L^p(\mathbb{R}^n_+)} + \| \partial_n f \|^p_{L^p(\mathbb{R}^n_+)}. \end{aligned}$$

By density and completeness of $L^p(\mathbb{R}^{n-1})$, restriction has a unique continuous linear extension $\gamma_0 \colon W^{1,p}(\mathbb{R}^n_+) \to L^p(\mathbb{R}^{n-1})$ for every $1 \le p < \infty$.
Now let $m \ge 1$, $|\beta| \le m-1$, and $f \in W^{m,p}(\mathbb{R}^n_+)$. Each $D^\beta f$ belongs to $W^{1,p}(\mathbb{R}^n_+)$, so its trace is defined. Take $f_\nu \in C_c^\infty(\overline{\mathbb{R}^n_+})$ with $f_\nu \to f$ in $W^{m,p}$. For every tangential multi-index $\alpha \in \mathbb{N}_0^{n-1}$ with $|\alpha| \le m-1-|\beta|$, the

first-order estimate implies

$$\gamma_0 D^{\beta+(\alpha,0)} f_\nu \longrightarrow \gamma_0 D^{\beta+(\alpha,0)} f \quad \text{on } L^p(\mathbb{R}^{n-1}).$$

For smooth functions,

$$D^\alpha_{x'}(\gamma_0 D^\beta f_\nu) = \gamma_0 D^{\beta+(\alpha,0)} f_\nu.$$

Integrate this identity against a test function $\varphi \in C_c^\infty(\mathbb{R}^{n-1})$ and pass to the limit on both sides. Hölder's inequality justifies this passage also for $p = 1$, using $\varphi, D^\alpha\varphi \in L^\infty$. Thus,

$$D^\alpha_{x'}(\gamma_0 D^\beta f) = \gamma_0 D^{\beta+(\alpha,0)} f$$

in the weak sense. Summing the first-order estimates for these finitely many multi-indices gives

$$\|\gamma_0 D^\beta f\|_{W^{m-1-|\beta|,p}(\mathbb{R}^{n-1})} \le C(n,m,p)\|f\|_{W^{m,p}(\mathbb{R}^n_+)}.$$

The density already established also proves uniqueness of this extension.

To characterize the kernel, if $f \in W_0^{m,p}(\mathbb{R}^n_+)$, approximate by functions in $C_c^\infty(\mathbb{R}^n_+)$. All their derivatives restrict to zero on the boundary; continuity of the traces implies $\gamma_0 D^\beta f = 0$ for every $|\beta| \le m-1$.

Conversely, suppose that these traces vanish. First justify the integration-by-parts identity that allows extension by zero. If $v \in W^{1,p}(\mathbb{R}^n_+)$ and $\varphi \in C_c^\infty(\mathbb{R}^n)$, smooth approximation up to the boundary and continuity of γ_0 give

$$\int_{\mathbb{R}^n_+} v\,\partial_i\varphi\,dx = -\int_{\mathbb{R}^n_+} (D_i v)\varphi\,dx - \delta_{in}\int_{\mathbb{R}^{n-1}} (\gamma_0 v)(x')\varphi(x',0)\,dx'.$$

For smooth functions, the formula follows from the fundamental theorem of calculus and tangential integration by parts; all integrals pass to the limit by Hölder's inequality on the fixed support of φ. If $\gamma_0 v = 0$ and $E_0 v$ denotes extension by zero to $\mathbb{R}^n$, the preceding identity is precisely

$$D_i(E_0 v) = E_0(D_i v) \quad \text{in the sense of distributions on } \mathbb{R}^n.$$

Apply this identity successively to $v = D^\alpha f$. At order zero, $E_0 f \in L^p(\mathbb{R}^n)$. If we already know $D^\alpha(E_0 f) = E_0(D^\alpha f)$ for some $|\alpha| \le m-1$, then $D^\alpha f \in W^{1,p}(\mathbb{R}^n_+)$ and $\gamma_0 D^\alpha f = 0$. For each $i \in \{1,\dots,n\}$, the first-order step gives

$$D^{\alpha+e_i}(E_0 f) = D_i E_0(D^\alpha f) = E_0(D^{\alpha+e_i} f).$$

Induction proves, for all multi-indices of order at most m,

$$D^\alpha(E_0 f) = E_0(D^\alpha f), \qquad \|E_0 f\|_{W^{m,p}(\mathbb{R}^n)} = \|f\|_{W^{m,p}(\mathbb{R}^n_+)}.$$

Set $F := E_0 f$. For $t > 0$, the function $F_t(x) := F(x - te_n)$ belongs to $W^{m,p}(\mathbb{R}^n)$, vanishes when $x_n < t$, and converges to F in $W^{m,p}(\mathbb{R}^n)$ as $t \to 0^+$. Indeed, $D^\alpha F_t = (D^\alpha F)(\cdot - te_n)$, and continuity of translations in L^p applies to each of the finitely many derivatives $|\alpha| \le m$.

For fixed t, choose $\chi \in C_c^\infty(\mathbb{R}^n)$ with $\chi = 1$ on a neighborhood of $\overline{B_{\mathrm{euc}}(0,1)}$ and set $\chi_R(x) = \chi(x/R)$. The Leibniz rule and $\|D^\alpha \chi_R\|_\infty = R^{-|\alpha|}\|D^\alpha\chi\|_\infty$ show that $\chi_R F_t \to F_t$ in $W^{m,p}(\mathbb{R}^n)$ as $R \to \infty$: terms with no derivatives on χ_R converge by domination, while the others contain the factor $R^{-|\alpha|}$, $|\alpha| \ge 1$. The product

still vanishes on $\{x_n < t\}$. If ρ_ε is a mollifier supported in $\overline{B_{\mathrm{euc}}(0,\varepsilon)}$ and $0 < \varepsilon < t/2$, then

$$\rho_\varepsilon * (\chi_R F_t) \in C_c^\infty(\mathbb{R}^n_+),$$

since its support is contained in $\{x_n \geq t - \varepsilon\}$. For fixed t, R, these convolutions converge to $\chi_R F_t$ in $W^{m,p}(\mathbb{R}^n)$ as $\varepsilon \to 0^+$. For each $\nu \in \mathbb{N}$, choose successively $t_\nu > 0$, R_ν, and $0 < \varepsilon_\nu < t_\nu/2$ so that each of the three errors is less than $1/(3\nu)$. The restriction of $\rho_{\varepsilon_\nu} * (\chi_{R_\nu} F_{t_\nu})$ converges to f in $W^{m,p}(\mathbb{R}^n_+)$. By definition, $f \in W_0^{m,p}(\mathbb{R}^n_+)$, completing the characterization of the kernel. □

We shall use the following convention from now on. If $v \in W^{m,p}(B^+)$ satisfies the support assumption in Lemma 3.6.8 and $\widetilde{v}$ denotes its extension by zero to $\mathbb{R}^n_+$, then for $|\beta| \leq m-1$ we shall write $\gamma_0 D^\beta v = 0$ on B' to mean that

$$(\gamma_0 D^\beta \widetilde{v}) \restriction_{B'} = 0 \qquad \text{on } W^{m-1-|\beta|,p}(B').$$

This notation does not introduce an independent trace on the half-ball; it merely abbreviates the half-space trace after extension by zero.

Lemma 3.7.2. (Locality of the half-space trace) Let $1 \leq p < \infty$, let $O \subset \partial\mathbb{R}^n_+$ be a relatively open subset, and let $F \in W^{1,p}(\mathbb{R}^n_+)$. Suppose that there is an open subset $V \subset \mathbb{R}^n$, with $O \subset V \cap \partial\mathbb{R}^n_+$, such that $F = 0$ almost everywhere on $V \cap \mathbb{R}^n_+$. Then $\gamma_0 F = 0$ in O.

Proof. Fix $x_0 \in O$. Since O is relatively open in $\partial\mathbb{R}^n_+$ and V is open in $\mathbb{R}^n$, we may choose $r > 0$ such that $B_{\mathrm{euc}}(x_0, 2r) \subset V$ and $B_{\mathrm{euc}}(x_0, 2r) \cap \partial\mathbb{R}^n_+ \subset O$. Take a function $\chi \in C_c^\infty(\mathbb{R}^n)$ such that $\operatorname{supp}\chi \subset B_{\mathrm{euc}}(x_0, 2r)$ and $\chi \equiv 1$ on $B_{\mathrm{euc}}(x_0, r)$. Upon restricting χ to $\mathbb{R}^n_+$, the product χF is well defined as an element of $W^{1,p}(\mathbb{R}^n_+)$. Since $\operatorname{supp}\chi \cap \mathbb{R}^n_+ \subset V \cap \mathbb{R}^n_+$ and $F = 0$ almost everywhere on $V \cap \mathbb{R}^n_+$, we have $\chi F = 0$ in $W^{1,p}(\mathbb{R}^n_+)$. Therefore, $\gamma_0(\chi F) = 0$.

We now prove that $\gamma_0(\chi G) = \chi \restriction_{\partial\mathbb{R}^n_+} \gamma_0 G$ for every $G \in W^{1,p}(\mathbb{R}^n_+)$. If $G \in C_c^\infty(\overline{\mathbb{R}^n_+})$, the identity is immediate, since both sides are the restriction of χG to $\partial\mathbb{R}^n_+$. For $G \in W^{1,p}(\mathbb{R}^n_+)$, take a sequence $G_j \in C_c^\infty(\overline{\mathbb{R}^n_+})$ such that $G_j \to G$ in $W^{1,p}(\mathbb{R}^n_+)$. Since multiplication by the fixed function $\chi|_{\mathbb{R}^n_+}$ is continuous on $W^{1,p}(\mathbb{R}^n_+)$, we have $\chi G_j \to \chi G$ in $W^{1,p}(\mathbb{R}^n_+)$. Moreover, continuity of the trace gives

$$\gamma_0(\chi G_j) \longrightarrow \gamma_0(\chi G) \qquad \text{on } L^p(\partial\mathbb{R}^n_+),$$

and, since multiplication by $\chi \restriction_{\partial\mathbb{R}^n_+}$ is continuous on $L^p(\partial\mathbb{R}^n_+)$,

$$\chi \restriction_{\partial\mathbb{R}^n_+} \gamma_0 G_j \longrightarrow \chi \restriction_{\partial\mathbb{R}^n_+} \gamma_0 G \qquad \text{on } L^p(\partial\mathbb{R}^n_+).$$

Passing to the limit in the smooth identity yields

$$\gamma_0(\chi G) = \chi \restriction_{\partial\mathbb{R}^n_+} \gamma_0 G.$$

Applying this to $G = F$ gives

$$0 = \gamma_0(\chi F) = \chi \restriction_{\partial\mathbb{R}^n_+} \gamma_0 F.$$

Since $\chi \equiv 1$ on $B_{\mathrm{euc}}(x_0, r)$, it follows that $\gamma_0 F = 0$ in $B_{\mathrm{euc}}(x_0, r) \cap \partial\mathbb{R}^n_+$. Second countability of O allows us to cover it by a countable family of these neighborhoods. The union of their exceptional sets has measure

zero, so $\gamma_0 F = 0$ almost everywhere on O. □

Corollary 3.7.3. (Local characterization on a half-ball) Let $B^+ = B_{\text{euc}}(0,R) \cap \mathbb{R}^n_+$, let $B' = B_{\text{euc}}(0,R) \cap \partial\mathbb{R}^n_+$, and let $v \in W^{m,p}(B^+)$. Suppose that there is a compact set $K \subset B_{\text{euc}}(0,R) \cap \{x_n \geq 0\}$, lying at a positive distance from the spherical portion $\partial B_{\text{euc}}(0,R) \cap \{x_n \geq 0\}$, such that $v = 0$ almost everywhere on $B^+ \setminus K$.
If $\gamma_0 D^\beta v = 0$ on B', in the sense of the preceding convention, for every $|\beta| \leq m-1$, then v belongs to the closure of $C_c^\infty(B^+)$ in $W^{m,p}(B^+)$.

Proof. If $K = \varnothing$, then $v = 0$ almost everywhere on B^+, and the result is immediate. Thus assume $K \neq \varnothing$.
Let $\widetilde{v}$ be the extension by zero of v to $\mathbb{R}^n_+$. By Lemma 3.6.8, we have $\widetilde{v} \in W^{m,p}(\mathbb{R}^n_+)$ and $D^\beta \widetilde{v} = \widetilde{D^\beta v}$ for every $|\beta| \leq m$. By hypothesis, $(\gamma_0 D^\beta \widetilde{v}) \restriction_{B'} = 0$ for every $|\beta| \leq m-1$. We show that in fact $\gamma_0 D^\beta \widetilde{v} = 0$ on all of $\partial\mathbb{R}^n_+$.
Fix $|\beta| \leq m-1$. We already know that the trace vanishes upon restriction to B'. It remains to examine what happens on $\partial\mathbb{R}^n_+ \setminus B'$. Again denote the spherical portion of the half-ball by $\Gamma_R := \partial B_{\text{euc}}(0,R) \cap \{x_n \geq 0\}$, take $\delta := \operatorname{dist}(K, \Gamma_R) > 0$, and set $U := B^+ \cap \{x \in \mathbb{R}^n \mid \|x\| > R - \frac{\delta}{2}\}$. As in the proof of the lemma, $D^\alpha v = 0$ almost everywhere on U for every $|\alpha| \leq m$.
Let $x_0 = (x_0', 0) \in \partial\mathbb{R}^n_+ \setminus B'$. Then $\|x_0'\| \geq R$. If $\|x_0'\| > R$, take $\rho := \frac{\|x_0'\| - R}{2} > 0$. Then $B_{\text{euc}}(x_0, \rho) \cap \mathbb{R}^n_+ \subset \mathbb{R}^n_+ \setminus B^+$, and the definition of extension by zero gives $D^\beta \widetilde{v} = 0$ almost everywhere on $B_{\text{euc}}(x_0, \rho) \cap \mathbb{R}^n_+$.
If $\|x_0'\| = R$, take $\rho := \frac{\delta}{4}$. If $x \in B_{\text{euc}}(x_0, \rho) \cap \mathbb{R}^n_+$, then either $x \notin B^+$, where $D^\beta \widetilde{v} = 0$, or $x \in B^+$. In the latter case, $\|x\| \geq R - \rho = R - \frac{\delta}{4} > R - \frac{\delta}{2}$, so $x \in U$, where $D^\beta v = 0$ almost everywhere. Thus in this case too, $D^\beta \widetilde{v} = 0$ almost everywhere on $B_{\text{euc}}(x_0, \rho) \cap \mathbb{R}^n_+$.
Thus, $D^\beta \widetilde{v}$ vanishes almost everywhere on a relative neighborhood of each point of $\partial\mathbb{R}^n_+ \setminus B'$. Since $|\beta| \leq m-1$, we have $D^\beta \widetilde{v} \in W^{1,p}(\mathbb{R}^n_+)$, and Lemma 3.7.2, applied to $F = D^\beta \widetilde{v}$, yields $\gamma_0 D^\beta \widetilde{v} = 0$ in $\partial\mathbb{R}^n_+$. Since this holds for every $|\beta| \leq m-1$, Theorem 3.7.1 implies $\widetilde{v} \in W_0^{m,p}(\mathbb{R}^n_+)$. Hence there is a sequence $(\eta_k)_{k\in\mathbb{N}} \subset C_c^\infty(\mathbb{R}^n_+)$ such that $\eta_k \to \widetilde{v}$ in $W^{m,p}(\mathbb{R}^n_+)$.
Take a function $\chi \in C_c^\infty(\mathbb{R}^n)$ such that $\operatorname{supp}\chi \subset B_{\text{euc}}(0,R)$ and $\chi \equiv 1$ on a neighborhood of K. Since multiplication by $\chi|_{\mathbb{R}^n_+}$ is continuous on $W^{m,p}(\mathbb{R}^n_+)$, we have $\chi\eta_k \to \chi\widetilde{v} = \widetilde{v}$ in $W^{m,p}(\mathbb{R}^n_+)$. Moreover, $(\chi\eta_k) \restriction_{B^+} \in C_c^\infty(B^+)$, because η_k has compact support in $\mathbb{R}^n_+$ and $\operatorname{supp}\chi \subset B_{\text{euc}}(0,R)$. Restricting to B^+ gives a sequence in $C_c^\infty(B^+)$ converging to v in $W^{m,p}(B^+)$. Therefore, v belongs to the closure of $C_c^\infty(B^+)$ in $W^{m,p}(B^+)$. □

4

Distributions and Fourier analysis

Oliver Heaviside (1850–1925)

Figure 4.1. Oliver Heaviside systematically used the step function and operational calculus methods to study electrical problems, anticipating ideas that later received a rigorous formulation in distribution theory.

Distribution theory extends the notion of a function and makes it possible to differentiate objects that have neither a classical derivative nor a weak derivative representable by a locally integrable function. Its modern formulation, due to Laurent Schwartz, rigorously organizes ideas that had already appeared in operational calculus and in the study of discontinuous signals.

Sobolev spaces showed that integration by parts makes it possible to assign derivatives to functions of limited regularity. The distributional framework takes this idea one step further: a distribution is defined by its action on test functions, and its derivatives are obtained by formally transferring differentiation to those functions. This provides a unified treatment of the Heaviside function, the Dirac delta, and many other singularities arising in differential equations, mathematical physics, and Fourier analysis.

A weak solution may therefore have derivatives only in the distributional sense. For differential operators with constant coefficients, the Fourier transform turns those derivatives into multiplication: with the unitary normalization to be fixed below,

$$\widehat{D^{\alpha}u}(\xi) = (i\xi)^{\alpha}\,\widehat{u}(\xi).$$

This identity reduces linear equations to algebraic relations in the frequency variable. It also allows us to construct fundamental solutions and regularizations, and to distinguish the behavior of low frequencies from that of high

frequencies. Tempered distributions will provide the common domain on which these operations remain well defined.

The step function introduced by Oliver Heaviside provides an immediate motivation. Among other phenomena, it models the instantaneous switching on of a signal and has a jump at the origin; its derivative cannot be represented by a locally integrable function, but it can be represented by a distribution.

Example 4.0.1. (The Heaviside function) We define the Heaviside function $H\colon \mathbb{R} \longrightarrow \mathbb{R}$ by

$$H(x) = \begin{cases} 0, & x < 0, \\ 1, & x \geq 0. \end{cases}$$

Although H is locally integrable, it is not weakly differentiable in the sense of having its derivative represented by a function in $L^1_{\mathrm{loc}}(\mathbb{R})$. This difficulty motivates the distributional extension of the derivative. Suppose, seeking a contradiction, that there exists $v \in L^1_{\mathrm{loc}}(\mathbb{R})$ satisfying

$$\int_{\mathbb{R}} H(x)\varphi'(x)dx = -\int_{\mathbb{R}} v(x)\varphi(x)dx \qquad \forall \varphi \in C_c^\infty(\mathbb{R}).$$

Since $H = 0$ on $(-\infty, 0)$ and $H = 1$ on $[0, \infty)$, we obtain

$$\int_{\mathbb{R}} H(x)\varphi'(x)dx = \int_0^\infty \varphi'(x)dx.$$

Since φ has compact support, there exists $R > 0$ such that $\varphi(x) = 0$ for $x \geq R$, so

$$\int_0^\infty \varphi'(x)dx = \int_0^R \varphi'(x)dx.$$

This integral is defined over a finite interval, and since φ is smooth, the Lebesgue integral agrees with the Riemann integral. Theorem B.6.5 gives

$$\int_0^R \varphi'(x)dx = \varphi(R) - \varphi(0) = -\varphi(0).$$

Consequently, the preceding equality would imply

$$\int_{\mathbb{R}} v(x)\varphi(x)dx = \varphi(0), \qquad \forall \varphi \in C_c^\infty(\mathbb{R}).$$

Now, if we take a family of functions $\varphi_\varepsilon \in C_c^\infty(\mathbb{R})$ with $0 \leq \varphi_\varepsilon \leq 1$, $\varphi_\varepsilon(0) = 1$, and $\mathrm{supp}(\varphi_\varepsilon) \subset (-\varepsilon, \varepsilon)$, it follows that

$$\int_{\mathbb{R}} v(x)\varphi_\varepsilon(x)dx = 1.$$

But since $v \in L^1_{\mathrm{loc}}(\mathbb{R})$,

$$\left| \int_{\mathbb{R}} v(x)\varphi_\varepsilon(x)dx \right| \leq \int_{-\varepsilon}^{\varepsilon} |v(x)|dx \xrightarrow[\varepsilon \to 0]{} 0,$$

where the limit is justified by applying the *Lebesgue dominated convergence theorem* (Theorem B.6.14), since $v \in L^1_{\mathrm{loc}}(\mathbb{R})$ ensures integrability on the intervals $(-\varepsilon, \varepsilon)$. This contradicts the fact that the integral always

equals 1. Thus no such function v exists, and we conclude that H has no weak derivative.

This calculation makes clear the need to extend the notion of a weak derivative: we must allow new objects that, although not ordinary functions, act consistently on test functions. This new object is precisely the *Dirac delta*.

Before formalizing the definition, it is helpful to recall the physical motivation: in his study of quantum mechanics, Paul Dirac (1902–1984) formally introduced the symbol δ_0 to model *point sources of energy*. In that setting, the delta was an indispensable tool for describing systems in which all the mass or charge is concentrated at a single point, and engineers and physicists used it long before a rigorous mathematical foundation became available through the distribution theory developed by Laurent Schwartz. We now formalize the Dirac delta.

Example 4.0.2. (The Dirac delta) We define the ***Dirac delta*** to be the linear functional $\delta_0 \colon C_c^\infty(\mathbb{R}^n) \longrightarrow \mathbb{R}$ given by

$$\delta_0(\varphi) = \varphi(0).$$

The preceding identity suggests that δ_0 should be interpreted as the derivative of the Heaviside function. It is not an ordinary function, but it can act linearly on test functions. For this action to have analytical stability, linearity alone is insufficient: continuity is needed. Before defining a distribution, we must therefore specify the topology of the space $C_c^\infty(\mathbb{R}^n)$.

4.1 The space $\mathcal{D}(\Omega)$

Let $\Omega \subseteq \mathbb{R}^n$ be an open subset. The space $C_c^\infty(\Omega)$ of smooth functions with compact support will be the basic space of test functions. To use it in functional analysis, we need to equip it with a topology that simultaneously records the behavior of a function and all its derivatives, without reducing this information to a single norm.

We first carry out the construction by fixing a compact set $K \subseteq \Omega$ and considering the functions whose support is contained in K. We will use the general results on topologies induced by families of seminorms, locally convex spaces, metrizability, and Fréchet spaces collected in Appendix B.10.

In particular, we will use Definition B.10.18, Theorem B.10.19, Propositions B.10.21, B.10.23, and B.10.24, as well as Theorem B.10.38.

We first consider the space of all smooth functions with support contained in a fixed compact subset $K \subseteq \Omega$, which we denote by $\mathcal{D}_K(\Omega)$:

$$\mathcal{D}_K(\Omega) := \{\varphi \in C_c^\infty(\Omega) \mid \operatorname{supp}(\varphi) \subseteq K\}.$$

The topology on this subspace must be consistent with the natural notion of uniform convergence of functions and their partial derivatives of every order on the compact set K. For each $j \in \mathbb{N}_0$, we define

$$\|\varphi\|_{C^j(K)} := \max_{|\alpha| \leq j} \sup_{x \in K} |D^\alpha \varphi(x)|.$$

Since the case $\alpha = 0$ is included and $\operatorname{supp}(\varphi) \subseteq K$, each $\|\cdot\|_{C^j(K)}$ is a norm on $\mathcal{D}_K(\Omega)$. If $\|\varphi\|_{C^j(K)} = 0$, then in particular $\|\varphi\|_{C^0(K)} = 0$, so $\varphi = 0$ on K. On the other hand, since $\operatorname{supp}(\varphi) \subseteq K$, if $x \in \Omega \setminus K$, then $\varphi(x) = 0$. Therefore, $\varphi = 0$ throughout Ω.

By Theorem B.10.19, the family of norms $\{\|\cdot\|_{C^j(K)}\}_{j \in \mathbb{N}_0}$ induces a topology τ_K on $\mathcal{D}_K(\Omega)$ under which this space is a locally convex topological vector space. A neighborhood base at the origin for this topology consists of finite

intersections of sets of the form

$$\bigcap_{q=1}^{k} \left\{ \varphi \in \mathcal{D}_K(\Omega) \,\middle|\, \|\varphi\|_{C^{j_q}(K)} < r_q \right\},$$

where $j_1, \dots, j_k \in \mathbb{N}_0$, $r_1, \dots, r_k > 0$, and $k \in \mathbb{N}$. The neighborhoods of an arbitrary element $\varphi \in \mathcal{D}_K(\Omega)$ have the form $\varphi + U$, where U is a neighborhood of the origin.

Lemma 4.1.1. The family

$$V_{K,j,\ell} := \left\{ \varphi \in \mathcal{D}_K(\Omega) \,\middle|\, \|\varphi\|_{C^j(K)} < \frac{1}{\ell} \right\}, \qquad j \in \mathbb{N}_0, \quad \ell \in \mathbb{N},$$

is a countable neighborhood base at the origin for τ_K. In particular, $(\mathcal{D}_K(\Omega), \tau_K)$ has a countable local base at each point.

Proof. First, observe that each $V_{K,j,\ell}$ is a neighborhood of the origin, since it is one of the neighborhoods determined by the norm $\|\cdot\|_{C^j(K)}$.
Now let U be a neighborhood of the origin in τ_K. By the description of the local base, there exists a basic neighborhood

$$W := \bigcap_{q=1}^{k} \left\{ \varphi \in \mathcal{D}_K(\Omega) \,\middle|\, \|\varphi\|_{C^{j_q}(K)} < r_q \right\}$$

such that $W \subseteq U$. We define $j := \max\{j_1, \dots, j_k\}$ and choose $\ell \in \mathbb{N}$ such that $\frac{1}{\ell} < \min\{r_1, \dots, r_k\}$.
Since the norms $\|\cdot\|_{C^j(K)}$ are increasing in j, if $\psi \in V_{K,j,\ell}$, then, for each $q \in \{1, \dots, k\}$,

$$\|\psi\|_{C^{j_q}(K)} \le \|\psi\|_{C^j(K)} < \frac{1}{\ell} < r_q.$$

Therefore, $\psi \in W$. Thus, $V_{K,j,\ell} \subseteq W \subseteq U$.
This proves that $\{V_{K,j,\ell} \mid j \in \mathbb{N}_0,\ \ell \in \mathbb{N}\}$ is a local base at the origin. Moreover, this family is countable, since $\mathbb{N}_0 \times \mathbb{N}$ is countable.
Finally, since translations are homeomorphisms in the topology induced by seminorms, for each $\varphi \in \mathcal{D}_K(\Omega)$ the family

$$\{\varphi + V_{K,j,\ell} \mid j \in \mathbb{N}_0,\ \ell \in \mathbb{N}\}$$

is a countable neighborhood base at φ. □

Since the family $\{\|\cdot\|_{C^j(K)}\}_{j \in \mathbb{N}_0}$ separates points, Proposition B.10.21 implies that the space $(\mathcal{D}_K(\Omega), \tau_K)$ is Hausdorff. If $\varphi \neq 0$, then, since $\operatorname{supp}(\varphi) \subseteq K$, it is impossible for φ to vanish throughout K; therefore, $\|\varphi\|_{C^0(K)} > 0$.

In particular, singletons in $(\mathcal{D}_K(\Omega), \tau_K)$ are closed. Moreover, by Lemma 4.1.1, this space has a countable local base at the origin. By Theorem B.10.9, we conclude that $(\mathcal{D}_K(\Omega), \tau_K)$ is metrizable.

Furthermore, in this case we can write down a compatible metric explicitly. By Proposition B.10.24, the topology τ_K is induced by the translation-invariant metric

$$d_K(\varphi, \psi) := \sum_{j=0}^{\infty} \frac{1}{2^j} \frac{\|\varphi - \psi\|_{C^j(K)}}{1 + \|\varphi - \psi\|_{C^j(K)}}, \qquad \varphi, \psi \in \mathcal{D}_K(\Omega).$$

By Proposition B.10.23, a sequence $(\varphi_n)_{n\in\mathbb{N}}$ converges to φ in $\mathcal{D}_K(\Omega)$ if and only if

$$\|\varphi_n - \varphi\|_{C^j(K)} \to 0 \qquad \text{for every } j \in \mathbb{N}_0.$$

This means that $\varphi_n \to \varphi$ if and only if, for every multi-index α, the sequence $(D^\alpha \varphi_n)_{n\in\mathbb{N}}$ converges uniformly on K to $D^\alpha \varphi$. If $\|\varphi_n - \varphi\|_{C^j(K)} \to 0$ for all j, then, given a multi-index α, it suffices to take $j \geq |\alpha|$ to obtain

$$\|D^\alpha \varphi_n - D^\alpha \varphi\|_{C^0(K)} \leq \|\varphi_n - \varphi\|_{C^j(K)} \to 0.$$

Conversely, if for every multi-index α the sequence $(D^\alpha \varphi_n)_{n\in\mathbb{N}}$ converges uniformly on K to $D^\alpha \varphi$, then, for each $j \in \mathbb{N}_0$, the set of multi-indices α with $|\alpha| \leq j$ is finite. Therefore,

$$\|\varphi_n - \varphi\|_{C^j(K)} = \max_{|\alpha|\leq j} \|D^\alpha \varphi_n - D^\alpha \varphi\|_{C^0(K)} \to 0.$$

Likewise, a sequence $(\varphi_n)_{n\in\mathbb{N}}$ is Cauchy in $\mathcal{D}_K(\Omega)$ if and only if

$$\|\varphi_n - \varphi_m\|_{C^j(K)} \to 0 \qquad \text{as } n, m \to \infty,$$

for every $j \in \mathbb{N}_0$. Equivalently, for every multi-index α, the sequence $(D^\alpha \varphi_n)_{n\in\mathbb{N}}$ is uniformly Cauchy on K.

4.2 Projective limits

A natural question is whether the space $\mathcal{D}_K(\Omega)$ is complete under the topology τ_K we have just constructed. It is indeed complete. Moreover, $\mathcal{D}_K(\Omega)$ is not only a locally convex space generated by a countable family of norms, but can also be described as a *projective limit of Banach spaces*.

The same description by projective limits will be used again for spaces of test sections of smooth vector bundles and for the space of rapidly decreasing functions, usually called the *Schwartz class*. The latter will be the test function space for tempered distributions.

From the topological point of view, the projective topology we will use is not a new construction: it is precisely an initial topology in the sense of Definition B.10.39. We call it *projective* because it is associated with a family of linear maps into known topological spaces.

Definition 4.2.1. (Projective topology) Let X be a vector space, let $\{X_i\}_{i\in I}$ be a family of topological vector spaces, and, for each $i \in I$, let $T_i \colon X \longrightarrow X_i$ be a linear map. The *projective topology* on X associated with the family $(T_i)_{i\in I}$ is the initial topology determined by these maps.
Equivalently, it is the coarsest topology on X for which all the maps $T_i \colon X \longrightarrow X_i$ are continuous. A neighborhood base at the origin for this topology consists of the sets

$$\bigcap_{q=1}^{r} T_{i_q}^{-1}(U_{i_q}),$$

where $r \in \mathbb{N}$, $i_1, \ldots, i_r \in I$, and each U_{i_q} is a neighborhood of the origin in X_{i_q}.

Proposition 4.2.2. Let X be a vector space, let $\{X_i\}_{i\in I}$ be a family of topological vector spaces, and, for each $i \in I$, let $T_i \colon X \longrightarrow X_i$ be a linear map. Then the projective topology associated with $(T_i)_{i\in I}$ makes X a topological vector space.
Moreover:

(a) if each X_i is locally convex, then X is locally convex;

(b) if each X_i is Hausdorff and the family $(T_i)_{i\in I}$ separates points of X, then X is Hausdorff.

Proof. Denote the projective topology on X by τ_{proj}.
We first prove that addition is continuous. Since it suffices to check continuity on basic neighborhoods, let $x, y \in X$ and let W be a basic neighborhood of $x+y$ in τ_{proj}. We can write

$$W = \bigcap_{q=1}^{r} T_{i_q}^{-1}(U_q),$$

where, for each $q \in \{1,\dots,r\}$, the set U_q is a neighborhood of $T_{i_q}(x+y)$ in X_{i_q}.
Since addition is continuous in X_{i_q}, there exist neighborhoods V_q of $T_{i_q}(x)$ and W_q of $T_{i_q}(y)$ such that $V_q + W_q \subseteq U_q$. We define

$$V := \bigcap_{q=1}^{r} T_{i_q}^{-1}(V_q), \qquad W' := \bigcap_{q=1}^{r} T_{i_q}^{-1}(W_q).$$

Then V is a neighborhood of x and W' is a neighborhood of y. If $u \in V$ and $v \in W'$, then, for each $q \in \{1,\dots,r\}$, we have $T_{i_q}(u) \in V_q$ and $T_{i_q}(v) \in W_q$. Since T_{i_q} is linear,

$$T_{i_q}(u+v) = T_{i_q}(u) + T_{i_q}(v) \in V_q + W_q \subseteq U_q.$$

Therefore, $u+v \in W$. Thus, $V + W' \subseteq W$, and addition is continuous.
We now show that scalar multiplication is continuous. Since it suffices to check continuity on basic neighborhoods, let $\lambda \in \mathbb{K}$, $x \in X$, and let W be a basic neighborhood of λx. We write

$$W = \bigcap_{q=1}^{r} T_{i_q}^{-1}(U_q),$$

where U_q is a neighborhood of $\lambda T_{i_q}(x)$ in X_{i_q}. Since scalar multiplication is continuous in X_{i_q}, there exist a neighborhood A_q of λ in $\mathbb{K}$ and a neighborhood V_q of $T_{i_q}(x)$ in X_{i_q} such that $A_q V_q \subseteq U_q$. We define

$$A := \bigcap_{q=1}^{r} A_q, \qquad V := \bigcap_{q=1}^{r} T_{i_q}^{-1}(V_q).$$

Then A is a neighborhood of λ in $\mathbb{K}$ and V is a neighborhood of x in X. If $\mu \in A$ and $u \in V$, then, for each $q \in \{1,\dots,r\}$, we have $\mu \in A_q$ and $T_{i_q}(u) \in V_q$. Therefore,

$$T_{i_q}(\mu u) = \mu T_{i_q}(u) \in A_q V_q \subseteq U_q.$$

Thus, $\mu u \in W$. We conclude that scalar multiplication is continuous.

This proves that (X, τ_{proj}) is a topological vector space.
We prove (a). Suppose that each X_i is locally convex. For each $i \in I$, take a neighborhood base at the origin in X_i consisting of convex balanced sets. Then the basic neighborhoods of the origin in X may be taken to have the form

$$\bigcap_{q=1}^{r} T_{i_q}^{-1}(U_{i_q}),$$

where each U_{i_q} is convex and balanced. Since the inverse image of a convex balanced set under a linear map retains both properties, and since finite intersections of convex balanced sets are also convex and balanced, we conclude that X is locally convex.
We prove (b). Suppose that each X_i is Hausdorff and that the family $(T_i)_{i\in I}$ separates points of X. Then

$$\bigcap_{i\in I} \ker(T_i) = \{0\}.$$

Since X_i is Hausdorff, the set $\{0\}$ is closed in X_i. Since T_i is continuous, $\ker(T_i) = T_i^{-1}(\{0\})$ is closed in X. Therefore, $\{0\}$ is closed in X, being an intersection of closed sets. By Proposition B.10.20, we conclude that X is Hausdorff. □

The general formulation of projective limits uses systems of spaces and transition maps. In the applications in this book, we will mainly encounter the concrete case in which a space is realized as an intersection of Banach spaces contained in a common topological vector space.

Definition 4.2.3. (Projective limit realized as an intersection) Let Y be a Hausdorff topological vector space and let $\{X_n\}_{n\in\mathbb{N}}$ be a family of Banach spaces such that each X_n is a vector subspace of Y and the inclusion $X_n \hookrightarrow Y$ is continuous. We define

$$X := \bigcap_{n\in\mathbb{N}} X_n.$$

For each $n \in \mathbb{N}$, denote the natural inclusion by $\iota_n \colon X \longrightarrow X_n$ and equip X with the projective topology associated with the family $(\iota_n)_{n\in\mathbb{N}}$.
In this setting we write

$$X = \varprojlim_{n\in\mathbb{N}} X_n$$

and say that X is the *projective limit* of the family $\{X_n\}_{n\in\mathbb{N}}$. Some texts also use the term *inverse limit*.

Proposition 4.2.4. (Sequential completeness of a projective intersection) Let Y be a Hausdorff topological vector space and let $\{X_n\}_{n\in\mathbb{N}}$ be a family of Banach spaces such that each X_n is a vector subspace of Y and the inclusion $X_n \hookrightarrow Y$ is continuous. Consider

$$X = \bigcap_{n\in\mathbb{N}} X_n$$

equipped with the projective topology associated with the inclusions $\iota_n \colon X \longrightarrow X_n$. Then X is sequentially complete: every Cauchy sequence in X converges in X.

Proof. Let $(x^{(q)})_{q\in\mathbb{N}}$ be a Cauchy sequence in X with respect to the projective topology. Fix $n \in \mathbb{N}$. We will prove that $(x^{(q)})_{q\in\mathbb{N}}$ is a Cauchy sequence in X_n.
Let U_n be a neighborhood of the origin in X_n. Since $\iota_n \colon X \longrightarrow X_n$ is continuous by definition of the projective topology, the set $\iota_n^{-1}(U_n)$ is a neighborhood of the origin in X. Since $(x^{(q)})_{q\in\mathbb{N}}$ is Cauchy in X, there exists $q_0 \in \mathbb{N}$ such that

$$x^{(q)} - x^{(p)} \in \iota_n^{-1}(U_n) \qquad \forall q, p \geq q_0.$$

Therefore,

$$x^{(q)} - x^{(p)} \in U_n \qquad \forall q, p \geq q_0.$$

This proves that $(x^{(q)})_{q\in\mathbb{N}}$ is Cauchy in X_n.
Since X_n is Banach, there exists $x_n \in X_n$ such that $x^{(q)} \to x_n$ in X_n as $q \to \infty$.
We show that the limits x_n do not depend on n when regarded as elements of Y. Let $n, m \in \mathbb{N}$. Since the inclusions $X_n \hookrightarrow Y$ and $X_m \hookrightarrow Y$ are continuous, $x^{(q)} \to x_n$ in X_n implies $x^{(q)} \to x_n$ in Y, and $x^{(q)} \to x_m$ in X_m implies $x^{(q)} \to x_m$ in Y. Since Y is Hausdorff, the limit of a convergent sequence is unique. Consequently, $x_n = x_m$ in Y.
There is therefore a unique element $x \in Y$ such that $x = x_n$ for every $n \in \mathbb{N}$. Since $x_n \in X_n$ for each n, we conclude that $x \in \bigcap_{n\in\mathbb{N}} X_n = X$.
It remains to prove that $x^{(q)} \to x$ in the projective topology of X. Let V be a neighborhood of the origin in X. By definition of this topology, there is a basic neighborhood

$$V_0 = \bigcap_{s=1}^{r} \iota_{n_s}^{-1}(U_{n_s})$$

such that $V_0 \subseteq V$, where $r \in \mathbb{N}$, $n_1, \ldots, n_r \in \mathbb{N}$, and each U_{n_s} is a neighborhood of the origin in X_{n_s}.
For each $s \in \{1, \ldots, r\}$, we know that $x^{(q)} \to x$ in X_{n_s}. Therefore, there exists $q_s \in \mathbb{N}$ such that $x^{(q)} - x \in U_{n_s}$ for every $q \geq q_s$. Taking $q_* := \max\{q_1, \ldots, q_r\}$, we obtain, for every $q \geq q_*$,

$$x^{(q)} - x \in \bigcap_{s=1}^{r} \iota_{n_s}^{-1}(U_{n_s}) = V_0 \subseteq V.$$

Consequently, $x^{(q)} \to x$ in X. We conclude that X is sequentially complete. □

Remark 4.2.5. If completeness of a topological vector space is formulated in terms of Cauchy nets or filters, the same argument shows that $\varprojlim_{n\in\mathbb{N}} X_n$ is complete in that sense. In the immediate applications, the sequential formulation will suffice, since the spaces we will study are metrizable.

We now return to the space $\mathcal{D}_K(\Omega)$. For each $j \in \mathbb{N}_0$, we define

$$C_K^j(\Omega) := \left\{ \varphi \in C^j(\Omega) \;\middle|\; \operatorname{supp}(\varphi) \subseteq K \right\},$$

and equip it with the norm

$$\|\varphi\|_{C^j(K)} := \max_{|\alpha|\leq j} \sup_{x\in K} |D^\alpha \varphi(x)|.$$

Lemma 4.2.6. For each $j \in \mathbb{N}_0$, the space $\left(C_K^j(\Omega), \|\cdot\|_{C^j(K)}\right)$ is a Banach space.

Proof. Let $(\varphi_n)_{n\in\mathbb{N}}$ be a Cauchy sequence in $C_K^j(\Omega)$. Fix a multi-index α with $|\alpha| \le j$.
If $x \in \Omega \setminus K$, then, since $\operatorname{supp}(\varphi_n) \subseteq K$, we have $x \notin \operatorname{supp}(\varphi_n)$. Therefore, there is an open neighborhood of x on which φ_n vanishes. Consequently, $D^\alpha \varphi_n(x) = 0$. Thus, $D^\alpha \varphi_n$ vanishes on $\Omega \setminus K$ for every $n \in \mathbb{N}$.
Moreover, for any $n, m \in \mathbb{N}$,

$$\|D^\alpha \varphi_n - D^\alpha \varphi_m\|_{L^\infty(\Omega)} = \|D^\alpha \varphi_n - D^\alpha \varphi_m\|_{C^0(K)} \le \|\varphi_n - \varphi_m\|_{C^j(K)}.$$

Since $(\varphi_n)_{n\in\mathbb{N}}$ is Cauchy in $C_K^j(\Omega)$, it follows that $(D^\alpha \varphi_n)_{n\in\mathbb{N}}$ is uniformly Cauchy on Ω.
We now define the corresponding limit. For each $x \in \Omega$, the real sequence $(D^\alpha \varphi_n(x))_{n\in\mathbb{N}}$ is Cauchy and therefore converges in $\mathbb{R}$. We define

$$g_\alpha(x) := \lim_{n\to\infty} D^\alpha \varphi_n(x), \qquad x \in \Omega.$$

We show that the convergence is uniform. Let $\varepsilon > 0$. Since $(D^\alpha \varphi_n)_{n\in\mathbb{N}}$ is uniformly Cauchy, there exists $N \in \mathbb{N}$ such that, if $n, m \ge N$, then

$$\|D^\alpha \varphi_n - D^\alpha \varphi_m\|_{L^\infty(\Omega)} < \varepsilon.$$

Fix $n \ge N$ and let $m \to \infty$. For each $x \in \Omega$,

$$|D^\alpha \varphi_n(x) - g_\alpha(x)| \le \varepsilon.$$

Taking the supremum over $x \in \Omega$, we obtain

$$\|D^\alpha \varphi_n - g_\alpha\|_{L^\infty(\Omega)} \le \varepsilon.$$

Therefore, $D^\alpha \varphi_n \to g_\alpha$ uniformly on Ω.
Since each $D^\alpha \varphi_n$ is continuous and the convergence is uniform, g_α is continuous on Ω. Moreover, since $D^\alpha \varphi_n = 0$ on $\Omega \setminus K$ for every n, passing to the limit gives

$$g_\alpha = 0 \qquad \text{in } \Omega \setminus K.$$

We define $\varphi := g_0$. We will prove that $\varphi \in C_K^j(\Omega)$ and that $D^\alpha \varphi = g_\alpha$ for every multi-index α with $|\alpha| \le j$.
We begin by showing compatibility between the limits. We claim that, if β is a multi-index with $|\beta| \le j-1$ and $i \in \{1, \dots, n\}$, then

$$\partial_i g_\beta = g_{\beta+e_i} \qquad \text{in } \Omega.$$

Fix $x \in \Omega$. Since Ω is open, there exists $\delta > 0$ such that $x + te_i \in \Omega$ for every $t \in [-\delta, \delta]$. If $h \in (-\delta, \delta)$, then, for each $n \in \mathbb{N}$, Theorem B.6.5 applied to the function $t \mapsto D^\beta \varphi_n(x + te_i)$ gives

$$D^\beta \varphi_n(x + he_i) - D^\beta \varphi_n(x) = \int_0^h D^{\beta+e_i} \varphi_n(x + te_i)\, dt.$$

Let $n \to \infty$. By the uniform convergence $D^\beta \varphi_n \to g_\beta$, the left-hand side converges to

$$g_\beta(x + he_i) - g_\beta(x).$$

On the other hand,

$$\left| \int_0^h \left(D^{\beta+e_i}\varphi_n(x+te_i) - g_{\beta+e_i}(x+te_i) \right) dt \right| \le |h| \| D^{\beta+e_i}\varphi_n - g_{\beta+e_i} \|_{L^\infty(\Omega)}.$$

Since $D^{\beta+e_i}\varphi_n \to g_{\beta+e_i}$ uniformly on Ω, the right-hand side converges to 0. Therefore,

$$g_\beta(x + he_i) - g_\beta(x) = \int_0^h g_{\beta+e_i}(x+te_i)\, dt.$$

If $h \neq 0$, we divide by h:

$$\frac{g_\beta(x + he_i) - g_\beta(x)}{h} = \frac{1}{h} \int_0^h g_{\beta+e_i}(x+te_i)\, dt.$$

Since $g_{\beta+e_i}$ is continuous at x, we have

$$\left| \frac{1}{h} \int_0^h g_{\beta+e_i}(x+te_i)\, dt - g_{\beta+e_i}(x) \right| \le \sup_{t \in [-|h|,|h|]} |g_{\beta+e_i}(x+te_i) - g_{\beta+e_i}(x)| \longrightarrow 0$$

as $h \to 0$. Consequently,

$$\partial_i g_\beta(x) = g_{\beta+e_i}(x).$$

Since $x \in \Omega$ was arbitrary, we conclude that $\partial_i g_\beta = g_{\beta+e_i}$ on Ω.
Using this relation, we will prove by induction on $r \in \{0, \dots, j\}$ that:

$$\varphi \in C^r(\Omega) \qquad \text{and} \qquad D^\alpha \varphi = g_\alpha \quad \text{for every } |\alpha| \le r.$$

For $r = 0$, this is immediate, since $\varphi = g_0$ and g_0 is continuous.
Now suppose that the assertion holds for some $r \in \{0, \dots, j-1\}$. We will prove that it holds for $r+1$. Let α be a multi-index with $|\alpha| = r+1$. Choose $i \in \{1, \dots, n\}$ such that $\alpha_i \ge 1$ and write $\alpha = \beta + e_i$, where $|\beta| = r$.
By the induction hypothesis, $D^\beta \varphi = g_\beta$. Since $|\beta| = r \le j-1$, the identity proved above gives

$$\partial_i g_\beta = g_{\beta+e_i} = g_\alpha.$$

Therefore,

$$D^\alpha \varphi = \partial_i (D^\beta \varphi) = \partial_i g_\beta = g_\alpha.$$

Moreover, g_α is continuous. Since this holds for every multi-index α with $|\alpha| = r+1$, we conclude that $\varphi \in C^{r+1}(\Omega)$ and that $D^\alpha \varphi = g_\alpha$ for every $|\alpha| \le r+1$.
By induction, $\varphi \in C^j(\Omega)$ and $D^\alpha \varphi = g_\alpha$ for every multi-index α with $|\alpha| \le j$.
Since $g_0 = 0$ on $\Omega \setminus K$, we have $\varphi = 0$ on $\Omega \setminus K$. Since K is closed in Ω, we conclude that $\operatorname{supp}(\varphi) \subseteq K$. Therefore, $\varphi \in C_K^j(\Omega)$.
Finally, for every multi-index α with $|\alpha| \le j$, we already know that $D^\alpha \varphi_n \to D^\alpha \varphi$ uniformly on Ω, and in

particular uniformly on K. Since the set of multi-indices α with $|\alpha| \le j$ is finite,

$$\|\varphi_n - \varphi\|_{C^j(K)} = \max_{|\alpha|\le j} \|D^\alpha \varphi_n - D^\alpha \varphi\|_{C^0(K)} \longrightarrow 0.$$

Thus every Cauchy sequence in $C_K^j(\Omega)$ converges in $C_K^j(\Omega)$. We conclude that $\left(C_K^j(\Omega), \|\cdot\|_{C^j(K)}\right)$ is a Banach space. □

Now observe that

$$\mathcal{D}_K(\Omega) = \bigcap_{j\in\mathbb{N}_0} C_K^j(\Omega).$$

If $\varphi \in \mathcal{D}_K(\Omega)$, then $\varphi \in C_K^j(\Omega)$ for every $j \in \mathbb{N}_0$. Conversely, if $\varphi \in \bigcap_{j\in\mathbb{N}_0} C_K^j(\Omega)$, then φ is of class C^j for every $j \in \mathbb{N}_0$, so $\varphi \in C^\infty(\Omega)$. Moreover, $\operatorname{supp}(\varphi) \subseteq K$. Therefore, $\varphi \in \mathcal{D}_K(\Omega)$.

For each $j \in \mathbb{N}_0$, consider the natural inclusion $\iota_j \colon \mathcal{D}_K(\Omega) \longrightarrow C_K^j(\Omega)$. Equip $\mathcal{D}_K(\Omega)$ with the projective topology associated with the family $(\iota_j)_{j\in\mathbb{N}_0}$, and denote it by τ_K^{proj}.

A neighborhood base at the origin for τ_K^{proj} consists of finite intersections of sets of the form

$$\iota_j^{-1}\left(\left\{\varphi \in C_K^j(\Omega) \;\middle|\; \|\varphi\|_{C^j(K)} < r\right\}\right), \qquad j \in \mathbb{N}_0, \quad r > 0.$$

Since ι_j is the natural inclusion, these sets agree with

$$\left\{\varphi \in \mathcal{D}_K(\Omega) \;\middle|\; \|\varphi\|_{C^j(K)} < r\right\}.$$

Therefore, a neighborhood base at the origin for τ_K^{proj} consists of the sets

$$\bigcap_{q=1}^{k} \left\{\varphi \in \mathcal{D}_K(\Omega) \;\middle|\; \|\varphi\|_{C^{j_q}(K)} < r_q\right\},$$

where $k \in \mathbb{N}$, $j_1, \dots, j_k \in \mathbb{N}_0$, and $r_1, \dots, r_k > 0$.

This family is the neighborhood base at the origin defining the topology τ_K constructed earlier from the family of norms $\{\|\cdot\|_{C^j(K)}\}_{j\in\mathbb{N}_0}$. Consequently, $\tau_K^{\text{proj}} = \tau_K$.

In other words,

$$\left(\mathcal{D}_K(\Omega), \tau_K\right) = \varprojlim_{j\in\mathbb{N}_0} C_K^j(\Omega).$$

Since each $C_K^j(\Omega)$ is a Banach space and the family is indexed by $\mathbb{N}_0$, we can reindex it using $n \mapsto n-1$ to write it as a family indexed by $\mathbb{N}$. Proposition 4.2.4 then implies that $\mathcal{D}_K(\Omega)$ is sequentially complete with respect to τ_K.

It remains to translate this sequential completeness into completeness of the metric d_K already constructed. Let $(\varphi_n)_{n\in\mathbb{N}}$ be a Cauchy sequence with respect to d_K. Fix $j \in \mathbb{N}_0$ and $\varepsilon > 0$. Since $\dfrac{1}{2^j}\dfrac{\varepsilon}{1+\varepsilon} > 0$, there exists $N \in \mathbb{N}$ such that, if $n, m \ge N$, then

$$d_K(\varphi_n, \varphi_m) < \frac{1}{2^j}\frac{\varepsilon}{1+\varepsilon}.$$

By definition of d_K,

$$\frac{1}{2^j}\frac{\|\varphi_n-\varphi_m\|_{C^j(K)}}{1+\|\varphi_n-\varphi_m\|_{C^j(K)}} \le d_K(\varphi_n,\varphi_m).$$

Therefore,

$$\frac{\|\varphi_n-\varphi_m\|_{C^j(K)}}{1+\|\varphi_n-\varphi_m\|_{C^j(K)}} < \frac{\varepsilon}{1+\varepsilon}.$$

Since the function $t \mapsto \dfrac{t}{1+t}$ is strictly increasing on $[0,\infty)$, we conclude that $\|\varphi_n-\varphi_m\|_{C^j(K)} < \varepsilon$ for any $n,m \ge N$.

We have proved that, for each $j \in \mathbb{N}_0$, $\|\varphi_n-\varphi_m\|_{C^j(K)} \to 0$ as $n,m \to \infty$. By Proposition B.10.23, $(\varphi_n)_{n\in\mathbb{N}}$ is Cauchy with respect to τ_K. Since $\mathcal{D}_K(\Omega)$ is sequentially complete for this topology, there exists $\varphi \in \mathcal{D}_K(\Omega)$ such that $\varphi_n \to \varphi$ in τ_K.

Finally, since the metric d_K induces the topology τ_K, it follows that $d_K(\varphi_n,\varphi) \to 0$. Thus every Cauchy sequence with respect to d_K converges in $\mathcal{D}_K(\Omega)$, and therefore d_K is complete.

We conclude that $(\mathcal{D}_K(\Omega),\tau_K)$ is a locally convex, Hausdorff, metrizable, and complete space. By Theorem B.10.38, $\mathcal{D}_K(\Omega)$ is a Fréchet space.

4.3 The topology of $\mathcal{D}(\Omega)$

The construction in this section follows the treatment in [97, Section 10.1]. To construct a topology on $C_c^\infty(\Omega)$, let $\mathcal{B}_0$ be the collection of subsets $U \subseteq C_c^\infty(\Omega)$ such that:

(a) $0 \in U$,

(b) U is balanced[1] and convex,

(c) for every compact set $K \subseteq \Omega$, the set $U \cap \mathcal{D}_K(\Omega)$ is a neighborhood of the origin in $(\mathcal{D}_K(\Omega),\tau_K)$.

The collection $\mathcal{B}_0$ is designed to serve as a neighborhood base at the origin in $C_c^\infty(\Omega)$. From it, we define

$$\mathcal{B} := \{\varphi + V \mid \varphi \in C_c^\infty(\Omega),\ V \in \mathcal{B}_0\}.$$

These conditions determine the topology through its neighborhoods.

Theorem 4.3.1. Let $\Omega \subseteq \mathbb{R}^n$ be open. There is a unique topology τ_{LF} on $C_c^\infty(\Omega)$ for which $\mathcal{B}_0$ is a neighborhood base at the origin and the vector space operations are continuous. This topology is Hausdorff and locally convex. For each $\varphi \in C_c^\infty(\Omega)$, the family $\varphi+\mathcal{B}_0$ is a neighborhood base at φ; a set O is open if and only if for each $\varphi \in O$ there exists $V \in \mathcal{B}_0$ with $\varphi + V \subseteq O$. We denote the topological vector space $(C_c^\infty(\Omega),\tau_{LF})$ by $\mathcal{D}(\Omega)$ and call its elements *test functions*.

Proof. The family $\mathcal{B}_0$ is nonempty, since it contains the entire space. Each $U \in \mathcal{B}_0$ is absorbing: if $\varphi \in C_c^\infty(\Omega)$, take a compact set K containing its support. The neighborhood $U \cap \mathcal{D}_K(\Omega)$ absorbs φ in that space, and hence U also absorbs it in $C_c^\infty(\Omega)$. Moreover, $\mathcal{B}_0$ is stable under finite intersections and multiplication by positive scalars. Indeed, these operations preserve convexity and balancedness, and the intersections with each $\mathcal{D}_K(\Omega)$ remain neighborhoods of the origin. Proposition B.10.26 therefore yields a unique locally convex topology with neighborhood base $\mathcal{B}_0$.

[1] A subset U of a vector space is said to be balanced if for every scalar λ with $|\lambda| \le 1$ we have $\lambda U \subseteq U$.

To check that it is Hausdorff, consider

$$V_\varepsilon := \left\{ \varphi \in C_c^\infty(\Omega) \;\middle|\; \|\varphi\|_{L^\infty(\Omega)} < \varepsilon \right\}, \qquad \varepsilon > 0.$$

This set belongs to $\mathcal{B}_0$, because its intersection with $\mathcal{D}_K(\Omega)$ is the open ball of radius ε for the uniform norm. If $\varphi \neq \psi$, choose $3\varepsilon < \|\varphi - \psi\|_{L^\infty(\Omega)}$. The neighborhoods $\varphi + V_\varepsilon$ and $\psi + V_\varepsilon$ are disjoint: otherwise, the triangle inequality would give a uniform distance less than 2ε between φ and ψ. Their interiors are disjoint open neighborhoods. The description of the open sets and uniqueness follow from Proposition B.10.2. □

The norms introduced earlier depend on the compact set K containing the support of the functions. A natural question is whether it is possible to avoid this dependence and define a topology directly on $C_c^\infty(\Omega)$ using global norms.

With this in mind, we could consider, for each $j \in \mathbb{N}_0$, the function

$$\|\varphi\|_j := \sup_{\substack{x \in \Omega \\ |\alpha| \leq j}} |D^\alpha \varphi(x)|. \tag{4.1}$$

Observe that this supremum is finite, since every function $\varphi \in C_c^\infty(\Omega)$ has compact support. Moreover, each $\|\cdot\|_j$ defines a norm on $C_c^\infty(\Omega)$.

We could then try to define a topology on $C_c^\infty(\Omega)$ as the topology induced by the family of norms $\{\|\cdot\|_j\}_{j \in \mathbb{N}_0}$. However, this construction is unsuitable. Intuitively, these norms do not uniformly control the behavior of the supports of the functions, which leads to a topology that is too weak.

In particular, the resulting space is not complete, as the following example shows.

Example 4.3.2. Consider $\Omega = \mathbb{R}$, and let $\varphi \in C_c^\infty(\mathbb{R})$ be a function such that $\operatorname{supp}(\varphi) \subseteq [0,1]$ and $\varphi(x) > 0$ for every $x \in (0,1)$. Define the sequence of functions $(\varphi_k)_{k \in \mathbb{N}}$ by

$$\varphi_k(x) := \sum_{m=1}^{k} \frac{1}{m} \varphi(x-m) = \varphi(x-1) + \frac{1}{2}\varphi(x-2) + \cdots + \frac{1}{k}\varphi(x-k).$$

We will show that this is a Cauchy sequence with respect to the topology generated by the family of seminorms

$$\|\cdot\|_j = \sup_{\substack{x\in\mathbb{R}\\ i\le j}} |D^i(\cdot)(x)|,$$

but its limit does not have compact support, concluding that $C_c^\infty(\mathbb{R})$ is not complete under this topology.
Let $l,k\in\mathbb{N}$ with $k>l$. The difference between the terms of the sequence is

$$\varphi_k(x)-\varphi_l(x)=\sum_{m=l+1}^{k}\frac{1}{m}\varphi(x-m).$$

Since $\operatorname{supp}(\varphi)\subseteq[0,1]$, the support of each translated term $\varphi(x-m)$ is contained in the interval $[m,m+1]$. The interiors of these intervals are disjoint and all derivatives of φ vanish at their endpoints. Therefore, at each point there is at most one nonzero term, even after differentiation.
We evaluate the jth seminorm of the difference. For any derivative of order $i\le j$, we have

$$|D^i(\varphi_k-\varphi_l)(x)|=\left|\sum_{m=l+1}^{k}\frac{1}{m}D^i\varphi(x-m)\right|.$$

Since at each point there is at most one nonzero summand, the supremum over $\mathbb{R}$ is obtained by maximizing over each interval $[m,m+1]$, giving

$$\|D^i(\varphi_k-\varphi_l)\|_{L^\infty(\mathbb{R})}=\max_{l+1\le m\le k}\left(\frac{1}{m}\|D^i\varphi\|_{L^\infty(\mathbb{R})}\right).$$

Since $\varphi\in C_c^\infty(\mathbb{R})$, its derivatives are bounded, so

$$C_j:=\max_{i\le j}\|D^i\varphi\|_{L^\infty(\mathbb{R})}<\infty.$$

Then

$$\|\varphi_k-\varphi_l\|_j\le\frac{1}{l+1}C_j.$$

As $l,k\to\infty$, the quantity $\dfrac{1}{l+1}C_j$ tends to zero, which shows that $(\varphi_k)_{k\in\mathbb{N}}$ is a Cauchy sequence with respect to each seminorm in the family.
In particular, for $j=0$ we obtain

$$\|\varphi_k-\varphi_l\|_{L^\infty(\mathbb{R})}\le\frac{C_0}{l+1}\to 0,\qquad \text{if } l,k\to\infty,$$

so (φ_k) is uniformly Cauchy on $\mathbb{R}$, and consequently there exists a bounded function Φ such that

$$\|\varphi_k-\Phi\|_{L^\infty(\mathbb{R})}\longrightarrow 0,\qquad k\to\infty,$$

that is, $\varphi_k\to\Phi$ uniformly on $\mathbb{R}$.
The same argument applied to each derivative shows that for every $i\in\mathbb{N}_0$ the sequence $(D^i\varphi_k)$ is uniformly

Cauchy on $\mathbb{R}$, and therefore there exists a continuous bounded function ψ_i such that

$$\|D^i\varphi_k - \psi_i\|_{L^\infty(\mathbb{R})} \longrightarrow 0, \qquad k \to \infty.$$

Since also $\varphi_k(0) = 0$ for every k, the sequence converges pointwise on 0. The theorem on uniform convergence of derivatives implies that $\Phi \in C^\infty(\mathbb{R})$ and that

$$D^i\Phi(x) = \psi_i(x) \qquad \text{for every } x \in \mathbb{R},\ i \in \mathbb{N}_0.$$

Moreover, since φ_k are the partial sums of the series, we have

$$\Phi(x) = \sum_{m=1}^{\infty} \frac{1}{m}\varphi(x-m).$$

To prove convergence in each seminorm, fix $j \in \mathbb{N}_0$ and $k \in \mathbb{N}$. For every $l > k$, the triangle inequality gives

$$\|\varphi_k - \Phi\|_j \le \|\varphi_k - \varphi_l\|_j + \|\varphi_l - \Phi\|_j.$$

By the estimate already obtained, for every $l > k$ we have

$$\|\varphi_k - \varphi_l\|_j \le \frac{C_j}{k+1}.$$

On the other hand, since $D^i\varphi_l \to D^i\Phi$ uniformly on $\mathbb{R}$ for every $i \le j$, we have

$$\|\varphi_l - \Phi\|_j = \max_{i\le j} \|D^i\varphi_l - D^i\Phi\|_{L^\infty(\mathbb{R})} \longrightarrow 0, \qquad l \to \infty.$$

Letting $l \to \infty$ in the preceding triangle inequality gives

$$\|\varphi_k - \Phi\|_j \le \frac{C_j}{k+1} \to 0, \qquad \text{if } k \to \infty.$$

Since j was arbitrary, we conclude that for each $j \in \mathbb{N}_0$ we have $\|\varphi_k - \Phi\|_j \to 0$ as $k \to \infty$. This shows that φ_k converges to Φ with respect to each seminorm in the family, and therefore φ_k converges to Φ with respect to the topology generated by this family of seminorms.

To analyze the support of Φ, note that by hypothesis $\varphi > 0$ on $(0,1)$. For each $m \in \mathbb{N}$, choose the point $x_m = m + \frac{1}{2}$. Evaluating the limit function at this point gives

$$\Phi\left(m + \frac{1}{2}\right) = \frac{1}{m}\varphi\left(\frac{1}{2}\right) > 0.$$

This implies that Φ takes strictly positive values at arbitrarily large points, so its support is unbounded. Consequently, $\operatorname{supp}(\Phi)$ is not compact and $\Phi \notin C_c^\infty(\mathbb{R})$.

Although the family of seminorms $\{\|\cdot\|_j\}_{j\in\mathbb{N}_0}$ does not generate the topology of $\mathcal{D}(\Omega)$—since these seminorms do not control the supports of the functions—it is possible to describe the topology τ_{LF} using suitable families of seminorms that simultaneously incorporate the behavior of the derivatives and of the supports. The following exercise presents one such construction.

Exercise 4.3.3. Let $\Omega \subseteq \mathbb{R}^n$ be open. Consider a sequence $\{K_l\}_{l\in\mathbb{N}_0}$ of compact sets in Ω, with $K_0 := \varnothing$, such that for $l \geq 1$ the sequence is increasing and nested, $K_l \subseteq \operatorname{int}(K_{l+1})$, and $\Omega = \bigcup_{l=1}^{\infty} K_l$.

Let $\mathbf{m} := \{m_l\}_{l\in\mathbb{N}_0}$ be a sequence in $\mathbb{N}_0$ such that $m_l \to \infty$, and let $\mathbf{a} := \{a_l\}_{l\in\mathbb{N}_0}$ be a sequence in $(0,\infty)$ such that $a_l \to 0$. For each $\varphi \in \mathcal{D}(\Omega)$ we define

$$p_{\mathbf{m},\mathbf{a}}(\varphi) := \sup_{l\in\mathbb{N}_0} \sup_{x\in\Omega\setminus K_l} \frac{1}{a_l} \sum_{|\alpha|\leq m_l} |D^\alpha \varphi(x)|.$$

(a) Prove that $p_{\mathbf{m},\mathbf{a}}$ is a seminorm on $\mathcal{D}(\Omega)$.

(b) Prove that the family of seminorms $\{p_{\mathbf{m},\mathbf{a}}\}_{\mathbf{m},\mathbf{a}}$ generates the topology τ_{LF} of Theorem 4.3.1.

Observe that the preceding family of seminorms is, in general, uncountable. This reflects the fact that $\mathcal{D}(\Omega)$ will turn out not to be metrizable (as the reader will justify later) and, in particular, is not a Fréchet space.

Fixing the support recovers exactly the topology we already defined on $\mathcal{D}_K(\Omega)$.

Theorem 4.3.4. Let $\Omega \subseteq \mathbb{R}^n$ be open. For any compact set $K \subseteq \Omega$, the topology τ_K agrees with the subspace topology on $\mathcal{D}_K(\Omega)$ induced by τ_{LF} as a subset of $\mathcal{D}(\Omega)$.

Proof. The inclusion $\mathcal{D}_K(\Omega) \hookrightarrow \mathcal{D}(\Omega)$ is continuous: the inverse image of each $U \in \mathcal{B}_0$ is, by definition, a neighborhood of the origin in $\mathcal{D}_K(\Omega)$. Thus the induced topology is no finer than τ_K.
Conversely, for $j \in \mathbb{N}_0$ and $\varepsilon > 0$, the ball

$$V_{j,\varepsilon} := \{\varphi \in C_c^\infty(\Omega) \mid \|\varphi\|_j < \varepsilon\}$$

belongs to $\mathcal{B}_0$: on any compact support, the global norm in (4.1) agrees with the norm corresponding to that compact set. Hence

$$V_{j,\varepsilon} \cap \mathcal{D}_K(\Omega) = \{\varphi \in \mathcal{D}_K(\Omega) \mid \|\varphi\|_{C^j(K)} < \varepsilon\}$$

is a neighborhood for the induced topology. These balls form a neighborhood base for τ_K, proving the reverse inclusion. □

We next study the topologically bounded sets[2] in $\mathcal{D}(\Omega)$, for which we will need the following result:

Lemma 4.3.5. Let $\Omega \subseteq \mathbb{R}^n$ be an open set, let $K \subseteq \Omega$ be compact, and let $x_0 \in \Omega$. Then, for every $r > 0$, the set $U := \{\varphi \in \mathcal{D}_K(\Omega) \mid |\varphi(x_0)| < r\}$ is open in $(\mathcal{D}_K(\Omega), \tau_K)$.

Proof. First observe that if $x_0 \notin K$, then every function $\varphi \in \mathcal{D}_K(\Omega)$ satisfies $\varphi(x_0) = 0$, so $U = \mathcal{D}_K(\Omega)$, which is open.
Now suppose that $x_0 \in K$. Let $\varphi \in U$, that is, $|\varphi(x_0)| < r$. Define $\varepsilon := r - |\varphi(x_0)| > 0$. Consider the neighborhood of φ given by $V := \{\psi \in \mathcal{D}_K(\Omega) \mid \|\psi - \varphi\|_{K,0} < \varepsilon\}$. Recall that $\|\psi-\varphi\|_{C^0(K)} = \|\psi-\varphi\|_{C^0(K)}$. Then, for every $\psi \in V$, we have in particular $|\psi(x_0) - \varphi(x_0)| \leq \|\psi - \varphi\|_{C^0(K)} < \varepsilon$.
Therefore, $|\psi(x_0)| \leq |\varphi(x_0)| + |\psi(x_0) - \varphi(x_0)| < |\varphi(x_0)| + \varepsilon = r$. This shows that $\psi \in U$, and consequently $V \subseteq U$.
We have proved that every $\varphi \in U$ has a neighborhood contained in U, so U is open in τ_K. □

[2] Let X be a topological vector space. A subset $B \subseteq X$ is said to be topologically bounded if for every neighborhood U of the origin there exists $\lambda > 0$ such that $B \subseteq \lambda U$.

Theorem 4.3.6. Let $\Omega \subseteq \mathbb{R}^n$ be an open set and let $W \subseteq \mathcal{D}(\Omega)$ be a topologically bounded set. Then there exists a compact set $K \subseteq \Omega$ such that $W \subseteq \mathcal{D}_K(\Omega)$. Moreover, for each $j \in \mathbb{N}_0$, there exists $M_j > 0$ such that $\|\varphi\|_j \leq M_j$ for every $\varphi \in W$, where $\|\cdot\|_j$ is given by (4.1).

Proof. We argue by contradiction. Suppose that $W \nsubseteq \mathcal{D}_K(\Omega)$ for every compact set $K \subseteq \Omega$. Let $\{K_l\}_{l\in\mathbb{N}}$ be an increasing sequence of compact sets such that $K_l \subseteq \operatorname{int}(K_{l+1})$ and $\Omega = \bigcup_{l=1}^{\infty} K_l$.

Then, for each $l \in \mathbb{N}$, there exists $\varphi_l \in W$ such that $\operatorname{supp}(\varphi_l) \nsubseteq K_l$. Therefore, we can choose a point $y_l \in \operatorname{supp}(\varphi_l) \setminus K_l$.

Since K_l is closed in Ω, the set $\Omega \setminus K_l$ is an open neighborhood of y_l. Moreover, by definition of support, $y_l \in \operatorname{supp}(\varphi_l)$ implies that every neighborhood of y_l intersects the set $\{x \in \Omega \mid \varphi_l(x) \neq 0\}$. In particular, there exists a point $x_l \in \Omega \setminus K_l$ such that $\varphi_l(x_l) \neq 0$.

We define

$$U := \left\{ \varphi \in \mathcal{D}(\Omega) \;\middle|\; |\varphi(x_l)| < \frac{|\varphi_l(x_l)|}{l},\ \forall l \in \mathbb{N} \right\}.$$

We claim that $U \in \mathcal{B}_0$. First, $0 \in U$, since $|0(x_l)| = 0 < \dfrac{|\varphi_l(x_l)|}{l}$ for every $l \in \mathbb{N}$.

Moreover, U is balanced. If $\varphi \in U$ and $|\lambda| \leq 1$, then

$$|(\lambda\varphi)(x_l)| = |\lambda||\varphi(x_l)| \leq |\varphi(x_l)| < \frac{|\varphi_l(x_l)|}{l}$$

for every $l \in \mathbb{N}$. Therefore, $\lambda\varphi \in U$.

Also, U is convex. If $\varphi, \psi \in U$ and $s \in [0,1]$, then, for every $l \in \mathbb{N}$,

$$|(s\varphi + (1-s)\psi)(x_l)| \leq s|\varphi(x_l)| + (1-s)|\psi(x_l)| < s\frac{|\varphi_l(x_l)|}{l} + (1-s)\frac{|\varphi_l(x_l)|}{l} = \frac{|\varphi_l(x_l)|}{l}.$$

Thus, $s\varphi + (1-s)\psi \in U$.

It remains to check that, for every compact set $K \subseteq \Omega$, the set $U \cap \mathcal{D}_K(\Omega)$ is a neighborhood of the origin in $(\mathcal{D}_K(\Omega), \tau_K)$. Let $K \subseteq \Omega$ be compact. Since $\Omega = \bigcup_{l=1}^{\infty} K_l$ and the sequence (K_l) is increasing, there exists $L \in \mathbb{N}$ such that $K \subseteq K_L$. Then, if $l \geq L$, we have $K \subseteq K_l$ and, since $x_l \notin K_l$, we conclude that $x_l \notin K$.

We define

$$I_K := \{l \in \mathbb{N} \mid x_l \in K\}.$$

By the preceding argument, $I_K \subseteq \{1, \ldots, L-1\}$, so I_K is finite.

If $\varphi \in \mathcal{D}_K(\Omega)$ and $l \notin I_K$, then $x_l \notin K$ and, since $\operatorname{supp}(\varphi) \subseteq K$, we have $\varphi(x_l) = 0$. Consequently, the conditions corresponding to these indices are automatically satisfied. Therefore,

$$U \cap \mathcal{D}_K(\Omega) = \left\{ \varphi \in \mathcal{D}_K(\Omega) \;\middle|\; |\varphi(x_l)| < \frac{|\varphi_l(x_l)|}{l},\ \forall l \in I_K \right\}.$$

Since I_K is finite, this set is a finite intersection of sets of the form

$$\{\varphi \in \mathcal{D}_K(\Omega) \mid |\varphi(x_l)| < c_l\},$$

which are open in $(\mathcal{D}_K(\Omega), \tau_K)$ by Lemma 4.3.5. Moreover, they contain the origin. Consequently, $U \cap \mathcal{D}_K(\Omega)$ is a neighborhood of the origin in $(\mathcal{D}_K(\Omega), \tau_K)$.
Since this holds for every compact set $K \subseteq \Omega$, we conclude that $U \in \mathcal{B}_0$. In particular, $U = 0 + U \in \mathcal{B}$, so U is a neighborhood of the origin in $(\mathcal{D}(\Omega), \tau_{LF})$.
Since W is topologically bounded, there exists $t > 0$ such that $W \subseteq tU$. Let $l \in \mathbb{N}$ satisfy $l \geq t$. Then

$$\frac{|\varphi_l(x_l)|}{t} \geq \frac{|\varphi_l(x_l)|}{l},$$

and therefore

$$\left|t^{-1}\varphi_l(x_l)\right| = \frac{|\varphi_l(x_l)|}{t} \geq \frac{|\varphi_l(x_l)|}{l}.$$

Thus, $t^{-1}\varphi_l \notin U$, which is equivalent to $\varphi_l \notin tU$. This contradicts the fact that $\varphi_l \in W \subseteq tU$.
Therefore, there exists a compact set $K \subseteq \Omega$ such that $W \subseteq \mathcal{D}_K(\Omega)$.
Finally, by Theorem 4.3.4, the set $W = W \cap \mathcal{D}_K(\Omega)$ is bounded with respect to the topology τ_K. By Corollary B.10.22, for each $j \in \mathbb{N}_0$ there exists $M_j > 0$ such that

$$\|\varphi\|_{C^j(K)} \leq M_j \qquad \text{for every } \varphi \in W.$$

Since $\operatorname{supp}(\varphi) \subseteq K$ for every $\varphi \in W$, we have $\|\varphi\|_j = \|\varphi\|_{C^j(K)}$ on W. Therefore,

$$\|\varphi\|_j \leq M_j \qquad \text{for every } \varphi \in W.$$

This completes the proof. □

The space $\mathcal{D}(\Omega)$ with the topology τ_{LF} of Theorem 4.3.1 will turn out to be a (sequentially) complete topological vector space, and we will be able to characterize convergence of sequences quite conveniently:

Theorem 4.3.7. Let $\Omega \subseteq \mathbb{R}^n$ be an open set. Then the space $(\mathcal{D}(\Omega), \tau_{LF})$ is sequentially complete. Moreover, a sequence $\{\varphi_k\}_{k\in\mathbb{N}} \subseteq \mathcal{D}(\Omega)$ converges to $\varphi \in \mathcal{D}(\Omega)$ with respect to τ_{LF} if and only if:

(a) there exists a compact set $K \subseteq \Omega$ such that $\operatorname{supp}(\varphi_k) \subseteq K$ for every $k \in \mathbb{N}$,

(b) $\lim_{k\to\infty} D^\alpha \varphi_k = D^\alpha \varphi$ uniformly on Ω for every multi-index $\alpha \in \mathbb{N}_0^n$.

Proof. Let $\{\varphi_k\}_{k\in\mathbb{N}}$ be a Cauchy sequence in $\mathcal{D}(\Omega)$. By Proposition B.10.13, the set $\{\varphi_k \mid k \in \mathbb{N}\}$ is topologically bounded in $\mathcal{D}(\Omega)$. By Theorem 4.3.6, there exists a compact set $K \subseteq \Omega$ such that

$$\{\varphi_k \mid k \in \mathbb{N}\} \subseteq \mathcal{D}_K(\Omega).$$

By Theorem 4.3.4, the sequence $\{\varphi_k\}_{k\in\mathbb{N}}$ is Cauchy in $\mathcal{D}_K(\Omega)$ with respect to τ_K. Since $\mathcal{D}_K(\Omega)$ is complete, there exists $\varphi \in \mathcal{D}_K(\Omega)$ such that

$$\varphi_k \longrightarrow \varphi$$

in $\mathcal{D}_K(\Omega)$ with respect to τ_K.
Applying Theorem 4.3.4 again, we conclude that $\varphi_k \to \varphi$ in $\mathcal{D}(\Omega)$ with respect to τ_{LF}. Therefore, $\mathcal{D}(\Omega)$ is sequentially complete.

We now prove the equivalence. Let $\{\varphi_k\}_{k\in\mathbb{N}} \subseteq \mathcal{D}(\Omega)$ and let $\varphi \in \mathcal{D}(\Omega)$.
($\Rightarrow$) Suppose that $\varphi_k \to \varphi$ with respect to τ_{LF}. Then the sequence is Cauchy and, by Proposition B.10.13, $\{\varphi_k \mid k \in \mathbb{N}\}$ is topologically bounded in $\mathcal{D}(\Omega)$. By Theorem 4.3.6, there exists a compact set $K \subseteq \Omega$ such that

$$\varphi_k \in \mathcal{D}_K(\Omega)$$

for every $k \in \mathbb{N}$. That is, $\operatorname{supp}(\varphi_k) \subseteq K$ for every $k \in \mathbb{N}$. Since also $\varphi \in \mathcal{D}(\Omega)$, we have $\varphi \in \mathcal{D}_{K'}(\Omega)$ for some compact set $K' \subseteq \Omega$. Replacing K by $K \cup K'$, we may assume that $\varphi \in \mathcal{D}_K(\Omega)$.
By Theorem 4.3.4, the topology induced by τ_{LF} on $\mathcal{D}_K(\Omega)$ agrees with τ_K. In particular, $\varphi_k \to \varphi$ in $\mathcal{D}_K(\Omega)$ with respect to τ_K. By definition of τ_K, this is equivalent to saying that, for every $j \in \mathbb{N}_0$,

$$\|\varphi_k - \varphi\|_{C^j(K)} \to 0.$$

Consequently, for every multi-index $\alpha \in \mathbb{N}_0^n$ we have

$$D^\alpha \varphi_k \to D^\alpha \varphi$$

uniformly on K. Since $\varphi_k, \varphi \in \mathcal{D}_K(\Omega)$, their derivatives vanish on $\Omega \setminus K$. Consequently,

$$\|D^\alpha \varphi_k - D^\alpha \varphi\|_{L^\infty(\Omega)} = \|D^\alpha \varphi_k - D^\alpha \varphi\|_{C^0(K)} \longrightarrow 0.$$

The convergence is therefore uniform on Ω. This proves both conditions.
($\Leftarrow$) Now suppose that there exists a compact set $K \subseteq \Omega$ such that $\operatorname{supp}(\varphi_k) \subseteq K$ for every $k \in \mathbb{N}$ and that

$$D^\alpha \varphi_k \to D^\alpha \varphi$$

uniformly on Ω for every multi-index $\alpha \in \mathbb{N}_0^n$. The case $\alpha = 0$ implies pointwise convergence throughout Ω. If $x \in \Omega \setminus K$, then $\varphi_k(x) = 0$ for every k, so $\varphi(x) = \lim_{k\to\infty} \varphi_k(x) = 0$. Since K is closed in Ω, it follows that $\operatorname{supp}(\varphi) \subseteq K$. Then $\varphi_k, \varphi \in \mathcal{D}_K(\Omega)$ and, for every $j \in \mathbb{N}_0$,

$$\|\varphi_k - \varphi\|_{C^j(K)} = \max_{|\alpha|\le j} \|D^\alpha \varphi_k - D^\alpha \varphi\|_{C^0(K)} \to 0.$$

Therefore, $\varphi_k \to \varphi$ in $\mathcal{D}_K(\Omega)$ with respect to τ_K. Since τ_K agrees with the subspace topology induced by τ_{LF} on $\mathcal{D}_K(\Omega)$, we conclude that $\varphi_k \to \varphi$ in $\mathcal{D}(\Omega)$ with respect to τ_{LF}. □

When $\Omega \subseteq \mathbb{R}^n$ is open and nonempty, with $n \ge 1$, the space $\mathcal{D}(\Omega)$ is not metrizable:

Exercise 4.3.8. Let $\Omega \subseteq \mathbb{R}^n$ be open and nonempty, with $n \ge 1$.

(a) Prove that for every compact set $K \subseteq \Omega$, $\mathcal{D}_K(\Omega)$ is closed and has empty interior in $\mathcal{D}(\Omega)$.

(b) Prove that $\mathcal{D}(\Omega)$ is not metrizable.

Hint: To prove that $\mathcal{D}_K(\Omega)$ has empty interior in the first part, construct a sequence of functions in $\mathcal{D}(\Omega) \setminus \mathcal{D}_K(\Omega)$ converging to the constant 0 in the topology of $\mathcal{D}(\Omega)$. For the second part, consider an exhaustion by compact sets $(K_j)_{j\in\mathbb{N}}$ such that $\Omega = \bigcup_{j=1}^{\infty} K_j$. Use the preceding part and the Baire category theorem

(Theorem B.1.14), recalling the relation between complete metric spaces and Baire spaces.

4.4 LF spaces

The spaces $\mathcal{D}(\Omega)$ can be obtained as a particular case of a general construction in functional analysis known as a *strict inductive limit of Fréchet spaces*. Spaces obtained in this way are called *LF spaces*.

To formalize this notion, recall that, given a family of maps $g_i\colon X_i \longrightarrow X$, there is a final topology on X, characterized as the finest topology making all the g_i continuous. In the setting of topological vector spaces, however, this purely topological final topology need not be compatible with the linear structure of X, nor need it be locally convex.

Thus, when the spaces X_i are locally convex and the maps g_i are linear, we are interested in the finest among the locally convex topologies on X making all the g_i continuous. In the case of inclusions of subspaces, this construction takes the following form.

Theorem 4.4.1. (Locally convex final topology) Let X be a vector space and let $(X_i)_{i\in I}$ be a family of subspaces of X such that

$$X = \bigcup_{i\in I} X_i.$$

Suppose that each X_i is equipped with a locally convex topology τ_i. Then there is a unique locally convex topology τ_{LC} on X that is the finest among all locally convex topologies making the canonical inclusions

$$\iota_i\colon X_i \hookrightarrow X, \qquad i \in I.$$

continuous.
The topology τ_{LC} is called the *locally convex final topology* associated with the family $\big((X_i,\tau_i),\iota_i\big)_{i\in I}$.

Proof. Let $\mathcal{U}$ be the collection of all absolutely convex subsets[3] $U \subseteq X$ such that, for each $i \in I$, $U \cap X_i$ is a neighborhood of the origin in (X_i,τ_i).
First observe that every element of $\mathcal{U}$ is absorbing. Let $U \in \mathcal{U}$ and let $x \in X$. Since

$$X = \bigcup_{i\in I} X_i,$$

there exists $i \in I$ such that $x \in X_i$. By hypothesis, $U \cap X_i$ is a neighborhood of the origin in the topological vector space X_i and is therefore absorbing in X_i. Consequently, there exists $\lambda > 0$ such that

$$x \in t(U \cap X_i) \qquad \text{for every } t \geq \lambda.$$

Since $t(U \cap X_i) \subseteq tU$ for every $t > 0$, it follows that

$$x \in tU \qquad \text{for every } t \geq \lambda.$$

Since $x \in X$ was arbitrary, we conclude that U is absorbing.
We now show that $\mathcal{U}$ satisfies the hypotheses of Proposition B.10.26.

(a) By definition, each $U \in \mathcal{U}$ is absolutely convex, and we have just proved that it is also absorbing.

(b) Let $U, V \in \mathcal{U}$. Then $U \cap V$ is absolutely convex. Moreover, for each $i \in I$,

$$(U \cap V) \cap X_i = (U \cap X_i) \cap (V \cap X_i).$$

Since $U \cap X_i$ and $V \cap X_i$ are neighborhoods of the origin in (X_i, τ_i), their intersection is as well. Therefore, $U \cap V \in \mathcal{U}$.

(c) Let $U \in \mathcal{U}$ and let $\lambda > 0$. Define $W := \frac{\lambda}{2} U$. Since U is absolutely convex, so is W. Moreover, for each $i \in I$, since X_i is a subspace of X, we have

$$W \cap X_i = \left(\frac{\lambda}{2} U\right) \cap X_i = \frac{\lambda}{2}(U \cap X_i).$$

Since multiplication by the nonzero scalar $\frac{\lambda}{2}$ is a homeomorphism of (X_i, τ_i) onto itself, the set $\frac{\lambda}{2}(U \cap X_i)$ is a neighborhood of the origin in X_i. Thus, W is absolutely convex and $W \cap X_i$ is a neighborhood of the origin in X_i for every $i \in I$. By definition of $\mathcal{U}$, we conclude that $W \in \mathcal{U}$.

Finally, since U is balanced and $\frac{\lambda}{2} \leq \lambda$, we have

$$W = \frac{\lambda}{2} U \subseteq \lambda U.$$

By Proposition B.10.26, the family $\mathcal{U}$ is a local base at the origin for a unique locally convex topology τ_{LC} on X.

We show that each canonical inclusion

$$\iota_i \colon X_i \hookrightarrow X$$

is continuous with respect to τ_{LC}. Since ι_i is linear, it suffices to check continuity at the origin. Let A be a neighborhood of the origin in (X, τ_{LC}). Since $\mathcal{U}$ is a local base at the origin, there exists $U \in \mathcal{U}$ such that $U \subseteq A$. Then $\iota_i^{-1}(U) = U \cap X_i$ is a neighborhood of the origin in (X_i, τ_i), and $\iota_i^{-1}(U) \subseteq \iota_i^{-1}(A)$. Therefore, $\iota_i^{-1}(A)$ is a neighborhood of the origin in X_i, proving that ι_i is continuous.

Finally, we show that τ_{LC} is the finest among all locally convex topologies with this property. Let τ' be another locally convex topology on X such that all the inclusions ι_i are continuous. Let V be an absolutely convex neighborhood of the origin in (X, τ'). Then, for each $i \in I$,

$$V \cap X_i = \iota_i^{-1}(V)$$

is a neighborhood of the origin in (X_i, τ_i), by continuity of ι_i. Therefore, $V \in \mathcal{U}$.

Now, by Proposition B.10.15, the absolutely convex neighborhoods of the origin form a local base in (X, τ'). Thus, if A is a neighborhood of the origin in (X, τ'), there is an absolutely convex neighborhood V of the origin such that $V \subseteq A$. By the preceding argument, $V \in \mathcal{U}$. Since $\mathcal{U}$ is a local base at the origin for τ_{LC}, the set V is a neighborhood of the origin with respect to τ_{LC}; since it is contained in A, we conclude that A is also a neighborhood of the origin with respect to τ_{LC}. We have proved that every neighborhood of the origin for τ' is also a neighborhood of the origin for τ_{LC}. Consequently, $\tau' \subseteq \tau_{LC}$.

Thus, τ_{LC} is the finest among all locally convex topologies making the inclusions ι_i continuous.

Uniqueness follows immediately from this maximality property. □

With this construction, we can formally define LF spaces.

Definition 4.4.2. Let X be a vector space over $\mathbb{R}$ or $\mathbb{C}$. Suppose there is a sequence of subspaces $(X_n)_{n\in\mathbb{N}}$ such that:

(a) $X_1 \subseteq X_2 \subseteq X_3 \subseteq \dots$ and $X = \bigcup_{n=1}^{\infty} X_n$.

(b) For each n, the space X_n, equipped with a topology τ_n, is a Fréchet space.

(c) For each n, the topology τ_n agrees with the subspace topology induced on X_n by (X_{n+1}, τ_{n+1}).

Let τ_{LF} be the locally convex final topology on X associated with the inclusions $\iota_n \colon (X_n, \tau_n) \hookrightarrow X$, guaranteed by Theorem 4.4.1. Then (X, τ_{LF}) is called the *strict inductive limit* of the sequence (X_n, τ_n), and we write

$$(X, \tau_{LF}) = \varinjlim_{n\in\mathbb{N}} (X_n, \tau_n).$$

In this case, (X, τ_{LF}) is said to be an *LF space*. The adjective *strict* refers to compatibility of the topologies of the stages, not to the inclusions being proper. Stationary sequences are allowed; in particular, every Fréchet space is obtained by taking $X_n = X$ with the same topology for every n.

Remark 4.4.3. If in the preceding definition each space X_n is Banach, then X is called an LB space. In particular, every LB space is an LF space.

Remark 4.4.4. The notion of an LF space arose naturally in the development of functional analysis and distribution theory during the first half of the twentieth century. At that time, it was observed that many fundamental spaces in analysis could not be adequately described within the category of Banach spaces or even Fréchet spaces, although they could be constructed as increasing unions of the latter.
One of the most important examples appeared in Laurent Schwartz's distribution theory. The space of smooth functions with compact support, $\mathcal{D}(\Omega) = C_c^\infty(\Omega)$, has a topological structure essential to the study of distributions and partial differential equations, but is not metrizable under its natural topology. However, it can be written as a countable increasing union of the spaces $\mathcal{D}_K(\Omega) = \{f \in C^\infty(\Omega) \mid \operatorname{supp}(f) \subseteq K\}$, where $K \Subset \Omega$ ranges over the compact subsets of Ω. Each of these spaces turns out to be a Fréchet space, which motivated the systematic study of countable inductive limits of Fréchet spaces.
The theory was subsequently developed within the general framework of locally convex spaces by authors such as Jean Dieudonné and Alexander Grothendieck, becoming a fundamental tool in functional analysis, distribution theory, differential geometry, and global analysis.

To show that $\mathcal{D}(\Omega)$ is an LF space, we first construct an exhaustion of Ω by compact sets.
For each $l \in \mathbb{N}$, we define $C_l := \left\{ x \in \Omega \;\middle|\; d\left(x, \mathbb{R}^n \setminus \Omega\right) \geq \frac{1}{l} \right\}$, and then $K_l := C_l \cap \overline{B}_{\text{euc}}(0, l)$.

The geometric idea behind this construction is twofold: on the one hand, the sets C_l force points to remain at a positive distance from the boundary $\partial\Omega$; on the other, intersection with the closed ball $\overline{B}_{\text{euc}}(0, l)$ prevents points from escaping to infinity.

It is immediate to check that each K_l is compact, that $K_l \subseteq \operatorname{int}(K_{l+1})$, and that $\Omega = \bigcup_{l=1}^{\infty} K_l$.

[3] A subset U of a vector space is said to be *absolutely convex* (or a *disk*) if it is both convex and balanced.

Geometric interpretation

The set $K_l = C_l \cap \overline{B}_{\mathrm{euc}}(0,l)$ is obtained by combining two complementary restrictions:

(a) C_l removes points too close to $\partial\Omega$;

(b) $\overline{B}_{\mathrm{euc}}(0,l)$ controls behavior at infinity.

Consequently, the boundary of K_l consists of:

$$\partial K_l \subseteq \left\{ x \in \Omega \mid d(x,\partial\Omega) = \frac{1}{l} \right\} \cup \partial B_{\mathrm{euc}}(0,l).$$

In this way, the sequence $(K_l)_{l\in\mathbb{N}}$ provides a natural exhaustion of Ω by compact sets.

Figure 4.2. Construction of a compact exhaustion of Ω.

Now taking $X_l := \mathcal{D}_{K_l}(\Omega)$, conditions (a)–(c) of Definition 4.4.2 are satisfied. The family is increasing and exhaustive, each space X_l is Fréchet, and the topologies are compatible by Theorem 4.3.4.

It remains to check that the topology τ_{LF} agrees with the locally convex inductive topology associated with the inclusions $\mathcal{D}_{K_l}(\Omega) \hookrightarrow \mathcal{D}(\Omega)$.

Proposition 4.4.5. The topology τ_{LF} on $\mathcal{D}(\Omega)$ agrees with the locally convex inductive topology associated with the family of inclusions

$$\iota_l \colon \mathcal{D}_{K_l}(\Omega) \hookrightarrow \mathcal{D}(\Omega), \qquad l \in \mathbb{N}.$$

Proof. Denote by τ_{LC} the locally convex inductive topology on $\mathcal{D}(\Omega)$ associated with the family

$$\big((\mathcal{D}_{K_l}(\Omega), \tau_{K_l}), \iota_l\big)_{l\in\mathbb{N}}.$$

By Theorem 4.4.1, a local base at the origin for τ_{LC} is given by the family $\mathcal{U}$ of all absolutely convex subsets $U \subseteq \mathcal{D}(\Omega)$ such that $U \cap \mathcal{D}_{K_l}(\Omega)$ is a neighborhood of the origin in $(\mathcal{D}_{K_l}(\Omega), \tau_{K_l})$ for every $l \in \mathbb{N}$.
We compare this family with the local base $\mathcal{B}_0$ defining the topology τ_{LF}. Recall that, by definition, $V \in \mathcal{B}_0$ if and only if $0 \in V$, V is absolutely convex, and $V \cap \mathcal{D}_K(\Omega)$ is a neighborhood of the origin in $(\mathcal{D}_K(\Omega), \tau_K)$ for every compact set $K \subseteq \Omega$.
Thus, the only apparent difference between the families $\mathcal{U}$ and $\mathcal{B}_0$ is that, in the definition of $\mathcal{U}$, the neighborhood condition is required only for the compact sets in the exhaustion $(K_l)_{l\in\mathbb{N}}$, whereas in the definition of $\mathcal{B}_0$ it is required for every compact set $K \subseteq \Omega$. We show that the two conditions are equivalent.
First we prove that $\mathcal{B}_0 \subseteq \mathcal{U}$. Let $V \in \mathcal{B}_0$. Since each K_l is compact, the definition of $\mathcal{B}_0$ implies that $V \cap \mathcal{D}_{K_l}(\Omega)$ is a neighborhood of the origin in $(\mathcal{D}_{K_l}(\Omega), \tau_{K_l})$ for every $l \in \mathbb{N}$. Since V is also absolutely convex, we conclude that $V \in \mathcal{U}$.

We now prove the reverse inclusion. Let $U \in \mathcal{U}$ and let $K \subseteq \Omega$ be an arbitrary compact set. Since $(K_l)_{l\in\mathbb{N}}$ is an exhaustion of Ω by compact sets, there exists $l \in \mathbb{N}$ such that $K \subseteq K_l$.
Then $\mathcal{D}_K(\Omega) \subseteq \mathcal{D}_{K_l}(\Omega)$.
Moreover, the topology τ_K agrees with the topology induced by τ_{K_l} on the subspace $\mathcal{D}_K(\Omega)$. Since $U \cap \mathcal{D}_{K_l}(\Omega)$ is a neighborhood of the origin in $(\mathcal{D}_{K_l}(\Omega), \tau_{K_l})$, it follows that

$$\big(U \cap \mathcal{D}_{K_l}(\Omega)\big) \cap \mathcal{D}_K(\Omega) = U \cap \mathcal{D}_K(\Omega)$$

is a neighborhood of the origin in $(\mathcal{D}_K(\Omega), \tau_K)$.
Since $K \subseteq \Omega$ was an arbitrary compact set, U satisfies the neighborhood condition required in the definition of $\mathcal{B}_0$. Moreover, since $U \cap \mathcal{D}_{K_l}(\Omega)$ is a neighborhood of the origin for any $l \in \mathbb{N}$, we have $0 \in U$. Therefore, $U \in \mathcal{B}_0$.
We have proved that $\mathcal{B}_0 = \mathcal{U}$.
Consequently, τ_{LF} and τ_{LC} have the same local base at the origin. By Proposition B.10.2, the two topologies agree. That is, $\tau_{LF} = \tau_{LC}$. □

Consequently, $(\mathcal{D}(\Omega), \tau_{LF})$ is the strict inductive limit

$$\mathcal{D}(\Omega) = \varinjlim_{l\in\mathbb{N}} \mathcal{D}_{K_l}(\Omega),$$

and is therefore an LF space.

The advantage of this description is that many fundamental properties of $\mathcal{D}(\Omega)$ follow directly from its LF structure in a purely topological framework. These properties will allow us to construct spaces of distributions on vector bundles without repeating the constructions and proofs.

Theorem 4.4.6. Let (X, τ) be an *LF* space with defining sequence $(X_n)_{n\in\mathbb{N}}$. Then:

(a) X is Hausdorff.

(b) A set $B \subseteq X$ is topologically bounded if and only if there exists $m \in \mathbb{N}$ such that $B \subseteq X_m$ and B is topologically bounded in X_m.

(c) X is complete; in particular, it is sequentially complete.

(d) A sequence $(x_k)_{k\in\mathbb{N}}$ converges to $x \in X$ if and only if there exists $m \in \mathbb{N}$ such that $\{x\} \cup \{x_k \mid k \in \mathbb{N}\} \subseteq X_m$ and $x_k \to x$ in the topology of X_m.

The argument for strict inductive limits comes from [149, Chapter 13].

Proof. We will prove completeness using filters, since an *LF* space need not be metrizable.
We will repeatedly use the following elementary observation. If A is an absolutely convex set, $u, v \in A$ and $\alpha, \beta \in \mathbb{K}$ satisfy $|\alpha| + |\beta| \le 1$, then $\alpha u + \beta v \in A$.
If $\alpha = 0$ or $\beta = 0$, the assertion follows from the balancedness of A. Now suppose that $\alpha \neq 0$ and $\beta \neq 0$, and define $s := |\alpha| + |\beta|$. Since $0 < s \le 1$, we have

$$\alpha u + \beta v = s\left(\frac{|\alpha|}{s}\frac{\alpha}{|\alpha|}u + \frac{|\beta|}{s}\frac{\beta}{|\beta|}v\right).$$

Since A is balanced, $\frac{\alpha}{|\alpha|}u, \frac{\beta}{|\beta|}v \in A$; since $\frac{|\alpha|}{s} + \frac{|\beta|}{s} = 1$, the term in parentheses belongs to A by convexity. Finally, since $s \leq 1$ and A is balanced, we conclude that $\alpha u + \beta v \in A$.

(a) Let $x \in X \backslash \{0\}$. Since $X = \bigcup_{n=1}^{\infty} X_n$, there exists $m \in \mathbb{N}$ such that $x \in X_m$. Since X_m is Fréchet, it is Hausdorff; therefore, there is a neighborhood of the origin in X_m that does not contain x. By Proposition B.10.15, we can choose an absolutely convex neighborhood U_m of the origin in X_m such that $x \notin U_m$.

For $n < m$, define $U_n := U_m \cap X_n$. Since the topology of X_n agrees with the topology induced by X_m, each U_n is an absolutely convex neighborhood of the origin in X_n. Moreover, for $2 \leq n \leq m$ we have $U_n \cap X_{n-1} = U_{n-1}$.

We now construct U_n inductively for $n > m$. Suppose that U_{n-1} has been defined as an absolutely convex neighborhood of the origin in X_{n-1}. Since the topology of X_{n-1} agrees with the topology induced by X_n, there exists an absolutely convex neighborhood V_n of the origin in X_n such that $V_n \cap X_{n-1} \subseteq U_{n-1}$. Define

$$U_n := \operatorname{cobal}(V_n \cup U_{n-1})^4 = \left\{ \alpha v + \beta u \mid v \in V_n,\ u \in U_{n-1},\ |\alpha| + |\beta| \leq 1 \right\}.$$

By construction, U_n is absolutely convex and contains V_n; in particular, it is a neighborhood of the origin in X_n.

We claim that $U_n \cap X_{n-1} = U_{n-1}$. The inclusion $U_{n-1} \subseteq U_n \cap X_{n-1}$ is immediate, since $U_{n-1} \subseteq U_n$ and $U_{n-1} \subseteq X_{n-1}$. To prove the other inclusion, take $z \in U_n \cap X_{n-1}$. Then there exist $v \in V_n$, $u \in U_{n-1}$, and scalars $\alpha, \beta \in \mathbb{K}$ such that $|\alpha| + |\beta| \leq 1$ and $z = \alpha v + \beta u$. If $\alpha = 0$, then $z = \beta u \in U_{n-1}$, since U_{n-1} is balanced. If $\alpha \neq 0$, the preceding equality gives

$$v = \alpha^{-1}(z - \beta u) \in X_{n-1},$$

since $z, u \in X_{n-1}$. Therefore, $v \in V_n \cap X_{n-1} \subseteq U_{n-1}$. Since also $u \in U_{n-1}$ and $|\alpha| + |\beta| \leq 1$, the preliminary observation about absolutely convex sets gives $z = \alpha v + \beta u \in U_{n-1}$. The equality is proved.

Now define

$$U := \bigcup_{n=1}^{\infty} U_n.$$

The sequence $(U_n)_{n \in \mathbb{N}}$ is increasing, since $U_{n-1} = U_n \cap X_{n-1} \subseteq U_n$. It follows that U is absolutely convex. If $y, z \in U$, there exist indices $r, s \in \mathbb{N}$ such that $y \in U_r$ and $z \in U_s$. Taking $N := \max\{r, s\}$, we obtain $y, z \in U_N$; therefore, if $\alpha, \beta \in \mathbb{K}$ satisfy $|\alpha| + |\beta| \leq 1$, then $\alpha y + \beta z \in U_N \subseteq U$, since U_N is absolutely convex.

We show that $U \cap X_n = U_n$ for every $n \in \mathbb{N}$. If $r \geq n$, the equalities $U_j \cap X_{j-1} = U_{j-1}$ allow us to descend successively from r to n:

$$U_r \cap X_n = (U_r \cap X_{r-1}) \cap X_n = U_{r-1} \cap X_n = \cdots = U_n.$$

If, instead, $r < n$, then $U_r \subseteq U_n \subseteq X_n$, so $U_r \cap X_n = U_r \subseteq U_n$. Consequently,

$$U \cap X_n = \left(\bigcup_{r=1}^{\infty} U_r \right) \cap X_n = \bigcup_{r=1}^{\infty} (U_r \cap X_n) = U_n.$$

Thus, $U \cap X_n$ is a neighborhood of the origin in X_n for every $n \in \mathbb{N}$. By definition of the topology LF, U is a neighborhood of the origin in X. Applying the preceding equality to the index m fixed at the outset, we obtain $U \cap X_m = U_m$. Since $x \in X_m$ and $x \notin U_m$, we conclude that $x \notin U$.

For each $x \in X \setminus \{0\}$, we have found a neighborhood of the origin that does not contain x. Therefore, X is Hausdorff.

(b) First suppose that $B \subseteq X_m$ is topologically bounded in X_m. Let U be a neighborhood of the origin in X. Since the inclusion $\iota_m \colon X_m \hookrightarrow X$ is continuous, $U \cap X_m$ is a neighborhood of the origin in X_m. By the topological boundedness of B in X_m, there exists $\lambda > 0$ such that

$$B \subseteq \lambda (U \cap X_m) \subseteq \lambda U.$$

Thus, B is topologically bounded in X.

Conversely, suppose that B is topologically bounded in X and is not contained in any X_m. We recursively choose points $x_k \in B$ and indices $m_k \in \mathbb{N}$ as follows. Take $x_1 \in B \setminus X_1$ and let m_1 be the least index such that $x_1 \in X_{m_1}$. Once m_{k-1} has been chosen, take $x_k \in B \setminus X_{m_{k-1}}$ and let m_k be the least index such that $x_k \in X_{m_k}$. Then $(m_k)_{k \in \mathbb{N}}$ is strictly increasing and, for each k, $x_k \in X_{m_k} \setminus X_{m_k - 1}$.

Since the topology of $X_{m_k - 1}$ agrees with the topology induced by X_{m_k} and $X_{m_k - 1}$ is complete, being Fréchet, it follows that $X_{m_k - 1}$ is a closed subspace of X_{m_k}. Since $x_k \notin X_{m_k - 1}$, Corollary B.10.35 guarantees the existence of a continuous linear functional $f_k \in X'_{m_k}$ such that $f_k|_{X_{m_k - 1}} = 0$ and $f_k(x_k) = k$.

We construct a neighborhood U of the origin in X from an increasing sequence of absolutely convex neighborhoods $U_n \subseteq X_n$.

For $n = 1$, fix an absolutely convex neighborhood U_1 of the origin in X_1. Suppose that U_{n-1} has been constructed as an absolutely convex neighborhood of the origin in X_{n-1}. Since the topology of X_{n-1} agrees with the topology induced by X_n, there exists an absolutely convex neighborhood V_n of the origin in X_n such that $V_n \cap X_{n-1} \subseteq U_{n-1}$. Define

$$W_n := \operatorname{cobal}(V_n \cup U_{n-1}) = \left\{ \alpha v + \beta u \mid v \in V_n,\ u \in U_{n-1},\ |\alpha| + |\beta| \leq 1 \right\}.$$

Since W_n contains V_n, it is a neighborhood of the origin in X_n; moreover, by construction, it is absolutely convex. The same argument used in the preceding part shows that $W_n \cap X_{n-1} = U_{n-1}$.

Now define

$$U_n := \begin{cases} W_n, & \text{if } n \neq m_k \text{ for every } k, \\ W_n \cap \{x \in X_n \mid |f_k(x)| \leq 1\}, & \text{if } n = m_k. \end{cases}$$

Each U_n is absolutely convex. Moreover, if $n = m_k$, the set $\{x \in X_n \mid |f_k(x)| \leq 1\}$ is a neighborhood of the origin in X_n, since it contains the open set $\{x \in X_n \mid |f_k(x)| < 1\}$. Therefore, each U_n is an absolutely convex neighborhood of the origin in X_n.

The equality $U_n \cap X_{n-1} = U_{n-1}$ is preserved at every step. If $n \neq m_k$ for every k, we simply have $U_n \cap X_{n-1} = W_n \cap X_{n-1} = U_{n-1}$. If $n = m_k$, then

$$\begin{aligned} U_{m_k} \cap X_{m_k-1} &= W_{m_k} \cap \{x \in X_{m_k} \mid |f_k(x)| \leq 1\} \cap X_{m_k-1} \\ &= W_{m_k} \cap X_{m_k-1} = U_{m_k-1}, \end{aligned}$$

since f_k vanishes on X_{m_k-1}.

Since $U_{n-1} = U_n \cap X_{n-1} \subseteq U_n$, the sequence $(U_n)_{n\in\mathbb{N}}$ is increasing. Define $U := \bigcup_{n=1}^{\infty} U_n$. As the union of an increasing sequence of absolutely convex sets, U is absolutely convex; moreover, the preceding equalities give $U \cap X_n = U_n$ for every $n \in \mathbb{N}$. By definition of the topology LF, U is a neighborhood of the origin in X.

Since B is topologically bounded in X, there exists $\lambda > 0$ such that $B \subseteq \lambda U$. In particular, $x_k \in \lambda U$ for every k. Since $x_k \in X_{m_k}$, we have

$$x_k \in \lambda U \cap X_{m_k} = \lambda(U \cap X_{m_k}) = \lambda U_{m_k}.$$

By definition of U_{m_k}, every element $y \in U_{m_k}$ satisfies $|f_k(y)| \leq 1$. Since $\dfrac{x_k}{\lambda} \in U_{m_k}$,

$$\left|f_k\left(\frac{x_k}{\lambda}\right)\right| \leq 1,$$

and therefore $|f_k(x_k)| \leq \lambda$. However, by construction, $f_k(x_k) = k$. Thus, $k \leq \lambda$ for every $k \in \mathbb{N}$, which is impossible.

This contradiction shows that B must be contained in some X_m. It remains to show that it is topologically bounded in X_m. Let V be a neighborhood of the origin in X_m. Since the topology of X_m agrees with the topology induced by X, there exists a neighborhood W of the origin in X such that $V = W \cap X_m$. Since B is topologically bounded in X, there exists $\lambda > 0$ such that $B \subseteq \lambda W$. Since also $B \subseteq X_m$,

$$B \subseteq \lambda W \cap X_m = \lambda(W \cap X_m) = \lambda V.$$

Therefore, B is topologically bounded in X_m.

(c) We prove completeness using filters, since X is not necessarily metrizable. Recall that a filter $\mathscr{F}$ on X is a family of nonempty subsets closed under finite intersections and passage to supersets. We say that $\mathscr{F}$ is Cauchy if, for every neighborhood U of the origin, there exists $M \in \mathscr{F}$ such that $M - M \subseteq U$; the space is complete if every Cauchy filter converges.

Let $\mathscr{F}$ be a Cauchy filter on X. The sets

$$M + V, \qquad M \in \mathscr{F}, \quad V \text{ a neighborhood of the origin in } X,$$

form a filter base: the intersection of two of them contains $(M_1 \cap M_2) + (V_1 \cap V_2)$. Denote the filter they generate by $\mathscr{G}$. Each basic set $M + V$ belongs to $\mathscr{F}$, since it contains M; therefore, $\mathscr{F}$ is finer than $\mathscr{G}$. Moreover, $\mathscr{G}$ is Cauchy. Indeed, given a neighborhood U of the origin, choose an absolutely convex

neighborhood V such that $V + V - V \subseteq U$ and a set $M \in \mathscr{F}$ such that $M - M \subseteq V$. Then

$$(M + V) - (M + V) \subseteq V + V - V \subseteq U.$$

We claim that there exists $p \in \mathbb{N}$ such that

$$A \cap X_p \neq \varnothing \qquad \text{for every } A \in \mathscr{G}. \tag{$*$}$$

Suppose otherwise. For each n we could choose a basic set $A_n = M_n + V_n \in \mathscr{G}$ such that $A_n \cap X_n = \varnothing$, with $M_n \in \mathscr{F}$. By successively shrinking the neighborhoods, we may assume that each V_n is absolutely convex and that $V_{n+1} \subseteq V_n$. Define

$$W_n := \operatorname{conv}\left(V_n \cup \bigcup_{k<n}(V_k \cap X_k)\right).$$

We have $(M_n + W_n) \cap X_n = \varnothing$. For $n = 1$ this follows from $W_1 = V_1$. If $n \geq 2$, every element of W_n can be written as $ty + (1-t)z$, with $0 \leq t \leq 1$, $y \in V_n$, and $z \in X_{n-1}$, after replacing z by an element of the convex hull of $\bigcup_{k<n}(V_k \cap X_k)$. If $m + ty + (1-t)z \in X_n$, with $m \in M_n$, then $m + ty \in (M_n + V_n) \cap X_n$, because V_n is balanced, contradicting the choice of A_n.

Now set

$$W := \operatorname{conv}\left(\bigcup_{k=1}^{\infty}(V_k \cap X_k)\right).$$

The set W is absolutely convex and $W \cap X_k$ contains the neighborhood $V_k \cap X_k$ of the origin in X_k; by definition of the topology LF, W is a neighborhood of the origin in X. The monotonicity of (V_k) also shows that $W \subseteq W_n$ for every n: the terms with index less than n appear in the definition of W_n, whereas those with index greater than or equal to n are contained in V_n.

Since $\mathscr{G}$ is Cauchy, there exists $B \in \mathscr{G}$ such that $B - B \subseteq W$. The set B also belongs to $\mathscr{F}$, and therefore $B \cap M_n \neq \varnothing$ for every n. If $b_n \in B \cap M_n$, then

$$B \subseteq b_n + (B - B) \subseteq M_n + W_n.$$

Consequently, $B \cap X_n = \varnothing$ for every n, which is impossible because $X = \bigcup_n X_n$ and a filter does not contain the empty set. This proves assertion $(*)$.

Fix p as in $(*)$. The sets $A \cap X_p$, with $A \in \mathscr{G}$, form a base for a filter $\mathscr{G}_p$ on X_p. This filter is Cauchy: if U_p is a neighborhood of the origin in X_p, equality of the original topology of X_p and the one induced by X allows us to choose a neighborhood U of the origin in X such that $U \cap X_p \subseteq U_p$, and it suffices to apply the Cauchy property of $\mathscr{G}$. Since X_p is Fréchet, there exists $x \in X_p$ such that $\mathscr{G}_p$ converges to x.

This implies that x is a cluster point of $\mathscr{G}$. A Cauchy filter with a cluster point converges to it: given a neighborhood U of the origin, choose a balanced neighborhood V with $V + V \subseteq U$ and $A \in \mathscr{G}$ with $A - A \subseteq V$; since $A \cap (x + V) \neq \varnothing$, if a belongs to this intersection, then $A \subseteq x + V + V \subseteq x + U$. Thus, $\mathscr{G}$ converges to x. Since $\mathscr{F}$ is finer than $\mathscr{G}$, $\mathscr{F}$ also converges to x. This proves that X is complete.

(d) First suppose that $x_k \to x$ in X. Then $(x_k)_{k\in\mathbb{N}}$ is a Cauchy sequence, and by Proposition B.10.13, the

set $\{x_k \mid k \in \mathbb{N}\}$ is topologically bounded in X. Since the singleton $\{x\}$ is also topologically bounded, the union $B := \{x\} \cup \{x_k \mid k \in \mathbb{N}\}$ is topologically bounded in X. By part (b), there exists $m \in \mathbb{N}$ such that $B \subseteq X_m$. Since the topology of X_m agrees with the topology induced by X, it follows that $x_k \to x$ in X_m.

Conversely, if there exists $m \in \mathbb{N}$ such that $\{x\} \cup \{x_k \mid k \in \mathbb{N}\} \subseteq X_m$ and $x_k \to x$ in X_m, then $x_k \to x$ in X by continuity of the canonical inclusion $X_m \hookrightarrow X$.

□

4.5 Distributions: the dual of $\mathcal{D}(\Omega)$

The concept of a distribution will be obtained from the dual of $\mathcal{D}(\Omega)$. To this end, we first study some properties of continuous linear functionals defined on $\mathcal{D}(\Omega)$.

Theorem 4.5.1. Let $\Omega \subseteq \mathbb{R}^n$ be an open set and let $T : \mathcal{D}(\Omega) \longrightarrow \mathbb{R}$ be linear. Then the following properties are equivalent:

(a) T is continuous.

(b) T is bounded.

(c) If $\{\varphi_\ell\}_{\ell\in\mathbb{N}}$ converges to $\varphi \in \mathcal{D}(\Omega)$ with respect to τ, then

$$\lim_{\ell\to\infty} T(\varphi_\ell) = T(\varphi).$$

(d) $T \restriction_{\mathcal{D}_K(\Omega)}$ is continuous for every compact set $K \subseteq \Omega$.

(e) For every compact set $K \subseteq \Omega$, there exist $j \in \mathbb{N}_0$ and $c_{K,j} > 0$ such that

$$|T(\varphi)| \le c_{K,j}\|\varphi\|_{C^j(K)} \qquad \forall \varphi \in \mathcal{D}_K(\Omega). \tag{4.2}$$

Proof. We show that (a) implies (b). If T is continuous, then T is bounded by Theorem B.10.29.
For (b)⇒(c), suppose that T is bounded and let $\{\varphi_\ell\}_{\ell\in\mathbb{N}}$ be a sequence in $\mathcal{D}(\Omega)$ such that $\varphi_\ell \to \varphi$ with respect to τ. By part (d) of Theorem 4.4.6, there exists a compact set $K \subseteq \Omega$ such that

$$\{\varphi\} \cup \{\varphi_\ell \mid \ell \in \mathbb{N}\} \subseteq \mathcal{D}_K(\Omega)$$

and $\varphi_\ell \to \varphi$ in the Fréchet topology of $\mathcal{D}_K(\Omega)$.
The restriction

$$T \restriction_{\mathcal{D}_K(\Omega)} : \mathcal{D}_K(\Omega) \longrightarrow \mathbb{R}$$

is bounded. Indeed, the inclusion $\mathcal{D}_K(\Omega) \hookrightarrow \mathcal{D}(\Omega)$ is continuous and therefore maps topologically bounded

[4] If $A \subseteq X$ is a subset of a vector space, its absolutely convex hull is defined by

$$\operatorname{cobal}(A) = \left\{ \sum_{j=1}^{r} \lambda_j x_j \;\middle|\; x_j \in A,\ \sum_{j=1}^{r} |\lambda_j| \le 1 \right\}.$$

It is the smallest absolutely convex subset of X containing A.

sets to topologically bounded sets; one then applies the boundedness of T. Since $\mathcal{D}_K(\Omega)$ is metrizable, Theorem B.10.29 shows that this restriction is continuous. Consequently,

$$T(\varphi_\ell) \longrightarrow T(\varphi).$$

(c)⇒(d). Let $K \subseteq \Omega$ be compact. Suppose that $\{\varphi_\ell\}_{\ell\in\mathbb{N}} \subseteq \mathcal{D}_K(\Omega)$ and that

$$d_K(\varphi_\ell, \varphi) \to 0.$$

By Proposition B.10.23, this means that $\varphi_\ell \to \varphi$ in $(\mathcal{D}_K(\Omega), \tau_K)$. Since the inclusion

$$\mathcal{D}_K(\Omega) \hookrightarrow \mathcal{D}(\Omega)$$

is continuous, it follows that $\varphi_\ell \to \varphi$ with respect to τ. By (c),

$$T(\varphi_\ell) \to T(\varphi).$$

Thus, $T \restriction_{\mathcal{D}_K(\Omega)}$ is sequentially continuous. Since $\mathcal{D}_K(\Omega)$ is metrizable, we conclude that $T \restriction_{\mathcal{D}_K(\Omega)}$ is continuous.
(d)⇒(a). Let $V \subseteq \mathbb{R}$ be an absolutely convex neighborhood of the origin and set

$$U := T^{-1}(V).$$

The set U is absolutely convex. For every compact set $K \subseteq \Omega$, continuity of $T \restriction_{\mathcal{D}_K(\Omega)}$ implies that

$$U \cap \mathcal{D}_K(\Omega) = \left(T \restriction_{\mathcal{D}_K(\Omega)}\right)^{-1}(V)$$

is a neighborhood of the origin in $\mathcal{D}_K(\Omega)$. By the description of neighborhoods of the origin for the locally convex final topology in Theorem 4.4.1, U is a neighborhood of the origin in $\mathcal{D}(\Omega)$. Thus, T is continuous at the origin and, by linearity, at every point.
(d)⇔(e). Suppose that (d) holds and let $K \subseteq \Omega$ be compact. Since $T \restriction_{\mathcal{D}_K(\Omega)}$ is continuous at the origin, given $\varepsilon = 1$, there exist $j \in \mathbb{N}_0$ and $n \in \mathbb{N}$ such that

$$V_{K,j,n} \subseteq T^{-1}((-1,1)).$$

This means that

$$|T(\varphi)| \leq 1 \qquad \forall \varphi \in \mathcal{D}_K(\Omega) \text{ with } \|\varphi\|_{C^j(K)} < \frac{1}{n}.$$

If $\varphi \in \mathcal{D}_K(\Omega)$ and $\varphi \neq 0$, then

$$\left\| \frac{1}{2n} \frac{\varphi}{\|\varphi\|_{C^j(K)}} \right\|_{C^j(K)} < \frac{1}{n}.$$

Therefore,

$$\left| T\left(\frac{1}{2n} \frac{\varphi}{\|\varphi\|_{C^j(K)}} \right) \right| \leq 1.$$

By linearity of T, it follows that

$$|T(\varphi)| \leq 2n\|\varphi\|_{C^j(K)}.$$

This proves (e). Conversely, suppose that (e) holds and let $K \subseteq \Omega$ be compact. We wish to prove that

$$T \restriction_{\mathcal{D}_K(\Omega)} : \mathcal{D}_K(\Omega) \longrightarrow \mathbb{R}$$

is continuous.
By hypothesis, there exist $j \in \mathbb{N}_0$ and $c_K > 0$ such that

$$|T(\varphi)| \leq c_{K,j}\|\varphi\|_{C^j(K)} \qquad \forall \varphi \in \mathcal{D}_K(\Omega).$$

It suffices to show that $T \restriction_{\mathcal{D}_K(\Omega)}$ is continuous at 0. Since T is linear, continuity at the origin implies continuity at every point.
Let $\varepsilon > 0$. By the Archimedean property, there exists $n \in \mathbb{N}$ such that $n > \frac{c_{K,j}}{\varepsilon}$, and therefore

$$\frac{c_{K,j}}{n} < \varepsilon.$$

Now consider $\varphi \in V_{K,j,n}$. By definition of $V_{K,j,n}$, this means that

$$\|\varphi\|_{C^j(K)} < \frac{1}{n}.$$

Applying the bound given by (e), we obtain

$$|T(\varphi)| \leq c_{K,j}\|\varphi\|_{C^j(K)} < \frac{c_{K,j}}{n} < \varepsilon.$$

Therefore,

$$\varphi \in V_{K,j,n} \quad \Longrightarrow \quad T(\varphi) \in (-\varepsilon, \varepsilon),$$

and consequently

$$V_{K,j,n} \subseteq \left(T \restriction_{\mathcal{D}_K(\Omega)}\right)^{-1}((-\varepsilon, \varepsilon)).$$

Since $V_{K,j,n}$ is a neighborhood of 0 in $\mathcal{D}_K(\Omega)$, we conclude that

$$\left(T \restriction_{\mathcal{D}_K(\Omega)}\right)^{-1}((-\varepsilon, \varepsilon))$$

is a neighborhood of 0. This proves that $T \restriction_{\mathcal{D}_K(\Omega)}$ is continuous at 0 and, by linearity, is continuous throughout $\mathcal{D}_K(\Omega)$. □

Definition 4.5.2. Let $\Omega \subseteq \mathbb{R}^n$ be open. The dual of $(\mathcal{D}(\Omega), \tau)$, denoted by $\mathcal{D}'(\Omega)$, is called ***the space of distributions defined on*** Ω, and its elements are called ***distributions***. We will frequently use the duality notation $\langle T, \varphi \rangle$ to denote $T(\varphi)$. The space $\mathcal{D}'(\Omega)$ is equipped with the weak-$*$ topology. Thus, a sequence $\{T_k\}_{k\in\mathbb{N}} \subseteq \mathcal{D}'(\Omega)$ converges to $T \in \mathcal{D}'(\Omega)$ if

$$T_k(\varphi) \to T(\varphi), \qquad \forall \varphi \in \mathcal{D}(\Omega).$$

In this case, we say that $\{T_k\}_{k\in\mathbb{N}}$ converges to T *in the sense of distributions* or *in the distributional sense*.

Example 4.5.3. If $\psi \in C^\infty(\Omega)$ and $T \in \mathcal{D}'(\Omega)$, then the functional $\psi T : \mathcal{D}(\Omega) \longrightarrow \mathbb{R}$ defined by

$$(\psi T)(\varphi) := T(\psi\varphi), \qquad \varphi \in \mathcal{D}(\Omega),$$

is a distribution.
First observe that ψT is linear. If $\varphi_1, \varphi_2 \in \mathcal{D}(\Omega)$ and $a, b \in \mathbb{R}$, then

$$(\psi T)(a\varphi_1 + b\varphi_2) = T\big(\psi(a\varphi_1 + b\varphi_2)\big) = T(a\psi\varphi_1 + b\psi\varphi_2) = a(\psi T)(\varphi_1) + b(\psi T)(\varphi_2).$$

We now show that ψT is continuous. Let $K \subseteq \Omega$ be compact. Since T is a distribution, by part (e) of Theorem 4.5.1, there exist $j \in \mathbb{N}_0$ and $c_K > 0$ such that

$$|T(\eta)| \leq c_K \|\eta\|_{C^j(K)}, \qquad \forall \eta \in \mathcal{D}_K(\Omega).$$

Now let $\varphi \in \mathcal{D}_K(\Omega)$. Then $\psi\varphi \in \mathcal{D}_K(\Omega)$ and therefore

$$|(\psi T)(\varphi)| = |T(\psi\varphi)| \leq c_K \|\psi\varphi\|_{C^j(K)}.$$

To estimate this seminorm, we use the Leibniz rule for partial derivatives with multi-indices (Proposition 1.1.17). If $|\alpha| \leq j$, then

$$\partial^\alpha(\psi\varphi) = \sum_{\beta \leq \alpha} \binom{\alpha}{\beta} (\partial^\beta \psi)(\partial^{\alpha-\beta}\varphi).$$

Taking the supremum over K gives

$$\|\partial^\alpha(\psi\varphi)\|_{C^0(K)} \leq \sum_{\beta \leq \alpha} \binom{\alpha}{\beta} \|\partial^\beta \psi\|_{C^0(K)} \|\partial^{\alpha-\beta}\varphi\|_{C^0(K)}.$$

Since $\psi \in C^\infty(\Omega)$ and K is compact, each derivative $\partial^\beta\psi$ is bounded on K. Define

$$M_\beta := \|\partial^\beta \psi\|_{C^0(K)}.$$

Then

$$\|\partial^\alpha(\psi\varphi)\|_{C^0(K)} \leq \sum_{\beta \leq \alpha} \binom{\alpha}{\beta} M_\beta \|\partial^{\alpha-\beta}\varphi\|_{C^0(K)}.$$

Summing over $|\alpha| \leq j$ shows that there exists a constant $C_K > 0$ such that

$$\|\psi\varphi\|_{C^j(K)} \leq C_K \|\varphi\|_{C^j(K)}.$$

Substituting into the preceding estimate yields

$$|(\psi T)(\varphi)| \leq c_K C_K \|\varphi\|_{C^j(K)}.$$

Applying part (e) of Theorem 4.5.1 again, we conclude that ψT is a distribution, that is,

$$\psi T \in \mathcal{D}'(\Omega).$$

Example 4.5.4. Let $f \in L^1_{\text{loc}}(\Omega)$. Define the functional

$$T_f : \mathcal{D}(\Omega) \longrightarrow \mathbb{R}, \qquad T_f(\varphi) := \int_\Omega f(x)\varphi(x)\,dx.$$

Then T_f is a distribution. Linearity follows from linearity of the integral. To prove continuity, let $K \subseteq \Omega$ be compact and let $\varphi \in \mathcal{D}_K(\Omega)$. Then

$$|T_f(\varphi)| = \left| \int_K f(x)\varphi(x)\,dx \right| \leq \int_K |f(x)||\varphi(x)|\,dx.$$

Since $|\varphi(x)| \leq \|\varphi\|_{K,0}$ for every $x \in K$, we obtain

$$|T_f(\varphi)| \leq \|\varphi\|_{K,0} \int_K |f(x)|\,dx.$$

Defining

$$c_K := \int_K |f(x)|\,dx,$$

we have

$$|T_f(\varphi)| \leq c_K \|\varphi\|_{K,0}.$$

By part (e) of Theorem 4.5.1, we conclude that T_f is a distribution.

Example 4.5.5. Let $x_0 \in \Omega$. The functional

$$\delta_{x_0} : \mathcal{D}(\Omega) \longrightarrow \mathbb{R}, \qquad \delta_{x_0}(\varphi) := \varphi(x_0),$$

is called the **Dirac delta** centered at x_0. Linearity is immediate. We show that it is continuous. Let $K \subseteq \Omega$ be compact with $x_0 \in K$ and let $\varphi \in \mathcal{D}_K(\Omega)$. Then

$$|\delta_{x_0}(\varphi)| = |\varphi(x_0)| \leq \|\varphi\|_{C^0(K)} = \|\varphi\|_{K,0}.$$

Therefore,

$$|\delta_{x_0}(\varphi)| \leq \|\varphi\|_{K,0}.$$

Applying part (e) of Theorem 4.5.1, we conclude that δ_{x_0} is a distribution.

An important operation on distributions is the *restriction* of a distribution:

Definition 4.5.6. Let $\Omega \subseteq \mathbb{R}^n$ be an open set and let $v \in \mathcal{D}'(\mathbb{R}^n)$. We define the restriction of v to Ω to be the distribution $v \restriction_\Omega \in \mathcal{D}'(\Omega)$ given by

$$\langle v \restriction_\Omega, \varphi \rangle := \langle v, \tilde{\varphi} \rangle, \qquad \forall \varphi \in \mathcal{D}(\Omega),$$

where $\tilde{\varphi} \in \mathcal{D}(\mathbb{R}^n)$ is the extension of φ by zero outside Ω.

4.6 Order of a distribution

In this section we define the order of a distribution. The preceding examples show that the integer $j \in \mathbb{N}_0$ in (4.2) may change with the choice of distribution and compact set. If the same integer works for every compact set $K \subseteq \Omega$, then the smallest integer for which (4.2) holds is known as the *order of the distribution* T.

Definition 4.6.1. Let $T \in \mathcal{D}'(\Omega)$. We say that T is a distribution of *order less than or equal to* m if there exists $m \in \mathbb{N}_0$ such that for every compact set $K \subseteq \Omega$ there exists a constant $c_K > 0$ with the property that

$$|T(\varphi)| \leq c_K \|\varphi\|_{K,m} \qquad \forall \varphi \in \mathcal{D}_K(\Omega).$$

If such an integer m exists, the smallest one is called the *order of the distribution* T and is denoted by $\operatorname{ord}(T)$. If no such integer exists, we say that T is a distribution of *infinite order*.

Example 4.6.2. The preceding examples allow us to identify the order of several important distributions.

(a) If $f \in L^1_{\text{loc}}(\Omega)$, then the distribution

$$T_f(\varphi) = \int_\Omega f(x)\varphi(x)\,dx$$

has order 0.

If $K \subseteq \Omega$ is compact and $\varphi \in \mathcal{D}_K(\Omega)$, then

$$|T_f(\varphi)| = \left| \int_K f(x)\varphi(x)\,dx \right| \leq \int_K |f(x)||\varphi(x)|\,dx \leq \|\varphi\|_{K,0} \int_K |f(x)|\,dx.$$

Defining

$$c_K := \int_K |f(x)|\,dx,$$

we obtain

$$|T_f(\varphi)| \leq c_K \|\varphi\|_{K,0}.$$

Therefore, the integer $m = 0$ works in the preceding definition, and we conclude that

$$\operatorname{ord}(T_f) = 0.$$

(b) For $x_0 \in \Omega$, the Dirac delta

$$\delta_{x_0}(\varphi) = \varphi(x_0)$$

is also a distribution of order 0.

If $K \subseteq \Omega$ is compact and $x_0 \in K$, then for $\varphi \in \mathcal{D}_K(\Omega)$

$$|\delta_{x_0}(\varphi)| = |\varphi(x_0)| \leq \|\varphi\|_{C^0(K)} = \|\varphi\|_{K,0}.$$

Therefore,

$$|\delta_{x_0}(\varphi)| \leq \|\varphi\|_{K,0},$$

and again the integer $m = 0$ satisfies the condition in the definition, implying

$$\operatorname{ord}(\delta_{x_0}) = 0.$$

(c) If $\psi \in C^\infty(\Omega)$ and $T \in \mathcal{D}'(\Omega)$ has order m, then ψT also has order less than or equal to m.

The estimate in the preceding example provides a constant $C_K > 0$ such that

$$\|\psi\varphi\|_{K,m} \le C_K \|\varphi\|_{K,m}.$$

Since T has order m, there exists $c_K > 0$ such that

$$|T(\eta)| \le c_K \|\eta\|_{K,m}.$$

Taking $\eta = \psi\varphi$, we obtain

$$|(\psi T)(\varphi)| = |T(\psi\varphi)| \le c_K \|\psi\varphi\|_{K,m} \le c_K C_K \|\varphi\|_{K,m}.$$

Therefore, ψT satisfies the definition with the same integer m, and thus

$$\operatorname{ord}(\psi T) \le m.$$

(d) Now let μ be a signed Radon measure[1] on Ω. Define

$$T_\mu(\varphi) = \int_\Omega \varphi \, d\mu, \qquad \varphi \in \mathcal{D}(\Omega).$$

First observe that T_μ is linear by linearity of the integral.

We show that it is continuous. Let $K \subseteq \Omega$ be compact and let $\varphi \in \mathcal{D}_K(\Omega)$. Since φ vanishes outside K, we have

$$T_\mu(\varphi) = \int_K \varphi \, d\mu.$$

Let $|\mu|$ be the total variation[2] of μ. Then

$$|T_\mu(\varphi)| = \left| \int_K \varphi \, d\mu \right| \le \int_K |\varphi| \, d|\mu|.$$

Since $|\varphi(x)| \le \|\varphi\|_{K,0}$ for every $x \in K$, we obtain

$$|T_\mu(\varphi)| \le \|\varphi\|_{K,0} \int_K d|\mu| = |\mu|(K) \, \|\varphi\|_{K,0}.$$

Defining

$$c_K := |\mu|(K),$$

we obtain

$$|T_\mu(\varphi)| \le c_K \|\varphi\|_{K,0}.$$

By the definition of the order of a distribution, we conclude that

$$\operatorname{ord}(T_\mu) = 0.$$

It turns out that all distributions of order 0 can be identified with measures.

Theorem 4.6.3. Let $\Omega \subseteq \mathbb{R}^n$ be an open set and let $T \in \mathcal{D}'(\Omega)$.

(a) If T is positive, that is, if

$$T(\varphi) \geq 0, \qquad \forall \varphi \in \mathcal{D}(\Omega) \text{ with } \varphi \geq 0,$$

then there exists a unique positive Radon measure $\mu\colon \mathcal{B}(\Omega) \longrightarrow [0,\infty]$ such that

$$T(\varphi) = \int_\Omega \varphi \, d\mu, \qquad \forall \varphi \in \mathcal{D}(\Omega).$$

(b) If T has order 0, then there exist two positive Radon measures

$$\mu_1, \mu_2\colon \mathcal{B}(\Omega) \longrightarrow [0,\infty]$$

such that

$$T(\varphi) = \int_\Omega \varphi \, d\mu_1 - \int_\Omega \varphi \, d\mu_2, \qquad \forall \varphi \in \mathcal{D}(\Omega).$$

Proof. Recall that $C_c(\Omega)$ is equipped with the strict inductive limit topology

$$C_c(\Omega) = \varinjlim_{i\in\mathbb{N}} C_{K_i}(\Omega),$$

where $\{K_i\}_{i\in\mathbb{N}}$ is an increasing exhaustion of Ω by compact sets and

$$C_{K_i}(\Omega) := \{u \in C_c(\Omega) \mid \operatorname{supp}(u) \subseteq K_i\}$$

is equipped with the uniform norm

$$\|u\|_{K_i,\infty} := \|u\|_{C^0(K_i)}.$$

In particular, a linear functional $L\colon C_c(\Omega) \longrightarrow \mathbb{R}$ is continuous if and only if for every compact set $K \subset \Omega$ there exists a constant $C_K > 0$ such that

$$|L(u)| \leq C_K \|u\|_{K,\infty}, \qquad \forall u \in C_c(\Omega) \text{ with } \operatorname{supp}(u) \subset K.$$

[1] A *signed measure* on Ω is a function $\mu\colon \mathcal{B}(\Omega) \longrightarrow [-\infty,\infty]$ defined on the Borel σ-algebra $\mathcal{B}(\Omega)$ such that $\mu(\varnothing) = 0$, taking at most one of the values ∞ and $-\infty$, and satisfying $\mu\left(\bigcup_{k=1}^\infty E_k\right) = \sum_{k=1}^\infty \mu(E_k)$ for every countable family $\{E_k\}_{k\in\mathbb{N}} \subseteq \mathcal{B}(\Omega)$ of disjoint sets. This is the global notion of Definition B.5.19. To be Radon, its positive and negative variations must additionally be Radon; see Definition B.5.22.

[2] Let μ be a signed measure. Its *total variation* is the positive measure $|\mu|\colon \mathcal{B}(\Omega) \longrightarrow [0,\infty]$ defined by

$$|\mu|(E) = \sup\left\{ \sum_{k=1}^\infty |\mu(E_k)| \;\middle|\; E = \bigcup_{k=1}^\infty E_k,\ E_k \in \mathcal{B}(\Omega),\ E_i \cap E_j = \varnothing,\ i \neq j \right\}.$$

Equivalently, if $\mu = \mu^+ - \mu^-$ is the Jordan decomposition of μ, then $|\mu| = \mu^+ + \mu^-$.

(a) First suppose that T is positive. We will show that T has order 0.

Let $K \subset \Omega$ be compact. Take a bounded open set $U \subset \Omega$ such that

$$K \subset U \subset \overline{U} \subset \Omega.$$

Consider a cutoff function $\psi \in C^\infty(\Omega)$ such that

$$\psi \equiv 1 \text{ in } K, \qquad \operatorname{supp}(\psi) \subset U, \qquad 0 \le \psi \le 1.$$

In particular, $\psi \in \mathcal{D}(\Omega)$.

Now let $\varphi \in \mathcal{D}_K(\Omega)$. Since $\psi \equiv 1$ on K and $\operatorname{supp}(\varphi) \subset K$, we have

$$|\varphi(x)| \le \|\varphi\|_{K,0}\psi(x), \qquad \forall x \in \Omega.$$

It follows that

$$\|\varphi\|_{K,0}\psi - \varphi \ge 0, \qquad \|\varphi\|_{K,0}\psi + \varphi \ge 0.$$

Since T is positive,

$$T(\|\varphi\|_{K,0}\psi - \varphi) \ge 0, \qquad T(\|\varphi\|_{K,0}\psi + \varphi) \ge 0.$$

By linearity,

$$-\|\varphi\|_{K,0}T(\psi) \le T(\varphi) \le \|\varphi\|_{K,0}T(\psi),$$

and therefore

$$|T(\varphi)| \le T(\psi)\|\varphi\|_{K,0}, \qquad \forall \varphi \in \mathcal{D}_K(\Omega).$$

This shows that T has order 0.

Now take a sequence of bounded open sets $\{\Omega_i\}_{i\in\mathbb{N}}$ such that

$$\Omega_i \Subset \Omega_{i+1}, \qquad \bigcup_{i=1}^{\infty} \Omega_i = \Omega,$$

and define $K_i := \overline{\Omega_i}$. Then each K_i is compact and $K_i \subset \Omega$.

Since T has order 0, for each i there exists $c_i > 0$ such that

$$|T(\varphi)| \le c_i\|\varphi\|_{K_i,0}, \qquad \forall \varphi \in \mathcal{D}_{K_i}(\Omega). \tag{4.3}$$

Let $u \in C_c(\Omega_i)$. Since $\operatorname{supp}(u)$ is compact and contained in Ω_i, there exists a sequence

$$u_k \in \mathcal{D}_{K_i}(\Omega)$$

such that

$$u_k \to u$$

uniformly on K_i.

By (4.3),

$$|T(u_k - u_\ell)| \le c_i \|u_k - u_\ell\|_{K_i,0} \to 0 \qquad (k,\ell \to \infty).$$

Consequently, $\{T(u_k)\}$ is Cauchy in $\mathbb{R}$, and we define

$$T_i(u) := \lim_{k\to\infty} T(u_k).$$

We show that this definition does not depend on the approximating sequence. Suppose that

$$v_k \in \mathcal{D}_{K_i}(\Omega), \qquad v_k \to u$$

uniformly on K_i. Then

$$|T(u_k - v_k)| \le c_i \|u_k - v_k\|_{K_i,0} \le c_i \left(\|u_k - u\|_{K_i,0} + \|u - v_k\|_{K_i,0}\right) \to 0,$$

and it follows that

$$\lim_{k\to\infty} T(u_k) = \lim_{k\to\infty} T(v_k).$$

Therefore, $T_i(u)$ is well defined.

Now let $u, v \in C_c(\Omega_i)$ and $\alpha, \beta \in \mathbb{R}$. Take sequences

$$u_k \to u, \qquad v_k \to v$$

uniformly on K_i, with

$$u_k, v_k \in \mathcal{D}_{K_i}(\Omega).$$

Then

$$\alpha u_k + \beta v_k \to \alpha u + \beta v$$

uniformly on K_i, and by linearity of T we obtain

$$T_i(\alpha u + \beta v) = \lim_{k\to\infty} T(\alpha u_k + \beta v_k) = \alpha T_i(u) + \beta T_i(v).$$

Thus, T_i is linear.

Moreover, if $u \ge 0$, we can choose an approximating sequence $u_k \ge 0$. Then

$$T(u_k) \ge 0,$$

and passing to the limit gives

$$T_i(u) \ge 0.$$

Therefore, T_i is positive.

Passing to the limit in (4.3) gives

$$|T_i(u)| \le c_i \|u\|_{K_i,0}, \qquad \forall u \in C_c(\Omega_i),$$

and consequently T_i is continuous with respect to the uniform norm.

If $u \in C_c(\Omega_i)$, any approximating sequence valid for T_i is also valid for T_{i+1}, so

$$T_{i+1}(u) = T_i(u).$$

Thus the functionals T_i are compatible and define a linear functional

$$L\colon C_c(\Omega) \longrightarrow \mathbb{R}$$

given by

$$L(u) = T_i(u) \qquad (u \in C_c(\Omega_i)).$$

Now let $K \subset \Omega$ be compact. Choose i such that $K \subset \Omega_i$. If $\operatorname{supp}(u) \subset K$, then

$$|L(u)| = |T_i(u)| \le c_i \|u\|_{K_i,0} = c_i \|u\|_{K,0}.$$

This shows that L is locally bounded and therefore continuous on $C_c(\Omega)$.

Applying the Riesz representation theorem (Theorem B.5.23), we obtain a unique positive Radon measure μ such that

$$L(u) = \int_\Omega u \, d\mu, \qquad \forall u \in C_c(\Omega).$$

Since L extends T, we conclude that

$$T(\varphi) = \int_\Omega \varphi \, d\mu, \qquad \forall \varphi \in \mathcal{D}(\Omega).$$

(b) Now suppose that T has order 0. Then, for every compact set $K \subset \Omega$ there exists $C_K > 0$ such that

$$|T(\varphi)| \le C_K \|\varphi\|_{K,0}, \qquad \forall \varphi \in \mathcal{D}_K(\Omega).$$

Repeating the preceding procedure, we obtain mutually compatible continuous linear functionals

$$T_i\colon C_c(\Omega_i) \longrightarrow \mathbb{R}$$

inducing a linear functional

$$L\colon C_c(\Omega) \longrightarrow \mathbb{R}$$

that extends T.

Moreover, the same argument shows that L is locally bounded. Since Ω is locally compact, Hausdorff, and σ-compact, part (b) of Theorem B.5.23 directly provides two positive Radon measures μ_1, μ_2 such that

$$L(u) = \int_\Omega u \, d\mu_1 - \int_\Omega u \, d\mu_2, \qquad \forall u \in C_c(\Omega).$$

Each integral is finite because u has compact support. The difference of the measures need not be defined on every Borel subset of Ω; the representation is understood in the local sense of Definition B.5.22. Therefore,

$$T(\varphi) = \int_\Omega \varphi \, d\mu_1 - \int_\Omega \varphi \, d\mu_2, \qquad \forall \varphi \in \mathcal{D}(\Omega).$$

□

4.7 Distributional derivatives

The notion of a weak derivative motivated the concept of a distribution because, as we saw earlier, some functions have no weak derivatives but are *sufficiently well behaved* in the sense that they should admit some kind of *generalized* derivative. The concept of a distribution will allow us to extend the notion of a derivative as follows:

Definition 4.7.1. Let $\Omega \subseteq \mathbb{R}^n$ be an open set and let $T \in \mathcal{D}'(\Omega)$. Given a multi-index $\alpha \in \mathbb{N}_0^n \setminus \{0\}$, we define the αth *distributional* derivative of T by

$$D^\alpha T(\varphi) := (-1)^{|\alpha|} T(D^\alpha \varphi), \qquad \varphi \in \mathcal{D}(\Omega).$$

For $j \in \mathbb{N}$, the symbol $\nabla^j T$ represents the collection of all αth distributional derivatives of T with $|\alpha| = j$.

Remark 4.7.2. Naturally, the αth distributional derivative of a distribution T must again be a distribution. To prove this, note that by Theorem 4.5.1, if $T \in \mathcal{D}'(\Omega)$ and $K \subseteq \Omega$ is compact, then there exist $j \in \mathbb{N}_0$ and a constant $c_K > 0$ such that

$$|T(\varphi)| \leq c_K \|\varphi\|_{C^j(K)}, \qquad \forall \varphi \in \mathcal{D}_K(\Omega).$$

Then

$$|D^\alpha T(\varphi)| = |T(D^\alpha \varphi)| \leq c_K \|D^\alpha \varphi\|_{C^j(K)} \leq c_K \|\varphi\|_{C^{j+|\alpha|}(K)}, \qquad \forall \varphi \in \mathcal{D}_K(\Omega).$$

Again by Theorem 4.5.1, we obtain $D^\alpha T \in \mathcal{D}'(\Omega)$.
Moreover, this estimate allows us to control the order of the distributional derivative. If T has finite order $m = \operatorname{ord}(T)$, taking $j = m$ in the preceding inequality gives

$$\operatorname{ord}(D^\alpha T) \leq m + |\alpha|.$$

If T does not have finite order, then $\operatorname{ord}(T) = \infty$ and the preceding inequality remains valid in $\mathbb{N}_0 \cup \{\infty\}$, since

$$\operatorname{ord}(D^\alpha T) \leq \infty = \infty + |\alpha|.$$

In particular, if $u \in L^1_{\mathrm{loc}}(\Omega)$, T_u is the distribution induced by u, and α is a multi-index, then the αth weak derivative of u, $D^\alpha u \in L^1_{\mathrm{loc}}(\Omega)$ (if it exists), has the property that its induced distribution $T_{D^\alpha u} \in \mathcal{D}'(\Omega)$ is the αth distributional derivative of T_u, that is,

$$D^\alpha T_u = T_{D^\alpha u}.$$

If $\varphi \in \mathcal{D}(\Omega)$, then by definition of distributional derivative

$$D^\alpha T_u(\varphi) = (-1)^{|\alpha|} T_u(D^\alpha \varphi) = (-1)^{|\alpha|} \int_\Omega u\, D^\alpha \varphi.$$

Since $D^\alpha u$ is the weak derivative of u, we have

$$\int_\Omega u\, D^\alpha \varphi = (-1)^{|\alpha|} \int_\Omega D^\alpha u\, \varphi,$$

and therefore

$$D^\alpha T_u(\varphi) = \int_\Omega D^\alpha u\, \varphi = T_{D^\alpha u}(\varphi).$$

Since this holds for every $\varphi \in \mathcal{D}(\Omega)$, we conclude that

$$D^\alpha T_u = T_{D^\alpha u}.$$

Directional derivatives extend similarly:

Definition 4.7.3. Let $\Omega \subseteq \mathbb{R}^n$ be an open set and let $T \in \mathcal{D}'(\Omega)$. Given a vector $\nu \in \mathbb{R}^n \setminus \{0\}$, we define the kth directional derivative of T in the direction of ν by

$$\frac{\partial^k T}{\partial \nu^k}(\varphi) := (-1)^k T\left(\frac{\partial^k \varphi}{\partial \nu^k}\right), \qquad \varphi \in \mathcal{D}(\Omega).$$

In particular, if $u \in L^1_{\mathrm{loc}}(\Omega)$, $\nu \in \mathbb{R}^n \setminus \{0\}$, and $k \in \mathbb{N}$, then the kth weak or distributional directional derivative of u in the direction ν is the distribution

$$\frac{\partial^k T_u}{\partial \nu^k} \in \mathcal{D}'(\Omega).$$

Other differential operators, such as the Laplacian, admit extensions to the distributional sense.

Example 4.7.4. Let $\Omega \subseteq \mathbb{R}^n$ be an open set and let $u \in L^1_{\mathrm{loc}}(\Omega)$. The Laplacian of u in the distributional sense is defined as the distribution

$$T_{\Delta u} := \sum_{i=1}^n \partial_i^2 T_u.$$

In other words, for each $\varphi \in \mathcal{D}(\Omega)$ we have

$$\begin{aligned} T_{\Delta u}(\varphi) &= \sum_{i=1}^n \partial_i^2 T_u(\varphi) = \sum_{i=1}^n T_u(\partial_i^2 \varphi) \\ &= \sum_{i=1}^n \int_\Omega u\, \partial_i^2 \varphi = \int_\Omega u\, \Delta \varphi. \end{aligned}$$

We say that u is *subharmonic* on Ω if its distributional Laplacian is positive, that is, if

$$T_{\Delta u}(\varphi) \geq 0, \qquad \forall \varphi \in \mathcal{D}(\Omega) \text{ with } \varphi \geq 0.$$

In this case, $T_{\Delta u}$ is a positive distribution. By Theorem 4.6.3, every positive distribution is a positive Radon measure. Therefore, there exists a unique positive Radon measure μ on Ω such that

$$T_{\Delta u}(\varphi) = \int_\Omega \varphi\, d\mu, \qquad \forall \varphi \in \mathcal{D}(\Omega).$$

Consequently, the distributional Laplacian of a subharmonic function can be identified with a positive Radon measure.

Example 4.7.5. Let $\Omega \subseteq \mathbb{R}^n$ be an open set and let $F = (F_1, \dots, F_n) \in L^1_{\text{loc}}(\Omega, \mathbb{R}^n)$. The divergence of F in the distributional sense is defined as the distribution

$$T_{\operatorname{div} F} := \sum_{i=1}^{n} \partial_i T_{F_i}.$$

In other words, for each $\varphi \in \mathcal{D}(\Omega)$ we have

$$\begin{aligned} T_{\operatorname{div} F}(\varphi) &= \sum_{i=1}^{n} \partial_i T_{F_i}(\varphi) = -\sum_{i=1}^{n} T_{F_i}(\partial_i \varphi) \\ &= -\sum_{i=1}^{n} \int_\Omega F_i \, \partial_i \varphi = -\int_\Omega F \cdot \nabla \varphi. \end{aligned}$$

Exercise 4.7.6. Let $u : \mathbb{R} \longrightarrow \mathbb{R}$ be defined by

$$u(x) := \begin{cases} \cos(x), & \text{if } -\pi \le x \le 0, \\ 1 - \dfrac{x}{\pi}, & \text{if } 0 < x \le \pi, \\ 0, & \text{otherwise.} \end{cases}$$

(a) Compute the derivative of u in the distributional sense and find its order.

(b) Let $v := u \restriction_{(-\pi,\pi)}$. Compute the first and second derivatives of v in the distributional sense on $(-\pi, \pi)$ and find their orders.

(c) Let $w : \mathbb{R} \longrightarrow \mathbb{R}$ be differentiable on $\mathbb{R} \setminus \{a\}$ and suppose that

$$\lim_{x \to a^-} w(x), \qquad \lim_{x \to a^+} w(x).$$

exist. Compute the derivative of w in the distributional sense. What can you say about its order? Under what conditions can one conclude that it has order 0?

Solution. (a) Let $\varphi \in \mathcal{D}(\mathbb{R})$. Since $u \in L^1_{\text{loc}}(\mathbb{R})$, the function u induces a distribution

$$T_u : \mathcal{D}(\mathbb{R}) \longrightarrow \mathbb{R}, \qquad T_u(\varphi) := \int_{\mathbb{R}} u(x)\varphi(x)\, dx.$$

By definition of distributional derivative,

$$T_u'(\varphi) := -T_u(\varphi') = -\int_{\mathbb{R}} u(x)\varphi'(x)\, dx.$$

Since u is given by different expressions on $[-\pi, 0]$ and on $(0, \pi]$, we have

$$T_u'(\varphi) = -\int_{-\pi}^{0} \cos(x)\varphi'(x)\,dx - \int_{0}^{\pi} \left(1 - \frac{x}{\pi}\right)\varphi'(x)\,dx.$$

We integrate each term by parts. For the first,

$$\begin{aligned} -\int_{-\pi}^{0} \cos(x)\varphi'(x)\,dx &= -\Big[\cos(x)\varphi(x)\Big]_{-\pi}^{0} + \int_{-\pi}^{0} (-\sin x)\varphi(x)\,dx \\ &= -\varphi(0) - \varphi(-\pi) + \int_{-\pi}^{0} (-\sin x)\varphi(x)\,dx, \end{aligned}$$

since $\cos(0) = 1$ and $\cos(-\pi) = -1$.

For the second term,

$$-\int_{0}^{\pi} \left(1 - \frac{x}{\pi}\right)\varphi'(x)\,dx = -\Big[\left(1 - \frac{x}{\pi}\right)\varphi(x)\Big]_{0}^{\pi} - \frac{1}{\pi}\int_{0}^{\pi} \varphi(x)\,dx$$

$$= \varphi(0) - \frac{1}{\pi}\int_{0}^{\pi} \varphi(x)\,dx.$$

Adding the two expressions gives

$$T_u'(\varphi) = -\varphi(-\pi) + \int_{-\pi}^{0} (-\sin x)\varphi(x)\,dx - \frac{1}{\pi}\int_{0}^{\pi} \varphi(x)\,dx.$$

This can be written as

$$T_u'(\varphi) = T_f(\varphi) - \delta_{-\pi}(\varphi),$$

where $f : \mathbb{R} \longrightarrow \mathbb{R}$ is given by

$$f(x) := \begin{cases} -\sin x, & \text{if } -\pi < x < 0, \\ -\dfrac{1}{\pi}, & \text{if } 0 < x < \pi, \\ 0, & \text{otherwise.} \end{cases}$$

Therefore,

$$T_u' = T_f - \delta_{-\pi}.$$

In other words,

$$u' = f - \delta_{-\pi}$$

in the distributional sense.

We now determine its order. Since $f \in L^1_{\text{loc}}(\mathbb{R})$, the distribution T_f has order 0. Moreover, $\delta_{-\pi}$ also has order 0. It follows that u', being a sum of distributions of order 0, is a distribution of order 0.

(b) Now consider $v := u \restriction_{(-\pi,\pi)}$. Then

$$v(x) = \begin{cases} \cos(x), & \text{if } -\pi < x \le 0, \\ 1 - \dfrac{x}{\pi}, & \text{if } 0 < x < \pi. \end{cases}$$

Moreover,

$$\lim_{x\to 0^-} v(x) = \cos(0) = 1 \qquad \text{and} \qquad \lim_{x\to 0^+} v(x) = 1 - \frac{0}{\pi} = 1,$$

so v is continuous at 0. In particular, $v \in L^1_{\text{loc}}((-\pi,\pi))$, and therefore it induces a distribution

$$T_v \colon \mathcal{D}((-\pi,\pi)) \longrightarrow \mathbb{R}, \qquad T_v(\varphi) := \int_{-\pi}^{\pi} v(x)\varphi(x)\,dx.$$

We compute its first distributional derivative. Let $\varphi \in \mathcal{D}((-\pi,\pi))$. By definition,

$$T_v'(\varphi) := -T_v(\varphi') = -\int_{-\pi}^{\pi} v(x)\varphi'(x)\,dx.$$

Splitting the integral according to the definition of v gives

$$T_v'(\varphi) = -\int_{-\pi}^{0} \cos(x)\varphi'(x)\,dx - \int_{0}^{\pi} \left(1 - \frac{x}{\pi}\right)\varphi'(x)\,dx.$$

We integrate by parts on each interval. For the first,

$$\begin{aligned} -\int_{-\pi}^{0} \cos(x)\varphi'(x)\,dx &= -\Big[\cos(x)\varphi(x)\Big]_{-\pi}^{0} + \int_{-\pi}^{0} (-\sin x)\varphi(x)\,dx \\ &= -\varphi(0) - \varphi(-\pi) + \int_{-\pi}^{0} (-\sin x)\varphi(x)\,dx. \end{aligned}$$

Now, since $\varphi \in \mathcal{D}((-\pi,\pi))$, we have $\varphi(-\pi) = 0$. Consequently,

$$-\int_{-\pi}^{0} \cos(x)\varphi'(x)\,dx = -\varphi(0) + \int_{-\pi}^{0} (-\sin x)\varphi(x)\,dx.$$

For the second term,

$$\begin{aligned} -\int_{0}^{\pi} \left(1 - \frac{x}{\pi}\right)\varphi'(x)\,dx &= -\left[\left(1 - \frac{x}{\pi}\right)\varphi(x)\right]_{0}^{\pi} - \frac{1}{\pi}\int_{0}^{\pi} \varphi(x)\,dx \\ &= \varphi(0) - \frac{1}{\pi}\int_{0}^{\pi} \varphi(x)\,dx, \end{aligned}$$

since $\left(1 - \frac{\pi}{\pi}\right)\varphi(\pi) = 0$.

Adding the two expressions, the terms at $\varphi(0)$ cancel and we obtain

$$T_v'(\varphi) = \int_{-\pi}^{0} (-\sin x)\varphi(x)\,dx - \frac{1}{\pi}\int_{0}^{\pi} \varphi(x)\,dx.$$

This can be written as

$$T_v'(\varphi) = \int_{-\pi}^{\pi} g(x)\varphi(x)\,dx,$$

where

$$g(x) := \begin{cases} -\sin x, & \text{if } -\pi < x < 0, \\ -\dfrac{1}{\pi}, & \text{if } 0 < x < \pi. \end{cases}$$

Therefore,

$$T_v' = T_g.$$

Consequently,

$$v' = \begin{cases} -\sin x, & \text{if } -\pi < x < 0, \\ -\dfrac{1}{\pi}, & \text{if } 0 < x < \pi, \end{cases} \qquad \text{in the distributional sense.}$$

Since $g \in L^1_{\mathrm{loc}}((-\pi,\pi))$, the distribution T_g has order 0. Consequently, v' is a distribution of order 0.

We now compute the second distributional derivative of v. Since $T_v' = T_g$, we have

$$T_v'' = (T_v')' = (T_g)'.$$

Let $\varphi \in \mathcal{D}((-\pi,\pi))$. Then

$$T_v''(\varphi) = T_g'(\varphi) = -T_g(\varphi') = -\int_{-\pi}^{0} (-\sin x)\varphi'(x)\,dx + \frac{1}{\pi}\int_0^{\pi} \varphi'(x)\,dx.$$

We integrate each term by parts. For the first,

$$-\int_{-\pi}^{0} (-\sin x)\varphi'(x)\,dx = -\Big[(-\sin x)\varphi(x)\Big]_{-\pi}^{0} + \int_{-\pi}^{0} (-\cos x)\varphi(x)\,dx.$$

Since $\sin(0) = 0$ and $\sin(-\pi) = 0$, the boundary term vanishes, so

$$-\int_{-\pi}^{0} (-\sin x)\varphi'(x)\,dx = \int_{-\pi}^{0} (-\cos x)\varphi(x)\,dx.$$

For the second term,

$$\frac{1}{\pi}\int_0^{\pi} \varphi'(x)\,dx = \frac{1}{\pi}\big[\varphi(x)\big]_0^{\pi} = -\frac{1}{\pi}\varphi(0),$$

since $\varphi(\pi) = 0$.

Substituting into the expression for $T_v''(\varphi)$ gives

$$T_v''(\varphi) = \int_{-\pi}^{0} (-\cos x)\varphi(x)\,dx - \frac{1}{\pi}\varphi(0).$$

This means that

$$T_v'' = T_h - \frac{1}{\pi}\delta_0,$$

where

$$h(x) := \begin{cases} -\cos x, & \text{if } -\pi < x < 0, \\ 0, & \text{if } 0 < x < \pi. \end{cases}$$

In other words,

$$v'' = \begin{cases} -\cos x, & \text{if } -\pi < x < 0, \\ 0, & \text{if } 0 < x < \pi, \end{cases} \; - \frac{1}{\pi}\delta_0$$

in the distributional sense.

We now examine its order. Since $h \in L^1_{\mathrm{loc}}((-\pi,\pi))$, the distribution T_h has order 0. Moreover, δ_0 has order 0, so v'' is a distribution of order 0.

(c) Now let $w\colon \mathbb{R} \longrightarrow \mathbb{R}$ be a function differentiable on $\mathbb{R}\setminus\{a\}$, and suppose that the one-sided limits

$$\lim_{x\to a^-} w(x) \qquad \text{and} \qquad \lim_{x\to a^+} w(x).$$

exist. We denote these limits by

$$w(a^-) := \lim_{x\to a^-} w(x), \qquad w(a^+) := \lim_{x\to a^+} w(x).$$

By hypothesis, both real numbers are well defined.

Since w is differentiable on $\mathbb{R}\setminus\{a\}$, it is in particular continuous on $(-\infty,a)$ and on (a,∞). Moreover, since the finite one-sided limits at a exist, the function w is locally bounded near a. It follows that

$$w \in L^1_{\mathrm{loc}}(\mathbb{R}),$$

and therefore w induces a distribution

$$T_w\colon \mathcal{D}(\mathbb{R}) \longrightarrow \mathbb{R}, \qquad T_w(\varphi) := \int_{\mathbb{R}} w(x)\varphi(x)\,dx.$$

We compute its distributional derivative. Let $\varphi \in \mathcal{D}(\mathbb{R})$. By definition,

$$T_w'(\varphi) := -T_w(\varphi') = -\int_{\mathbb{R}} w(x)\varphi'(x)\,dx.$$

We split the integral over the intervals $(-\infty,a)$ and (a,∞):

$$T_w'(\varphi) = -\int_{-\infty}^{a} w(x)\varphi'(x)\,dx - \int_{a}^{\infty} w(x)\varphi'(x)\,dx.$$

Suppose also that the classical derivative of w on $\mathbb{R}\setminus\{a\}$, denoted by w'_{cl}, belongs to $L^1_{\mathrm{loc}}(\mathbb{R})$ after being extended arbitrarily at the point a. We can then integrate by parts on each of the two preceding intervals. We obtain

$$\begin{aligned} -\int_{-\infty}^{a} w(x)\varphi'(x)\,dx &= -\Big[w(x)\varphi(x)\Big]_{-\infty}^{a} + \int_{-\infty}^{a} w'_{\mathrm{cl}}(x)\varphi(x)\,dx \\ &= -w(a^-)\varphi(a) + \int_{-\infty}^{a} w'_{\mathrm{cl}}(x)\varphi(x)\,dx, \end{aligned}$$

since φ has compact support.

Similarly,

$$\begin{aligned} -\int_{a}^{\infty} w(x)\varphi'(x)\,dx &= -\Big[w(x)\varphi(x)\Big]_{a}^{\infty} + \int_{a}^{\infty} w'_{\mathrm{cl}}(x)\varphi(x)\,dx \\ &= w(a^+)\varphi(a) + \int_{a}^{\infty} w'_{\mathrm{cl}}(x)\varphi(x)\,dx. \end{aligned}$$

Adding the two equalities gives

$$T_w'(\varphi) = \int_{-\infty}^{a} w_{\mathrm{cl}}'(x)\varphi(x)\,dx + \int_{a}^{\infty} w_{\mathrm{cl}}'(x)\varphi(x)\,dx + \big(w(a^+) - w(a^-)\big)\varphi(a).$$

Since a point has measure zero, we can write

$$\int_{-\infty}^{a} w_{\mathrm{cl}}'(x)\varphi(x)\,dx + \int_{a}^{\infty} w_{\mathrm{cl}}'(x)\varphi(x)\,dx = \int_{\mathbb{R}} w_{\mathrm{cl}}'(x)\varphi(x)\,dx.$$

Consequently,

$$T_w'(\varphi) = \int_{\mathbb{R}} w_{\mathrm{cl}}'(x)\varphi(x)\,dx + \big(w(a^+) - w(a^-)\big)\varphi(a),$$

that is,

$$T_w' = T_{w_{\mathrm{cl}}'} + \big(w(a^+) - w(a^-)\big)\delta_a.$$

In other words,

$$w' = w_{\mathrm{cl}}' + \big(w(a^+) - w(a^-)\big)\delta_a$$

in the distributional sense.

We now consider the order of T_w'. Since T_w is a distribution of order 0, Remark 4.7.2 implies that T_w' is a distribution of order at most 1.

If also $w_{\mathrm{cl}}' \in L^1_{\mathrm{loc}}(\mathbb{R})$, then $T_{w_{\mathrm{cl}}'}$ has order 0, and since δ_a also has order 0, we conclude that

$$T_w' = T_{w_{\mathrm{cl}}'} + \big(w(a^+) - w(a^-)\big)\delta_a$$

is a distribution of order 0.

In particular, this occurs if the two branches of w, extended at a with the values $w(a^-)$ and $w(a^+)$, are absolutely continuous on $[b,a]$ and $[a,c]$ for any $b < a < c$. The fundamental theorem of calculus for absolutely continuous functions gives integrability of $|w_{\mathrm{cl}}'|$ on (b,a) and on (a,c). Every compact subset of $\mathbb{R}$ is contained in some interval $[b,c]$ of this type, so $w_{\mathrm{cl}}' \in L^1_{\mathrm{loc}}(\mathbb{R})$. This condition controls the derivative as one approaches a; absolute continuity on compact intervals separated from a is insufficient for this.

□

After studying several examples of distributions obtained as derivatives, it is natural to ask to what extent every distribution admits such a representation. The following theorem gives a local answer:

Theorem 4.7.7. Let $\Omega \subseteq \mathbb{R}^n$ be open and let $T \in \mathcal{D}'(\Omega)$. Then for every compact set $K \subseteq \Omega$ there exist a continuous function $u\colon \Omega \longrightarrow \mathbb{R}$ and a multi-index α (both depending on K) such that

$$T(\varphi) = (-1)^{|\alpha|} \int_{\Omega} u D^{\alpha}\varphi, \qquad \forall \varphi \in \mathcal{D}_K(\Omega).$$

Proof. Let $K \subseteq \Omega$ be a fixed compact set. Since K is compact and Ω is open, there exists an open set U_0 such that $K \subseteq U_0 \Subset \Omega$. By Proposition 1.3.6, there exists $\chi \in C^{\infty}(\Omega)$ such that $\chi = 1$ on K and $\operatorname{supp}(\chi) \subseteq U_0$. In

particular, $\chi \in \mathcal{D}(\Omega)$. Define $S \in \mathcal{D}'(\mathbb{R}^n)$ by

$$S(\psi) := T\big((\chi\psi)\restriction_\Omega\big), \qquad \psi \in \mathcal{D}(\mathbb{R}^n).$$

Multiplication by χ and restriction to Ω are continuous on the corresponding test function spaces; therefore, S is a distribution. Moreover, $\operatorname{supp}(S) \subseteq \operatorname{supp}(\chi)$.
Choose a closed cube

$$Q = [a_1, b_1] \times \cdots \times [a_n, b_n] \subseteq \mathbb{R}^n$$

such that $\operatorname{supp}(\chi) \subseteq \operatorname{Int}(Q)$. This choice does not require Q to be contained in Ω. If $\varphi \in \mathcal{D}_K(\Omega)$ and $\widetilde{\varphi}$ denotes its extension by zero to $\mathbb{R}^n$, then $\widetilde{\varphi} \in \mathcal{D}_Q(\mathbb{R}^n)$ and

$$S(\widetilde{\varphi}) = T(\chi\varphi) = T(\varphi). \tag{4.4}$$

Denote by $\beta := (1, \dots, 1)$ the multi-index whose components are all equal to 1.
Now let $\psi \in \mathcal{D}_Q(\mathbb{R}^n)$. For $x \in Q$ define the subcube

$$Q(x) := \{y \in Q \mid a_i \le y_i \le x_i,\ i = 1, \dots, n\}.$$

Since $\psi \in \mathcal{D}_Q(\mathbb{R}^n)$, its support is contained in the closed cube Q. Since ψ is of class C^∞ and vanishes identically on $\mathbb{R}^n \setminus Q$, both ψ and all its partial derivatives must vanish on the boundary ∂Q. This ensures that when Theorem B.6.5 is applied in each variable, integrating from the lower endpoint a_i, the boundary terms vanish.
Theorem B.6.5, applied in the first variable, gives

$$\psi(x) = \psi(a_1, x_2, \dots, x_n) + \int_{a_1}^{x_1} \partial_1\psi(y_1, x_2, \dots, x_n)\, dy_1 = \int_{a_1}^{x_1} \partial_1\psi(y_1, x_2, \dots, x_n)\, dy_1.$$

Since $\partial_1\psi$ vanishes on ∂Q, it is in particular zero when the second coordinate is exactly a_2. This allows us to apply Theorem B.6.5 to the integrand with respect to the second variable without boundary terms appearing. Repeating this argument successively in each of the n variables—and using at each step the fact that the intermediate derivatives also vanish on the boundary of Q—gives the integral identity

$$\psi(x) = \int_{Q(x)} D^\beta\psi(y)\, dy, \qquad \forall x \in Q. \tag{4.5}$$

Since $S \in \mathcal{D}'(\mathbb{R}^n)$, the restriction of S to $\mathcal{D}_Q(\mathbb{R}^n)$ is continuous by Theorem 4.5.1. Therefore, there exist an integer $j \ge 0$ and a constant $C'_Q > 0$ such that

$$|S(\psi)| \le C'_Q \|\psi\|_{C^j(Q)}, \qquad \forall \psi \in \mathcal{D}_Q(\mathbb{R}^n),$$

where

$$\|\psi\|_{C^j(Q)} = \max_{|\alpha| \le j} \|D^\alpha\psi\|_{C^0(Q)}.$$

Now let α be a multi-index with $|\alpha| \le j$ and set $\gamma := (j+1)\beta - \alpha$. Since $\alpha_i \le j$, we have $\gamma_i \ge 1$ for every i. Applying the fundamental theorem of calculus γ_i times in the variable i and using the fact that all

intermediate derivatives vanish when $x_i = a_i$ gives

$$D^{\alpha}\psi(x) = \int_{a_1}^{x_1} \cdots \int_{a_n}^{x_n} \left(\prod_{i=1}^{n} \frac{(x_i - y_i)^{\gamma_i - 1}}{(\gamma_i - 1)!} \right) D^{(j+1)\beta}\psi(y)\, dy_n \cdots dy_1.$$

Indeed, for a single variable this is the repeated integration formula, proved by induction on γ_i; the displayed formula results from applying it successively in the n variables and using Fubini. Since $0 \le x_i - y_i \le b_i - a_i$ on the integration region, taking absolute values and enlarging that region to all of Q gives

$$|D^{\alpha}\psi(x)| \le C_{Q,\alpha} \int_Q |D^{(j+1)\beta}\psi(y)|\, dy,$$

where the constant

$$C_{Q,\alpha} := \prod_{i=1}^{n} \frac{(b_i - a_i)^{\gamma_i - 1}}{(\gamma_i - 1)!}$$

depends only on the side lengths of the cube Q and the multi-index $\gamma = (j+1)\beta - \alpha$. Taking the supremum over $x \in Q$, the maximum over $|\alpha| \le j$, and defining

$$C_Q := \max_{|\alpha| \le j} C_{Q,\alpha},$$

we deduce that

$$\|\psi\|_{C^j(Q)} \le C_Q \int_Q |D^{(j+1)\beta}\psi(y)|\, dy.$$

Consequently, absorbing C_Q into a new global constant $C := C'_Q C_Q$, we obtain the bound

$$|S(\psi)| \le C \int_Q |D^{(j+1)\beta}\psi(y)|\, dy, \qquad \forall \psi \in \mathcal{D}_Q(\mathbb{R}^n). \tag{4.6}$$

Now define the linear operator

$$L\colon \mathcal{D}_Q(\mathbb{R}^n) \longrightarrow L^1(Q), \qquad L(\psi) = D^{(j+1)\beta}\psi.$$

The operator L is injective. Indeed, suppose that $D^{(j+1)\beta}\psi = 0$. We will prove by descending induction that $D^{q\beta}\psi = 0$ for $q = j, j-1, \ldots, 0$. If $q = j$, identity (4.5), applied to $D^{j\beta}\psi$, gives $D^{j\beta}\psi = 0$ on Q. If $0 \le q < j$ and we already know that $D^{(q+1)\beta}\psi = 0$, the same identity, now applied to $D^{q\beta}\psi$, gives $D^{q\beta}\psi = 0$. Upon reaching $q = 0$ we obtain $\psi = 0$ on Q; the argument also directly covers the case $j = 0$. All applications are legitimate because the derivatives of ψ belong to $\mathcal{D}_Q(\mathbb{R}^n)$ and hence vanish on ∂Q. Outside Q the function ψ is already zero, so $\psi = 0$ on $\mathbb{R}^n$.

Let $Y := L(\mathcal{D}_Q(\mathbb{R}^n))$ be the image of L. Define a linear functional $T_1 : Y \longrightarrow \mathbb{R}$ by $T_1(L(\psi)) := S(\psi)$. Injectivity of L ensures that T_1 is well defined. Moreover, by (4.6),

$$|T_1(w)| \le C\|w\|_{L^1(Q)}, \qquad \forall w \in Y.$$

By the analytic form of the Hahn–Banach theorem (Theorem B.2.27), we can extend T_1 to a continuous linear functional on all of $L^1(Q)$. Since the dual space $(L^1(Q))^*$ is isometrically identified with $L^\infty(Q)$ with

respect to Lebesgue measure, there exists a function $v \in L^\infty(Q)$ such that

$$T_1(\psi) = \int_Q v\psi, \qquad \forall \psi \in L^1(Q).$$

In particular, for $\psi \in \mathcal{D}_Q(\mathbb{R}^n)$ we obtain

$$S(\psi) = \int_Q v D^{(j+1)\beta}\psi.$$

Extend v by zero outside Q and define

$$u_0(x) = \int_{-\infty}^{x_1} \cdots \int_{-\infty}^{x_n} v(y_1, \ldots, y_n)\, dy_n \cdots dy_1.$$

Since v is bounded and has compact support, the function u_0 is well defined. Moreover, if $x, x' \in \mathbb{R}^n$, the symmetric difference between the regions $\{y \in Q : y \le x\}$ and $\{y \in Q : y \le x'\}$ is contained in the union of n strips whose measures tend to zero as $x' \to x$. Consequently,

$$|u_0(x') - u_0(x)| \le \|v\|_{L^\infty(Q)} \lambda_n\big(\{y \in Q : y \le x'\} \triangle \{y \in Q : y \le x\}\big) \longrightarrow 0,$$

and u_0 is continuous on $\mathbb{R}^n$. We check that it satisfies the distributional equation $D^\beta u_0 = v$. For any test function $\varphi \in \mathcal{D}(\mathbb{R}^n)$, we evaluate the dual action:

$$\begin{aligned}\langle D^\beta u_0, \varphi\rangle &= (-1)^{|\beta|} \int_{\mathbb{R}^n} u_0(x)\, D^\beta\varphi(x)\, dx \\ &= (-1)^n \int_{\mathbb{R}^n} \left(\int_{\{y \le x\}} v(y_1, \ldots, y_n)\, dy_1 \cdots dy_n \right) D^\beta\varphi(x)\, dx,\end{aligned}$$

where the notation $y \le x$ means $y_i \le x_i$ for every i. By Theorem B.6.18, we interchange the order of integration; for fixed y, the variable x ranges over the domain $\{x \ge y\}$:

$$\langle D^\beta u_0, \varphi\rangle = (-1)^n \int_{\mathbb{R}^n} v(y_1, \ldots, y_n) \left(\int_{\{x \ge y\}} D^\beta\varphi(x)\, dx \right) dy_1 \cdots dy_n.$$

Integrating $D^\beta\varphi = \partial_1 \cdots \partial_n \varphi$ in each variable x_i from y_i to ∞ gives exactly $(-1)^n \varphi(y_1, \ldots, y_n)$ because φ has compact support. Therefore,

$$\langle D^\beta u_0, \varphi\rangle = (-1)^n \int_{\mathbb{R}^n} v(y_1, \ldots, y_n)(-1)^n\, \varphi(y_1, \ldots, y_n)\, dy_1 \cdots dy_n = \langle v, \varphi\rangle.$$

This proves that $D^\beta u_0 = v$ in the sense of distributions.
Substituting this fact into the preceding expression for $S(\psi)$ and using the definition of distributional derivative, we obtain, for every $\psi \in \mathcal{D}_Q(\mathbb{R}^n)$,

$$S(\psi) = \langle D^\beta u_0, D^{(j+1)\beta}\psi\rangle = (-1)^{|\beta|} \int_{\mathbb{R}^n} u_0\, D^{(j+2)\beta}\psi = (-1)^n \int_{\mathbb{R}^n} u_0\, D^{(j+2)\beta}\psi.$$

Now define the multi-index $\alpha := (j+2)\beta$, so that $|\alpha| = (j+2)n$. To adjust the sign, define the continuous

function

$$\widehat{u} := (-1)^{n-|\alpha|} u_0 = (-1)^{(j+1)n} u_0,$$

where in the second equality we used $n - |\alpha| = -(j+1)n$ and $(-1)^{-(j+1)n} = (-1)^{(j+1)n}$ (since an integer and its negative have the same parity). Let $u := \widehat{u}\,|_\Omega$. With this choice, we have $(-1)^{|\alpha|}\widehat{u} = (-1)^n u_0$. Finally, if $\varphi \in \mathcal{D}_K(\Omega)$, then, by (4.4) and because $\operatorname{supp}(D^\alpha \widetilde{\varphi}) \subseteq K \subseteq \Omega$,

$$T(\varphi) = S(\widetilde{\varphi}) = (-1)^{|\alpha|} \int_{\mathbb{R}^n} \widehat{u}\, D^\alpha \widetilde{\varphi} = (-1)^{|\alpha|} \int_\Omega u\, D^\alpha \varphi.$$

This completes the proof. □

4.8 Rapidly decreasing functions and the Schwartz class

Compactly supported test functions are suitable for studying local phenomena, but compact support is not preserved by the Fourier transform. To analyze a function and its frequencies simultaneously, it is helpful to replace this condition with one controlling behavior at infinity. The Schwartz class consists of smooth functions whose derivatives decrease faster than any power. Its topology records all these controls at once and will be the natural test function space for tempered distributions. The development in this section follows [97, Chapter 10, §§10.4–10.8], with the unitary Fourier normalization to be fixed below.

We work with complex-valued functions. Real-valued functions are viewed through their canonical inclusion into the complex-valued ones; whenever a real result is needed, it will suffice to restrict the resulting operators.

Definition 4.8.1. (Schwartz class) The *Schwartz class* on $\mathbb{R}^n$ is

$$\mathcal{S}(\mathbb{R}^n) := \left\{ \varphi \in C^\infty(\mathbb{R}^n, \mathbb{C}) \;\middle|\; p_{\alpha,\beta}(\varphi) < \infty \text{ for any } \alpha, \beta \in \mathbb{N}_0^n \right\},$$

where $p_{\alpha,\beta}(\varphi) := \sup_{x \in \mathbb{R}^n} |x^\alpha D^\beta \varphi(x)|$. For $N \in \mathbb{N}_0$ we also write

$$q_N(\varphi) := \max_{|\alpha|+|\beta| \le N} p_{\alpha,\beta}(\varphi).$$

We equip $\mathcal{S}(\mathbb{R}^n)$ with the locally convex topology generated by the countable family $(q_N)_{N \in \mathbb{N}_0}$.

The preceding condition is equivalent to saying that, for each $m \in \mathbb{N}_0$ and each multi-index β, the function $(1 + \|x\|)^m D^\beta \varphi(x)$ is bounded. In particular, $D^\beta \varphi(x) \to 0$ faster than $\|x\|^{-m}$ for any m. The function $x \mapsto e^{-\|x\|^2}$ belongs to $\mathcal{S}(\mathbb{R}^n)$ and does not have compact support, whereas $\mathcal{D}(\mathbb{R}^n) \subseteq \mathcal{S}(\mathbb{R}^n)$.

Proposition 4.8.2. (Equivalent seminorms) For $N \in \mathbb{N}_0$ define

$$r_N(\varphi) := \max_{|\beta| \le N} \sup_{x \in \mathbb{R}^n} (1 + \|x\|)^N |D^\beta \varphi(x)|.$$

The families (q_N) and (r_N) generate the same topology on $\mathcal{S}(\mathbb{R}^n)$. More precisely, for each N there exist $M \in \mathbb{N}_0$ and positive constants c_N, C_N such that $q_N \le c_N r_N$ and $r_N \le C_N q_M$.

Proof. If $|\alpha|+|\beta| \le N$, then $|x^\alpha D^\beta \varphi(x)| \le (1+\|x\|)^N |D^\beta \varphi(x)|$, giving $q_N \le r_N$. For the reverse inequality, we use the fact that there exists a constant $C_N > 0$ such that

$$(1+\|x\|)^N \le C_N \sum_{|\alpha|\le N} |x^\alpha|, \qquad x \in \mathbb{R}^n.$$

This estimate is obtained by expanding $(1+|x_1|+\cdots+|x_n|)^N$ and observing that $\|x\| \le |x_1|+\cdots+|x_n|$. Therefore, $r_N(\varphi) \le C_N q_{2N}(\varphi)$. □

Theorem 4.8.3. (Fréchet structure of the Schwartz class) The space $\mathcal{S}(\mathbb{R}^n)$ is a Fréchet space. A sequence (φ_j) converges to φ in $\mathcal{S}(\mathbb{R}^n)$ if and only if $q_N(\varphi_j - \varphi) \to 0$ for every $N \in \mathbb{N}_0$.

Proof. By Proposition B.10.24, the countable family (q_N) induces an invariant metric compatible with the topology. It remains to check completeness. Let (φ_j) be a Cauchy sequence. For each pair of multi-indices α, β, the sequence $(x^\alpha D^\beta \varphi_j)_j$ is Cauchy in the Banach space $C_b(\mathbb{R}^n)$ and converges uniformly to a continuous function $g_{\alpha,\beta}$.
Set $\varphi := g_{0,0}$. For $i \in \{1,\dots,n\}$, $x \in \mathbb{R}^n$, and $t \in \mathbb{R}$, Theorem B.6.5 gives

$$\varphi_j(x+te_i) - \varphi_j(x) = \int_0^t D_i\varphi_j(x+se_i)\,ds.$$

Uniform convergence allows us to pass to the limit inside the integral and obtain

$$\varphi(x+te_i) - \varphi(x) = \int_0^t g_{0,e_i}(x+se_i)\,ds.$$

Thus, $D_i\varphi = g_{0,e_i}$. Repeating the argument, we conclude that $\varphi \in C^\infty(\mathbb{R}^n)$ and $D^\beta\varphi = g_{0,\beta}$ for every β. Since multiplication by x^α commutes with the uniform limit, $x^\alpha D^\beta \varphi = g_{\alpha,\beta}$ and therefore $\varphi \in \mathcal{S}(\mathbb{R}^n)$. Finally, $p_{\alpha,\beta}(\varphi_j - \varphi) \to 0$ for every α, β, proving convergence in $\mathcal{S}(\mathbb{R}^n)$. □

Proposition 4.8.4. (Continuous operations on $\mathcal{S}$) Let $\alpha \in \mathbb{N}_0^n$, $a \in \mathbb{R}^n$, and $A \in \mathrm{GL}(n,\mathbb{R})$. The maps

$$\varphi \longmapsto D^\alpha\varphi, \qquad \varphi \longmapsto x^\alpha\varphi, \qquad \varphi \longmapsto \varphi(\cdot - a), \qquad \varphi \longmapsto \varphi \circ A$$

are continuous linear endomorphisms of $\mathcal{S}(\mathbb{R}^n)$. Multiplication $\mathcal{S}(\mathbb{R}^n) \times \mathcal{S}(\mathbb{R}^n) \longrightarrow \mathcal{S}(\mathbb{R}^n)$ is bilinear and continuous.

Proof. The first two assertions follow directly from the definition. For translations, we use $\|x\| \le \|x-a\|+\|a\|$ and the binomial formula. If $A \in \mathrm{GL}(n,\mathbb{R})$, then

$$\|A^{-1}\|^{-1}\|x\| \le \|Ax\| \le \|A\|\|x\|, \qquad x \in \mathbb{R}^n.$$

The chain rule and these inequalities show that, for each pair of multi-indices α, β, there exists a constant

$C_{\alpha,\beta,A} > 0$, depending only on α, β, A, and the fixed Euclidean norm, such that

$$p_{\alpha,\beta}(\varphi \circ A) \le C_{\alpha,\beta,A} \max_{\substack{|\delta|=|\alpha| \\ |\gamma|=|\beta|}} p_{\delta,\gamma}(\varphi).$$

Indeed, $\|x\|^{|\alpha|} \le \|A^{-1}\|^{|\alpha|}\|Ax\|^{|\alpha|}$, the power $\|Ax\|^{|\alpha|}$ is bounded by a finite sum of monomials of degree $|\alpha|$, and each derivative of $\varphi \circ A$ is a finite linear combination of derivatives of φ of order $|\beta|$, with coefficients depending only on A. Finally, the Leibniz rule gives

$$x^\alpha D^\beta(\varphi\psi) = \sum_{\gamma \le \beta} \binom{\beta}{\gamma} (x^\alpha D^\gamma \varphi) D^{\beta-\gamma}\psi,$$

and each summand is controlled by a seminorm of φ and a seminorm of ψ. □

Proposition 4.8.5. (Density) The space $\mathcal{D}(\mathbb{R}^n)$ is dense in $\mathcal{S}(\mathbb{R}^n)$. Moreover, for every $1 \le p < \infty$, the inclusions

$$\mathcal{D}(\mathbb{R}^n) \subseteq \mathcal{S}(\mathbb{R}^n) \subseteq L^p(\mathbb{R}^n)$$

have dense image and the inclusion $\mathcal{S}(\mathbb{R}^n) \hookrightarrow L^p(\mathbb{R}^n)$ is continuous.

Proof. Take $\eta \in C_c^\infty(\mathbb{R}^n)$ with $0 \le \eta \le 1$ and $\eta = 1$ on $\overline{B}_{\mathrm{euc}}(0,1)$, and define $\eta_R(x) := \eta(\frac{x}{R})$. For $\varphi \in \mathcal{S}(\mathbb{R}^n)$, the function $\eta_R\varphi$ belongs to $\mathcal{D}(\mathbb{R}^n)$. The Leibniz rule shows that $D^\beta((1-\eta_R)\varphi)$ is a sum of terms of the form $R^{-|\gamma|}(D^\gamma\eta)(\frac{x}{R})D^{\beta-\gamma}\varphi(x)$. When $\gamma = 0$, the term vanishes on $\|x\| \le R$ and its seminorm tends to zero by the rapid decrease of φ; when $|\gamma| > 0$, it is supported in an annulus with radii comparable to R, and the same decrease absorbs any power of R. Consequently, $\eta_R\varphi \to \varphi$ in $\mathcal{S}(\mathbb{R}^n)$.
If $m > \frac{n}{p}$, then

$$\|\varphi\|_{L^p(\mathbb{R}^n)}^p \le r_m(\varphi)^p \int_{\mathbb{R}^n} (1+\|x\|)^{-mp}\, dx,$$

so the inclusion into $L^p(\mathbb{R}^n)$ is continuous. Density follows from $\mathcal{D}(\mathbb{R}^n) \subseteq \mathcal{S}(\mathbb{R}^n)$ and Proposition B.7.18. □

4.9 Tempered distributions

The topology of $\mathcal{S}$ makes it possible to impose controlled growth on a distribution. Unlike a general distribution, a tempered distribution can be Fourier transformed because the transform preserves the Schwartz class.

Definition 4.9.1. (Tempered distribution) A *tempered distribution* is a continuous linear functional $T : \mathcal{S}(\mathbb{R}^n) \longrightarrow \mathbb{C}$. The continuous dual of $\mathcal{S}(\mathbb{R}^n)$ is denoted by $\mathcal{S}'(\mathbb{R}^n)$ and is equipped, unless otherwise stated, with the weak-$*$ topology $\sigma(\mathcal{S}'(\mathbb{R}^n), \mathcal{S}(\mathbb{R}^n))$.

Proposition 4.9.2. (Continuity criterion) A linear functional $T : \mathcal{S}(\mathbb{R}^n) \longrightarrow \mathbb{C}$ belongs to $\mathcal{S}'(\mathbb{R}^n)$ if and only if there exist $N \in \mathbb{N}_0$ and $C > 0$ such that

$$|\langle T, \varphi\rangle| \le C q_N(\varphi) \qquad \text{for every } \varphi \in \mathcal{S}(\mathbb{R}^n).$$

Proof. Sufficiency is immediate. Suppose that T is continuous at the origin. There exists a basic neighborhood

$$U = \{\varphi \in \mathcal{S}(\mathbb{R}^n) \mid q_{N_1}(\varphi) < \varepsilon_1, \dots, q_{N_k}(\varphi) < \varepsilon_k\}$$

such that $|T(\varphi)| < 1$ for $\varphi \in U$. Since the seminorms q_N are increasing, if $N := \max_j N_j$ and $\varepsilon := \min_j \varepsilon_j$, then $q_N(\varphi) < \varepsilon$ implies $\varphi \in U$. For $q_N(\varphi) > 0$, we apply the preceding argument to $\frac{\varepsilon\varphi}{2q_N(\varphi)}$ and obtain $|T(\varphi)| \le 2\varepsilon^{-1} q_N(\varphi)$. If $q_N(\varphi) = 0$, then $\varphi = 0$. □

Proposition 4.9.3. (Natural inclusions) For every $1 \le p \le \infty$ there is a continuous injective linear embedding

$$L^p(\mathbb{R}^n) \hookrightarrow \mathcal{S}'(\mathbb{R}^n), \qquad f \longmapsto T_f, \qquad \langle T_f, \varphi\rangle := \int_{\mathbb{R}^n} f(x)\varphi(x)\,dx.$$

Every locally integrable function of at most polynomial growth also defines a tempered distribution. Every distribution with compact support is tempered.

Proof. Let p' be the conjugate exponent. By Hölder's inequality in Proposition B.7.9 and continuity of $\mathcal{S}(\mathbb{R}^n) \hookrightarrow L^{p'}(\mathbb{R}^n)$,

$$|\langle T_f, \varphi\rangle| \le \|f\|_{L^p(\mathbb{R}^n)} \|\varphi\|_{L^{p'}(\mathbb{R}^n)} \le C\|f\|_{L^p(\mathbb{R}^n)} q_N(\varphi)$$

for some N. Injectivity follows from Proposition B.6.20.
If $|f(x)| \le C(1 + \|x\|)^m$ almost everywhere, choose $N > m + n$ and estimate

$$\int_{\mathbb{R}^n} |f\varphi| \le C r_N(\varphi) \int_{\mathbb{R}^n} (1 + \|x\|)^{m-N}\,dx.$$

For the last assertion, let $T \in \mathcal{D}'(\mathbb{R}^n)$ have compact support K. Choose $\chi \in \mathcal{D}(\mathbb{R}^n)$ equal to one on a neighborhood of K and define, for $\varphi \in \mathcal{S}(\mathbb{R}^n)$,

$$\langle \widetilde{T}, \varphi\rangle := \langle T, \chi\varphi\rangle.$$

The definition does not depend on the cutoff: if χ_1 and χ_2 equal one near K, then $(\chi_1 - \chi_2)\varphi$ vanishes on a neighborhood of $\operatorname{supp}(T)$ and, by definition of the support of a distribution, $\langle T, (\chi_1 - \chi_2)\varphi\rangle = 0$. By the local finite-order estimate for T on $\operatorname{supp}(\chi)$, there exist $C > 0$ and $N \in \mathbb{N}_0$ such that

$$|\langle \widetilde{T}, \varphi\rangle| \le C \max_{|\alpha| \le N} \|D^\alpha(\chi\varphi)\|_{C^0(\operatorname{supp}(\chi))} \le C_\chi q_N(\varphi).$$

Thus, $\widetilde{T} \in \mathcal{S}'(\mathbb{R}^n)$ and its restriction to $\mathcal{D}(\mathbb{R}^n)$ agrees with T. □

Example 4.9.4. Every polynomial defines a tempered distribution. More generally, if μ is a Radon measure for which there exist $C, m > 0$ with $|\mu|(B_{\mathrm{euc}}(0,R)) \le C(1+R)^m$ for $R \ge 1$, then $\langle T_\mu, \varphi\rangle := \int \varphi\,d\mu$ defines an element of $\mathcal{S}'(\mathbb{R}^n)$. To see this, decompose $\mathbb{R}^n$ into the unit ball and the annuli $k \le \|x\| < k+1$; the growth of μ is absorbed by a seminorm $r_N(\varphi)$ with $N > m + 1$.

Definition 4.9.5. (Differentiation and multiplication) Let $T \in \mathcal{S}'(\mathbb{R}^n)$ and $\alpha \in \mathbb{N}_0^n$. Define

$$\langle D^\alpha T, \varphi\rangle := (-1)^{|\alpha|}\langle T, D^\alpha\varphi\rangle, \qquad \langle x^\alpha T, \varphi\rangle := \langle T, x^\alpha\varphi\rangle.$$

Both functionals belong to $\mathcal{S}'(\mathbb{R}^n)$.

The final assertion follows from continuity of the operations in Proposition 4.8.4. The same argument allows us to multiply T by any function $a \in C^\infty(\mathbb{R}^n)$ whose derivatives have at most polynomial growth: the Leibniz rule shows that $\varphi \mapsto a\varphi$ is continuous on $\mathcal{S}(\mathbb{R}^n)$.

4.10 Convolution and regularization

Convolution connects regularization by mollifiers with multiplication in frequency. We first recall the inequality ensuring its existence in the spaces $L^p(\mathbb{R}^n)$.

Theorem 4.10.1. (Young's inequality for convolutions) Let $1 \le p, q, r \le \infty$ satisfy $\frac{1}{p} + \frac{1}{q} = 1 + \frac{1}{r}$. If $f \in L^p(\mathbb{R}^n)$ and $g \in L^q(\mathbb{R}^n)$, then $f * g$ is defined almost everywhere, belongs to $L^r(\mathbb{R}^n)$, and

$$\|f * g\|_{L^r(\mathbb{R}^n)} \le \|f\|_{L^p(\mathbb{R}^n)} \|g\|_{L^q(\mathbb{R}^n)}.$$

In particular, $L^1(\mathbb{R}^n) * L^p(\mathbb{R}^n) \subseteq L^p(\mathbb{R}^n)$ continuously.

Proof. The case $r = \infty$ is Proposition B.7.9 applied to $y \mapsto f(x-y)g(y)$. The case $p = 1$ follows from Theorem B.8.2 and translation invariance:

$$\|f * g\|_{L^q(\mathbb{R}^n)} \le \int_{\mathbb{R}^n} |f(y)| \, \|g(\cdot - y)\|_{L^q(\mathbb{R}^n)} \, dy = \|f\|_{L^1(\mathbb{R}^n)} \|g\|_{L^q(\mathbb{R}^n)}.$$

The case $q = 1$ follows by commutativity. In the other cases $1 < p, q \le r < \infty$; if $p = r$ or $q = r$, the factor whose conjugate exponent is infinite is omitted in the following application of Hölder. In the remaining case, we write

$$|f(x-y)g(y)| = \left(|f(x-y)|^p |g(y)|^q\right)^{\frac{1}{r}} |f(x-y)|^{1-\frac{p}{r}} |g(y)|^{1-\frac{q}{r}}.$$

Proposition B.7.9 with exponents r, $\frac{pr}{r-p}$, and $\frac{qr}{r-q}$, followed by Theorem B.6.17 and the case $L^1(\mathbb{R}^n) * L^1(\mathbb{R}^n) \subseteq L^1(\mathbb{R}^n)$, gives

$$\|f * g\|_{L^r(\mathbb{R}^n)}^r \le \|f\|_{L^p(\mathbb{R}^n)}^p \|g\|_{L^q(\mathbb{R}^n)}^q \|f\|_{L^p(\mathbb{R}^n)}^{r-p} \|g\|_{L^q(\mathbb{R}^n)}^{r-q},$$

which is the asserted inequality. □

Proposition 4.10.2. (Convolution in the Schwartz class) If $\varphi, \psi \in \mathcal{S}(\mathbb{R}^n)$, then $\varphi * \psi \in \mathcal{S}(\mathbb{R}^n)$ and

$$D^\alpha(\varphi * \psi) = (D^\alpha \varphi) * \psi = \varphi * (D^\alpha \psi).$$

The map $(\varphi, \psi) \mapsto \varphi * \psi$ is bilinear and continuous from $\mathcal{S}(\mathbb{R}^n) \times \mathcal{S}(\mathbb{R}^n)$ to $\mathcal{S}(\mathbb{R}^n)$.

Proof. Differentiation under the integral sign is justified by rapid decrease, which provides an integrable majorant for the difference quotients; we apply the dominated convergence theorem B.6.14. To control the variable x, we use $x^\alpha = (x - y + y)^\alpha$ and the multinomial formula. Each term of $x^\alpha D^\beta(\varphi * \psi)$ is the convolution of a function $y^\gamma D^\delta \psi(y)$ with a function $(x-y)^{\alpha-\gamma} D^{\beta-\delta}\varphi(x-y)$. Young's inequality $L^1(\mathbb{R}^n) * L^\infty(\mathbb{R}^n) \to L^\infty(\mathbb{R}^n)$ in Theorem 4.10.1 controls that term by Schwartz seminorms. The same estimate proves

bilinear continuity. □

For $\varphi \in \mathcal{S}(\mathbb{R}^n)$ we write $\check{\varphi}(x) := \varphi(-x)$.

Definition 4.10.3. (Convolution of a tempered distribution with a Schwartz function) Let $T \in \mathcal{S}'(\mathbb{R}^n)$ and $\varphi \in \mathcal{S}(\mathbb{R}^n)$. Define

$$(T * \varphi)(x) := \langle T, \varphi(x - \cdot)\rangle, \qquad x \in \mathbb{R}^n.$$

Proposition 4.10.4. (Tempered regularization) The function $T * \varphi$ is smooth and

$$D^\alpha(T * \varphi) = T * (D^\alpha \varphi) = (D^\alpha T) * \varphi.$$

For each α there exist $C_\alpha > 0$ and $N_\alpha \in \mathbb{N}_0$ such that $|D^\alpha(T * \varphi)(x)| \le C_\alpha(1 + \|x\|)^{N_\alpha}$. Moreover, if $\rho \in \mathcal{S}(\mathbb{R}^n)$ satisfies $\displaystyle\int_{\mathbb{R}^n} \rho = 1$ and $\rho_\varepsilon(x) := \varepsilon^{-n}\rho(\tfrac{x}{\varepsilon})$, then $T * \rho_\varepsilon \to T$ in $\mathcal{S}'(\mathbb{R}^n)$ as $\varepsilon \to 0^+$.

Proof. The difference quotient of $x \mapsto \varphi(x-\cdot)$ converges in $\mathcal{S}(\mathbb{R}^n)$ to the corresponding derivative; continuity of T allows passage to the limit and proves smoothness. The identity with $D^\alpha T$ is obtained by transferring the derivative to the test function.
By Proposition 4.9.2, $|\langle T, \psi\rangle| \le C q_N(\psi)$. The inequality $\|y\| \le \|x - y\| + \|x\|$ and the binomial formula show that $q_N(\varphi(x - \cdot)) \le C_\varphi(1 + \|x\|)^N$, giving polynomial growth.
Finally, for $\psi \in \mathcal{S}(\mathbb{R}^n)$, Fubini's theorem B.6.18 and the definition of convolution give

$$\langle T * \rho_\varepsilon, \psi\rangle = \langle T, \check{\rho}_\varepsilon * \psi\rangle.$$

Since $\displaystyle\int_{\mathbb{R}^n} \check{\rho} = 1$, the change of variable $y = \varepsilon z$ gives

$$(\check{\rho}_\varepsilon * \psi)(x) - \psi(x) = \int_{\mathbb{R}^n} \check{\rho}(z)\big(\psi(x - \varepsilon z) - \psi(x)\big)\, dz.$$

The fundamental theorem of calculus for Banach-space-valued functions B.6.5, applied after differentiating along the corresponding segment, and the inequality

$$1 + \|x\| \le (1 + \|x - \varepsilon z\|)(1 + \varepsilon\|z\|)$$

imply, for each $N \in \mathbb{N}_0$ and $0 < \varepsilon \le 1$,

$$q_N(\check{\rho}_\varepsilon * \psi - \psi) \le C_N \varepsilon\, q_{N+1}(\psi) \int_{\mathbb{R}^n} |\rho(z)|\,\|z\|(1 + \|z\|)^N\, dz.$$

The integral is finite because $\rho \in \mathcal{S}(\mathbb{R}^n)$. Therefore, $\check{\rho}_\varepsilon * \psi \to \psi$ in $\mathcal{S}(\mathbb{R}^n)$, and continuity of T completes the proof. □

4.11 The Fourier transform

The Fourier transform turns derivatives into multiplication and convolutions into products. This correspondence makes it possible to measure regularity through the behavior of a function in frequency. We choose the unitary normalization because it makes the transform an isometry of $L^2(\mathbb{R}^n)$ without additional constants. For the classical properties, the extension to distributions, and compatibility among the different definitions, we follow the development in [29, Sections 10.3–10.5], with our normalization in $\mathbb{R}^n$; the proofs are included to fix all constants and to avoid confusing the integral formula with the extensions by density or duality.

Definition 4.11.1. (Fourier transform on L^1) For $f \in L^1(\mathbb{R}^n)$ define

$$\widehat{f}(\xi) := \mathcal{F}f(\xi) := (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} e^{-ix\cdot\xi} f(x)\,dx, \qquad \xi \in \mathbb{R}^n.$$

For $g \in L^1(\mathbb{R}^n)$, the formal inverse transform is defined by

$$\mathcal{F}^{-1}g(x) := (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} e^{ix\cdot\xi} g(\xi)\,d\xi.$$

Proposition 4.11.2. (Properties on L^1) The map $\mathcal{F}\colon L^1(\mathbb{R}^n) \longrightarrow C_b(\mathbb{R}^n)$ is linear and

$$\|\widehat{f}\|_{L^\infty(\mathbb{R}^n)} \le (2\pi)^{-\frac{n}{2}} \|f\|_{L^1(\mathbb{R}^n)}.$$

Moreover, $\widehat{f}$ is uniformly continuous.

Proof. The estimate follows by taking the absolute value inside the integral. If $h \to 0$, then

$$|\widehat{f}(\xi+h) - \widehat{f}(\xi)| \le (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} |e^{-ix\cdot h} - 1|\,|f(x)|\,dx.$$

The right-hand side does not depend on ξ, converges to zero pointwise in the variable x, and is dominated by $2(2\pi)^{-\frac{n}{2}}|f| \in L^1(\mathbb{R}^n)$. Theorem B.6.14 proves uniform continuity. □

Proposition 4.11.3. (Fourier calculus on $\mathcal{S}$) If $\varphi \in \mathcal{S}(\mathbb{R}^n)$ and $\alpha \in \mathbb{N}_0^n$, then

$$\mathcal{F}(D^\alpha \varphi)(\xi) = (i\xi)^\alpha \widehat{\varphi}(\xi), \qquad \mathcal{F}(x^\alpha \varphi)(\xi) = i^{|\alpha|} D^\alpha \widehat{\varphi}(\xi).$$

In particular, $\mathcal{F}$ and $\mathcal{F}^{-1}$ are continuous linear operators from $\mathcal{S}(\mathbb{R}^n)$ to itself.

Proof. The first identity follows by integration by parts; the boundary terms disappear by rapid decrease. The second follows by differentiation under the integral sign. Combining both identities with

$$\|h\|_{L^1(\mathbb{R}^n)} \le C_N \sup_{x\in\mathbb{R}^n} (1+\|x\|)^N |h(x)|, \qquad N > n,$$

the Leibniz rule applied to $D^\alpha(x^\beta \varphi)$ and the preceding bound with the weight $(1+\|x\|)^{n+1}$ give explicitly

$$p_{\alpha,\beta}(\widehat{\varphi}) \le C_{\alpha,\beta}\, q_{n+1+|\alpha|+|\beta|}(\varphi).$$

Indeed, each summand contains a derivative of order at most $|\alpha|$ and a monomial whose degree, after incorporating the weight, does not exceed $|\beta|+n+1$; the factor $(1+\|x\|)^{-n-1}$ is integrable on $\mathbb{R}^n$. This proves that $\widehat{\varphi} \in \mathcal{S}(\mathbb{R}^n)$ and establishes continuity. The same calculation, with the sign of the phase reversed, proves the assertion for $\mathcal{F}^{-1}$. □

Lemma 4.11.4. (Transform of the Gaussian) For $a > 0$, the function $g_a(x) := e^{-\frac{a\|x\|^2}{2}}$ satisfies

$$\widehat{g_a}(\xi) = a^{-\frac{n}{2}} e^{-\frac{\|\xi\|^2}{2a}}.$$

In particular, g_1 is fixed by the Fourier transform.

Proof. By Fubini's theorem B.6.18, it suffices to treat $n = 1$. Let $G(\xi) := \widehat{g_a}(\xi)$. Proposition 4.11.3 and the identity $g_a' = -axg_a$ give $i\xi G = -aiG'$, that is, $G'(\xi) = -\dfrac{\xi G(\xi)}{a}$. Therefore, $G(\xi) = G(0)e^{-\frac{\xi^2}{2a}}$. To calculate the constant, set $I_a := \displaystyle\int_{\mathbb{R}} e^{-\frac{ax^2}{2}}\,dx$. Tonelli's theorem B.6.17 and the change to polar coordinates, justified by the change of variables theorem B.6.15, give

$$I_a^2 = \int_{\mathbb{R}^2} e^{-\frac{a\|x\|^2}{2}}\,dx = 2\pi \int_0^\infty e^{-\frac{ar^2}{2}}\, r\,dr = \frac{2\pi}{a}.$$

Thus, $G(0) = (2\pi)^{-\frac{1}{2}} I_a = a^{-\frac{1}{2}}$. The product of the one-dimensional formulas completes the proof. □

Lemma 4.11.5. (Gaussian approximation to the identity) For $\varepsilon > 0$, let

$$k_\varepsilon(x) := (2\pi\varepsilon)^{-\frac{n}{2}} e^{-\frac{\|x\|^2}{2\varepsilon}}.$$

Then $k_\varepsilon \geq 0$, $\displaystyle\int_{\mathbb{R}^n} k_\varepsilon = 1$, and, for every $\delta > 0$,

$$\int_{\{\|x\|\geq\delta\}} k_\varepsilon(x)\,dx \longrightarrow 0.$$

If $1 \leq p < \infty$ and $f \in L^p(\mathbb{R}^n)$, then $k_\varepsilon * f \to f$ in $L^p(\mathbb{R}^n)$; convergence is uniform when f is bounded and uniformly continuous.

Proof. The mass is computed using Lemma 4.11.4. The change of variable $x = \sqrt{\varepsilon}z$ and integrability of the Gaussian prove concentration. Moreover, Theorem B.8.2 gives

$$\|k_\varepsilon * f - f\|_{L^p(\mathbb{R}^n)} \leq \int_{\mathbb{R}^n} k_\varepsilon(y)\|\tau_y f - f\|_{L^p(\mathbb{R}^n)}\,dy.$$

Split the integral over $\{\|y\| < \delta\}$ and its complement; on the first part use Proposition B.8.17, and on the second use the bound $2\|f\|_{L^p(\mathbb{R}^n)}$ and concentration. The same argument with the uniform norm proves the final assertion. □

Theorem 4.11.6. (Fourier inversion in the Schwartz class) For every $\varphi \in \mathcal{S}(\mathbb{R}^n)$ we have

$$\mathcal{F}^{-1}(\mathcal{F}\varphi) = \varphi = \mathcal{F}(\mathcal{F}^{-1}\varphi).$$

Consequently, $\mathcal{F}\colon \mathcal{S}(\mathbb{R}^n) \longrightarrow \mathcal{S}(\mathbb{R}^n)$ is a topological isomorphism with inverse $\mathcal{F}^{-1}$.

Proof. Fix $x \in \mathbb{R}^n$ and $\varepsilon > 0$. Fubini's theorem B.6.18 and Lemma 4.11.4 give

$$(2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} e^{ix\cdot\xi} e^{-\frac{\varepsilon\|\xi\|^2}{2}} \widehat{\varphi}(\xi)\, d\xi = \int_{\mathbb{R}^n} \varphi(y) k_\varepsilon(x-y)\, dy,$$

where k_ε is the function in Lemma 4.11.5. That lemma shows that the right-hand side converges to $\varphi(x)$. On the left-hand side, $e^{-\frac{\varepsilon\|\xi\|^2}{2}} \to 1$ and the integrand is dominated by $|\widehat{\varphi}| \in L^1(\mathbb{R}^n)$. Theorem B.6.14 gives $\mathcal{F}^{-1}\widehat{\varphi}(x) = \varphi(x)$. The second identity follows by reversing the sign of the phase. □

Corollary 4.11.7. (Inversion in L^1) If $f \in L^1(\mathbb{R}^n)$ and $\widehat{f} \in L^1(\mathbb{R}^n)$, then f agrees almost everywhere with a continuous function vanishing at infinity and

$$f(x) = (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} e^{ix\cdot\xi} \widehat{f}(\xi)\, d\xi$$

for almost every $x \in \mathbb{R}^n$. In particular, the Fourier transform is injective on $L^1(\mathbb{R}^n)$.

Proof. Let k_ε be the Gaussian in the preceding proof. By Fubini's theorem B.6.18,

$$(f * k_\varepsilon)(x) = (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} e^{ix\cdot\xi} e^{-\frac{\varepsilon\|\xi\|^2}{2}} \widehat{f}(\xi)\, d\xi.$$

The right-hand side converges uniformly to $\mathcal{F}^{-1}\widehat{f}$ by Theorem B.6.14. The left-hand side converges to f in $L^1(\mathbb{R}^n)$ by Lemma 4.11.5. A subsequence converges pointwise almost everywhere, so $f = \mathcal{F}^{-1}\widehat{f}$ almost everywhere. Set $h := \mathcal{F}^{-1}\widehat{f}$. By Proposition 4.11.2, applied with the opposite sign in the phase, h is uniformly continuous. Moreover, $h = f$ almost everywhere and $f \in L^1(\mathbb{R}^n)$, so $h \in L^1(\mathbb{R}^n)$.

These two properties imply that h vanishes at infinity. Indeed, otherwise there would exist $\varepsilon > 0$ and a sequence (x_j) with $\|x_j\| \to \infty$ and $|h(x_j)| \geq \varepsilon$. Uniform continuity provides a radius $r > 0$, independent of j, such that $|h(x)| \geq \varepsilon/2$ if $\|x - x_j\| < r$. Passing to a subsequence, we may assume that the balls $B(x_j, r)$ are pairwise disjoint: after finitely many centers have been chosen, take the next one at a distance greater than $2r$ from all of them. Then

$$\int_{\mathbb{R}^n} |h(x)|\, dx \geq \sum_{j=1}^{\infty} \int_{B(x_j,r)} |h(x)|\, dx \geq \sum_{j=1}^{\infty} \frac{\varepsilon}{2} \lambda_n(B(0,r)) = \infty,$$

which contradicts integrability of h. □

Theorem 4.11.8. (Riemann–Lebesgue lemma) The Fourier transform induces a continuous operator

$$\mathcal{F}\colon L^1(\mathbb{R}^n) \longrightarrow C_0(\mathbb{R}^n).$$

In particular, $\widehat{f}(\xi) \to 0$ as $\|\xi\| \to \infty$.

Proof. By Proposition 4.8.5, there exists $(\varphi_j) \subseteq \mathcal{S}(\mathbb{R}^n)$ with $\varphi_j \to f$ in $L^1(\mathbb{R}^n)$. Proposition 4.11.2 implies that $\widehat{\varphi}_j \to \widehat{f}$ uniformly. Each $\widehat{\varphi}_j$ belongs to $\mathcal{S}(\mathbb{R}^n) \subseteq C_0(\mathbb{R}^n)$, and $C_0(\mathbb{R}^n)$ is closed in the uniform norm. □

Proposition 4.11.9. (Convolution, product, and symmetries) Let $f, g \in \mathcal{S}(\mathbb{R}^n)$. Then

$$\mathcal{F}(f * g) = (2\pi)^{\frac{n}{2}} \widehat{f}\,\widehat{g}, \qquad \mathcal{F}(fg) = (2\pi)^{-\frac{n}{2}} \widehat{f} * \widehat{g}.$$

If $a \in \mathbb{R}^n$, $\lambda \neq 0$, and $A \in \mathrm{GL}(n, \mathbb{R})$, then

$$\mathcal{F}(f(\cdot - a))(\xi) = e^{-ia\cdot\xi} \widehat{f}(\xi), \qquad \mathcal{F}(e^{ia\cdot(\cdot)} f)(\xi) = \widehat{f}(\xi - a),$$

and

$$\mathcal{F}(f \circ A)(\xi) = |\det A|^{-1} \widehat{f}(A^{-T}\xi).$$

Proof. Since $f, g \in \mathcal{S}(\mathbb{R}^n)$, the function $(x, y) \mapsto f(y)g(x-y)$ is integrable on $\mathbb{R}^{2n}$ and Fubini's theorem B.6.18 applies. With $z = x - y$,

$$\mathcal{F}(f * g)(\xi) = (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} e^{-ix\cdot\xi} f(y) g(x-y)\, dy\, dx$$

$$= (2\pi)^{-\frac{n}{2}} \left(\int_{\mathbb{R}^n} e^{-iy\cdot\xi} f(y)\, dy \right) \left(\int_{\mathbb{R}^n} e^{-iz\cdot\xi} g(z)\, dz \right) = (2\pi)^{\frac{n}{2}} \widehat{f}(\xi)\widehat{g}(\xi).$$

Applying this identity to $\mathcal{F}^{-1}\widehat{f}$ and $\mathcal{F}^{-1}\widehat{g}$, and using Theorem 4.11.6, gives $\mathcal{F}(fg) = (2\pi)^{-\frac{n}{2}} \widehat{f} * \widehat{g}$.
For translation, substitute $y = x - a$; for modulation, combine the phase as $e^{-ix\cdot(\xi - a)}$. Finally, with $y = Ax$,

$$\mathcal{F}(f \circ A)(\xi) = (2\pi)^{-\frac{n}{2}} |\det A|^{-1} \int e^{-iy\cdot A^{-T}\xi} f(y)\, dy,$$

which is the last formula. Each interchange of order or change of variable is justified by absolute integrability of the Schwartz functions. □

4.11.1 The transform on L^2 and on the L^p scale

The initial definition of Fourier on integrable functions is insufficient for energy arguments. Plancherel's theorem extends the transform to $L^2(\mathbb{R}^n)$ and provides the starting point for studying which estimates survive away from the Hilbert space exponent.

Theorem 4.11.10. (Parseval and Plancherel) For $f, g \in \mathcal{S}(\mathbb{R}^n)$,

$$\int_{\mathbb{R}^n} f(x)\overline{g(x)}\, dx = \int_{\mathbb{R}^n} \widehat{f}(\xi)\overline{\widehat{g}(\xi)}\, d\xi.$$

In particular, $\|\widehat{f}\|_{L^2(\mathbb{R}^n)} = \|f\|_{L^2(\mathbb{R}^n)}$. The Fourier transform extends uniquely to a unitary operator $\mathcal{F} : L^2(\mathbb{R}^n) \longrightarrow L^2(\mathbb{R}^n)$, whose inverse is the extension of $\mathcal{F}^{-1}$.

Proof. Since $f, h \in \mathcal{S}(\mathbb{R}^n) \subseteq L^1(\mathbb{R}^n)$, the corresponding double integral is absolutely convergent. Fubini's theorem B.6.18 gives the bilinear identity

$$\int_{\mathbb{R}^n} \widehat{f}(\xi) h(\xi)\, d\xi = \int_{\mathbb{R}^n} f(x) \widehat{h}(x)\, dx$$

in which both pairings are bilinear. Take $h = \overline{\widehat{g}}$. By inversion,

$$\widehat{h}(x) = \mathcal{F}(\overline{\widehat{g}})(x) = \overline{\mathcal{F}^{-1}(\widehat{g})(x)} = \overline{g(x)}.$$

Substitution of this equality proves Parseval's identity. With $g = f$ we obtain $\|\widehat{f}\|_{L^2(\mathbb{R}^n)} = \|f\|_{L^2(\mathbb{R}^n)}$.
Now let $f \in L^2(\mathbb{R}^n)$ and choose $f_m \in \mathcal{S}(\mathbb{R}^n)$ with $f_m \to f$ in $L^2(\mathbb{R}^n)$. The isometry shows that $(\widehat{f_m})$ is Cauchy; define $\mathcal{F}f := \lim_{m\to\infty} \widehat{f_m}$ in $L^2(\mathbb{R}^n)$. If $(\widetilde{f_m})$ is another approximation, then

$$\|\widehat{f_m} - \widehat{\widetilde{f_m}}\|_{L^2(\mathbb{R}^n)} = \|f_m - \widetilde{f_m}\|_{L^2(\mathbb{R}^n)} \longrightarrow 0,$$

so the definition is independent of the sequence and preserves the norm. The same procedure extends $\mathcal{F}^{-1}$; the inversion identities on $\mathcal{S}(\mathbb{R}^n)$ and passage to the limit show that the two extended operators are inverses. In particular, $\mathcal{F}$ is unitary and surjective. By approximation, this also proves Parseval's identity for every pair of elements of $L^2(\mathbb{R}^n)$. □

When $f \in L^2(\mathbb{R}^n)$, the integral expression defining $\widehat{f}$ may fail to converge. The transform is then understood as the limit in $L^2(\mathbb{R}^n)$ constructed in the proof. If $f \in L^1(\mathbb{R}^n) \cap L^2(\mathbb{R}^n)$, take truncations and regularizations $f_m \in \mathcal{S}(\mathbb{R}^n)$ converging simultaneously in $L^1(\mathbb{R}^n)$ and in $L^2(\mathbb{R}^n)$. Their transforms converge uniformly to the integral transform by Proposition 4.11.2, and converge in $L^2(\mathbb{R}^n)$ to the Plancherel transform. A subsequence of the second limit converges almost everywhere; by uniqueness of the pointwise limit, the two transforms agree almost everywhere.

Proposition 4.11.11. (L^p functions as tempered distributions) For every $1 \le p \le \infty$, the map

$$L^p(\mathbb{R}^n) \longrightarrow \mathcal{S}'(\mathbb{R}^n), \qquad f \longmapsto T_f, \qquad \langle T_f, \varphi \rangle := \int f(x)\varphi(x)\, dx,$$

is linear, continuous, and injective. Therefore, $\widehat{f} := \widehat{T_f}$ is always defined as a tempered distribution. For $p = 2$ it agrees with the Plancherel transform, and for $f \in L^1(\mathbb{R}^n)$ it agrees with the integral formula.

Compatibility with regular distributions is recorded in [29, Section 10.5].

Proof. If $p < \infty$, Hölder's inequality in Proposition B.7.9 gives

$$|\langle T_f, \varphi \rangle| \le \|f\|_{L^p(\mathbb{R}^n)} \|\varphi\|_{L^{p'}(\mathbb{R}^n)}.$$

Choosing $N > \frac{n}{p'}$, we have

$$\|\varphi\|_{L^{p'}(\mathbb{R}^n)} \le \|(1 + \|x\|)^{-N}\|_{L^{p'}(\mathbb{R}^n)} \sup_{x \in \mathbb{R}^n} (1 + \|x\|)^N |\varphi(x)|.$$

For $p = \infty$, use the same estimate with $\|\varphi\|_{L^1(\mathbb{R}^n)}$ and any $N > n$. This proves continuity in the topology of

$\mathcal{S}(\mathbb{R}^n)$ and therefore $T_f \in \mathcal{S}'(\mathbb{R}^n)$. If $T_f = 0$, then the integral of f against every function in $C_c^\infty(\mathbb{R}^n)$ is zero; Proposition B.6.20 implies that $f = 0$ almost everywhere, proving injectivity.
Compatibility with Plancherel is first checked on $\mathcal{S}(\mathbb{R}^n)$ and extended to $L^2(\mathbb{R}^n)$ by density and continuity. For the integral definition on $L^1(\mathbb{R}^n)$, the identity follows directly by pairing with a Schwartz function and applying Fubini's theorem B.6.18. □

4.11.2 Fourier on tempered distributions

Weak solutions and symbols of polynomial growth require us to go beyond the framework of functions. Since the transform preserves the Schwartz space, duality provides a canonical extension to $\mathcal{S}'(\mathbb{R}^n)$.

Definition 4.11.12. (Transform of a tempered distribution) For $T \in \mathcal{S}'(\mathbb{R}^n)$ define $\widehat{T} \in \mathcal{S}'(\mathbb{R}^n)$ and $\mathcal{F}^{-1}T \in \mathcal{S}'(\mathbb{R}^n)$ by

$$\langle \widehat{T}, \varphi \rangle := \langle T, \widehat{\varphi} \rangle, \qquad \langle \mathcal{F}^{-1}T, \varphi \rangle := \langle T, \mathcal{F}^{-1}\varphi \rangle.$$

The definition uses the topological transpose of the transform on $\mathcal{S}(\mathbb{R}^n)$. No conjugation is introduced because distributions are viewed as linear functionals.

Theorem 4.11.13. (Fourier on $\mathcal{S}'$) The Fourier transform is a linear, weak-$*$ continuous isomorphism from $\mathcal{S}'(\mathbb{R}^n)$ to itself, with inverse $\mathcal{F}^{-1}$. For every $T \in \mathcal{S}'(\mathbb{R}^n)$ and every multi-index α,

$$\mathcal{F}(D^\alpha T) = (i\xi)^\alpha \widehat{T}, \qquad \mathcal{F}(x^\alpha T) = i^{|\alpha|} D^\alpha \widehat{T}.$$

If $\varphi \in \mathcal{S}(\mathbb{R}^n)$, then

$$\mathcal{F}(T * \varphi) = (2\pi)^{\frac{n}{2}} \widehat{T}\, \widehat{\varphi}.$$

Proof. Continuity and the inversion formula follow by transposing Theorem 4.11.6. For the derivative,

$$\langle \mathcal{F}(D^\alpha T), \varphi \rangle = (-1)^{|\alpha|} \langle T, D^\alpha \widehat{\varphi} \rangle = \langle T, \mathcal{F}((i\,\cdot)^\alpha \varphi) \rangle,$$

which is the action of $(i\xi)^\alpha \widehat{T}$. The identity involving $x^\alpha T$ is analogous. The convolution formula is first checked by pairing both sides with a Schwartz function and applying Fubini's theorem B.6.18; continuity then gives the conclusion for every $T \in \mathcal{S}'(\mathbb{R}^n)$. □

4.12 Littlewood–Paley dyadic decomposition

The Fourier transform makes it possible to separate a distribution into frequency bands. Instead of studying the entire spectrum simultaneously, we first isolate the low frequencies and then annuli whose characteristic scale is 2^j, with $j \in \mathbb{N}$. This inhomogeneous decomposition preserves the information in the entire distribution and will allow us to measure regularity by observing how each block decreases as frequency increases. It will provide the common foundation for Bessel, Besov, and Triebel–Lizorkin spaces.

Proposition 4.12.1. (Dyadic resolution of unity) There exists a radial function $\chi \in C_c^\infty(\mathbb{R}^n)$ such that

$0 \le \chi \le 1$, $\chi = 1$ on $\overline{B}_{\mathrm{euc}}(0,1)$, and $\operatorname{supp}(\chi) \subseteq B_{\mathrm{euc}}(0,2)$. If

$$\varphi_0(\xi) := \chi(\xi), \qquad \varphi_j(\xi) := \chi(2^{-j}\xi) - \chi(2^{-j+1}\xi), \quad j \in \mathbb{N},$$

then $\varphi_j \in C_c^\infty(\mathbb{R}^n)$, φ_j is supported in an annulus $c2^j \le \|\xi\| \le C2^j$ for $j \in \mathbb{N}$, and

$$\sum_{j \in \mathbb{N}_0} \varphi_j(\xi) = 1, \qquad \xi \in \mathbb{R}^n.$$

At each point, only a uniformly bounded number of enlarged annuli intersect.

Proof. The existence of χ follows from a radial cutoff function. The partial sum is telescoping:

$$\sum_{j=0}^{N} \varphi_j(\xi) = \chi(2^{-N}\xi),$$

and converges to one. The assertions about supports follow from where $\chi(2^{-j}\xi)$ and $\chi(2^{-j+1}\xi)$ can differ. □

Definition 4.12.2. (Dyadic blocks) Fixing a resolution as above, for $T \in \mathcal{S}'(\mathbb{R}^n)$ define

$$\Delta_j T := \mathcal{F}^{-1}(\varphi_j \widehat{T}), \qquad j \in \mathbb{N}_0.$$

The distributions $\Delta_j T$ are called the *dyadic blocks* of T.

Theorem 4.12.3. (Littlewood–Paley decomposition) For every $T \in \mathcal{S}'(\mathbb{R}^n)$,

$$T = \sum_{j \in \mathbb{N}_0} \Delta_j T$$

with convergence in $\mathcal{S}'(\mathbb{R}^n)$. If $T \in \mathcal{S}(\mathbb{R}^n)$, convergence takes place in $\mathcal{S}(\mathbb{R}^n)$.

Proof. The partial sum is $\mathcal{F}^{-1}(\chi(2^{-N}\cdot)\widehat{T})$. For $\varphi \in \mathcal{S}(\mathbb{R}^n)$, it suffices to prove that $\chi(2^{-N}\cdot)\varphi \to \varphi$ in $\mathcal{S}(\mathbb{R}^n)$. The difference vanishes on a ball whose radius tends to infinity; differentiating it produces terms $2^{-N|\alpha|}(D^\alpha \chi)(2^{-N}\xi) D^\beta \varphi(\xi)$. The rapid decrease of φ makes each seminorm tend to zero. Continuity of T proves convergence in $\mathcal{S}'(\mathbb{R}^n)$. If $T \in \mathcal{S}(\mathbb{R}^n)$, the same calculation applies directly to $\widehat{T}$. □

Theorem 4.12.4. (Bernstein inequalities) Let $1 \le p \le q \le \infty$, $m \in \mathbb{N}_0$, and $R > 0$.

(a) If $f \in L^p(\mathbb{R}^n)$ and $\operatorname{supp}(\widehat{f}) \subseteq \overline{B}_{\mathrm{euc}}(0,R)$, then

$$\|D^\alpha f\|_{L^q(\mathbb{R}^n)} \le C R^{|\alpha| + n(\frac{1}{p} - \frac{1}{q})} \|f\|_{L^p(\mathbb{R}^n)}, \qquad |\alpha| \le m.$$

(b) If $f \in L^p(\mathbb{R}^n)$ and $\operatorname{supp}(\widehat{f}) \subseteq \{\xi \in \mathbb{R}^n \mid cR \le \|\xi\| \le CR\}$, then

$$C_1 R^m \|f\|_{L^p(\mathbb{R}^n)} \le \sum_{|\alpha| = m} \|D^\alpha f\|_{L^p(\mathbb{R}^n)} \le C_2 R^m \|f\|_{L^p(\mathbb{R}^n)}.$$

The constants depend only on the indicated parameters and on c, C, not on R or f.

Proof. By scaling, it suffices to consider $R = 1$. Choose $\eta \in C_c^\infty(\mathbb{R}^n)$ equal to one on a neighborhood of the support of $\widehat{f}$. Then $f = (2\pi)^{-\frac{n}{2}}(\mathcal{F}^{-1}\eta) * f$ and

$$D^\alpha f = (2\pi)^{-\frac{n}{2}}(D^\alpha \mathcal{F}^{-1}\eta) * f.$$

Theorem 4.10.1, with $1 + \frac{1}{q} = \frac{1}{p} + \frac{1}{r}$, proves the first estimate. For the lower bound in the second, choose η supported away from the origin and equal to one on the annulus. If $m = 0$, the assertion is immediate. If $m \geq 1$, set

$$D_m(\xi) := \sum_{\ell=1}^n \xi_\ell^{2m}, \qquad m_{me_\ell}(\xi) := i^{-m}\eta(\xi)\frac{\xi_\ell^m}{D_m(\xi)},$$

where $(e_\ell)_{\ell=1}^n$ is the standard basis. The denominator is positive away from the origin; therefore, $m_{me_\ell} \in C_c^\infty(\mathbb{R}^n \setminus \{0\})$ and

$$\eta(\xi) = \sum_{\ell=1}^n m_{me_\ell}(\xi)(i\xi_\ell)^m.$$

Since $\eta\widehat{f} = \widehat{f}$, taking the inverse Fourier transform gives

$$f = (2\pi)^{-\frac{n}{2}} \sum_{\ell=1}^n (\mathcal{F}^{-1} m_{me_\ell}) * D_\ell^m f.$$

Each $\mathcal{F}^{-1} m_{me_\ell}$ belongs to $\mathcal{S}(\mathbb{R}^n) \subseteq L^1(\mathbb{R}^n)$; Theorem 4.10.1 then gives

$$\|f\|_{L^p(\mathbb{R}^n)} \leq C \sum_{\ell=1}^n \|D_\ell^m f\|_{L^p(\mathbb{R}^n)}.$$

The upper bound is the first part. □

The finite overlap of the dyadic annuli will be the mechanism allowing us later to compare norms constructed from different resolutions.

5

Interpolation spaces

Intermediate spaces often arise between two spaces measuring different levels of size or regularity. Interpolation makes this idea precise and allows continuity of an operator at intermediate levels to be deduced from its bounds at two endpoints. It also yields compactness results under assumptions to be specified. In this book, the theory will serve three purposes: deriving fractional inequalities from integer-order results, distinguishing the real and complex Sobolev scales, and transferring Euclidean definitions to charts and trivializations. We shall use the functional analysis, integration, and Hardy inequality results from the analysis appendix, as well as the Fourier transform from Chapter 4. The results of this chapter will be applied to the scales in Chapter 6 and, later, to spaces of functions and sections on manifolds.

We shall develop the Lions–Peetre real method and the Calderón complex method. Our general references will be [97, Chapters 16–17] and [20]; applications to function spaces are compared with [146, §1.6] and [130, §2.3].

Interpolating instead of proving anew

Interpolation theory matured with the recognition that many endpoint estimates contain information about all intermediate levels. The Lions–Peetre methods quantify the decomposition of an element between two spaces, while Calderón's complex method uses holomorphic families. An estimate for an operator on two spaces can thus yield estimates on an entire family of intermediate spaces. In the study of regularity, this allows passage from integer to fractional orders.

5.1 Compatible pairs of Banach spaces

Interpolation compares two levels of regularity within a common ambient space. Compatibility ensures that the sum and intersection of the endpoint spaces are well defined and suitable for measuring decompositions.

Definition 5.1.1. (Compatible pair) A pair (X_0, X_1) of normed spaces is called *compatible* if there are continuous linear embeddings of X_0 and X_1 into a common Hausdorff topological vector space X. We shall identify both spaces with their images in X.

The ambient space serves only to give meaning to equality between elements of X_0 and X_1. Define

$$X_0 \cap X_1 \quad \text{with} \quad \|x\|_{X_0\cap X_1} := \max\{\|x\|_{X_0}, \|x\|_{X_1}\},$$

and

$$X_0 + X_1 := \{x_0 + x_1 \mid x_0 \in X_0,\ x_1 \in X_1\}, \qquad \|x\|_{X_0+X_1} := \inf_{\substack{x_0\in X_0,\ x_1\in X_1\\ x=x_0+x_1}} \big(\|x_0\|_{X_0} + \|x_1\|_{X_1}\big).$$

Proposition 5.1.2. If (X_0, X_1) is a compatible pair of Banach spaces, then $X_0 \cap X_1$ and $X_0 + X_1$ are Banach spaces. The inclusions $X_0 \cap X_1 \hookrightarrow X_j \hookrightarrow X_0 + X_1$, $j = 0, 1$, are continuous.

Proof. A Cauchy sequence in $X_0 \cap X_1$ converges in each X_j. The two limits agree in X because the embeddings are continuous and X is Hausdorff; their common limit belongs to the intersection.
For the sum, consider $X_0 \times X_1$ with the norm $\|(x_0, x_1)\| := \|x_0\|_{X_0} + \|x_1\|_{X_1}$ and the subspace

$$N := \{(x, -x) \mid x \in X_0 \cap X_1\}.$$

The subspace N is closed: if $(x_k, -x_k) \to (a, b)$ in $X_0 \times X_1$, then $x_k \to a$ and $x_k \to -b$ in X, whence $a = -b \in X_0 \cap X_1$. The map $(x_0, x_1) \mapsto x_0 + x_1$ induces an isometry from the quotient $(X_0 \times X_1)/N$ onto $X_0 + X_1$. Completeness of quotients of Banach spaces by closed subspaces completes the proof. □

Unless otherwise stated, all compatible pairs used from now on will consist of Banach spaces.

5.2 The real method: the K-functional

To compare x with the two endpoint spaces, we decompose it as $x = x_0 + x_1$. The same decomposition may be suitable at one scale and inefficient at another. The following functional chooses the smallest possible cost when the norm of the second component is multiplied by t.

Definition 5.2.1. (K-functional) Let (X_0, X_1) be a compatible pair. For $x \in X_0 + X_1$ and $t > 0$, define

$$K(t, x; X_0, X_1) := \inf_{\substack{x_0\in X_0,\ x_1\in X_1\\ x=x_0+x_1}} \big(\|x_0\|_{X_0} + t\|x_1\|_{X_1}\big).$$

When the pair is clear, we shall simply write $K(t, x)$.

For each $t > 0$, $K(t, \cdot)$ is a norm on $X_0 + X_1$ and satisfies

$$\min\{1, t\}\,\|x\|_{X_0+X_1} \le K(t, x) \le \max\{1, t\}\,\|x\|_{X_0+X_1}, \qquad x \in X_0 + X_1.$$

The parameter t weights the component x_1: when t is small, its norm contributes less to the cost. If X_1 represents greater regularity than X_0, the functional quantifies the cost of separating a more regular part from x.

Proposition 5.2.2. (Elementary properties of the K-functional) Let $x, y \in X_0 + X_1$ and $s, t > 0$. Then:

(a) $K(t, x + y) \le K(t, x) + K(t, y)$ and $K(t, \lambda x) = |\lambda| K(t, x)$;

(b) $t \mapsto K(t, x)$ is increasing and concave;

(c) $t \mapsto t^{-1}K(t,x)$ is decreasing;

(d) $K(t,x;X_0,X_1) = tK(t^{-1},x;X_1,X_0)$;

(e) $K(t,x) \le \min\{\|x\|_{X_0}, t\|x\|_{X_1}\}$ when $x \in X_0 \cap X_1$;

(f) $\min\{1,t\}\|x\|_{X_0+X_1} \le K(t,x) \le \max\{1,t\}\|x\|_{X_0+X_1}$.

Proof. The algebraic properties follow by adding decompositions and taking the infimum. Each function $t \mapsto \|x_0\|_{X_0} + t\|x_1\|_{X_1}$ is affine and increasing; the infimum of this family is increasing and concave. Moreover, $t^{-1}K(t,x)$ is the infimum of the decreasing functions $t \mapsto t^{-1}\|x_0\|_{X_0} + \|x_1\|_{X_1}$, taken over decompositions of x, and is therefore decreasing. Symmetry follows by interchanging x_0 and x_1. The last two estimates follow from the decompositions $x = x + 0$, $x = 0 + x$ and from comparing the coefficients $1, t$ with their minimum and maximum. □

Intermediate regularity requires simultaneous control at all scales $t \in (0,\infty)$. The factor $t^{-\theta}$ fixes the intermediate level; the exponent q determines how the costs are combined. The measure dt/t assigns the same weight to intervals related by dilation.

Definition 5.2.3. (Real interpolation space) Let $0 < \theta < 1$ and $1 \le q \le \infty$. Define

$$(X_0,X_1)_{\theta,q} := \{x \in X_0 + X_1 \mid \|x\|_{\theta,q;K} < \infty\},$$

where, if $q < \infty$,

$$\|x\|_{\theta,q;K} := \left(\int_0^\infty \left(t^{-\theta}K(t,x)\right)^q \frac{dt}{t}\right)^{\frac{1}{q}},$$

and $\|x\|_{\theta,\infty;K} := \sup_{t\in(0,\infty)} t^{-\theta}K(t,x)$.

Theorem 5.2.4. (Basic properties of the K-method) If (X_0,X_1) is a compatible pair of Banach spaces, then $(X_0,X_1)_{\theta,q}$ is a Banach space and

$$X_0 \cap X_1 \hookrightarrow (X_0,X_1)_{\theta,q} \hookrightarrow X_0 + X_1$$

continuously. If $X_1 \hookrightarrow X_0$, let C_E be the norm of the embedding, let $T_E := \max\{1, C_E\}$, and set, for $q < \infty$,

$$N_{\theta,q}(x) := \|x\|_{X_0} + \left(\int_0^1 \left(t^{-\theta}K(t,x)\right)^q \frac{dt}{t}\right)^{\frac{1}{q}}$$

and, for $q = \infty$,

$$N_{\theta,\infty}(x) := \|x\|_{X_0} + \sup_{t\in(0,1]} t^{-\theta}K(t,x).$$

Then, if $q < \infty$,

$$\frac{\|x\|_{\theta,q;K}}{\max\{1,(\theta q)^{-\frac{1}{q}}\}} \le N_{\theta,q}(x) \le \left(1 + (\theta q)^{\frac{1}{q}} T_E^\theta\right)\|x\|_{\theta,q;K},$$

whereas

$$\|x\|_{\theta,\infty;K} \le N_{\theta,\infty}(x) \le (1 + T_E^{\theta})\|x\|_{\theta,\infty;K}.$$

Proof. If $x \in X_0 \cap X_1$, Proposition 5.2.2 gives $K(t,x) \le \min\{1,t\}\|x\|_{X_0\cap X_1}$. Since

$$\int_0^1 t^{(1-\theta)q}\,\frac{dt}{t} + \int_1^\infty t^{-\theta q}\,\frac{dt}{t} < \infty,$$

we obtain the first embedding when $q < \infty$. For $q = \infty$, use $\sup_{t\in(0,\infty)} t^{-\theta}\min\{1,t\} = 1$ directly. For the second embedding, Proposition 5.2.2 implies $\|x\|_{X_0+X_1} \le K(t,x)$ for $1 \le t \le 2$. Thus, if $q < \infty$,

$$\|x\|_{X_0+X_1} \le (\log 2)^{-\frac{1}{q}}\, 2^{\theta}\|x\|_{\theta,q;K};$$

if $q = \infty$, evaluation at $t = 1$ suffices.
Now let (x_j) be Cauchy in $(X_0,X_1)_{\theta,q}$. The second embedding implies $x_j \to x$ in $X_0 + X_1$ for some x. For $q < \infty$, continuity of the norm $K(t,\cdot)$ on $X_0 + X_1$ and Fatou's lemma B.6.12 give

$$\|x_j - x\|_{\theta,q;K}^q \le \liminf_{k\to\infty} \|x_j - x_k\|_{\theta,q;K}^q.$$

The case $q = \infty$ follows by taking the supremum after passing to the limit for each t. Thus $x_j \to x$ in the interpolation space.
If $X_1 \hookrightarrow X_0$, let C_E be the norm of the embedding and let $T_E := \max\{1, C_E\}$. Then $X_0 + X_1 = X_0$ and, for every decomposition $x = x_0 + x_1$,

$$\|x\|_{X_0} \le \|x_0\|_{X_0} + C_E\|x_1\|_{X_1}.$$

Consequently, if $t \ge T_E$, we have $K(t,x) \ge \|x\|_{X_0}$; the decomposition $x = x + 0$ gives the reverse inequality. Hence

$$\int_{T_E}^\infty \left(t^{-\theta}K(t,x)\right)^q \frac{dt}{t} = \frac{T_E^{-\theta q}}{\theta q}\|x\|_{X_0}^q.$$

Moreover, $K(t,x) \le \|x\|_{X_0}$ for every $t > 0$. If $I_0 := \displaystyle\int_0^1 (t^{-\theta}K(t,x))^q\,dt/t$, it follows that

$$\|x\|_{\theta,q;K} \le \left(I_0 + (\theta q)^{-1}\|x\|_{X_0}^q\right)^{\frac{1}{q}} \le \max\{1, (\theta q)^{-\frac{1}{q}}\}N_{\theta,q}(x).$$

The tail identity starting at T_E gives, in the opposite direction, $\|x\|_{X_0} \le (\theta q)^{\frac{1}{q}} T_E^{\theta}\|x\|_{\theta,q;K}$, while $I_0^{\frac{1}{q}} \le \|x\|_{\theta,q;K}$. This proves both bounds for $q < \infty$. For $q = \infty$, the inequality $K(t,x) \le \|x\|_{X_0}$ shows that $\|x\|_{\theta,\infty;K} \le N_{\theta,\infty}(x)$, and the equality $K(T_E,x) = \|x\|_{X_0}$ gives $\|x\|_{X_0} \le T_E^{\theta}\|x\|_{\theta,\infty;K}$; this yields the remaining bound. □

Lemma 5.2.5. (Dyadic discretization) For $0 < \theta < 1$ and $1 \le q \le \infty$, there are constants $c_{\theta,q}, C_{\theta,q} > 0$ such that

$$c_{\theta,q}\left\|\left(2^{-k\theta}K(2^k,x)\right)_{k\in\mathbb{Z}}\right\|_{\ell^q(\mathbb{Z})} \le \|x\|_{\theta,q;K} \le C_{\theta,q}\left\|\left(2^{-k\theta}K(2^k,x)\right)_{k\in\mathbb{Z}}\right\|_{\ell^q(\mathbb{Z})}.$$

The constants depend only on θ and q.

Proof. If $2^k \le t \le 2^{k+1}$, monotonicity of K and $\frac{K(t,x)}{t}$ gives

$$2^{-\theta}2^{-k\theta}K(2^k,x) \le t^{-\theta}K(t,x) \le 2^{1-\theta}2^{-k\theta}K(2^k,x).$$

Integrate over each interval $[2^k, 2^{k+1}]$ with respect to dt/t and sum. The argument with suprema covers $q = \infty$. □

Corollary 5.2.6. (Monotonicity in the second index) If $1 \le q_0 \le q_1 \le \infty$, then

$$(X_0, X_1)_{\theta,q_0} \hookrightarrow (X_0, X_1)_{\theta,q_1}.$$

Moreover, $(X_0, X_1)_{\theta,q} = (X_1, X_0)_{1-\theta,q}$ and, for every x,

$$\|x\|_{\theta,q;K,(X_0,X_1)} = \|x\|_{1-\theta,q;K,(X_1,X_0)}.$$

Proof. The first assertion follows from Lemma 5.2.5 and $\ell^{q_0} \hookrightarrow \ell^{q_1}$. For the second, use $K(t,x;X_0,X_1) = tK(t^{-1},x;X_1,X_0)$ and the change of variable $s = t^{-1}$. □

Proposition 5.2.7. (Multiplicative inequality) There is $C_{\theta,q} > 0$ such that for every $x \in X_0 \cap X_1$,

$$\|x\|_{(X_0,X_1)_{\theta,q}} \le C_{\theta,q}\|x\|_{X_0}^{1-\theta}\|x\|_{X_1}^{\theta}.$$

Proof. If $x = 0$, the assertion is immediate. Otherwise, set $a := \|x\|_{X_0} > 0$, $b := \|x\|_{X_1} > 0$, and $t_0 := a/b$. If $q < \infty$, Proposition 5.2.2 gives

$$\begin{aligned}\|x\|_{\theta,q;K}^q &\le b^q \int_0^{t_0} t^{(1-\theta)q}\,\frac{dt}{t} + a^q \int_{t_0}^{\infty} t^{-\theta q}\,\frac{dt}{t} \\ &= \left(\frac{1}{(1-\theta)q} + \frac{1}{\theta q}\right) a^{(1-\theta)q} b^{\theta q}.\end{aligned}$$

For $q = \infty$, the function $t^{-\theta}\min\{a, tb\}$ attains its maximum at $t = t_0$, where its value is $a^{1-\theta}b^{\theta}$. □

5.3 Interpolation of operators

The analytic value of the K-method lies in transferring known endpoint bounds to intermediate spaces. The following result makes this transfer precise and retains control of the operator norm.

Theorem 5.3.1. (Interpolation theorem for the K-method) Let (X_0, X_1) and (Y_0, Y_1) be compatible pairs of Banach spaces. Let $T\colon X_0 + X_1 \longrightarrow Y_0 + Y_1$ be linear, and suppose that its restrictions $T\colon X_j \longrightarrow Y_j$ are continuous, with norms M_j, $j = 0, 1$. Then

$$T\colon (X_0, X_1)_{\theta,q} \longrightarrow (Y_0, Y_1)_{\theta,q}$$

is continuous and

$$\|T\| \le M_0^{1-\theta} M_1^{\theta}.$$

Proof. If $x = x_0 + x_1$, then

$$K(t, Tx; Y_0, Y_1) \le M_0 \|x_0\|_{X_0} + tM_1 \|x_1\|_{X_1}.$$

Taking the infimum,

$$K(t, Tx; Y_0, Y_1) \le M_0 K\left(t\frac{M_1}{M_0}, x; X_0, X_1\right).$$

The conclusion follows from the change of variable $s = \frac{tM_1}{M_0}$. If one of the norms M_j is zero, approximate it by $M_j + \varepsilon$ and let $\varepsilon \to 0^+$. □

Corollary 5.3.2. (Interpolation of embeddings) If $X_j \hookrightarrow Y_j$ for $j \in \{0,1\}$, then $(X_0, X_1)_{\theta,q} \hookrightarrow (Y_0, Y_1)_{\theta,q}$. If there are linear operators $R\colon X_j \longrightarrow Y_j$ and $S\colon Y_j \longrightarrow X_j$, continuous at both endpoints and satisfying $SR = I$ on $X_0 + X_1$, then S induces a retraction and R a coretraction between the interpolated spaces.

Proof. The inclusion $I\colon X_0 + X_1 \to Y_0 + Y_1$ restricted to each endpoint is a continuous operator $I\colon X_j \to Y_j$. The operator interpolation theorem, applied to I, provides a continuous operator

$$I\colon (X_0, X_1)_{\theta,q} \longrightarrow (Y_0, Y_1)_{\theta,q},$$

which is precisely the embedding in the first assertion.
In the second situation, applying the same theorem separately to R and S gives continuous operators

$$R\colon (X_0, X_1)_{\theta,q} \longrightarrow (Y_0, Y_1)_{\theta,q}, \qquad S\colon (Y_0, Y_1)_{\theta,q} \longrightarrow (X_0, X_1)_{\theta,q}.$$

For $x \in (X_0, X_1)_{\theta,q} \subseteq X_0 + X_1$, the assumed identity on the sum space implies

$$S(Rx) = x.$$

Thus $S \circ R = I$ on the interpolated space: S is a retraction, and R is its corresponding coretraction. □

Theorem 5.3.3. (Compactness into a common target space) Let Y be a Banach space and let $T\colon X_0 + X_1 \longrightarrow Y$ be linear. If $T\colon X_0 \longrightarrow Y$ is compact and $T\colon X_1 \longrightarrow Y$ is continuous, then

$$T\colon (X_0, X_1)_{\theta,q} \longrightarrow Y$$

is compact for $0 < \theta < 1$ and $1 \le q \le \infty$.

Proof. Let B be a bounded subset of $(X_0, X_1)_{\theta,q}$. By Lemma 5.2.5, including when $q = \infty$, there is $C > 0$ such that $K(t,x) \le Ct^\theta$ for every $t > 0$ and $x \in B$. For each $x \in B$, choose $x = a_{x,t} + b_{x,t}$ with

$$\|a_{x,t}\|_{X_0} + t\|b_{x,t}\|_{X_1} \le 2Ct^\theta.$$

Given a tolerance $\varepsilon > 0$, choose t sufficiently large that $2C\|T\|_{X_1 \to Y} t^{\theta-1} < \varepsilon$. The set $\{a_{x,t} \mid x \in B\}$ is bounded in X_0 and, by compactness of $T\colon X_0 \longrightarrow Y$, its image can be covered by finitely many balls of radius ε. Since

$$\|Tb_{x,t}\|_Y \le 2C\|T\|_{X_1 \to Y} t^{\theta-1} < \varepsilon,$$

$T(B)$ admits a finite cover by balls of radius 2ε. Thus $T(B)$ is totally bounded; since Y is complete, its closure is compact. This proves the assertion. □

5.4 The J-method

The K-functional describes an element through a single scale-dependent decomposition. The J-method instead uses a continuous superposition of elements belonging to both endpoint spaces simultaneously.

Definition 5.4.1. (J-functional) For $a \in X_0 \cap X_1$ and $t > 0$, define

$$J(t, a; X_0, X_1) := \max\{\|a\|_{X_0}, t\|a\|_{X_1}\}.$$

A function $u : (0,\infty) \longrightarrow X_0 \cap X_1$ is admissible for $x \in X_0 + X_1$ if it is strongly measurable, the Bochner integral $\int_0^\infty u(t)\,dt/t$ converges in $X_0 + X_1$, and

$$x = \int_0^\infty u(t)\,\frac{dt}{t}.$$

Definition 5.4.2. (Space defined by the J-method) Let $0 < \theta < 1$ and $1 \le q \le \infty$. Define $(X_0, X_1)_{\theta,q;J}$ as the set of $x \in X_0 + X_1$ admitting a representation as above for which

$$t \longmapsto t^{-\theta} J(t, u(t))$$

belongs to $L^q((0,\infty), dt/t)$. Its norm is the infimum of the $L^q((0,\infty), dt/t)$ norm over all admissible representations.

Lemma 5.4.3. (From a J-representation to a K-estimate) If $x = \int_0^\infty u(t)\,dt/t$ is an admissible representation with $t^{-\theta} J(t, u(t)) \in L^q((0,\infty), dt/t)$, then for $r > 0$,

$$K(r, x) \le \int_0^r \|u(t)\|_{X_0}\,\frac{dt}{t} + r\int_r^\infty \|u(t)\|_{X_1}\,\frac{dt}{t}.$$

Proof. Split the integral over $(0, r)$ and (r,∞). If $g(t) := t^{-\theta} J(t, u(t)) \in L^q((0,\infty), dt/t)$, then

$$\int_0^r \|u(t)\|_{X_0}\,\frac{dt}{t} \le \int_0^r t^\theta g(t)\,\frac{dt}{t} < \infty$$

and

$$\int_r^\infty \|u(t)\|_{X_1}\,\frac{dt}{t} \le \int_r^\infty t^{\theta-1} g(t)\,\frac{dt}{t} < \infty.$$

Finiteness follows from Proposition B.7.9, or directly if $q = 1, \infty$. By the Bochner integrability criterion in Proposition B.6.23, the first part converges in X_0 and the second in X_1. This splitting is an admissible decomposition for $K(r, x)$, and the triangle inequality for the Bochner integral gives the stated estimate. □

Theorem 5.4.4. (Equivalence of the K- and J-methods) For every compatible pair of Banach spaces, $0 < \theta < 1$ and $1 \le q \le \infty$,

$$(X_0, X_1)_{\theta,q;K} = (X_0, X_1)_{\theta,q;J}$$

and there are constants $c_{\theta,q}, C_{\theta,q} > 0$, independent of the pair and the element, such that

$$c_{\theta,q}\|x\|_{\theta,q;K} \le \|x\|_{\theta,q;J} \le C_{\theta,q}\|x\|_{\theta,q;K}$$

for every x in the common space.

Proof. First let x be given by a J-representation. Lemma 5.4.3, followed by the two integral Hardy inequalities from Theorem B.8.6,

$$\left\| r^{-\theta} \int_0^r h(t)\,\frac{dt}{t} \right\|_{L^q((0,\infty),dr/r)} \le \frac{1}{\theta}\|t^{-\theta}h(t)\|_{L^q((0,\infty),dt/t)}$$

and

$$\left\| r^{1-\theta} \int_r^\infty h(t)\,\frac{dt}{t} \right\|_{L^q((0,\infty),dr/r)} \le \frac{1}{1-\theta}\|t^{1-\theta}h(t)\|_{L^q((0,\infty),dt/t)},$$

gives $\|x\|_{\theta,q;K} \le C_{\theta,q}\|x\|_{\theta,q;J}$. In the first inequality, we use $h(t) = \|u(t)\|_{X_0}$, and in the second, $h(t) = \|u(t)\|_{X_1}$. For the reverse inclusion, use a dyadic construction. Choose decompositions $x = a_k + b_k$ such that

$$\|a_k\|_{X_0} + 2^k\|b_k\|_{X_1} \le 2K(2^k, x).$$

Lemma 5.2.5 gives $K(2^k, x) \le C2^{k\theta}\|x\|_{\theta,q;K}$. Set $v_k := a_{k+1} - a_k = b_k - b_{k+1}$. Then

$$\|a_k\|_{X_0} \longrightarrow 0 \quad (k \to -\infty), \qquad \|b_k\|_{X_1} \longrightarrow 0 \quad (k \to \infty).$$

Truncating the sum gives $\displaystyle\sum_{k=-N}^{N} v_k = a_{N+1} - a_{-N} \to x$ in $X_0 + X_1$. Therefore, $x = \displaystyle\sum_{k\in\mathbb{Z}} v_k$ in $X_0 + X_1$. Moreover,

$$J(2^k, v_k) \le C\big(K(2^k, x) + K(2^{k+1}, x)\big).$$

Define $u(t) := (\log 2)^{-1} v_k$ for $2^k \le t < 2^{k+1}$. For $k \le 0$, use $\|v_k\|_{X_0} \le C2^{k\theta}\|x\|_{\theta,q;K}$; for $k > 0$, use $\|v_k\|_{X_1} \le C2^{-k(1-\theta)}\|x\|_{\theta,q;K}$. Both geometric series converge. Thus u is integrable in $X_0 + X_1$ and $x = \displaystyle\int_0^\infty u(t)\,dt/t$. Lemma 5.2.5 and the preceding estimate give $\|x\|_{\theta,q;J} \le C\|x\|_{\theta,q;K}$. □

Lemma 5.4.5. (Discrete characterization of the J-method) Let $0 < \theta < 1$ and $1 \le q \le \infty$. An element $x \in X_0 + X_1$ belongs to $(X_0, X_1)_{\theta,q}$ if and only if it admits a representation

$$x = \sum_{k\in\mathbb{Z}} u_k \quad \text{in } X_0 + X_1, \qquad u_k \in X_0 \cap X_1,$$

for which

$$\big(2^{-k\theta} J(2^k, u_k; X_0, X_1)\big)_{k\in\mathbb{Z}} \in \ell^q(\mathbb{Z}).$$

Moreover, the interpolation norm is equivalent to the infimum of the norm of this sequence over all such representations. If $q < \infty$, $X_0 \cap X_1$ is dense in $(X_0, X_1)_{\theta,q}$.

Proof. First suppose that a discrete representation is given, and write $c_k := 2^{-k\theta} J(2^k, u_k)$. For $k \le 0$,

$$\|u_k\|_{X_0} \le 2^{k\theta} c_k,$$

and, for $k > 0$,

$$\|u_k\|_{X_1} \le 2^{-k(1-\theta)} c_k.$$

Proposition B.7.9 for sequences and summation of the geometric series show that the two tails converge in X_0 and X_1, respectively. Defining $u(t) := (\log 2)^{-1} u_k$ on $[2^k, 2^{k+1})$ yields an admissible representation and, for every $t \in [2^k, 2^{k+1})$,

$$\frac{2^{-\theta}}{\log 2} 2^{-k\theta} J(2^k, u_k) \le t^{-\theta} J(t, u(t)) \le \frac{2}{\log 2} 2^{-k\theta} J(2^k, u_k).$$

This proves one of the norm estimates.
Conversely, given an admissible representation $u(t)$, set

$$u_k := \int_{2^k}^{2^{k+1}} u(t) \frac{dt}{t}.$$

Proposition B.6.27 allows these integrals to be summed in $X_0 + X_1$ and gives $x = \sum_{k\in\mathbb{Z}} u_k$. The triangle inequality for the Bochner integral and $2^k \le t$ imply

$$J(2^k, u_k) \le \int_{2^k}^{2^{k+1}} J(t, u(t)) \frac{dt}{t}.$$

Proposition B.7.9 on each dyadic interval, followed by Theorem B.6.17, yields

$$\left\| \left(2^{-k\theta} J(2^k, u_k)\right)_{k\in\mathbb{Z}} \right\|_{\ell^q(\mathbb{Z})} \le C_{\theta,q} \| t^{-\theta} J(t, u(t)) \|_{L^q((0,\infty), dt/t)}.$$

The case $q = \infty$ follows by taking suprema. Taking the infimum over representations and using Theorem 5.4.4 completes the equivalence of norms. If $q < \infty$, the finite sums $\sum_{\substack{k\in\mathbb{Z} \\ |k|\le N}} u_k \in X_0 \cap X_1$ converge to x in the interpolation norm, since tails of a sequence in $\ell^q(\mathbb{Z})$ tend to zero. This proves the final assertion. □

5.5 Reiteration

Interpolation can be applied more than once. The following result states that interpolating between two already interpolated levels produces no new scales.

Lemma 5.5.1. (Holmstedt's formula) Let (X_0, X_1) be a compatible pair of Banach spaces, and let $0 < \theta_0 < \theta_1 < 1$ and $1 \le q_0, q_1 \le \infty$. Set $X_{\theta_j} := (X_0, X_1)_{\theta_j, q_j}$. There are constants $c, C > 0$ such that for $x \in X_0 + X_1$ and $r > 0$,

$$c\big(A_0(r,x) + r^{\theta_1-\theta_0} A_1(r,x)\big) \le K(r^{\theta_1-\theta_0}, x; X_{\theta_0}, X_{\theta_1}) \le C\big(A_0(r,x) + r^{\theta_1-\theta_0} A_1(r,x)\big),$$

where

$$A_0(r,x) := \left\| t^{-\theta_0} K(t,x;X_0,X_1) \right\|_{L^{q_0}((0,r),dt/t)},$$

and

$$A_1(r,x) := \left\| t^{-\theta_1} K(t,x;X_0,X_1) \right\|_{L^{q_1}((r,\infty),dt/t)},$$

with suprema when some $q_j = \infty$. If $x \notin X_{\theta_0} + X_{\theta_1}$, the functional in the middle is interpreted as $+\infty$. The constants c and C depend only on $\theta_0, \theta_1, q_0, q_1$.

Proof. Set $\delta := \theta_1 - \theta_0$ and choose $m \in \mathbb{Z}$ so that $2^m \le r < 2^{m+1}$. First suppose that $A_0(r,x) + r^\delta A_1(r,x) < \infty$. For each $k \in \mathbb{Z}$, choose a decomposition $x = a_k + b_k$ such that

$$\|a_k\|_{X_0} + 2^k \|b_k\|_{X_1} \le 2K(2^k, x; X_0, X_1)$$

and set $u_k := a_{k+1} - a_k = b_k - b_{k+1}$. Comparison of K on dyadic intervals gives $K(2^k,x) \le C 2^{k\theta_0} A_0(r,x)$ for $2^{k+1} \le r$ and $K(2^k,x) \le C 2^{k\theta_1} A_1(r,x)$ for $2^{k-1} \ge r$. Thus $a_k \to 0$ in X_0 as $k \to -\infty$, and $b_k \to 0$ in X_1 as $k \to \infty$. Therefore, $x = \sum_{k\in\mathbb{Z}} u_k$ in $X_0 + X_1$, and

$$\|u_k\|_{X_0} + 2^k \|u_k\|_{X_1} \le C\big(K(2^k,x) + K(2^{k+1},x)\big).$$

Define

$$x_0 := \sum_{\substack{k\in\mathbb{Z}\\ k\le m}} u_k, \qquad x_1 := \sum_{\substack{k\in\mathbb{Z}\\ k>m}} u_k.$$

The discrete characterization of the J-method in Lemma 5.4.5, Lemma 5.2.5, and comparison of r with 2^m give

$$\|x_0\|_{X_{\theta_0}} \le C A_0(r,x), \qquad \|x_1\|_{X_{\theta_1}} \le C A_1(r,x).$$

For the terms near the splitting point, use $K(2^{m+1},x) \le 4K(2^{m-1},x)$ and the interval $[2^{m-1}, 2^m] \subseteq (0,r)$; for the other tail, use $[2^{m+1}, 2^{m+2}] \subseteq (r,\infty)$. Thus the constants also control the terms adjacent to r. Each series converges in $X_0 + X_1$ and defines a J-representation of the indicated space; this proves membership even when $q_j = \infty$, without requiring convergence of partial sums in the norm of that space. Since $x = x_0 + x_1$, this decomposition proves

$$K(r^\delta, x; X_{\theta_0}, X_{\theta_1}) \le C\big(A_0(r,x) + r^\delta A_1(r,x)\big).$$

If either tail is infinite, this inequality holds automatically.
For the reverse bound, let $x = y_0 + y_1$ with $y_j \in X_{\theta_j}$. Lemma 5.2.5 implies the pointwise estimate

$$K(t, y_j; X_0, X_1) \le C t^{\theta_j} \|y_j\|_{X_{\theta_j}}, \qquad t > 0.$$

The triangle inequality for $K(t,\cdot)$ gives

$$A_0(r,x) \le C\big(\|y_0\|_{X_{\theta_0}} + r^\delta \|y_1\|_{X_{\theta_1}}\big)$$

and

$$r^\delta A_1(r,x) \le C\big(\|y_0\|_{X_{\theta_0}} + r^\delta \|y_1\|_{X_{\theta_1}}\big).$$

Here we integrate only the powers $t^{\delta q_0}$ on $(0,r)$ and $t^{-\delta q_1}$ on (r,∞); if an exponent is infinite, take suprema. Taking the infimum over decompositions $x = y_0 + y_1$ yields the remaining inequality. □

Theorem 5.5.2. (Real reiteration theorem) Let $0 \le \theta_0 < \theta_1 \le 1$, $0 < \eta < 1$, and $1 \le q, q_0, q_1 \le \infty$. If $X_{\theta_j} = (X_0, X_1)_{\theta_j, q_j}$ when $0 < \theta_j < 1$, while $X_{\theta_0} = X_0$ if $\theta_0 = 0$ and $X_{\theta_1} = X_1$ if $\theta_1 = 1$, then

$$(X_{\theta_0}, X_{\theta_1})_{\eta,q} = (X_0, X_1)_{\theta,q}, \qquad \theta := (1-\eta)\theta_0 + \eta\theta_1,$$

and there are constants $c, C > 0$, depending only on $\theta_0, \theta_1, \eta, q, q_0, q_1$, such that

$$c\|x\|_{(X_0,X_1)_{\theta,q}} \le \|x\|_{(X_{\theta_0},X_{\theta_1})_{\eta,q}} \le C\|x\|_{(X_0,X_1)_{\theta,q}}$$

for every x in the common space.

Proof. First assume $0 < \theta_0 < \theta_1 < 1$ and set $\delta := \theta_1 - \theta_0$, so that $\theta = \theta_0 + \eta\delta$. Write

$$K_*(\tau, x) := K(\tau, x; X_{\theta_0}, X_{\theta_1}), \qquad c_k := 2^{-k\theta} K(2^k, x; X_0, X_1).$$

The proof of Lemma 5.2.5, with geometric base 2^δ in place of 2, provides constants $d_*, D_* > 0$ such that

$$d_* \left\| (2^{-k\eta\delta} K_*(2^{k\delta}, x))_k \right\|_{\ell^q} \le \|x\|_{(X_{\theta_0},X_{\theta_1})_{\eta,q}} \le D_* \left\| (2^{-k\eta\delta} K_*(2^{k\delta}, x))_k \right\|_{\ell^q}.$$

By Lemma 5.5.1, the sequence between the norm signs is bounded above and below, term by term, by multiples of

$$B_{0,k} := 2^{-k\eta\delta} A_0(2^k, x), \qquad B_{1,k} := 2^{k(1-\eta)\delta} A_1(2^k, x).$$

Splitting the integrals defining A_0 and A_1 into the intervals $[2^j, 2^{j+1}]$ and using monotonicity of K and $\frac{K(t,x)}{t}$, as in the proof of the discretization lemma, reduces the upper bound to the two sequence operators

$$(\mathsf{H}^-_{a,r} c)_k := \left(\sum_{\substack{j \in \mathbb{Z} \\ j \le k}} (2^{-a(k-j)} |c_j|)^r \right)^{\frac{1}{r}},$$

$$(\mathsf{H}^+_{a,r} c)_k := \left(\sum_{\substack{j \in \mathbb{Z} \\ j \ge k}} (2^{-a(j-k)} |c_j|)^r \right)^{\frac{1}{r}},$$

with suprema if $r = \infty$, taking $(a, r) = (\eta\delta, q_0)$ and $(a, r) = ((1-\eta)\delta, q_1)$, respectively. For any $a > 0$ and $1 \le q, r \le \infty$, there is $C_{a,q,r} > 0$ such that

$$\|\mathsf{H}^-_{a,r} c\|_{\ell^q} + \|\mathsf{H}^+_{a,r} c\|_{\ell^q} \le C_{a,q,r} \|c\|_{\ell^q}.$$

Indeed, if $q \ge r < \infty$, raise to the power r and apply Young's inequality in $\ell^{\frac{q}{r}}$ to the geometric kernel

$(2^{-arm}\mathbf{1}_{\{m\ge 0\}})_m$. If $q<r$, use

$$\left(\sum_{j\in\mathbb{Z}} d_j^r\right)^{\frac{q}{r}} \le \sum_{j\in\mathbb{Z}} d_j^q$$

and sum first over the outer index; the geometric series $\sum_{m\in\mathbb{N}_0} 2^{-aqm}$ appears. For $r=\infty$, the supremum is bounded by the sum of powers q, and for $q=\infty$ the assertion follows directly. The tail operator is treated with the reflected kernel. We deduce

$$\|x\|_{(X_{\theta_0},X_{\theta_1})_{\eta,q}} \le C\|(c_k)_k\|_{\ell^q} \le C'\|x\|_{(X_0,X_1)_{\theta,q}}.$$

For the reverse bound, the interval $[2^k,2^{k+1}]$ in the definition of $A_0(2^{k+1},x)$ and monotonicity of K give a constant $d_0=d_0(\theta_0,q_0)>0$ such that

$$2^{-(k+1)\eta\delta}A_0(2^{k+1},x) \ge d_0 c_k.$$

This also holds for $q_0=\infty$, interpreting the norm as a supremum. Holmstedt's lower bound and the two discretizations yield

$$\|x\|_{(X_0,X_1)_{\theta,q}} \le C\|x\|_{(X_{\theta_0},X_{\theta_1})_{\eta,q}}.$$

Now consider $\theta_0=0<\theta_1<1$. We first prove

$$K(r^{\theta_1},x;X_0,X_{\theta_1}) \asymp K(r,x)+r^{\theta_1}A_1(r,x), \tag{5.1}$$

where $\asymp$ means that each side is bounded by a positive constant times the other, uniformly in x and r.
If the right-hand side is finite and $x\neq 0$, choose $x=a+b$ with

$$\|a\|_{X_0}+r\|b\|_{X_1} \le 2K(r,x).$$

For $t<r$, use $K(t,b)\le t\|b\|_{X_1}$; for $t\ge r$, the triangle inequality and monotonicity give

$$K(t,b) \le K(t,x)+\|a\|_{X_0} \le 3K(t,x).$$

Integrating on both intervals, or taking suprema, yields

$$\|b\|_{X_{\theta_1}} \le C\big(r^{-\theta_1}K(r,x)+A_1(r,x)\big).$$

This decomposition proves one bound in (5.1). For the other, write $x=y_0+y_1$, where $y_0\in X_0$ and $y_1\in X_{\theta_1}$. The pointwise estimate for K and the integral of $t^{-\theta_1 q_1}$ over (r,∞) give

$$K(r,x) \le \|y_0\|_{X_0}+Cr^{\theta_1}\|y_1\|_{X_{\theta_1}},$$
$$r^{\theta_1}A_1(r,x) \le C\|y_0\|_{X_0}+r^{\theta_1}\|y_1\|_{X_{\theta_1}}.$$

Take the infimum over y_0,y_1.
The case $0<\theta_0<\theta_1=1$ follows by applying the preceding formula to the pair (X_1,X_0) with parameter $1-\theta_0$ and scale r^{-1}. Indeed, symmetry of the K-functional and the substitution $t\mapsto t^{-1}$ transform that

formula into

$$K(r^{1-\theta_0}, x; X_{\theta_0}, X_1) \asymp A_0(r,x) + r^{-\theta_0} K(r,x). \tag{5.2}$$

Multiply (5.1) by $r^{-\eta\theta_1}$, or (5.2) by $r^{-\eta(1-\theta_0)}$. In both cases, the term containing $K(r,x)$ is $r^{-\theta}K(r,x)$. The other term is controlled by $\mathsf{H}^+_{(1-\eta)\theta_1,q_1}$ or $\mathsf{H}^-_{\eta(1-\theta_0),q_0}$, respectively. The estimates already proved for these operators give the upper bound, and the term $r^{-\theta}K(r,x)$ gives the lower bound. If $\theta_0 = 0$ and $\theta_1 = 1$, the assertion is the definition. □

Definition 5.5.3. (ℓ^q-sums of a family of Banach spaces) Let I be a set and let $(Z_i)_{i\in I}$ be a family of Banach spaces. For $1 \le q < \infty$, define

$$\ell^q\big(I;(Z_i)_{i\in I}\big) := \left\{ z = (z_i)_{i\in I} \;\middle|\; z_i \in Z_i \text{ for every } i \in I, \quad \sum_{i\in I} \|z_i\|_{Z_i}^q < \infty \right\},$$

with the norm

$$\|z\|_{\ell^q(I;(Z_i)_{i\in I})} := \left(\sum_{i\in I} \|z_i\|_{Z_i}^q \right)^{\frac{1}{q}}.$$

A sum over an arbitrary set is understood as the supremum of sums over finite subsets. For $q = \infty$, set

$$\ell^\infty\big(I;(Z_i)_{i\in I}\big) := \left\{ z = (z_i)_{i\in I} \;\middle|\; z_i \in Z_i \text{ for every } i \in I, \quad \sup_{i\in I} \|z_i\|_{Z_i} < \infty \right\},$$

with the supremum norm. If all the spaces equal a single space Z, write simply $\ell^q(I;Z)$. When $I = \mathbb{Z}$ and the family is indicated in the argument, we shall also use the abbreviation $\ell^q((Z_k)_{k\in\mathbb{Z}})$.

Lemma 5.5.4. (Duality of ℓ^q-sums) Let I be a set, let $(Z_i)_{i\in I}$ be a family of Banach spaces, and let $1 \le q < \infty$. Then

$$\big(\ell^q\big(I;(Z_i)_{i\in I}\big)\big)' = \ell^{q'}\big(I;(Z_i')_{i\in I}\big)$$

isometrically, through the pairing

$$\langle z, \lambda\rangle := \sum_{i\in I} \lambda_i(z_i).$$

Proof. Hölder's inequality for summable families shows that each $\lambda = (\lambda_i)_{i\in I}$ in the space on the right defines a continuous functional whose norm does not exceed $\|\lambda\|_{\ell^{q'}(I;(Z_i')_{i\in I})}$.
Conversely, let Λ be a continuous functional on the space on the left. For each $i \in I$, denote by

$$\iota_i \colon Z_i \longrightarrow \ell^q\big(I;(Z_j)_{j\in I}\big)$$

the inclusion into coordinate i and set $\lambda_i := \Lambda \circ \iota_i$. If $F \subseteq I$ is finite, choose $z_i \in Z_i$ of norm one that realizes $\|\lambda_i\|_{Z_i'}$ with arbitrarily small error. Duality of $\ell^q(F)$ gives

$$\left(\sum_{i\in F} \|\lambda_i\|_{Z_i'}^{q'} \right)^{\frac{1}{q'}} \le \|\Lambda\|,$$

with the usual interpretation as a maximum when $q' = \infty$. Taking the supremum over finite subsets F, we

obtain $\lambda \in \ell^{q'}(I;(Z_i')_{i\in I})$ and $\|\lambda\| \le \|\Lambda\|$.
Finitely supported families are dense in $\ell^q(I;(Z_i)_{i\in I})$ for $q<\infty$. Thus the equality

$$\Lambda(z) = \sum_{i\in I} \lambda_i(z_i)$$

is first proved for finite support and then extended by continuity. The first estimate gives equality of norms. The argument includes $q=1$, in which case $q'=\infty$. □

A Banach pair (X_0,X_1) is called *regular* if $X_0\cap X_1$ is dense in each X_j. In that case, the duals X_0' and X_1' are viewed as subspaces of $(X_0\cap X_1)'$ by restriction and form a compatible pair.

Lemma 5.5.5. (Dual of the intersection of a regular pair) If (X_0,X_1) is a regular pair, restriction gives the isometric identification

$$(X_0\cap X_1)' = X_0' + X_1',$$

where the intersection carries the maximum norm and the sum of the duals carries the quotient norm. More generally, for $t>0$,

$$\|y\|_{(X_0\cap X_1, J(t,\cdot))'} = K(t^{-1}, y; X_0', X_1').$$

Proof. Consider the diagonal inclusion

$$D\colon X_0\cap X_1 \longrightarrow X_0\times X_1, \qquad Dx=(x,x),$$

where the product carries the norm $\max\{\|x_0\|_{X_0}, t\|x_1\|_{X_1}\}$. Every functional y on the diagonal extends without increasing its norm by the Hahn–Banach corollary B.2.29. A functional on the product has the form $(x_0,x_1)\mapsto y_0(x_0)+y_1(x_1)$ and norm $\|y_0\|_{X_0'}+t^{-1}\|y_1\|_{X_1'}$. Restricting it to the diagonal and taking the infimum over all extensions gives the formula. Regularity ensures that restriction $X_j'\to(X_0\cap X_1)'$ is injective, so the sum belongs to a compatible pair and is not merely an abstract quotient. □

5.6 Duality for real interpolation

Theorem 5.6.1. (Duality of the real method) Let (X_0,X_1) be a regular pair, let $0<\theta<1$, and let $1\le q<\infty$. Then the pairing between X_0+X_1 and $X_0'\cap X_1'$ extends to a topological isomorphism

$$\big((X_0,X_1)_{\theta,q}\big)' \cong (X_0',X_1')_{\theta,q'},$$

where q' is the conjugate exponent. For $q=\infty$, the continuous embedding of the space on the right into the dual on the left is retained, but surjectivity may fail. More precisely, if $1\le q<\infty$ and $\Lambda_y(x):=\langle x,y\rangle$, there are constants $c_{\theta,q}, C_{\theta,q}>0$ such that

$$c_{\theta,q}\|y\|_{(X_0',X_1')_{\theta,q'}} \le \|\Lambda_y\|_{((X_0,X_1)_{\theta,q})'} \le C_{\theta,q}\|y\|_{(X_0',X_1')_{\theta,q'}}.$$

Proof. Set $\Delta := X_0 \cap X_1$, $\Sigma := X_0 + X_1$, and $Y := (X_0', X_1')_{\theta,q'}$. Regularity allows all elements of Y to be viewed as functionals on Δ.
If $a \in \Delta$ and $v \in X_0' \cap X_1'$, every decomposition $a = a_0 + a_1$ satisfies

$$|\langle a, v\rangle| \le \bigl(\|a_0\|_{X_0} + t^{-1}\|a_1\|_{X_1}\bigr) J(t, v; X_0', X_1').$$

Thus,

$$|\langle a, v\rangle| \le K(t^{-1}, a; X_0, X_1) J(t, v; X_0', X_1'). \tag{5.3}$$

Represent $y \in Y$ by the J-method for the dual pair:

$$y = \int_0^\infty v(t)\,\frac{dt}{t} \quad \text{in } X_0' + X_1' = \Delta'.$$

The identification of the sum space with Δ' comes from Lemma 5.5.5. Evaluation at $a \in \Delta$ is continuous on this space, so (5.3), Hölder's inequality, and the substitution $r = t^{-1}$ give

$$\begin{aligned} |\langle a, y\rangle| &\le \int_0^\infty \bigl(t^\theta K(t^{-1}, a)\bigr)\bigl(t^{-\theta} J(t, v(t))\bigr)\,\frac{dt}{t} \\ &\le \|a\|_{\theta,q;K} \bigl\|t^{-\theta} J(t, v(t))\bigr\|_{L^{q'}((0,\infty), dt/t)}. \end{aligned}$$

Take the infimum over representations and apply Theorem 5.4.4. If $q < \infty$, density of Δ from Lemma 5.4.5 allows y to extend uniquely to a continuous functional Λ_y on $(X_0, X_1)_{\theta,q}$, with the asserted bound.
Conversely, let $\Lambda \in ((X_0, X_1)_{\theta,q})'$ and assume $q < \infty$. Define

$$Z_k := (\Delta, 2^{-k\theta} J(2^k, \cdot)), \qquad \mathcal{J}_{\theta,q} := \ell^q\bigl(\mathbb{Z}; (Z_k)_k\bigr).$$

Each Z_k is Banach by Proposition 5.1.2. Lemma 5.4.5 shows that $S((a_k)_{k\in\mathbb{Z}}) := \sum_{k\in\mathbb{Z}} a_k$ is continuous and surjective from $\mathcal{J}_{\theta,q}$ onto the interpolated space. Apply Lemma 5.5.4 directly to the functional $\Lambda \circ S$. We obtain functionals $\lambda_k \in \Delta'$ such that

$$\Bigl\|\bigl(2^{k\theta}\|\lambda_k\|_{(\Delta, J(2^k,\cdot))'}\bigr)_k\Bigr\|_{\ell^{q'}} \le C_{\theta,q}\|\Lambda\|.$$

Evaluation on a sequence whose only nonzero coordinate is $a \in \Delta$ gives $\lambda_k(a) = \Lambda(a)$. Thus all λ_k agree with $y := \Lambda|_\Delta$. Lemma 5.5.5 transforms the estimate into

$$\Bigl\|\bigl(2^{k\theta} K(2^{-k}, y; X_0', X_1')\bigr)_k\Bigr\|_{\ell^{q'}} \le C_{\theta,q}\|\Lambda\|.$$

Lemma 5.2.5, with the change of index $k \mapsto -k$, implies $y \in Y$ and gives the other norm bound. Since Δ is dense, $\Lambda = \Lambda_y$ on the whole space.
For $q = \infty$, the pairing outside Δ requires clarification. Let $x \in (X_0, X_1)_{\theta,\infty}$ and take the partial sums x_N of a nearly optimal discrete J-representation. Then $x_N \in \Delta$, $x_N \to x$ in Σ, and

$$\sup_{N\in\mathbb{N}} \|x_N\|_{\theta,\infty;K} \le C_\theta \|x\|_{\theta,\infty;K}.$$

If $y \in X_0' \cap X_1'$, its action is continuous on Σ. The estimate already obtained on Δ, followed by the limit in

N, gives

$$|\langle x, y\rangle| \le C_\theta \|x\|_{\theta,\infty;K} \|y\|_{(X_0', X_1')_{\theta,1}}.$$

Lemma 5.4.5, applied to the dual pair with second index 1, extends this pairing to all of $y \in (X_0', X_1')_{\theta,1}$. It is bilinear, continuous, and injective in y, since on Δ it agrees with the original action. The preceding proof of surjectivity requires duality of ℓ^q with $q < \infty$ and does not apply at the endpoint $q = \infty$. □

5.7 The complex method

In this section, the Banach spaces are complex. A function $F\colon U \subseteq \mathbb{C} \longrightarrow X$ is called holomorphic if the limit

$$F'(z) := \lim_{h\to 0} \frac{F(z+h) - F(z)}{h}$$

exists in the norm of X for each $z \in U$.

To apply the method to a real space X, use its complexification $X_{\mathbb{C}} := X + iX$ with the norm

$$\|x + iy\|_{X_{\mathbb{C}}} := \sup_{t\in\mathbb{R}} \|x\cos t - y \sin t\|_X.$$

Multiplication by a complex scalar rotates the pair (x, y) and multiplies it by the modulus of the scalar, so this expression is a complex norm. Moreover,

$$\max\{\|x\|_X, \|y\|_X\} \le \|x + iy\|_{X_{\mathbb{C}}} \le \|x\|_X + \|y\|_X,$$

which proves completeness. The inclusions of a real pair are complexified within a common ambient space. Define its real interpolated space as the fixed-point space of conjugation on $[X_{0,\mathbb{C}}, X_{1,\mathbb{C}}]_\theta$. Conjugation preserves the Calderón norm upon replacing $F(z)$ by $\overline{F(\bar z)}$. If T is real and continuous, its complex extension has the same norm: the inequality $\|T_{\mathbb{C}}(x + iy)\| \le \|T\|\|x + iy\|$ follows for each term in the supremum, and the reverse bound follows on X. Thus the operator theorems also apply to real spaces. The isometric equalities below are formulated for complex spaces with the indicated norms. Passage to their real parts retains the identifications with equivalent norms.

We shall denote by

$$\mathcal{T} := \{z \in \mathbb{C} \mid 0 < \operatorname{Re} z < 1\}, \qquad \overline{\mathcal{T}} = \{z \in \mathbb{C} \mid 0 \le \operatorname{Re} z \le 1\}$$

the open strip and its closure, respectively.

Before defining the Calderón space, we establish the complex analysis tools to be used in both the scalar and vector-valued cases.

Proposition 5.7.1. (Cauchy's integral formula with values in a Banach space) Let $U \subseteq \mathbb{C}$ be open, let X be a complex Banach space, and let $F\colon U \longrightarrow X$ be holomorphic. If $\overline{B}_{\mathrm{euc}}(z_0, r) \subseteq U$, then for $z \in B_{\mathrm{euc}}(z_0, r)$ and $m \in \mathbb{N}_0$,

$$F^{(m)}(z) = \frac{m!}{2\pi i} \int_{|\zeta - z_0| = r} \frac{F(\zeta)}{(\zeta - z)^{m+1}}\, d\zeta, \tag{5.4}$$

where the circle is traversed with positive orientation and the integral is a Bochner integral. In particular, F admits a Taylor series around each point, convergent in the norm of X. If $X = \mathbb{C}$ and two holomorphic functions agree on a set with an interior accumulation point, they agree on every connected component of

U containing that point.

Proof. Begin with the scalar case and Goursat's argument. If the integral of a holomorphic function over the boundary of a triangle were nonzero, subdividing the triangle into four congruent triangles would allow us to choose one whose integral has modulus at least one quarter of the original. Iteration produces nested triangles with diameters tending to zero and a common point a. For each $\varepsilon > 0$, differentiability of f at a provides $\delta > 0$ such that

$$|f(\zeta) - f(a) - f'(a)(\zeta - a)| \le \varepsilon |\zeta - a| \qquad \text{if } |\zeta - a| < \delta.$$

The integrals of the two affine terms over a triangular boundary vanish. If $d_k := \operatorname{diam}(T_k) < \delta$, every point of T_k is at distance at most d_k from a, and the length of ∂T_k does not exceed $3d_k$; consequently,

$$\left| \int_{\partial T_k} f(\zeta)\, d\zeta \right| \le 3\varepsilon d_k^2.$$

On the other hand, the triangles are congruent after rescaling by 2^{-k}, so $d_k = 2^{-k} d_0$, whereas the inductive choice implies

$$\left| \int_{\partial T_k} f(\zeta)\, d\zeta \right| \ge 4^{-k} \left| \int_{\partial T_0} f(\zeta)\, d\zeta \right|.$$

If the last integral were nonzero, division by d_k^2 and the choice $3\varepsilon < d_0^{-2} |\int_{\partial T_0} f(\zeta)\, d\zeta|$ would give a contradiction. Thus the integral over every triangular boundary is zero. Summing over a triangulation cancels the integrals along interior edges. This gives the result for polygonal regions, including those with holes. For the circles we shall use, approximate by inscribed polygons; uniform continuity of the integrand on a compact neighborhood and convergence of these parametrizations allow passage to the limit in the integrals.

Apply this fact to $\zeta \mapsto \frac{f(\zeta)}{\zeta - z}$ on the region between $|\zeta - z_0| = r$ and a small circle centered at z. Shrinking the latter circle yields

$$f(z) = \frac{1}{2\pi i} \int_{|\zeta - z_0| = r} \frac{f(\zeta)}{\zeta - z}\, d\zeta.$$

Differentiation of the kernel under the integral gives the formula for $f^{(m)}$.

Return to the vector-valued case. Continuity of F on the circle ensures existence of the Bochner integral. For every $\lambda \in X'$, the function $\lambda \circ F$ is holomorphic, and compatibility of the integral with continuous linear operators, Proposition B.6.27, allows application of the scalar formula to $m = 0$. The Hahn–Banach theorem B.2.27 shows that X' separates points and gives the vector-valued identity for $F(z)$. On each concentric disk of radius less than r, the difference quotients of $(\zeta - z)^{-1}$ converge uniformly on the circle to $(\zeta - z)^{-2}$. The Bochner integral inequality allows differentiation of the identity in the norm of X. Repetition gives all derivatives and the formula for each m.

If $|z - z_0| < \rho < r$, the geometric series for the kernel converges uniformly for $|z - z_0| \le \rho$; we may integrate term by term and obtain the Taylor series of F, converging uniformly in norm on that disk. In the scalar case, the first nonzero coefficient in this series shows that the zeros of a holomorphic function that is not identically zero are isolated. This proves the final assertion. □

Lemma 5.7.2. (Maximum principle and holomorphic limits) The following assertions hold.

(a) If $Q \subseteq \mathbb{C}$ is a compact rectangle and $f\colon Q \longrightarrow \mathbb{C}$ is continuous and holomorphic in the interior, then $\max_{z\in Q}|f(z)| = \max_{z\in \partial Q}|f(z)|$. Moreover, if $|f|$ attains its maximum at an interior point, then f is constant.

(b) A uniform limit on compact subsets of scalar holomorphic functions is holomorphic.

(c) If X is a Banach space, a uniform limit on compact subsets of holomorphic functions with values in X is holomorphic.

Proof. Proposition 5.7.1, with $m = 0$, gives the mean value property. If $|f|$ attains an interior maximum, equality in the triangle inequality for that formula forces f to be constant on a neighborhood; the final assertion of the same proposition propagates constancy throughout the connected interior of the rectangle. This proves (a).
For (b) and (c), let (F_j) be a sequence converging uniformly on compact subsets to F, with values in $\mathbb{C}$ or X, respectively. Each F_j satisfies Cauchy's formula from Proposition 5.7.1. Uniform convergence on the circle allows passage to the limit in the Bochner integral and gives

$$F(z) = \frac{1}{2\pi i}\int_{|\zeta - z_0| = r} \frac{F(\zeta)}{\zeta - z}\, d\zeta$$

on every disk whose closure is contained in the common domain. On a smaller concentric disk, the kernel and its derivative with respect to z are uniformly bounded on the circle. The fundamental theorem of calculus B.6.5 then allows differentiation under the integral and proves holomorphicity of F. □

Lemma 5.7.3. (Hadamard's three-lines lemma) Let $F\colon \overline{\mathcal{T}} \longrightarrow \mathbb{C}$ be continuous and bounded, holomorphic on $\mathcal{T}$, and suppose that $|F(j+it)| \le M_j$ for $t \in \mathbb{R}$ and $j = 0, 1$. Then

$$|F(\theta)| \le M_0^{1-\theta} M_1^{\theta}, \qquad 0 < \theta < 1.$$

Proof. We may assume $M_0 M_1 > 0$. For $\varepsilon > 0$, consider

$$G_\varepsilon(z) := F(z) M_0^{z-1} M_1^{-z} e^{\varepsilon(z-\theta)^2}.$$

On the vertical sides of a rectangle $0 \le \operatorname{Re} z \le 1$, $|\operatorname{Im} z| \le R$, its modulus is bounded by $e^{\varepsilon}\max\{\theta^2, (1-\theta)^2\}$; on the horizontal sides, it tends to zero as $R \to \infty$. The maximum principle from Lemma 5.7.2, applied to the rectangle and followed by the limit $R \to \infty$, gives $|G_\varepsilon(\theta)| \le e^{\varepsilon}\max\{\theta^2, (1-\theta)^2\}$. Finally, let $\varepsilon \to 0^+$. If $M_j = 0$, apply the preceding argument with $M_j + \delta$ and let $\delta \to 0^+$. □

The two lines bounding $\mathcal{T}$ represent the endpoint spaces: on it we measure in X_0, and on $1 + it$ in X_1, for $t \in \mathbb{R}$. A holomorphic function joins these boundary values. Evaluation at $z = \theta$ produces the intermediate element, and the three-lines lemma controls its size.

Definition 5.7.4. (Calderón space) Let (X_0, X_1) be a compatible pair of complex Banach spaces. Denote by $\mathscr{F}(X_0, X_1)$ the space of functions $F\colon \overline{\mathcal{T}} \longrightarrow X_0 + X_1$ that are continuous and bounded, holomorphic on $\mathcal{T}$, satisfy $F(j+it) \in X_j$, have restrictions $t \mapsto F(j+it)$ continuous in the norm of X_j with $F(j+it) \to 0$ in X_j as

$|t| \to \infty$, and have norm

$$\|F\|_{\mathscr{F}} := \max_{j\in\{0,1\}} \sup_{t\in\mathbb{R}} \|F(j+it)\|_{X_j} < \infty.$$

For $0 < \theta < 1$, define

$$[X_0, X_1]_\theta := \{F(\theta) \mid F \in \mathscr{F}(X_0, X_1)\}, \qquad \|x\|_{[X_0,X_1]_\theta} := \inf_{\substack{F\in\mathscr{F}(X_0,X_1)\\ F(\theta)=x}} \|F\|_{\mathscr{F}}.$$

Theorem 5.7.5. (Complex interpolation of operators) The space $[X_0, X_1]_\theta$ is Banach. If $T\colon X_0 + X_1 \longrightarrow Y_0 + Y_1$ is linear and $T\colon X_j \longrightarrow Y_j$ has norm M_j, then

$$T\colon [X_0, X_1]_\theta \longrightarrow [Y_0, Y_1]_\theta$$

is continuous and $\|T\| \le M_0^{1-\theta} M_1^\theta$.

Proof. Write $\Sigma := X_0 + X_1$. For $\lambda \in \Sigma'$ of norm at most one, the restrictions of λ to X_j have norm at most one. Lemma 5.7.3, applied to $z \mapsto \lambda(F(z+it))$, and Hahn–Banach give

$$\sup_{z\in\overline{T}} \|F(z)\|_\Sigma \le \|F\|_{\mathscr{F}}. \tag{5.5}$$

Thus a Cauchy sequence in $\mathscr{F}$ converges uniformly in Σ on the closed strip and uniformly in X_j on each boundary line. The limit is continuous in the indicated norms, its boundary values tend to zero, and Lemma 5.7.2 preserves holomorphicity. Hence $\mathscr{F}$ is Banach. Evaluation $F \mapsto F(\theta)$ is continuous by (5.5), so its kernel is closed. The space $[X_0, X_1]_\theta$, with its defining norm, is the quotient by that kernel and is Banach. In particular,

$$\|x\|_\Sigma \le \|x\|_{[X_0,X_1]_\theta}.$$

If $x \in X_0 \cap X_1$, the representative $F(z) = e^{\varepsilon(z-\theta)^2} x$ also gives the continuous embedding $X_0 \cap X_1 \hookrightarrow [X_0, X_1]_\theta$. The operator T is continuous between the sum spaces: apply its endpoint bounds to a decomposition and take the infimum. If $M_0 M_1 > 0$ and $F \in \mathscr{F}(X_0, X_1)$, set

$$G(z) := M_0^{z-1} M_1^{-z} T(F(z)).$$

This function belongs to $\mathscr{F}(Y_0, Y_1)$ and satisfies $\|G\|_{\mathscr{F}} \le \|F\|_{\mathscr{F}}$. Since $G(\theta) = M_0^{\theta-1} M_1^{-\theta} T(F(\theta))$, the infimum over F gives the required bound. If some M_j is zero, use the bounds $M_j + \varepsilon$ and let $\varepsilon \to 0^+$. □

Lemma 5.7.6. (Dual criterion for the Lebesgue norm) Let (A, μ) be a σ-finite measure space and let h be a measurable function finite almost everywhere. For $1 \le s \le \infty$,

$$\|h\|_{L^s(A)} = \sup\left\{ \left| \int_A hg\, d\mu \right| \;\middle|\; \begin{array}{l} g \text{ simple, supported on a set of finite measure,} \\ hg \in L^1(A), \quad \|g\|_{L^{s'}(A)} \le 1 \end{array} \right\},$$

allowing both sides to be infinite.

Proof. Hölder's inequality proves one bound if $h \in L^s$; if the norm of h is infinite, this bound holds automatically. For the reverse bound, take an increasing sequence of sets of finite measure whose union is A and intersect them with $\{|h| \le N\}$. On each resulting set, when $1 < s < \infty$, use the function $\overline{\operatorname{sgn} h}|h|^{s-1}$ normalized in $L^{s'}$. It is bounded and can be approximated uniformly by simple functions; if necessary, divide each approximant by the maximum of one and its norm. The supremum is at least the L^s norm of h restricted to that set. For $s = 1$, use $\overline{\operatorname{sgn} h}$, of norm at most one in L^∞. Monotone convergence gives the conclusion in both cases. If $s = \infty$, for each $0 < a < \|h\|_\infty$ choose a set of positive finite measure on which $a < |h| \le N$, and use its normalized indicator function multiplied by $\overline{\operatorname{sgn} h}$. The same simple approximations show that the supremum is at least a. □

Theorem 5.7.7. (Riesz–Thorin) Let (A, μ) and (B, ν) be σ-finite measure spaces, let $1 \le p_0, p_1, q_0, q_1 \le \infty$, and let

$$T : L^{p_0}(A) + L^{p_1}(A) \longrightarrow L^{q_0}(B) + L^{q_1}(B)$$

be a linear operator. Suppose that

$$\|Tf\|_{L^{q_j}(B)} \le M_j \|f\|_{L^{p_j}(A)}, \qquad j = 0, 1.$$

If $0 < \theta < 1$ and

$$\frac{1}{p_\theta} = \frac{1-\theta}{p_0} + \frac{\theta}{p_1}, \qquad \frac{1}{q_\theta} = \frac{1-\theta}{q_0} + \frac{\theta}{q_1},$$

then the restriction of T to $L^{p_\theta}(A)$ takes values in $L^{q_\theta}(B)$ and

$$\|Tf\|_{L^{q_\theta}(B)} \le M_0^{1-\theta} M_1^{\theta} \|f\|_{L^{p_\theta}(A)}.$$

Proof. First assume $p_\theta < \infty$ and $q_\theta > 1$. By homogeneity, it suffices to consider simple functions

$$f = \sum_{k=1}^{N} a_k \mathbf{1}_{E_k}, \qquad g = \sum_{\ell=1}^{L} b_\ell \mathbf{1}_{F_\ell},$$

with disjoint sets of finite measure and $\|f\|_{L^{p_\theta}(A)} = \|g\|_{L^{q'_\theta}(B)} = 1$. For $a \neq 0$, write $\omega(a) := \frac{a}{|a|}$ and set

$$\frac{1}{p(z)} := \frac{1-z}{p_0} + \frac{z}{p_1}, \qquad \frac{1}{q'(z)} := \frac{1-z}{q'_0} + \frac{z}{q'_1}.$$

With the convention that zero coefficients are omitted, define

$$f_z := \sum_{k=1}^{N} |a_k|^{\frac{p_\theta}{p(z)}} \omega(a_k) \mathbf{1}_{E_k}, \qquad g_z := \sum_{\ell=1}^{L} |b_\ell|^{\frac{q'_\theta}{q'(z)}} \omega(b_\ell) \mathbf{1}_{F_\ell}.$$

Then $f_\theta = f$, $g_\theta = g$, and, for $j \in \{0, 1\}$ and $t \in \mathbb{R}$,

$$\|f_{j+it}\|_{L^{p_j}(A)} = 1, \qquad \|g_{j+it}\|_{L^{q'_j}(B)} = 1.$$

If $p_j = \infty$ or $q'_j = \infty$, the equality is interpreted with $\frac{1}{\infty} = 0$ and verified by taking the essential maximum.

The function

$$\Phi(z) := \int_B (Tf_z)(y) g_z(y)\, d\nu(y)$$

is holomorphic and bounded on the closed strip; expanding the two sums reduces it to a finite sum of exponential functions of z. The boundary hypothesis and Hölder's inequality from Proposition B.7.9 give $|\Phi(j+it)| \le M_j$. Lemma 5.7.3 yields

$$\left| \int_B (Tf) g\, d\nu \right| \le M_0^{1-\theta} M_1^{\theta}.$$

Undoing the normalization and using the criterion in Lemma 5.7.6 gives the estimate for $1 < q_\theta < \infty$. If $q_\theta = 1$, necessarily $q_0 = q_1 = 1$; take $g_z = g \in L^\infty(B)$, and the same argument works. If $q_\theta = \infty$, necessarily $q_0 = q_1 = \infty$; obtain the bound by applying the argument to functions $g \in L^1(B)$ and using duality again. If $p_\theta = \infty$, then $p_0 = p_1 = \infty$, and take $f_z = f$.

Finally, Proposition B.7.5 allows passage from simple functions to every function in $L^{p_\theta}(A)$ when $p_\theta < \infty$. This limit preserves the original operator: $L^{p_\theta}(A)$ embeds continuously into $L^{p_0}(A) + L^{p_1}(A)$. To see this, if $p_0 < p_1$ and $f \neq 0$, split f over the sets $\{|f| > \|f\|_{p_\theta}\}$ and $\{|f| \le \|f\|_{p_\theta}\}$; the two parts have norms in L^{p_0} and L^{p_1} at most $\|f\|_{p_\theta}$. If $p_1 < p_0$, interchange the roles, and if $p_0 = p_1$ the embedding is immediate. The operator T is continuous between the sum spaces by its endpoint bounds, and both limits agree locally in measure. When $p_\theta = \infty$, the argument with $f_z = f$ applies to each $f \in L^\infty(A)$ without approximation in that norm. This completes the proof. □

Theorem 5.7.8. (Hausdorff–Young inequality) Let $1 \le p \le 2$ and let p' be its conjugate exponent. The Fourier transform extends uniquely to a continuous operator

$$\mathcal{F} : L^p(\mathbb{R}^n) \longrightarrow L^{p'}(\mathbb{R}^n)$$

and satisfies

$$\|\widehat{f}\|_{L^{p'}(\mathbb{R}^n)} \le (2\pi)^{-n(\frac{1}{p}-\frac{1}{2})} \|f\|_{L^p(\mathbb{R}^n)}.$$

Proof. The norm of the operator from $L^1(\mathbb{R}^n)$ to $L^\infty(\mathbb{R}^n)$ is at most $(2\pi)^{-\frac{n}{2}}$ by Proposition 4.11.2; on $L^2(\mathbb{R}^n)$ it is one by Plancherel's theorem 4.11.10. The Riesz–Thorin theorem 5.7.7, applied initially to simple functions of finite support, gives the result for $1 < p < 2$ with the indicated constant. Density of that subspace in $L^p(\mathbb{R}^n)$, given by Proposition B.7.5, provides the unique extension. □

The interval $1 \le p \le 2$ in Hausdorff–Young is essential. For $p > 2$, Proposition 4.11.11 still defines the transform in $\mathcal{S}'(\mathbb{R}^n)$, but in general there is no continuous operator $L^p(\mathbb{R}^n) \to L^{p'}(\mathbb{R}^n)$. For $p = \infty$, the simplest instance already appears: the constant function one satisfies

$$\mathcal{F}1 = (2\pi)^{\frac{n}{2}} \delta_0$$

in $\mathcal{S}'(\mathbb{R}^n)$, which is not a function. For $2 < p < \infty$, failure of a bound $L^p(\mathbb{R}^n) \to L^{p'}(\mathbb{R}^n)$ can be seen through sums of modulations. If $\psi \in \mathcal{S}(\mathbb{R}^n)$, $\widehat{\psi}$ is supported in a sufficiently small ball, and $L > 0$ separates its translates, consider

$$f_N(x) := \psi(x) \sum_{k=1}^{N} \varepsilon_k e^{ikLx_1}, \qquad \varepsilon_k \in \{-1, 1\}.$$

Theorem B.8.8, integrated in x by Theorem B.6.17, allows the signs to be chosen so that $\|f_N\|_{L^p(\mathbb{R}^n)} \le C_p N^{\frac{1}{2}} \|\psi\|_{L^p(\mathbb{R}^n)}$. Disjointness of the supports of the frequency blocks gives $\|\widehat{f_N}\|_{L^{p'}(\mathbb{R}^n)} = N^{\frac{1}{p'}} \|\widehat{\psi}\|_{L^{p'}(\mathbb{R}^n)}$. Since $\frac{1}{p'} > \frac{1}{2}$, a uniform bound would be impossible.

Corollary 5.7.9. (Complex interpolation of Lebesgue spaces) Let (A, μ) be a σ-finite measure space, let $1 \le p_0, p_1 \le \infty$, and let $0 < \theta < 1$. If

$$\frac{1}{p} = \frac{1-\theta}{p_0} + \frac{\theta}{p_1},$$

then

$$[L^{p_0}(A), L^{p_1}(A)]_\theta = L^p(A)$$

with equality of norms under the usual normalization of the complex method.

Proof. Let $F \in \mathscr{F}(L^{p_0}(A), L^{p_1}(A))$. For a simple function g supported on a set of finite measure, with $\|g\|_{L^{p'}(A)} = 1$, construct as in the proof of Theorem 5.7.7 an analytic family g_z such that $g_\theta = g$ and $\|g_{j+it}\|_{L^{p_j'}(A)} = 1$. The three-lines lemma 5.7.3, applied to

$$z \longmapsto \int_A F(z,x) g_z(x)\, d\mu(x)$$

gives $\left| \int_A F(\theta, x) g(x)\, d\mu(x) \right| \le \|F\|_{\mathscr{F}}$. The dual criterion in Lemma 5.7.6 yields

$$\|F(\theta)\|_{L^p(A)} \le \|F\|_{\mathscr{F}},$$

and taking the infimum gives $[L^{p_0}(A), L^{p_1}(A)]_\theta \hookrightarrow L^p(A)$.

For the reverse inclusion, if $p < \infty$, begin with a nonzero simple function f supported on a set of finite measure and consider

$$F(z,x) := e^{\varepsilon(z-\theta)^2} \|f\|_{L^p(A)}^{1-\frac{p}{p(z)}} |f(x)|^{\frac{p}{p(z)}} \operatorname{sgn} f(x), \qquad \frac{1}{p(z)} = \frac{1-z}{p_0} + \frac{z}{p_1}.$$

Then $F(\theta) = f$ and, on the boundary $j + it$, the modulus of the power of f is $|f|^{\frac{p}{p_j}}$; hence

$$\|F(j+it)\|_{L^{p_j}(A)} \le e^{\varepsilon(j-\theta)^2} \|f\|_{L^p(A)}.$$

The Gaussian factor also ensures decay as $|t| \to \infty$. Letting $\varepsilon \to 0^+$ gives

$$\|f\|_{[L^{p_0}(A), L^{p_1}(A)]_\theta} \le \|f\|_{L^p(A)}.$$

Proposition B.7.5 and completeness from Theorem 5.7.5 allow passage to every $f \in L^p(A)$ when $p < \infty$. If an endpoint exponent is infinite, use the convention $\frac{1}{\infty} = 0$ in the same formula; if $p = \infty$, necessarily $p_0 = p_1 = \infty$: the function $z \mapsto e^{\varepsilon(z-\theta)^2} f$ gives one bound, and the three-lines lemma gives the other. □

5.7.1 Translations, regularization, and boundary estimates

To interpolate families of spaces, we shall need more than a bound by the maximum of the boundary norms. We first justify the approximations to be used, then obtain an estimate averaging those norms.

Lemma 5.7.10. (Translations and Gaussian regularization) Let $F \in \mathscr{F}(X_0, X_1)$ and $0 < \alpha < 1$. Then

$$t \longmapsto F(\alpha + it)$$

is continuous with values in $[X_0, X_1]_\alpha$, tends to zero as $|t| \to \infty$, and satisfies

$$\sup_{t\in\mathbb{R}} \|F(\alpha + it)\|_{[X_0,X_1]_\alpha} \le \|F\|_{\mathscr{F}}.$$

Moreover, there are functions $F_\varepsilon \in \mathscr{F}(X_0, X_1)$, entire with values in $X_0 \cap X_1$, such that $F_\varepsilon \to F$ in $\mathscr{F}$. In particular, $X_0 \cap X_1$ is dense in $[X_0, X_1]_\alpha$.

Proof. The function $z \mapsto F(z + it)$ belongs to $\mathscr{F}$ with the same norm as F, giving the bound. The boundary functions are continuous and tend to zero, so they are uniformly continuous. Hence

$$\|F(\cdot + ih) - F\|_{\mathscr{F}} \longrightarrow 0 \qquad (h \to 0),$$

and evaluation at $\alpha + it$ proves the asserted continuity. To justify the limit at infinity, fix $d > 0$ and use the representative $z \mapsto e^{d(z-\alpha)^2} F(z + it)$. We obtain

$$\|F(\alpha + it)\|_{[X_0,X_1]_\alpha} \le e^{d \max\{\alpha^2,(1-\alpha)^2\}} \max_{j\in\{0,1\}} \sup_{s\in\mathbb{R}} e^{-ds^2} \|F(j + i(t + s))\|_{X_j}.$$

On $|s| > R$, the Gaussian factor makes the right-hand side small uniformly in t; on $|s| \le R$, the boundary values tend uniformly to zero as $|t| \to \infty$.
For $\varepsilon > 0$, define, initially on the strip,

$$F_\varepsilon(z) := \frac{1}{\sqrt{\pi\varepsilon}} \int_{\mathbb{R}} e^{-t^2/\varepsilon} F(z + it)\, dt.$$

The integrals are Bochner integrals. Cauchy's theorem used in Proposition 5.7.1, applied to the integrand over rectangles, allows the integration line to be shifted and gives

$$F_\varepsilon(z) = \frac{1}{\sqrt{\pi\varepsilon}} \int_{\mathbb{R}} e^{(z-j-it)^2/\varepsilon} F(j + it)\, dt, \qquad j = 0, 1. \tag{5.6}$$

Indeed, on the horizontal sides, the modulus of the kernel is bounded by a constant times $e^{-(R-|\operatorname{Im} z|)^2/\varepsilon}$; their integrals tend to zero. First shift interior lines, then pass to the boundary by continuity and dominated convergence.
The right-hand side of (5.6) defines an entire function with values in X_j: on every compact subset of z, all derivatives of the kernel admit a bound integrable in t. The two expressions agree on the strip and, by the identity principle, throughout $\mathbb{C}$ with values in $X_0 + X_1$. They thus define an entire function in $X_0 \cap X_1$. On

the line $j + i\mathbb{R}$, they are Gaussian convolutions of the boundary function in X_j, whence

$$\|F_\varepsilon\|_{\mathscr{F}} \le \|F\|_{\mathscr{F}}, \qquad \|F_\varepsilon - F\|_{\mathscr{F}} \longrightarrow 0.$$

For the second assertion, split the integral into $|t| < \delta$, where uniform continuity is used, and $|t| \ge \delta$, where the Gaussian mass tends to zero. Evaluation at α proves density. □

Lemma 5.7.11. (Integral estimate for the interpolated norm) For $0 < \alpha < 1$, set

$$P_0(\alpha, t) := \frac{\sin(\pi\alpha)}{2(\cosh(\pi t) - \cos(\pi\alpha))}, \qquad P_1(\alpha, t) := \frac{\sin(\pi\alpha)}{2(\cosh(\pi t) + \cos(\pi\alpha))}.$$

These kernels are positive and integrable, with masses $m_0 := 1 - \alpha$ and $m_1 := \alpha$, respectively. If $F \in \mathscr{F}(X_0, X_1)$, then

$$\|F(\alpha)\|_{[X_0,X_1]_\alpha} \le \exp\left(\sum_{j=0}^{1} \int_{\mathbb{R}} P_j(\alpha, t) \log \|F(j + it)\|_{X_j}\, dt\right). \tag{5.7}$$

We use $\log 0 = -\infty$. In particular, if $1 \le r_0, r_1 \le \infty$,

$$\|F(\alpha)\|_{[X_0,X_1]_\alpha} \le B_0^{1-\alpha} B_1^{\alpha}, \tag{5.8}$$

where

$$B_j := \left(\frac{1}{m_j} \int_{\mathbb{R}} P_j(\alpha, t) \|F(j + it)\|_{X_j}^{r_j}\, dt\right)^{1/r_j}$$

if $r_j < \infty$, and $B_j := \sup_{t\in\mathbb{R}} \|F(j + it)\|_{X_j}$ if $r_j = \infty$. We also have

$$\|F(\alpha)\|_{[X_0,X_1]_\alpha} \le \sum_{j=0}^{1} \int_{\mathbb{R}} P_j(\alpha, t) \|F(j + it)\|_{X_j}\, dt. \tag{5.9}$$

The same estimates hold for a continuous bounded function on the strip, holomorphic in its interior, whose boundary restrictions are continuous and bounded in X_j, even if they do not tend to zero.

Proof. We first describe the harmonic function used in the proof. For smooth real functions φ_0, φ_1 constant outside a compact interval, set

$$u(x, y) := \sum_{j=0}^{1} \int_{\mathbb{R}} P_j(x, y - t)\varphi_j(t)\, dt, \qquad 0 < x < 1.$$

The kernels are obtained through the substitution $w = e^{\pi i z}$ in the Poisson kernel for the upper half-plane

$$\frac{\operatorname{Im} w}{\pi |s - w|^2}\, ds.$$

For $s > 0$, write $s = e^{-\pi t}$, and for $s < 0$, $s = -e^{-\pi t}$; these substitutions give exactly P_0 and P_1. The half-plane kernel is the imaginary part of $\pi^{-1}(s - w)^{-1}$ and is therefore harmonic. Its integral in s is one, and its mass outside a neighborhood of the boundary point tends to zero. This proves harmonicity of u and its boundary

values $u(j,y)=\varphi_j(y)$. Integrating the kernel over the positive and negative half-lines, using an arctangent antiderivative, gives the masses $1-x$ and x. In particular, u lies between the minimum and maximum of the boundary data. For smooth data as chosen, u and its first derivatives extend continuously to the boundary lines. This can be checked in the half-plane kernel: for the tangential derivative, integrate by parts and apply the kernel to the differentiated datum. For the normal derivative, subtract the first-order Taylor polynomial of the datum near the boundary point. The linear term has zero integral over symmetric intervals; the remainder is of second order and provides an integrable bound for the differentiated kernel. Outside that neighborhood there is no singularity. Dominated convergence justifies the limits and local continuity of both derivatives.

The function u has a harmonic conjugate on the strip. With the normalization $v(\alpha,0)=0$, we can construct it by

$$v(x,y):=-\int_\alpha^x u_y(s,0)\,ds+\int_0^y u_x(x,t)\,dt.$$

The equality $u_{xx}+u_{yy}=0$ gives $v_y=u_x$ and $v_x=-u_y$. Thus $h:=u+iv$ is holomorphic, $h(\alpha)=u(\alpha,0)$ is real, and $\operatorname{Re} h(j+it)=\varphi_j(t)$.

Fix $\varepsilon,\delta>0$. The functions $t\mapsto\log(\|F(j+it)\|_{X_j}+\varepsilon)$ are continuous and tend to $\log\varepsilon$. Using a cutoff outside a large interval and convolution with a smooth function, choose φ_j as above so that

$$\log(\|F(j+it)\|_{X_j}+\varepsilon)\le\varphi_j(t)\le\log(\|F(j+it)\|_{X_j}+\varepsilon)+\delta.$$

Construct h with these data and define

$$G(z):=e^{h(\alpha)-h(z)}F(z).$$

Boundedness of $\operatorname{Re} h$ proves that $G\in\mathscr{F}$; moreover, $G(\alpha)=F(\alpha)$ and

$$\|G(j+it)\|_{X_j}\le e^{u(\alpha,0)}\frac{\|F(j+it)\|_{X_j}}{\|F(j+it)\|_{X_j}+\varepsilon}\le e^{u(\alpha,0)}.$$

By the definition of the interpolated norm,

$$\log\|F(\alpha)\|_{[X_0,X_1]_\alpha}\le\delta+\sum_{j=0}^{1}\int_{\mathbb{R}}P_j(\alpha,t)\log(\|F(j+it)\|_{X_j}+\varepsilon)\,dt.$$

Let first $\delta\to0$ and then $\varepsilon\to0^+$. Monotone convergence, applied after subtracting a constant upper bound, justifies the limit even when the integral equals $-\infty$.

To obtain (5.8), apply concavity of the logarithm with respect to the probability measures $m_j^{-1}P_j(\alpha,t)\,dt$ to the powers r_j. This integral inequality follows from $\log s\le s-1$, first dividing by the average. If $r_j=\infty$, use the supremum. The same inequality with respect to the measure of total mass one on both lines gives (5.9).

Finally, for a function with bounded boundary values that do not vanish at infinity, apply the preceding argument to $e^{d(z-\alpha)^2}F(z)$. This function belongs to $\mathscr{F}$ and has the same value at α. Let $d\to0^+$ in the estimates, using dominated convergence; the kernels decay exponentially and the boundary values are bounded. □

5.7.2 Sums of spaces and Banach-valued functions

Applications to Fourier blocks and families of charts require interpolation of several components at once. We first study a finite family, where each component admits a Calderón representative. We then pass to infinite families by truncation and to measurable functions by approximation with simple functions. The restrictions on the exponents express exactly when these approximations converge in norm.

For a Banach space X, write $L^r(A;X)$ for the classes of strongly measurable functions with finite norm

$$\|f\|_{L^r(A;X)} := \Big(\int_A \|f(a)\|_X^r \, d\mu(a)\Big)^{1/r}$$

or with the essential supremum norm if $r = \infty$. These spaces are complete. Indeed, from a Cauchy sequence, extract a subsequence whose differences have summable norms. Minkowski's inequality and monotone convergence show that the pointwise sum of the norms of these differences belongs to L^r if $r < \infty$. Thus the series converges almost everywhere in X, and its tails tend to zero in L^r. If $r = \infty$, the same conclusion holds outside the countable union of the null sets for the essential bounds. The limit is strongly measurable by Lemma B.6.24.

Proposition 5.7.12. (Interpolation of ℓ^p-sums and Bochner spaces) Let I be a set, let $1 \le r_0, r_1 < \infty$ and $0 < \theta < 1$, and set

$$\frac{1}{r} = \frac{1-\theta}{r_0} + \frac{\theta}{r_1}.$$

For a family of compatible pairs of complex Banach spaces $(X_{0,i}, X_{1,i})_{i\in I}$, we have isometrically

$$\big[\ell^{r_0}\big(I;(X_{0,i})_{i\in I}\big), \ell^{r_1}\big(I;(X_{1,i})_{i\in I}\big)\big]_\theta = \ell^r\big(I;([X_{0,i},X_{1,i}]_\theta)_{i\in I}\big). \tag{5.10}$$

If $w_{0,i}, w_{1,i} > 0$, the same identity with weighted norms is

$$\big[\ell^{r_0}\big(I;(w_{0,i}X_{0,i})_{i\in I}\big), \ell^{r_1}\big(I;(w_{1,i}X_{1,i})_{i\in I}\big)\big]_\theta = \ell^r\big(I;(w_{0,i}^{1-\theta}w_{1,i}^{\theta}[X_{0,i},X_{1,i}]_\theta)_{i\in I}\big), \tag{5.11}$$

where wX denotes X with norm $w\|\cdot\|_X$. For a finite family, these identities also hold if some r_j is infinite, with $1/\infty = 0$.

If (A,μ) is σ-finite and (X_0, X_1) is a compatible pair, then for $r_0, r_1 < \infty$ we also have isometrically

$$[L^{r_0}(A;X_0), L^{r_1}(A;X_1)]_\theta = L^r(A;[X_0,X_1]_\theta). \tag{5.12}$$

Proof. Begin with a finite family. Let F be a Calderón function for the endpoint sums, and write F_i for its i coordinate. The coordinate projections are continuous at the endpoints, so $F_i \in \mathscr{F}(X_{0,i}, X_{1,i})$. Apply (5.8) to each F_i and set

$$b_{j,i} := \left(\frac{1}{m_j}\int_{\mathbb{R}} P_j(\theta,t)\|F_i(j+it)\|_{X_{j,i}}^{r_j}\, dt\right)^{1/r_j}, \quad m_0 = 1-\theta, \quad m_1 = \theta,$$

with suprema if $r_j = \infty$. We obtain

$$\|F_i(\theta)\|_{[X_{0,i},X_{1,i}]_\theta} \le b_{0,i}^{1-\theta} b_{1,i}^{\theta}.$$

If $r < \infty$, Hölder's inequality for sums, with $r(1-\theta)/r_0 + r\theta/r_1 = 1$, gives

$$\|(F_i(\theta))_i\|_{\ell^r([X_{0,i},X_{1,i}]_\theta)} \le \|(b_{0,i})_i\|_{\ell^{r_0}}^{1-\theta}\|(b_{1,i})_i\|_{\ell^{r_1}}^{\theta} \le \|F\|_{\mathscr{F}}.$$

The last bound follows by interchanging sum and integral using Tonelli's theorem. If some r_j is infinite, use the maximum of the $b_{j,i}$; if $r = \infty$, both endpoints are infinite and take the maximum in the coordinate estimate. This proves one inclusion.

For the other inclusion, let $x = (x_i)_i$ and set $a_i := \|x_i\|_{[X_{0,i},X_{1,i}]_\theta}$ and $A := \|(a_i)_i\|_{\ell^r}$. If $A = 0$, there is nothing to prove. Omit zero coordinates and choose representatives $F_i(\theta) = x_i$ with $\|F_i\|_{\mathscr{F}} \le (1+\varepsilon)a_i$. When $r < \infty$, define

$$\frac{1}{r(z)} := \frac{1-z}{r_0} + \frac{z}{r_1}, \qquad F(z) := \left(A^{1-r/r(z)} a_i^{r/r(z)-1} F_i(z)\right)_i.$$

This is a Calderón function for the sums, and $F(\theta) = x$. On each boundary,

$$\|F(j+it)\|_{\ell^{r_j}(X_{j,i})} \le (1+\varepsilon)A^{1-r/r_j} \left(\sum_{i\in I} a_i^r\right)^{1/r_j} = (1+\varepsilon)A,$$

with the maximum interpretation if $r_j = \infty$. If both endpoints are infinite, simply take $F = (F_i)_i$; the family is finite. Letting $\varepsilon \to 0^+$ proves equality of norms.

For arbitrary I and $r_0, r_1 < \infty$, restriction to finite subsets gives the first inclusion and its bound, since the norm of $\ell^r(I)$ is the supremum of the norms of its finite restrictions. Conversely, every element of $\ell^r(I)$ has at most countably many nonzero coordinates: for each integer $k \ge 1$, only finitely many coordinates have norm greater than $1/k$. Its truncations converge in ℓ^r, and the bound already proved makes them Cauchy in the interpolated space. Completeness and coordinate projections identify the limit. No density in an infinite ℓ^∞-sum has been used.

The weighted formula is obtained first in each coordinate. Indeed, multiplying a representative by $w_0^{z-\theta} w_1^{\theta-z}$ preserves its value at θ and changes its weighted boundary norms by the common factor $w_0^{1-\theta} w_1^{\theta}$. Multiplication by the inverse gives the reverse inequality. Then apply the sum formula just proved.

Turn now to Bochner functions. For disjoint measurable sets $E_1, \dots, E_N$ of positive finite measure, define

$$Pf := \sum_{\nu=1}^{N} \mathbf{1}_{E_\nu} \frac{1}{\mu(E_\nu)} \int_{E_\nu} f \, d\mu,$$

and set $Pf = 0$ outside their union. The Bochner integral inequality and Hölder's inequality show, for every Banach space X and $1 \le s < \infty$,

$$\|Pf\|_{L^s(A;X)} \le \|f\|_{L^s(A;X)}.$$

Its image is identified with a finite sum of copies of X whose norm has weights $\mu(E_\nu)^{1/s}$. The weighted formula gives exactly the weight $\mu(E_\nu)^{1/r}$ in the interpolated space.

Let $F \in \mathscr{F}(L^{r_0}(A;X_0), L^{r_1}(A;X_1))$. For each j, the image of the boundary line together with zero is compact in $L^{r_j}(A;X_j)$. Choose a finite net in that image and approximate its elements by simple functions supported on sets of finite measure. Such approximations exist by strong measurability and integrability of the norm: first truncate the domain and the size of the function, then use the simple functions in its definition. A common partition of the supports of these approximants produces an operator P fixing them. Its contractivity implies, for each function f in the net and its approximation g,

$$\|Pf - f\| \le \|P(f-g)\| + \|g - f\| \le 2\|f - g\|.$$

Taking sufficiently fine nets and small errors gives operators P_k such that $P_k F \to F$ in $\mathscr{F}$.

The equality for finite sums implies

$$\|P_k F(\theta) - P_l F(\theta)\|_{L^r(A;[X_0,X_1]_\theta)} \le \|(P_k - P_l)F\|_{\mathscr{F}}.$$

To use it, simply refine both partitions to a common partition. Thus $P_k F(\theta)$ converges in the Bochner space on the right-hand side of (5.12). That limit agrees with $F(\theta)$: both convergences imply local convergence in measure with values in $X_0 + X_1$, by Hölder's inequality on sets of finite measure. This proves the inclusion from the left-hand side. The bound is one, since $\|P_k F\|_{\mathscr{F}} \le \|F\|_{\mathscr{F}}$.
Finally, simple functions supported on sets of finite measure with values in $[X_0, X_1]_\theta$ are dense in their Bochner space. For each such function, the construction using coordinate representatives and the preceding weights gives the reverse inclusion with bound one. Differences of two simple functions are treated on a common partition; completeness allows passage to the limit. This completes the proof. □

5.7.3 Complex reiteration

To prove reiteration while retaining the general assumptions, we shall use a description through Fourier coefficients of periodic functions. The idea is to express an element in two ways: as the sum of a sequence and as the constant value of a sequence decomposed between the endpoints. The relationship between them is obtained by taking differences and partial sums. This procedure is related to the approach of [100, §§4 and 6].

Definition 5.7.13. (Fourier coefficient spaces) Let X be a complex Banach space. Denote by $\mathcal{C}(X)$ the space of sequences $u = (u_n)_{n\in\mathbb{Z}}$ of the form

$$u_n = \frac{1}{2\pi}\int_{-\pi}^{\pi} f(t)e^{-int}\,dt, \qquad f \in L^1((-\pi,\pi);X),$$

with the endpoints of the interval identified. Its norm is

$$\|u\|_{\mathcal{C}(X)} := \frac{1}{2\pi}\int_{-\pi}^{\pi} \|f(t)\|_X\,dt.$$

For $b > 1$ and $\rho \in \mathbb{R}$, write

$$\mathcal{C}_b(\rho;X) := \{u \mid (b^{\rho n}u_n)_n \in \mathcal{C}(X)\}, \qquad \|u\|_{\mathcal{C}_b(\rho;X)} := \|(b^{\rho n}u_n)_n\|_{\mathcal{C}(X)}.$$

These periodic coefficients use the measure $dt/(2\pi)$; they are not the Fourier transform on $\mathbb{R}$ defined in the preceding chapter.

We justify that the norm is well defined. The Fejér kernel

$$\Phi_N(t) := \frac{1}{N+1}\left|\sum_{k=0}^{N} e^{ikt}\right|^2$$

is nonnegative, has integral one with respect to $dt/(2\pi)$, and satisfies $\Phi_N(t) \le ((N+1)\sin^2(t/2))^{-1}$ outside $t = 0$. Its convolutions therefore approximate continuous periodic functions uniformly: use uniform continuity near zero and the preceding bound on the complement. Approximating a Bochner function in L^1 by simple functions and their scalar indicator functions by continuous periodic functions gives the same result in L^1, since the convolution

operators have norm at most one. Their coefficients are

$$(Q_N u)_n := \left(1 - \frac{|n|}{N+1}\right)_+ u_n.$$

Consequently, if all coefficients of f vanish, then $\Phi_N * f = 0$ for every N and $f = 0$. This proves uniqueness of f and completeness of $\mathcal{C}(X)$ through its isometric identification with L^1 with normalized measure. It also proves

$$\|Q_N u\|_{\mathcal{C}_b(\rho;X)} \le \|u\|_{\mathcal{C}_b(\rho;X)}, \qquad Q_N u \longrightarrow u \quad \text{in } \mathcal{C}_b(\rho;X). \tag{5.13}$$

Each coordinate satisfies $\|b^{\rho n} u_n\|_X \le \|u\|_{\mathcal{C}_b(\rho;X)}$. Thus the coefficient spaces form compatible pairs in the space of sequences with values in $X_0 + X_1$, equipped with the topology of coordinatewise convergence.

Lemma 5.7.14. (Discrete representations of the complex method) Let $b > 1$ and $0 < \theta < 1$. For a compatible pair (X_0, X_1), set

$$\mathcal{U}_0 := \mathcal{C}_b(-\theta; X_0), \qquad \mathcal{U}_1 := \mathcal{C}_b(1-\theta; X_1).$$

Then $x \in [X_0, X_1]_\theta$ if and only if there is $u \in \mathcal{U}_0 \cap \mathcal{U}_1$ such that

$$x = \sum_{n\in\mathbb{Z}} u_n \quad \text{in } X_0 + X_1.$$

Its norm is equivalent to the infimum of $\max\{\|u\|_{\mathcal{U}_0}, \|u\|_{\mathcal{U}_1}\}$ over these representations. It is also equivalent to

$$\|\underline{x}\|_{\mathcal{U}_0+\mathcal{U}_1}, \qquad \underline{x} := (x)_{n\in\mathbb{Z}}.$$

In particular, the last quantity is finite exactly for elements of $[X_0, X_1]_\theta$. The constants depend only on b and θ.

Proof. If $u \in \mathcal{U}_0 \cap \mathcal{U}_1$, the coordinate bounds give

$$\|u_n\|_{X_0} \le b^{\theta n}\|u\|_{\mathcal{U}_0}, \qquad \|u_n\|_{X_1} \le b^{-(1-\theta)n}\|u\|_{\mathcal{U}_1}.$$

Use the first for $n < 0$ and the second for $n \ge 0$. The geometric series prove absolute convergence in $X_0 + X_1$. The exponential polynomials

$$H_N(z) := \sum_{n\in\mathbb{Z}} b^{(z-\theta)n} (Q_N u)_n$$

take values in $X_0 \cap X_1$ and have imaginary period $P := 2\pi/\log b$. On the boundary $j + it$, the corresponding periodic function is the Fejér sum of the function with coefficients $b^{(j-\theta)n} u_n$.
Lemma 5.7.11, in its version for bounded functions, implies

$$\|H_N(\theta) - H_M(\theta)\|_{[X_0,X_1]_\theta} \le C_{b,\theta} \max_{j\in\{0,1\}} \|(Q_N - Q_M)u\|_{\mathcal{U}_j}. \tag{5.14}$$

To check the constant, split each Poisson integral into intervals of length P. The periodized kernel $\sum_{k\in\mathbb{Z}} P_j(\theta, t+kP)$ is uniformly bounded on $[0,P]$, since P_j is continuous and decays exponentially. This bounds the integral by a constant times the average $P^{-1}\int_0^P \|H_N(j+it) - H_M(j+it)\|_{X_j}\, dt$. By (5.13), the values $H_N(\theta)$

converge in the interpolated space; in the sum space they converge to $\sum_{n\in\mathbb{Z}} u_n$. This gives the first norm bound.

We prove the converse direction. If H is holomorphic on the strip, continuous and bounded up to the boundary in the corresponding norms, and has imaginary period P, define

$$u_n := b^{-(j-\theta)n}\frac{1}{P}\int_0^P H(j+it)e^{-in(\log b)t}\,dt, \qquad j=0,1. \tag{5.15}$$

The two expressions agree: apply Cauchy's theorem to $b^{-n(z-\theta)}H(z)$ on a rectangle of height P; the horizontal integrals cancel by periodicity. Continuity allows passage to the boundary lines. Thus $u_n \in X_0\cap X_1$, $u\in \mathcal{U}_0\cap\mathcal{U}_1$, and

$$\max_{j\in\{0,1\}}\|u\|_{\mathcal{U}_j} \le \max_{j\in\{0,1\}}\sup_{t\in\mathbb{R}}\|H(j+it)\|_{X_j}.$$

The same integrals on the line $\operatorname{Re} z=\theta$ show that $(u_n)_n$ are the coefficients of $H(\theta+it)$. Fejér convergence on that line and the absolute convergence already proved give $H(\theta)=\sum_{n\in\mathbb{Z}} u_n$.

Now let $x\in[X_0,X_1]_\theta$, $x\neq 0$, and choose $F(\theta)=x$ with $\|F\|_{\mathscr{F}}\le 2\|x\|_{[X_0,X_1]_\theta}$. Fix $d>0$ sufficiently large that

$$2\sum_{k\in\mathbb{Z}\setminus\{0\}} e^{-dk^2P^2}\le\frac{1}{2}$$

and periodize:

$$H(z):=\sum_{k\in\mathbb{Z}} e^{d(z+ikP-\theta)^2}F(z+ikP).$$

The series converges uniformly on compact subsets and on one period of each boundary, with values in X_j on the boundary j. Moreover,

$$\max_{j\in\{0,1\}}\sup_{t\in\mathbb{R}}\|H(j+it)\|_{X_j}\le C_{b,\theta}\|F\|_{\mathscr{F}},$$

since $\sup_{t\in\mathbb{R}}\sum_{k\in\mathbb{Z}} e^{-d(t+kP)^2}<\infty$. If $y:=H(\theta)$, Lemma 5.7.10 and the choice of d give

$$\|x-y\|_{[X_0,X_1]_\theta}\le\sum_{k\in\mathbb{Z}\setminus\{0\}} e^{-dk^2P^2}\|F(\theta+ikP)\|_{[X_0,X_1]_\theta}\le\frac{1}{2}\|x\|_{[X_0,X_1]_\theta}.$$

Formula (5.15) represents y with norm in $\mathcal{U}_0\cap\mathcal{U}_1$ at most $C_{b,\theta}\|x\|_{[X_0,X_1]_\theta}$. Repeat the construction for $x-y$ and successive remainders. Their norms are at most $2^{-l}\|x\|$. The resulting coefficient sequences form an absolutely convergent series in the Banach space $\mathcal{U}_0\cap\mathcal{U}_1$. Its sum u satisfies $\sum_{n\in\mathbb{Z}} u_n = x$ and has the required bound. Interchange of the two sums is justified by continuity of the operator $u\mapsto\sum_{n\in\mathbb{Z}} u_n$ into the sum space, proved using geometric series at the start.

It remains to establish the characterization through $\underline{x}$. Given a representation $x=\sum_{n\in\mathbb{Z}} u_n$, set

$$a_n:=\sum_{\substack{k\in\mathbb{Z}\\ k<n}} u_k\in X_0, \qquad c_n:=\sum_{\substack{k\in\mathbb{Z}\\ k\ge n}} u_k\in X_1.$$

Then $a_n + c_n = x$. For the weighted coefficients,

$$b^{-\theta n} a_n = \sum_{l \in \mathbb{N}} b^{-\theta l} b^{-\theta(n-l)} u_{n-l},$$
$$b^{(1-\theta)n} c_n = \sum_{l \in \mathbb{N}_0} b^{-(1-\theta)l} b^{(1-\theta)(n+l)} u_{n+l}.$$

Shifting the indices of a sequence in $\mathcal{C}(X)$ corresponds to multiplying its function by e^{ilt}, an isometry on L^1. The preceding geometric series give

$$\|a\|_{\mathcal{U}_0} + \|c\|_{\mathcal{U}_1} \le C_{b,\theta} \max_{j \in \{0,1\}} \|u\|_{\mathcal{U}_j}.$$

Conversely, if $x = a_n + c_n$ with $a \in \mathcal{U}_0$ and $c \in \mathcal{U}_1$, define

$$u_n := a_{n+1} - a_n = c_n - c_{n+1} \in X_0 \cap X_1.$$

The same shift invariance implies

$$\|u\|_{\mathcal{U}_0} \le (1 + b^{\theta}) \|a\|_{\mathcal{U}_0}, \qquad \|u\|_{\mathcal{U}_1} \le (1 + b^{-(1-\theta)}) \|c\|_{\mathcal{U}_1}.$$

The coordinate bounds show that $a_n \to 0$ in X_0 as $n \to -\infty$, and $c_n \to 0$ in X_1 as $n \to \infty$. Thus $\sum_{n=-N}^{N} u_n = a_{N+1} - a_{-N} \to x$ in the sum space. Taking infima completes the proof. □

Lemma 5.7.15. (Decomposition of coefficients at an intermediate level) Let $b > 1$ and $0 \le \alpha \le 1$, and set $E_\alpha := [X_0, X_1]_\alpha$ if $0 < \alpha < 1$, $E_0 := X_0$, and $E_1 := X_1$. Then

$$\mathcal{C}(E_\alpha) \hookrightarrow \mathcal{C}_b(-\alpha; X_0) + \mathcal{C}_b(1-\alpha; X_1) \tag{5.16}$$

with norm at most one.

Proof. If $\alpha = 0$ or 1, the space on the left equals one of the summands, and the assertion is immediate. Assume $0 < \alpha < 1$ and denote the sum space on the right by V. Begin with a trigonometric polynomial

$$f(t) = \sum_{\substack{n \in \mathbb{Z} \\ |n| \le N}} u_n e^{int}, \qquad u_n \in X_0 \cap X_1.$$

Thus its coefficient sequence belongs to V. Let $\Lambda \in V'$ have norm at most one. By (5.13), the functionals $\Lambda \circ Q_M$ have norm at most one and converge to Λ on each element of V. Each depends on only finitely many coordinates, so it has the form

$$(\Lambda \circ Q_M)(v) = \sum_{n \in \mathbb{Z}} y_n(v_n), \qquad y_n \in (X_0 + X_1)',$$

with only finitely many nonzero y_n. For $j \in \{0,1\}$, set

$$H(z,t) := \sum_{n\in\mathbb{Z}} b^{(\alpha-z)n} e^{-int} y_n.$$

The norm of $\Lambda \circ Q_M$ restricted to $\mathcal{C}_b(j-\alpha; X_j)$ is

$$\sup_{t\in[-\pi,\pi]} \|H(j,t)\|_{X_j'} \le 1. \tag{5.17}$$

To verify the equality giving this norm, if $(b^{(j-\alpha)n} v_n)_n$ are the coefficients of $g \in L^1((-\pi,\pi); X_j)$, then

$$(\Lambda \circ Q_M)(v) = \frac{1}{2\pi} \int_{-\pi}^{\pi} H(j,t)(g(t))\, dt.$$

This proves one inequality. For the other, choose a point t_0 and a unit vector in X_j realizing the value of $\|H(j,t_0)\|_{X_j'}$ with arbitrarily small error, and multiply it by the indicator of a small interval around t_0, normalized in L^1. Continuity of $H(j,\cdot)$ gives the required limit. No identification of the full dual of a Bochner space is needed.

If $F \in \mathscr{F}(X_0, X_1)$ and t is fixed, the scalar function $z \mapsto H(z,t)(F(z))$ is holomorphic and bounded on the strip. On the boundary $j + is$,

$$H(j+is,t) = H(j, t + s\log b),$$

so (5.17) and the three-lines lemma imply

$$|H(\alpha,t)(F(\alpha))| \le \|F\|_{\mathscr{F}}.$$

Taking the infimum over F shows that $H(\alpha,t)$ has norm at most one on E_α. Consequently,

$$|(\Lambda \circ Q_M)(u)| = \left| \frac{1}{2\pi} \int_{-\pi}^{\pi} H(\alpha,t)(f(t))\, dt \right| \le \frac{1}{2\pi} \int_{-\pi}^{\pi} \|f(t)\|_{E_\alpha}\, dt.$$

Let $M \to \infty$ and take the supremum over Λ. Hahn–Banach gives $\|u\|_V \le \|u\|_{\mathcal{C}(E_\alpha)}$.

Lemma 5.7.10 ensures that $X_0 \cap X_1$ is dense in E_α. Hence trigonometric polynomials with coefficients in that intersection are dense in $L^1((-\pi,\pi); E_\alpha)$: first apply Fejér approximation, then approximate its finitely many coefficients. The bound obtained and completeness of V extend the embedding to all of $\mathcal{C}(E_\alpha)$. Coordinate projections show that this extension preserves each coefficient, so it is the inclusion in (5.16). □

Theorem 5.7.16. (Complex reiteration) Let $0 \le \theta_0 < \theta_1 \le 1$, $0 < \eta < 1$, and $\theta := (1-\eta)\theta_0 + \eta\theta_1$. If $X_{\theta_j} := [X_0, X_1]_{\theta_j}$ at interior points, with X_0, X_1 retained at the endpoints, then

$$[X_{\theta_0}, X_{\theta_1}]_\eta = [X_0, X_1]_\theta$$

with equivalent norms. The constants depend only on θ_0, θ_1, η.

Proof. Set $Y_j := X_{\theta_j}$ and $\delta := \theta_1 - \theta_0$. For the first inclusion, let $F \in \mathscr{F}(X_0, X_1)$ and consider its regularizations F_ε from Lemma 5.7.10. The functions

$$G_\varepsilon(z) := F_\varepsilon(\theta_0 + \delta z)$$

are holomorphic on $X_0 \cap X_1$ and belong to $\mathscr{F}(Y_0, Y_1)$. The bound on interior lines in the same lemma gives

$$\|G_\varepsilon\|_{\mathscr{F}(Y_0,Y_1)} \le \|F_\varepsilon\|_{\mathscr{F}(X_0,X_1)} \le \|F\|_{\mathscr{F}(X_0,X_1)}.$$

On lines coinciding with an endpoint, use the boundary norm directly. To check boundedness in the sum space and the required holomorphicity, use the fact that F_ε is entire in the intersection and formula (5.6): its norms at both endpoints are bounded on every vertical strip of finite width. The same estimate applied to $F_\varepsilon - F_{\varepsilon'}$ shows that (G_ε) is Cauchy in $\mathscr{F}(Y_0, Y_1)$. Its limit takes the value $F(\theta)$ at η by continuity of the inclusions into $X_0 + X_1$. Thus,

$$\|F(\theta)\|_{[Y_0,Y_1]_\eta} \le \|F\|_{\mathscr{F}(X_0,X_1)}.$$

For the reverse inclusion, fix $b = e$ and $c := b^\delta > 1$. Let $x \in [Y_0, Y_1]_\eta$. The constant-sequence characterization in Lemma 5.7.14, applied to the pair (Y_0, Y_1) with base c, allows us to write

$$\underline{x} = v_0 + v_1, \qquad v_j \in \mathcal{C}_c(j - \eta; Y_j),$$

with sum of norms at most $C\|x\|_{[Y_0,Y_1]_\eta}$, up to arbitrarily small error. Since $\delta(j - \eta) = \theta_j - \theta$, the sequences

$$w_{j,n} := b^{(\theta_j - \theta)n} v_{j,n}$$

belong to $\mathcal{C}(Y_j)$ with the same norm as v_j in its weighted space. Lemma 5.7.15 decomposes them as

$$w_j = a_{j,0} + a_{j,1}, \qquad a_{j,0} \in \mathcal{C}_b(-\theta_j; X_0), \qquad a_{j,1} \in \mathcal{C}_b(1 - \theta_j; X_1),$$

with sum of norms at most $\|w_j\|_{\mathcal{C}(Y_j)}$, up to arbitrarily small error. Multiplying each coordinate by $b^{(\theta - \theta_j)n}$ and summing over $j \in \{0, 1\}$ gives

$$\underline{x} = a_0 + a_1, \qquad a_0 \in \mathcal{C}_b(-\theta; X_0), \qquad a_1 \in \mathcal{C}_b(1 - \theta; X_1).$$

The weights cancel exactly: for example, $b^{-\theta n} b^{(\theta - \theta_j)n} = b^{-\theta_j n}$. Therefore,

$$\|\underline{x}\|_{\mathcal{C}_b(-\theta;X_0)+\mathcal{C}_b(1-\theta;X_1)} \le C\|x\|_{[Y_0,Y_1]_\eta}.$$

Another application of Lemma 5.7.14 implies $x \in [X_0, X_1]_\theta$ and gives the reverse bound. The constants depend only on the bases b, c and the indicated parameters; the decomposition lemma has norm one. This includes $\theta_0 = 0$ or $\theta_1 = 1$. □

Lemma 5.7.17. (Calderón's gluing lemma) Let $0 \le \alpha_0 < \alpha_1 \le 1$, let $0 < \eta < 1$, and set $\alpha := (1 - \eta)\alpha_0 + \eta\alpha_1$. If $G \in \mathscr{F}(X_{\alpha_0}, X_{\alpha_1})$, then for each $\varepsilon > 0$ there is $F_\varepsilon \in \mathscr{F}(X_0, X_1)$ such that

$$F_\varepsilon(\alpha) = G(\eta), \qquad \|F_\varepsilon\|_{\mathscr{F}(X_0,X_1)} \le C_{\alpha_0,\alpha_1,\eta}\big(\|G\|_{\mathscr{F}(X_{\alpha_0},X_{\alpha_1})} + \varepsilon\big).$$

Also, for $F \in \mathscr{F}(X_0, X_1)$ and $0 < \alpha < 1$,

$$\sup_{t\in\mathbb{R}} \|F(\alpha + it)\|_{[X_0,X_1]_\alpha} \le \|F\|_{\mathscr{F}}.$$

Proof. Theorem 5.7.16 gives $G(\eta) \in [X_0, X_1]_\alpha$ with norm at most $C\|G\|_{\mathscr{F}}$. Choose a representative whose value at α is $G(\eta)$ and whose norm differs by less than ε from the infimum defining that norm. The final assertion is Lemma 5.7.10. □

Proposition 5.7.18. (Real interpolation of ℓ^p-sums) Let $1 \le p < \infty$. For every compatible pair (X_0, X_1) and $0 < \theta < 1$,

$$(\ell^p(X_0), \ell^p(X_1))_{\theta,p} = \ell^p((X_0, X_1)_{\theta,p})$$

as sets, and for every sequence $x = (x_j)$,

$$\|x\|_{\ell^p((X_0,X_1)_{\theta,p})} \le \|x\|_{(\ell^p(X_0),\ell^p(X_1))_{\theta,p}} \le 2^{1-\frac{1}{p}} \|x\|_{\ell^p((X_0,X_1)_{\theta,p})}.$$

Proof. For a sequence $x = (x_j)_{j\in\mathbb{N}}$, set $J := \mathbb{N}$ and

$$A(t,x) := \left(\sum_{j\in J} K(t, x_j; X_0, X_1)^p \right)^{\frac{1}{p}}.$$

If $x = a + b$, Minkowski's inequality from Theorem B.7.3, applied to the discrete measure space J, gives

$$A(t,x) \le \|a\|_{\ell^p(X_0)} + t\|b\|_{\ell^p(X_1)}.$$

Taking the infimum yields $A(t,x) \le K(t,x;\ell^p(X_0),\ell^p(X_1))$. Conversely, for each coordinate choose $x_j = a_j + b_j$ with $\|a_j\|_{X_0} + t\|b_j\|_{X_1} \le K(t,x_j) + \varepsilon_j$, where $(\varepsilon_j) \in \ell^p(J)$ is arbitrarily small. Then

$$\|a\|_{\ell^p(X_0)} + t\|b\|_{\ell^p(X_1)} \le 2^{1-\frac{1}{p}} \left(\sum_{j\in J} (\|a_j\|_{X_0} + t\|b_j\|_{X_1})^p \right)^{\frac{1}{p}}.$$

Letting (ε_j) tend to zero gives

$$A(t,x) \le K(t,x;\ell^p(X_0),\ell^p(X_1)) \le 2^{1-\frac{1}{p}} A(t,x).$$

Raise to the power p, integrate with respect to $t^{-\theta p}dt/t$, and apply Tonelli's theorem, Theorem B.6.17. The estimates also hold if either side is infinite. If the right-hand side is finite, the estimate at $t = 1$ and the chosen decompositions show that x belongs to the sum space; hence both inclusions have been justified. □

5.8 Lorentz spaces as interpolation spaces

Fractional embeddings obtained by the real method naturally take values in Lorentz spaces. We recall only what will be used later.

Definition 5.8.1. (Decreasing rearrangement and Lorentz spaces) Let (A,μ) be a σ-finite nonatomic measure space, and let $f : A \longrightarrow \mathbb{C}$ be measurable. Define

$$\mu_f(\lambda) := \mu(\{x \in A \mid |f(x)| > \lambda\}), \qquad f^*(t) := \inf\{\lambda \in (0,\infty) \mid \mu_f(\lambda) \le t\}, \qquad t > 0,$$

with $\inf \varnothing = \infty$. For $1 < p < \infty$ and $1 \le q \le \infty$, the space $L^{p,q}(A)$ consists of the classes of functions for which

$$\|f\|_{L^{p,q}(A)} := \|t^{1/p} f^*(t)\|_{L^q((0,\infty),dt/t)} < \infty,$$

and, if $q = \infty$, define explicitly

$$\|f\|_{L^{p,\infty}(A)} = \sup_{t\in(0,\infty)} t^{1/p} f^*(t).$$

We shall also use

$$f^{**}(t) := \frac{1}{t}\int_0^t f^*(s)\,ds, \qquad \|f\|^{\#}_{L^{p,q}(A)} := \|t^{1/p} f^{**}(t)\|_{L^q((0,\infty),dt/t)}.$$

The first expression is a quasinorm; the second will be an equivalent norm, as we shall prove below.

Lemma 5.8.2. (Rearrangement identities) Under the assumptions of the preceding definition, for $t > 0$ we have

$$\int_0^t f^*(s)\,ds = \sup_{\substack{E\subseteq A \text{ measurable}\\ \mu(E)\le t}} \int_E |f|\,d\mu.$$

Consequently, if $f = g + h$,

$$\int_0^t f^*(s)\,ds \le \int_0^t g^*(s)\,ds + \int_0^t h^*(s)\,ds.$$

Moreover, for $0 < p < \infty$,

$$\int_A |f|^p\,d\mu = \int_0^\infty f^*(t)^p\,dt.$$

Proof. The definition of the generalized inverse and right continuity of μ_f give

$$|\{s > 0 \mid f^*(s) > \lambda\}| = \mu_f(\lambda), \qquad \lambda > 0.$$

Indeed, $s \ge \mu_f(\lambda)$ implies $f^*(s) \le \lambda$. If $s < \mu_f(\lambda)$, right continuity provides $\delta > 0$ with $\mu_f(\lambda+\delta) > s$, and then $f^*(s) \ge \lambda + \delta$. This argument includes the case $\mu_f(\lambda) = \infty$, by continuity from below of measures as the level decreases to λ. Cavalieri's formula from Proposition B.8.1 therefore gives

$$\int_0^t f^*(s)\,ds = \int_0^\infty \min\{t, \mu_f(\lambda)\}\,d\lambda. \tag{5.18}$$

For $\mu(E) \le t$, Cavalieri's formula also implies

$$\int_E |f|\,d\mu = \int_0^\infty \mu(E \cap \{|f| > \lambda\})\,d\lambda \le \int_0^\infty \min\{t, \mu_f(\lambda)\}\,d\lambda.$$

For the reverse inequality, we shall use the fact that in a nonatomic space, a measurable set of finite measure contains subsets of every measure between zero and its own measure. Here is a justification. Every set of positive measure contains a subset of positive measure less than any $\varepsilon > 0$: split it into two parts of positive measure and repeat with the smaller part. To obtain a prescribed measure a, choose disjoint parts without exceeding a and, at each step, with measure greater than half the supremum of still admissible measures. If the sum of their measures tended to a value less than a, the remainder would contain a fixed part of positive measure smaller than the difference; it would remain admissible at every step, contradicting convergence

of the sum. The union of the parts has measure a.
If $|f|$ is simple and supported on a set of finite measure, choose E by taking its highest level sets first and, when necessary, a portion of the last level to reach measure t. This attains the quantity in (5.18). For a general function, approximate $|f|$ by an increasing sequence of nonnegative simple functions supported on sets of finite measure. Their distribution functions increase to μ_f; monotone convergence in (5.18) allows passage to the limit and proves equality of the suprema.
Applying that equality to $|g+h| \le |g|+|h|$ gives subadditivity. Finally, $|f|$ and f^* have the same distribution function; Cavalieri's formula applied to their pth powers gives the final identity. □

The preceding subadditivity and Minkowski's inequality show that $\|\cdot\|^{\#}_{L^{p,q}(A)}$ is a norm. Since $f^* \le f^{**}$, one comparison is immediate. For the other, set $g(t) := t^{1/p} f^*(t)$ and observe that

$$t^{1/p} f^{**}(t) = \int_0^t \left(\frac{s}{t}\right)^{1-1/p} g(s)\,\frac{ds}{s}.$$

Theorem B.8.6, with $1 - 1/p = 1/p' > 0$, gives

$$\|f\|_{L^{p,q}(A)} \le \|f\|^{\#}_{L^{p,q}(A)} \le p' \|f\|_{L^{p,q}(A)}. \tag{5.19}$$

This also proves the quasi-triangle inequality for the first expression. The next theorem will provide completeness for the equivalent norm.

Theorem 5.8.3. (Interpolation of L^p spaces) Let (A,μ) be a σ-finite nonatomic measure space. Let $1 \le p_0 < p_1 \le \infty$, $0 < \theta < 1$, $1 \le q \le \infty$, and

$$\frac{1}{p} = \frac{1-\theta}{p_0} + \frac{\theta}{p_1}.$$

Then

$$(L^{p_0}(A), L^{p_1}(A))_{\theta,q} = L^{p,q}(A)$$

as sets. More precisely, there are $c_{p_0,p_1,\theta,q}, C_{p_0,p_1,\theta,q} > 0$, independent of f and (A,μ), such that

$$c_{p_0,p_1,\theta,q} \|f\|_{L^{p,q}(A)} \le \|f\|_{(L^{p_0}(A),L^{p_1}(A))_{\theta,q}} \le C_{p_0,p_1,\theta,q} \|f\|_{L^{p,q}(A)}.$$

Moreover, $L^{p,p}(A) = L^p(A)$ with equality of norms, and if $q_0 \le q_1$, then $L^{p,q_0}(A) \hookrightarrow L^{p,q_1}(A)$.

Proof. We first prove the identity

$$K(t, f; L^1(A), L^\infty(A)) = \int_0^t f^*(s)\,ds. \tag{5.20}$$

If $f = g + h$, Lemma 5.8.2 gives

$$\int_0^t f^*(s)\,ds \le \|g\|_{L^1(A)} + t\|h\|_{L^\infty(A)}.$$

Taking the infimum proves one inequality. For the other, suppose that the integral is finite and set $\lambda := f^*(t) < \infty$. With $\operatorname{sgn} f = f/|f|$ where $f \ne 0$, and zero at its zeros, define

$$g := \operatorname{sgn} f\,(|f| - \lambda)_+, \qquad h := f - g.$$

Monotonicity of μ_f and the definition of λ imply $\mu_f(s) > t$ if $0 < s < \lambda$ and $\mu_f(s) \le t$ if $s > \lambda$. By Cavalieri's formula and (5.18),

$$\|g\|_{L^1(A)} + t\|h\|_{L^\infty(A)} \le \int_\lambda^\infty \mu_f(s)\,ds + t\lambda = \int_0^t f^*(s)\,ds.$$

In particular, this construction proves $f \in L^1 + L^\infty$ whenever the integral is finite. If it is infinite, the first inequality already precludes a decomposition of finite cost. This gives (5.20) with the extended interpretation.

For $1 < p < \infty$, set $\alpha := 1 - 1/p$. The preceding identity gives

$$\|f\|_{(L^1(A),L^\infty(A))_{\alpha,q}} = \|t^{1/p} f^{**}(t)\|_{L^q((0,\infty),dt/t)} = \|f\|^{\#}_{L^{p,q}(A)}.$$

The comparisons (5.19) prove $(L^1, L^\infty)_{1-1/p,q} = L^{p,q}$, as well as completeness with the norm $\|\cdot\|^{\#}$, by Theorem 5.2.4.

For general exponents, write $\alpha_j := 1 - 1/p_j$. If $1 < p_j < \infty$, the result just proved with second index p_j, together with the final identity in Lemma 5.8.2, identifies

$$L^{p_j}(A) = L^{p_j,p_j}(A) = (L^1(A), L^\infty(A))_{\alpha_j,p_j}$$

with equivalent norms. If $p_0 = 1$ or $p_1 = \infty$, retain the corresponding endpoint. Apply Theorem 5.5.2; its final parameter is

$$(1-\theta)\alpha_0 + \theta\alpha_1 = 1 - \left(\frac{1-\theta}{p_0} + \frac{\theta}{p_1}\right) = 1 - \frac{1}{p}.$$

We obtain the asserted identity. Equivalence of norms at the endpoints is transported by Theorem 5.3.1 applied to the identity in both directions; this gives the indicated dependence of the constants.

The equality $L^{p,p} = L^p$ is isometric for the quasinorm in Definition 5.8.1, since

$$\|f\|^p_{L^{p,p}(A)} = \int_0^\infty f^*(t)^p\,dt = \|f\|^p_{L^p(A)}.$$

Finally, monotonicity of f^* allows comparison, on each interval $[2^k, 2^{k+1}]$, of the norm defining $L^{p,q}$ with that of the sequence $(2^{k/p} f^*(2^k))_k$ in $\ell^q(\mathbb{Z})$. The lower bound uses the right endpoint and the upper bound the left; shifting the index only introduces the factor $2^{1/p}$. The embedding $\ell^{q_0} \hookrightarrow \ell^{q_1}$ when $q_0 \le q_1$ proves the final assertion. □

6

Intermediate regularity

Regularity does not increase only in integer steps. Between having m and $m+1$ integrable derivatives lies a continuous range of behaviors arising in trace problems, interpolation, nonlocal equations, and spectral theory. To measure these intermediate orders, we shall use differences of values, Fourier multipliers, and frequency decompositions.

Several scales for the same question

Bessel potentials connected regularity with the Fourier transform; Slobodeckij and Gagliardo developed difference-based seminorms; Besov and Triebel organized scales capable of separating the order of smoothness from the way frequencies are summed. Each construction reflects different properties of functions. Their agreements and differences allow us to choose the appropriate scale for localization in charts, taking traces, and interpolating operators.

The spaces $W^{m,p}(\mathbb{R}^n)$ measure regularity through integer-order derivatives. Nonlocal problems show that intermediate orders also need to be quantified. For $0 < s < 1$, the formal equation

$$(-\Delta)^s u = f$$

is associated with the energy

$$\mathcal{E}_s(u) = \frac{c_{n,s}}{4} \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \frac{|u(x) - u(y)|^2}{|x-y|^{n+2s}} \, dx\, dy - \int_{\mathbb{R}^n} f\, u \, dx.$$

The first term compares values of u at pairs of points instead of using a local derivative, leading to the Gagliardo–Slobodeckij seminorm. For $1 < p < \infty$, the analogous expression

$$\int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \frac{|u(x) - u(y)|^p}{|x-y|^{n+sp}} \, dx\, dy$$

motivates the spaces $W^{s,p}(\mathbb{R}^n)$ and appears in energies associated with the fractional p-Laplacian.

There is another route to fractional regularity. The operator $(I - \Delta)^{s/2}$ is defined through Fourier analysis and

leads to Bessel potentials and the spaces $H^{s,p}(\mathbb{R}^n)$. Both constructions recover $W^{m,p}(\mathbb{R}^n)$ when $s = m \in \mathbb{N}_0$, but for $s \notin \mathbb{N}_0$ they agree in general only in the Hilbert case $p = 2$. Traces and elliptic regularity also require negative orders and scales well suited to localization.

This is why Sobolev–Slobodeckij, Bessel, Besov, and Triebel–Lizorkin spaces appear together. Each scale organizes integrability, smoothness order, and frequency distribution differently. This chapter constructs these scales, relates their parameters, and proves the interpolation, localization, and embedding properties to be used on manifolds. We follow [98, Chapters 6–8 and 11–12], [146, Chapter 1], and [130, §§2.2–2.3].

6.1 Bessel potentials and the spaces $H^{s,p}(\mathbb{R}^n)$

Write

$$\langle \xi \rangle := (1 + \|\xi\|^2)^{\frac{1}{2}}, \qquad \xi \in \mathbb{R}^n.$$

Lemma 6.1.1. (Peetre's inequality) For every $\mu \in \mathbb{R}$ and any $\xi, \eta \in \mathbb{R}^n$,

$$\langle \xi + \eta \rangle^{\mu} \le 2^{\frac{|\mu|}{2}} \langle \xi \rangle^{\mu} \langle \eta \rangle^{|\mu|}.$$

Proof. The triangle inequality and $2ab \le a^2 + b^2$ give

$$\begin{aligned} \langle \xi + \eta \rangle^2 &= 1 + \|\xi + \eta\|^2 \\ &\le 1 + 2\|\xi\|^2 + 2\|\eta\|^2 \\ &\le 2(1 + \|\xi\|^2)(1 + \|\eta\|^2) = 2\langle \xi \rangle^2 \langle \eta \rangle^2. \end{aligned}$$

If $\mu \ge 0$, raise this inequality to the power $\frac{\mu}{2}$. If $\mu < 0$, apply the preceding inequality to $\xi = (\xi + \eta) - \eta$ to obtain

$$\langle \xi \rangle \le \sqrt{2} \langle \xi + \eta \rangle \langle \eta \rangle.$$

Dividing by $\langle \xi \rangle \langle \xi + \eta \rangle$ and raising to the power $|\mu|$ gives

$$\langle \xi + \eta \rangle^{\mu} \le 2^{\frac{|\mu|}{2}} \langle \xi \rangle^{\mu} \langle \eta \rangle^{|\mu|},$$

as required. □

For each $s \in \mathbb{R}$ and each multi-index α, there is $C_{s,\alpha} > 0$ such that

$$|D^{\alpha} \langle \xi \rangle^{s}| \le C_{s,\alpha} \langle \xi \rangle^{s - |\alpha|}, \qquad \xi \in \mathbb{R}^n.$$

In particular, all these derivatives have at most polynomial growth. By the remark following Definition 4.9.5, multiplication $T \mapsto \langle \cdot \rangle^s T$ is well defined and continuous on $\mathcal{S}'(\mathbb{R}^n)$.

Definition 6.1.2. (Bessel operator and space) Let $s \in \mathbb{R}$ and $1 < p < \infty$. Define

$$J^s u := \mathcal{F}^{-1}\big(\langle \cdot \rangle^s \widehat{u}\big), \qquad u \in \mathcal{S}'(\mathbb{R}^n),$$

and

$$H^{s,p}(\mathbb{R}^n) := \{u \in \mathcal{S}'(\mathbb{R}^n) \mid J^s u \in L^p(\mathbb{R}^n)\}, \qquad \|u\|_{H^{s,p}(\mathbb{R}^n)} := \|J^s u\|_{L^p(\mathbb{R}^n)}.$$

The operator J^{-s} is called the *Bessel potential* of order s.

Proposition 6.1.3. (Structure of the Bessel scale) Let $s, t \in \mathbb{R}$ and $1 < p < \infty$.

(a) $H^{s,p}(\mathbb{R}^n)$ is a Banach space, and $J^s \colon H^{s,p}(\mathbb{R}^n) \longrightarrow L^p(\mathbb{R}^n)$ is an isometric isomorphism with inverse J^{-s}.

(b) $J^t \colon H^{s,p}(\mathbb{R}^n) \longrightarrow H^{s-t,p}(\mathbb{R}^n)$ is an isometric isomorphism.

(c) $\mathcal{S}(\mathbb{R}^n)$ is dense in $H^{s,p}(\mathbb{R}^n)$.

(d) With respect to the distributional pairing extended from $\mathcal{S}(\mathbb{R}^n)$, the dual of $H^{s,p}(\mathbb{R}^n)$ is identified isometrically with $H^{-s,p'}(\mathbb{R}^n)$: if $\Lambda_v(u) := \langle v, u\rangle$, then

$$\|\Lambda_v\|_{(H^{s,p}(\mathbb{R}^n))'} = \|v\|_{H^{-s,p'}(\mathbb{R}^n)}.$$

Proof. The identities $J^s J^{-s} = I = J^{-s} J^s$ hold in $\mathcal{S}'(\mathbb{R}^n)$ because the symbols multiply. Thus J^s identifies $H^{s,p}(\mathbb{R}^n)$ with $L^p(\mathbb{R}^n)$, which is complete by Theorem B.7.3; this proves (a) and (b). If $f \in L^p(\mathbb{R}^n)$, density established in Proposition 4.8.5 allows us to choose $f_j \in \mathcal{S}(\mathbb{R}^n)$ with $f_j \to f$ in $L^p(\mathbb{R}^n)$. Set $u_j := J^{-s} f_j \in \mathcal{S}(\mathbb{R}^n)$; then $u_j \to J^{-s} f$ in $H^{s,p}(\mathbb{R}^n)$.
For duality, if $v \in H^{-s,p'}(\mathbb{R}^n)$ and $u \in \mathcal{S}(\mathbb{R}^n)$, Parseval's identity from Theorem 4.11.10, applied first to Schwartz functions and then by density, allows us to write

$$\langle v, u\rangle = \int_{\mathbb{R}^n} (J^{-s} v)(x)(J^s u)(x)\, dx.$$

Hölder's inequality from Proposition B.7.9 gives

$$|\Lambda_v(u)| \le \|J^{-s} v\|_{L^{p'}(\mathbb{R}^n)} \|J^s u\|_{L^p(\mathbb{R}^n)} = \|v\|_{H^{-s,p'}(\mathbb{R}^n)} \|u\|_{H^{s,p}(\mathbb{R}^n)}.$$

Conversely, a continuous functional on $H^{s,p}(\mathbb{R}^n)$ is transported by $J^{-s} \colon L^p(\mathbb{R}^n) \longrightarrow H^{s,p}(\mathbb{R}^n)$ to a functional on $L^p(\mathbb{R}^n)$. Theorem B.7.7 gives $g \in L^{p'}(\mathbb{R}^n)$, and $v := J^s g \in H^{-s,p'}(\mathbb{R}^n)$ represents the original functional and satisfies

$$\|v\|_{H^{-s,p'}(\mathbb{R}^n)} = \|g\|_{L^{p'}(\mathbb{R}^n)} = \|\Lambda_v\|_{(H^{s,p}(\mathbb{R}^n))'}.$$

□

For $s > 0$, the potential J^{-s} admits a convolution representation. This description links the Fourier construction to the later construction through the heat semigroup.

Proposition 6.1.4. (Euclidean Bessel kernel) Let $s > 0$. There is a positive radial function $G_s \in L^1(\mathbb{R}^n)$, with $\int_{\mathbb{R}^n} G_s = 1$, such that

$$J^{-s} f = G_s * f$$

for $f \in \mathcal{S}(\mathbb{R}^n)$ and, by continuity, for $f \in L^p(\mathbb{R}^n)$, $1 \le p \le \infty$. Moreover,

$$G_s(x) = \frac{1}{\Gamma(\frac{s}{2})} \int_0^\infty e^{-t} (4\pi t)^{-\frac{n}{2}} e^{-\frac{\|x\|^2}{4t}} t^{\frac{s}{2}-1}\, dt, \qquad x \in \mathbb{R}^n \setminus \{0\}.$$

The value at the origin may be chosen arbitrarily without changing the element of L^1; the integral there may diverge when $s \le n$.

Proof. The gamma identity

$$\langle \xi \rangle^{-s} = \frac{1}{\Gamma(\frac{s}{2})} \int_0^\infty e^{-t(1+\|\xi\|^2)} t^{\frac{s}{2}-1}\, dt$$

and the Gaussian transform formula from Lemma 4.11.4 show that the Fourier transform of G_s, with the normalization in Definition 4.11.1, is $(2\pi)^{-\frac{n}{2}} \langle \xi \rangle^{-s}$. The convolution formula from Proposition 4.11.9 gives $J^{-s} f = G_s * f$ for $f \in \mathcal{S}(\mathbb{R}^n)$. Tonelli's theorem B.6.17 proves that $G_s \ge 0$ and

$$\int_{\mathbb{R}^n} G_s(x)\, dx = \frac{1}{\Gamma(\frac{s}{2})} \int_0^\infty e^{-t} t^{\frac{s}{2}-1}\, dt = 1.$$

Young's inequality from Theorem 4.10.1, together with density of $\mathcal{S}(\mathbb{R}^n)$ in $L^p(\mathbb{R}^n)$ when $p < \infty$, extends the identity to these exponents. For $p = \infty$, the same formula directly defines $G_s * f \in L^\infty(\mathbb{R}^n)$, and the identity is understood in $\mathcal{S}'(\mathbb{R}^n)$, where it is verified by duality against Schwartz functions. □

Definition 6.1.5. (Bessel spaces on an open subset) Let $\Omega \subseteq \mathbb{R}^n$ be open. Define $H^{s,p}(\Omega)$ as the space of restrictions to Ω of elements of $H^{s,p}(\mathbb{R}^n)$, with the quotient norm

$$\|u\|_{H^{s,p}(\Omega)} := \inf \left\{ \|U\|_{H^{s,p}(\mathbb{R}^n)} \;\middle|\; U \restriction_\Omega = u \right\}.$$

This definition is extrinsic: it does not assert that a seminorm computed only within Ω is equivalent to the quotient norm. Such an equivalence requires an extension property of the open subset and will be proved for Lipschitz domains. This distinction will be essential when comparing $H^{s,p}(\Omega)$ with intrinsic Slobodeckij spaces.

6.1.1 The Euclidean Hilbert scale and localization

For elliptic regularity, we shall need only the case $p = 2$. Write $H^s(\mathbb{R}^n) := H^{s,2}(\mathbb{R}^n)$ and $\langle \xi \rangle := (1 + \|\xi\|^2)^{\frac{1}{2}}$. If $r \in \mathbb{N}$, define the space $H^s(\mathbb{R}^n, \mathbb{K}^r)$ componentwise and equip it with the norm

$$\|u\|^2_{H^s(\mathbb{R}^n,\mathbb{K}^r)} := \sum_{a=1}^{r} \|u^a\|^2_{H^s(\mathbb{R}^n)}.$$

Although the preceding definition is available for every $s \in \mathbb{R}$, the proof of local elliptic regularity will use only integer indices, including negative ones. Noninteger orders will be revisited when studying the scales associated with the heat semigroup.

Proposition 6.1.6. (Elementary properties of the $H^s(\mathbb{R}^n)$ scale) Let $s, t \in \mathbb{R}$ and $t \ge s$, and let α be a multi-index. Then the following assertions hold.

(a) $H^s(\mathbb{R}^n, \mathbb{K}^r)$ is a Hilbert space, and $\mathcal{S}(\mathbb{R}^n, \mathbb{K}^r)$ is dense in it.

(b) The inclusion $H^t(\mathbb{R}^n,\mathbb{K}^r) \hookrightarrow H^s(\mathbb{R}^n,\mathbb{K}^r)$ is continuous.

(c) The distributional derivative induces a continuous linear operator

$$D^\alpha : H^s(\mathbb{R}^n,\mathbb{K}^r) \longrightarrow H^{s-|\alpha|}(\mathbb{R}^n,\mathbb{K}^r).$$

(d) Translation $\tau_h u(x) := u(x-h)$ is an isometry of $H^s(\mathbb{R}^n,\mathbb{K}^r)$, and

$$\|\tau_h u - u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} \longrightarrow 0 \qquad \text{when } h \to 0.$$

(e) In the real case, the dual of $H^s(\mathbb{R}^n,\mathbb{R}^r)$ is identified isometrically with $H^{-s}(\mathbb{R}^n,\mathbb{R}^r)$. In the complex case, the correct complex-linear Hermitian identification is

$$H^{-s}(\mathbb{R}^n,\overline{\mathbb{C}^r}) \xrightarrow{\cong} \big(H^s(\mathbb{R}^n,\mathbb{C}^r)\big)'. \tag{6.1}$$

Moreover, the standard basis of $\mathbb{C}^r$ defines the complex-bilinear distributional pairing

$$H^{-s}(\mathbb{R}^n,\mathbb{C}^r) \times H^s(\mathbb{R}^n,\mathbb{C}^r) \longrightarrow \mathbb{C}, \qquad (v,u) \longmapsto \langle v,u\rangle_{\mathcal{D}',\mathcal{D}}, \tag{6.2}$$

which also induces an isometric complex-linear isomorphism from the first factor onto the dual of the second. This second identification uses the standard trivialization; the first is the intrinsic Hermitian form.

Proof. By Plancherel's theorem 4.11.10, the map

$$\Lambda^s : H^s(\mathbb{R}^n,\mathbb{K}^r) \longrightarrow L^2(\mathbb{R}^n,\mathbb{K}^r), \qquad \widehat{\Lambda^s u}(\xi) := \langle\xi\rangle^s \widehat{u}(\xi),$$

is a surjective isometry with inverse Λ^{-s}. In the real case, complexification is used when taking Fourier transforms. The multipliers $\langle\xi\rangle^{\pm s}$, being real and even, commute with conjugation in physical space and preserve real distributions. Thus the isometry and its inverse are well defined also for $\mathbb{K} = \mathbb{R}$. Completeness of $L^2(\mathbb{R}^n,\mathbb{K}^r)$ proves that $H^s(\mathbb{R}^n,\mathbb{K}^r)$ is a Hilbert space with the inner product transported by Λ^s.
For density, let $u \in H^s(\mathbb{R}^n,\mathbb{K}^r)$. Density in L^2 allows us to choose $(f_j) \subseteq C_c^\infty(\mathbb{R}^n,\mathbb{K}^r)$ such that $f_j \to \Lambda^s u$ in $L^2(\mathbb{R}^n,\mathbb{K}^r)$. Set $u_j := \Lambda^{-s} f_j$. Derivatives of the symbol $\langle\xi\rangle^{-s}$ have at most polynomial growth, so multiplication by it preserves the Schwartz class. Since the Fourier transform and its inverse also preserve that class, $u_j \in \mathcal{S}(\mathbb{R}^n,\mathbb{C}^r)$; if $\mathbb{K} = \mathbb{R}$, compatibility with conjugation also gives $u_j = \overline{u_j}$. Thus, in both cases, $u_j \in \mathcal{S}(\mathbb{R}^n,\mathbb{K}^r)$ and

$$\|u_j - u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} = \|f_j - \Lambda^s u\|_{L^2(\mathbb{R}^n,\mathbb{K}^r)} \longrightarrow 0.$$

If $t \geq s$, then $\langle\xi\rangle^s \leq \langle\xi\rangle^t$, whence

$$\|u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} = \|\langle\xi\rangle^s \widehat{u}\|_{L^2(\mathbb{R}^n,\mathbb{C}^r)} \leq \|\langle\xi\rangle^t \widehat{u}\|_{L^2(\mathbb{R}^n,\mathbb{C}^r)} = \|u\|_{H^t(\mathbb{R}^n,\mathbb{K}^r)}.$$

Likewise, since $\widehat{D^\alpha u}(\xi) = (i\xi)^\alpha \widehat{u}(\xi)$ and $|\xi^\alpha| \leq \langle\xi\rangle^{|\alpha|}$,

$$\|D^\alpha u\|_{H^{s-|\alpha|}(\mathbb{R}^n,\mathbb{K}^r)} \leq \|u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)}.$$

The Fourier transform of $\tau_h u$ is $e^{-ih\cdot\xi}\widehat{u}(\xi)$, so $\|\tau_h u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} = \|u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)}$. Moreover,

$$\|\tau_h u - u\|^2_{H^s(\mathbb{R}^n,\mathbb{K}^r)} = \int_{\mathbb{R}^n} \langle\xi\rangle^{2s}|e^{-ih\cdot\xi}-1|^2|\widehat{u}(\xi)|^2\,d\xi.$$

The integrand converges pointwise to zero and is dominated by $4\langle\xi\rangle^{2s}\|\widehat{u}(\xi)\|^2_{\mathbb{C}^r} \in L^1(\mathbb{R}^n)$. Lebesgue's dominated convergence theorem B.6.14 gives continuity of translations.
Finally, first let $\mathbb{K} = \mathbb{C}$. By the complex-linear form of Riesz's theorem, Corollary B.3.13, every functional F on H^s has a unique representative $\overline{g} \in \overline{L^2(\mathbb{R}^n,\mathbb{C}^r)}$ such that

$$F(u) = \langle \Lambda^s u, g\rangle_{L^2}.$$

If $w := \Lambda^s g \in H^{-s}(\mathbb{R}^n,\mathbb{C}^r)$, this equality reads

$$F(u) = \langle \Lambda^s u, \Lambda^{-s} w\rangle_{L^2}.$$

Pointwise conjugation identifies $\overline{H^{-s}(\mathbb{R}^n,\mathbb{C}^r)}$ complex-linearly with $H^{-s}(\mathbb{R}^n,\overline{\mathbb{C}^r})$; this gives (6.1), including equality of norms.
For the bilinear pairing, if u, v are Schwartz functions, Plancherel's theorem and the Fourier convention give

$$\langle v,u\rangle_{\mathcal{D}',\mathcal{D}} = \int_{\mathbb{R}^n}\sum_{a=1}^{r} \widehat{v^{,a}}(-\xi)\widehat{u^{,a}}(\xi)\,d\xi.$$

Inserting the weights $\langle\xi\rangle^{-s}$ and $\langle\xi\rangle^s$, Cauchy–Schwarz and the substitution $\xi \mapsto -\xi$ prove that its norm is at most $\|v\|_{H^{-s}(\mathbb{R}^n)}\|u\|_{H^s(\mathbb{R}^n)}$. Equality of norms and surjectivity follow from the preceding Hermitian identification through conjugation and reflection $\xi \mapsto -\xi$. Density of $\mathcal{S}$ extends the pairing and proves (6.2). In the real case, omit conjugation, and the same argument gives the stated assertion. □

Definition 6.1.7. (Local Sobolev spaces of real order) Let $\Omega \subseteq \mathbb{R}^n$ be open and let $s \in \mathbb{R}$. Define

$$H^s_{\mathrm{loc}(\mathbb{R}^n)}(\Omega,\mathbb{K}^r) := \left\{ u \in \mathcal{D}'(\Omega,\mathbb{K}^r) \;\middle|\; \chi u \in H^s(\mathbb{R}^n,\mathbb{K}^r) \text{ for every } \chi \in C^\infty_c(\Omega)\right\},$$

where χu is extended by zero outside Ω.

6.1.2 Multiplication, regularization, and commutators

Ordinary continuity of multiplication by a smooth function does not suffice to freeze coefficients at negative orders. We shall need to separate the principal term, controlled by the uniform norm of the coefficient, from a remainder losing one derivative.

Lemma 6.1.8. (Refined multiplication estimate) Let $s \in \mathbb{R}$ and $a \in C^\infty_c(\mathbb{R}^n)$. There is a constant $C_{a,s} > 0$ such that

$$\|av\|_{H^s(\mathbb{R}^n)} \le \|a\|_{L^\infty(\mathbb{R}^n)}\|v\|_{H^s(\mathbb{R}^n)} + C_{a,s}\|v\|_{H^{s-1}(\mathbb{R}^n)}$$

for every $v \in H^s(\mathbb{R}^n)$. For a matrix-valued function $A \in C^\infty_c(\mathbb{R}^n, M_{q\times r}(\mathbb{K}))$, there is a constant $C_{A,s} > 0$ such

that

$$\|Av\|_{H^s(\mathbb{R}^n,\mathbb{K}^q)} \le C_{q,r}\|A\|_{L^\infty(\mathbb{R}^n,M_{q\times r}(\mathbb{K}))}\|v\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} + C_{A,s}\|v\|_{H^{s-1}(\mathbb{R}^n,\mathbb{K}^r)}.$$

Proof. By density, it suffices to consider $v \in \mathcal{S}(\mathbb{R}^n)$. Write Λ^s for the Fourier multiplier with symbol $\langle\xi\rangle^s$. Then

$$\Lambda^s(av) = a\Lambda^s v + R_s(a,v),$$

where, up to the fixed constant determined by the normalization of the Fourier transform,

$$\widehat{R_s(a,v)}(\xi) = \int_{\mathbb{R}^n} \big(\langle\xi\rangle^s - \langle\xi-\eta\rangle^s\big)\widehat{a}(\eta)\widehat{v}(\xi-\eta)\,d\eta.$$

The fundamental theorem of calculus for Banach-valued functions B.6.5, applied to $t \mapsto \langle\xi - t\eta\rangle^s$, together with Peetre's inequality from Lemma 6.1.1, provides a constant $C_s > 0$ for which

$$\big|\langle\xi\rangle^s - \langle\xi-\eta\rangle^s\big| \le C_s\|\eta\|\langle\eta\rangle^{|s|+1}\langle\xi-\eta\rangle^{s-1}.$$

Since $a \in C_c^\infty$, its Fourier transform is rapidly decreasing, and the function

$$K_s(\eta) := C_s\|\eta\|\langle\eta\rangle^{|s|+1}|\widehat{a}(\eta)|$$

belongs to $L^1(\mathbb{R}^n)$. Young's convolution inequality from Theorem 4.10.1 gives

$$\|R_s(a,v)\|_{L^2(\mathbb{R}^n)} \le \|K_s\|_{L^1(\mathbb{R}^n)}\|v\|_{H^{s-1}(\mathbb{R}^n)}.$$

On the other hand,

$$\|a\Lambda^s v\|_{L^2(\mathbb{R}^n)} \le \|a\|_{L^\infty(\mathbb{R}^n)}\|v\|_{H^s(\mathbb{R}^n)}.$$

Adding the two estimates proves the scalar inequality. The matrix assertion follows by applying the result to each entry and summing finitely many components. □

Lemma 6.1.9. (Localization criterion) Let $u \in \mathcal{D}'(\Omega,\mathbb{K}^r)$ and $s \in \mathbb{R}$. The following conditions are equivalent.

(a) $u \in H^s_{\mathrm{loc}(\mathbb{R}^n)}(\Omega,\mathbb{K}^r)$.

(b) For every compact set $K \subseteq \Omega$, there is $\chi \in C_c^\infty(\Omega)$, with $\chi = 1$ on a neighborhood of K, such that $\chi u \in H^s(\mathbb{R}^n,\mathbb{K}^r)$.

(c) Every point $x \in \Omega$ has an open neighborhood $V \Subset \Omega$ and a function $\chi \in C_c^\infty(\Omega)$, with $\chi = 1$ on a neighborhood of $\overline{V}$, for which $\chi u \in H^s(\mathbb{R}^n,\mathbb{K}^r)$.

Proof. The implication (a)⇒(b) is immediate after choosing, by Proposition 1.3.6, a bump function equal to one on a neighborhood of K; (b)⇒(c) follows by taking a compact set containing the point in its interior. Assume (c) and let $\zeta \in C_c^\infty(\Omega)$. The compact set $\mathrm{supp}(\zeta)$ is covered by finitely many open sets $V_1,\dots,V_N$ as in (c). Choose a partition of unity $\eta_1,\dots,\eta_N$ on a neighborhood of $\mathrm{supp}(\zeta)$ subordinate to this cover, and

functions $\chi_j \in C_c^\infty(\Omega)$ such that $\chi_j = 1$ on a neighborhood of $\overline{V_j}$ and $\chi_j u \in H^s(\mathbb{R}^n)$. Then

$$\zeta u = \sum_{j=1}^{N} (\zeta \eta_j)(\chi_j u).$$

The refined multiplication estimate in Lemma 6.1.8 shows that each summand belongs to $H^s(\mathbb{R}^n, \mathbb{K}^r)$. The sum is finite, so $\zeta u \in H^s(\mathbb{R}^n)$. Therefore, $u \in H^s_{\mathrm{loc}(\mathbb{R}^n)}$. □

Proposition 6.1.10. (Local Sobolev order of a distribution) Let $\Omega \subseteq \mathbb{R}^n$ be open and let $T \in \mathcal{D}'(\Omega, \mathbb{K}^r)$. For every $\chi \in C_c^\infty(\Omega)$, there is $N \in \mathbb{N}$ such that

$$\chi T \in H^{-N}(\mathbb{R}^n, \mathbb{K}^r).$$

In particular, every distribution belongs locally to some Sobolev space of negative integer order, although the integer may depend on the compact set under consideration.

Proof. The argument is componentwise, so it suffices to treat the scalar case. Let $K \Subset \Omega$ be a compact set containing the support of χ in its interior. Continuity of T on $\mathcal{D}_K(\Omega)$ provides an integer $q \in \mathbb{N}_0$ and a constant $C > 0$ such that

$$|\langle T, \psi \rangle| \le C \max_{\substack{\alpha \in \mathbb{N}_0^n \\ |\alpha| \le q}} \sup_{x \in K} |D^\alpha \psi(x)| \qquad \text{for every } \psi \in \mathcal{D}_K(\Omega).$$

Applying this inequality to $\psi = \chi\varphi$, with $\varphi \in \mathcal{S}(\mathbb{R}^n)$, and using the Leibniz rule gives $C_1 > 0$ such that

$$|\langle \chi T, \varphi \rangle| \le C_1 \max_{\substack{\beta \in \mathbb{N}_0^n \\ |\beta| \le q}} \|D^\beta \varphi\|_{L^\infty(\mathbb{R}^n)}.$$

Choose an integer $N > q + \dfrac{n}{2}$. By the Fourier inversion theorem 4.11.6 and the Cauchy–Schwarz inequality from Theorem B.3.2, for $|\beta| \le q$ we have

$$|D^\beta \varphi(x)| \le C_2 \int_{\mathbb{R}^n} \|\xi\|^{|\beta|} |\widehat{\varphi}(\xi)| \, d\xi \le C_3 \left(\int_{\mathbb{R}^n} \langle \xi \rangle^{-2(N-|\beta|)} \, d\xi \right)^{\frac{1}{2}} \|\varphi\|_{H^N(\mathbb{R}^n)}.$$

The integral is finite because $N - |\beta| > \dfrac{n}{2}$. Thus,

$$|\langle \chi T, \varphi \rangle| \le C_4 \|\varphi\|_{H^N(\mathbb{R}^n)}.$$

Density of $\mathcal{S}(\mathbb{R}^n)$ in $H^N(\mathbb{R}^n)$, proved in Proposition 6.1.6, extends χT to a continuous functional on $H^N(\mathbb{R}^n)$. The dual identification in Proposition 6.1.6 yields $\chi T \in H^{-N}(\mathbb{R}^n)$. □

Let ρ be the radial mollifier from Theorem B.9.1, and set $J_\varepsilon u := \rho_\varepsilon * u$.

Proposition 6.1.11. (Mollifiers on the $H^s(\mathbb{R}^n)$ scale) Let $s \in \mathbb{R}$ and $0 < \varepsilon \le 1$. Then J_ε induces a continuous

linear operator on $H^s(\mathbb{R}^n,\mathbb{K}^r)$, and

$$\|J_\varepsilon u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} \le \|u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)}.$$

Moreover,

$$J_\varepsilon u \longrightarrow u \quad \text{in } H^s(\mathbb{R}^n,\mathbb{K}^r) \quad \text{when } \varepsilon \to 0^+.$$

If u has compact support, then $J_\varepsilon u \in C^\infty(\mathbb{R}^n,\mathbb{K}^r)$ and

$$\operatorname{supp}(J_\varepsilon u) \subseteq \{x \in \mathbb{R}^n \mid \operatorname{dist}_{\text{euc}}(x,\operatorname{supp}(u)) \le \varepsilon\}.$$

Finally, since ρ is radial, J_ε is self-adjoint with respect to the $L^2(\mathbb{R}^n,\mathbb{K}^r)$ pairing and the $H^{-s}(\mathbb{R}^n,\mathbb{K}^r)$–$H^s(\mathbb{R}^n,\mathbb{K}^r)$ duality.

Proof. The change of variable $y = \varepsilon z$ allows us to write

$$J_\varepsilon u = \int_{\mathbb{R}^n} \rho(z)\tau_{\varepsilon z} u \, dz,$$

where the integral is taken in the Hilbert space $H^s(\mathbb{R}^n,\mathbb{K}^r)$. Since translations are isometries,

$$\|J_\varepsilon u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} \le \int_{\mathbb{R}^n} \rho(z)\|\tau_{\varepsilon z} u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)}\, dz = \|u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)}.$$

Likewise,

$$\|J_\varepsilon u - u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)} \le \int_{\mathbb{R}^n} \rho(z)\|\tau_{\varepsilon z} u - u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)}\, dz.$$

For each fixed z, the integrand converges to zero by Proposition 6.1.6 and is dominated by $2\rho(z)\|u\|_{H^s(\mathbb{R}^n,\mathbb{K}^r)}$. The Bochner dominated convergence theorem B.6.25 proves convergence in $H^s(\mathbb{R}^n,\mathbb{K}^r)$.
If u has compact support, convolution of a compactly supported distribution with $\rho_\varepsilon \in C_c^\infty(\mathbb{R}^n)$ is smooth. The support inclusion follows directly from the fact that ρ_ε vanishes outside $\overline{B}_{\text{euc}}(0,\varepsilon)$. Finally, radiality implies $\rho_\varepsilon(x) = \rho_\varepsilon(-x)$; Fubini's theorem B.6.18, applied first to smooth functions, and density give $\langle J_\varepsilon u, v\rangle = \langle u, J_\varepsilon v\rangle$ and then the same identity by duality. □

Lemma 6.1.12. (Friedrichs commutator) Let $j \in \mathbb{Z}$ and $a \in C_c^\infty(\mathbb{R}^n)$. There is a constant $C_{a,j} > 0$, independent of $0 < \varepsilon \le 1$, such that

$$\|[a, J_\varepsilon]v\|_{H^{j+1}(\mathbb{R}^n)} \le C_{a,j}\|v\|_{H^j(\mathbb{R}^n)}$$

for every $v \in H^j(\mathbb{R}^n)$, where $[a, J_\varepsilon] := aJ_\varepsilon - J_\varepsilon a$. The same assertion holds componentwise for matrix coefficients.

Proof. Begin with $j = 0$ and fix $\ell \in \{1,\dots,n\}$. For $v \in C_c^\infty(\mathbb{R}^n)$,

$$[a, J_\varepsilon]v(x) = \int_{\mathbb{R}^n} \big(a(x) - a(x-y)\big)\rho_\varepsilon(y)v(x-y)\, dy.$$

The fundamental theorem of calculus for Banach-valued functions B.6.5, applied to $t \mapsto a(x - ty)$, gives

$$|a(x) - a(x-y)| \le \|Da\|_{L^\infty(\mathbb{R}^n)}\|y\|.$$

By Young's inequality from Theorem 4.10.1,

$$\|[a, J_\varepsilon]v\|_{L^2(\mathbb{R}^n)} \le \|Da\|_{L^\infty(\mathbb{R}^n)} \big\| \|y| \rho_\varepsilon(y) \big\|_{L^1(\mathbb{R}^n)} \|v\|_{L^2(\mathbb{R}^n)} \le C\varepsilon \|Da\|_{L^\infty(\mathbb{R}^n)} \|v\|_{L^2(\mathbb{R}^n)}.$$

Differentiating the identity $[a, J_\varepsilon]v = aJ_\varepsilon v - J_\varepsilon(av)$ yields

$$D_\ell[a, J_\varepsilon]v = (D_\ell a)J_\varepsilon v + \int_{\mathbb{R}^n} \big(a(x) - a(x-y)\big)(D_\ell \rho_\varepsilon)(y) v(x-y)\, dy.$$

The first term is bounded in $L^2(\mathbb{R}^n)$ by $\|D_\ell a\|_{L^\infty(\mathbb{R}^n)} \|v\|_{L^2(\mathbb{R}^n)}$. For the second, use Theorem B.6.5 again and observe that

$$\int_{\mathbb{R}^n} \|y\| |D_\ell \rho_\varepsilon(y)|\, dy = \int_{\mathbb{R}^n} \|z\| |D_\ell \rho(z)|\, dz,$$

which is independent of ε. This gives

$$\|[a, J_\varepsilon]v\|_{H^1(\mathbb{R}^n)} \le C_a \|v\|_{L^2(\mathbb{R}^n)}.$$

Density extends the inequality to all of $v \in L^2(\mathbb{R}^n)$.
Proceed by induction. Suppose that for some $q \in \mathbb{N}_0$, every coefficient $b \in C_c^\infty(\mathbb{R}^n)$ satisfies

$$\|[b, J_\varepsilon]w\|_{H^{q+1}(\mathbb{R}^n)} \le C_{b,q} \|w\|_{H^q(\mathbb{R}^n)}.$$

If $v \in H^{q+1}(\mathbb{R}^n)$, the distributional identity

$$D_\ell[a, J_\varepsilon]v = [D_\ell a, J_\varepsilon]v + [a, J_\varepsilon]D_\ell v$$

and the induction hypothesis, applied to $D_\ell a$ and a, give

$$\|D_\ell[a, J_\varepsilon]v\|_{H^{q+1}(\mathbb{R}^n)} \le C \|v\|_{H^{q+1}(\mathbb{R}^n)}.$$

Together with the bound in $L^2(\mathbb{R}^n)$, this yields

$$\|[a, J_\varepsilon]v\|_{H^{q+2}(\mathbb{R}^n)} \le C \|v\|_{H^{q+1}(\mathbb{R}^n)}.$$

By induction, the assertion holds for every $j \in \mathbb{N}_0$.
Now let $j = -q$, with $q \in \mathbb{N}$. Since J_ε is self-adjoint,

$$[a, J_\varepsilon]^* = -[\overline{a}, J_\varepsilon].$$

The part already proved, with index $q-1$, states that $[\overline{a}, J_\varepsilon] \colon H^{q-1}(\mathbb{R}^n) \longrightarrow H^q(\mathbb{R}^n)$ is uniformly continuous. By duality, $[a, J_\varepsilon] \colon H^{-q}(\mathbb{R}^n) \longrightarrow H^{-q+1}(\mathbb{R}^n)$ is uniformly continuous. This completes the proof for every $j \in \mathbb{Z}$. □

Corollary 6.1.13. (Commutator of a differential operator with a mollifier) Let

$$Q = \sum_{\substack{\alpha \in \mathbb{N}_0^n \\ |\alpha| \le m}} A_\alpha(x) D^\alpha$$

be a differential system on $\mathbb{R}^n$ whose matrix coefficients belong to C_c^∞. For every $j \in \mathbb{Z}$, there is a constant $C_{Q,j} > 0$, independent of $0 < \varepsilon \le 1$, such that

$$\|[Q, J_\varepsilon]v\|_{H^{j-m+1}(\mathbb{R}^n)} \le C_{Q,j} \|v\|_{H^j(\mathbb{R}^n)}$$

for every $v \in H^j(\mathbb{R}^n, \mathbb{K}^r)$.

Proof. Constant-coefficient derivatives commute with convolution, so

$$[Q, J_\varepsilon]v = \sum_{\substack{\alpha \in \mathbb{N}_0^n \\ |\alpha| \le m}} [A_\alpha, J_\varepsilon] D^\alpha v.$$

By Proposition 6.1.6, $D^\alpha v \in H^{j-|\alpha|}(\mathbb{R}^n)$. Lemma 6.1.12 gives

$$[A_\alpha, J_\varepsilon] D^\alpha v \in H^{j-|\alpha|+1}(\mathbb{R}^n).$$

Since $|\alpha| \le m$, the inclusion $H^{j-|\alpha|+1}(\mathbb{R}^n) \hookrightarrow H^{j-m+1}(\mathbb{R}^n)$ is continuous. Summing the finitely many terms gives the stated estimate. □

6.2 Slobodeckij spaces

Bessel potentials measure regularity through a Fourier multiplier. A second approach, intrinsic to the spatial variable, compares the values of a function at two points. The power in the denominator is chosen to make the expression invariant under Euclidean scaling. This construction leads to Sobolev–Slobodeckij spaces and remains meaningful on an open subset without first extending the function outside it.

Definition 6.2.1. (Gagliardo seminorm and Slobodeckij space) Let $\Omega \subseteq \mathbb{R}^n$ be open, and let $0 < \sigma < 1$ and $1 \le p < \infty$. For $u \in L^p(\Omega)$, define

$$[u]_{W^{\sigma,p}(\Omega)} := \left(\int_\Omega \int_\Omega \frac{|u(x) - u(y)|^p}{\|x - y\|^{n+\sigma p}} \, dx \, dy \right)^{\frac{1}{p}}.$$

The space $W^{\sigma,p}(\Omega)$ consists of functions for which this seminorm is finite and is equipped with

$$\|u\|_{W^{\sigma,p}(\Omega)} := \|u\|_{L^p(\Omega)} + [u]_{W^{\sigma,p}(\Omega)}.$$

If $s = m + \sigma$, where $m \in \mathbb{N}_0$ and $0 < \sigma < 1$, set

$$W^{s,p}(\Omega) := \{ u \in W^{m,p}(\Omega) \mid D^\alpha u \in W^{\sigma,p}(\Omega) \text{ for } |\alpha| = m \},$$

with the norm

$$\|u\|_{W^{s,p}(\Omega)} := \|u\|_{W^{m,p}(\Omega)} + \sum_{\substack{\alpha\in\mathbb{N}_0^n \\ |\alpha|=m}} [D^\alpha u]_{W^{\sigma,p}(\Omega)}.$$

For $s = m \in \mathbb{N}_0$, retain the usual definition of $W^{m,p}(\Omega)$.

The definition at integers is not obtained by formally setting $\sigma = 0$ or $\sigma = 1$: the corresponding integrals do not define the integer-order norm. We shall see later that this apparent discontinuity reflects a real difference between the fine indices of the Besov and Triebel–Lizorkin scales.

Proposition 6.2.2. (Increment formulation) If $u \in L^p(\mathbb{R}^n)$, $0 < \sigma < 1$, and $1 \le p < \infty$, then

$$[u]^p_{W^{\sigma,p}(\mathbb{R}^n)} = \int_{\mathbb{R}^n} \frac{\|\tau_h u - u\|^p_{L^p(\mathbb{R}^n)}}{\|h\|^{n+\sigma p}}\, dh, \qquad \tau_h u(x) := u(x+h).$$

In particular, the functional on the right is translation invariant.

Proof. The integrand is nonnegative. Theorem B.6.17 and the change of variables $y = x + h$ give

$$\int_{\mathbb{R}^n}\int_{\mathbb{R}^n} \frac{|u(x+h)-u(x)|^p}{\|h\|^{n+\sigma p}}\, dx\, dh = \int_{\mathbb{R}^n}\int_{\mathbb{R}^n} \frac{|u(y)-u(x)|^p}{\|y-x\|^{n+\sigma p}}\, dy\, dx.$$

Neither integral needs to be assumed finite beforehand. □

Theorem 6.2.3. (Functional structure and density) Let $s > 0$, $s \notin \mathbb{N}$, and $1 \le p < \infty$.

(a) $W^{s,p}(\Omega)$ is a Banach space for every open subset $\Omega \subseteq \mathbb{R}^n$.

(b) If $1 < p < \infty$, then $W^{s,p}(\Omega)$ is reflexive; for every $1 \le p < \infty$, it is separable.

(c) $C_c^\infty(\mathbb{R}^n)$ is dense in $W^{s,p}(\mathbb{R}^n)$.

Proof. First treat $0 < s < 1$. Let

$$d\mu_s(x,y) := \|x-y\|^{-n-sp}\, dx\, dy$$

on $\Omega\times\Omega \setminus \{x = y\}$. The map

$$\mathcal{J}\colon u \longmapsto \left(u, \frac{u(x)-u(y)}{\|x-y\|^{\frac{n}{p}+s}}\right)$$

identifies $W^{s,p}(\Omega)$ isometrically with a subspace of

$$L^p(\Omega) \times L^p(\Omega\times\Omega, dx\, dy)$$

when the product carries the sum norm. If instead the product carries the norm ℓ^p, and we set $a := \|u\|_{L^p(\Omega)}$ and $b := [u]_{W^{s,p}(\Omega)}$, then

$$(a^p + b^p)^{\frac{1}{p}} \le a + b \le 2^{1-\frac{1}{p}}(a^p + b^p)^{\frac{1}{p}}.$$

This subspace is closed. Indeed, if $u_j \to u$ in $L^p(\Omega)$ and the quotients converge to v in $L^p(\Omega\times\Omega)$, a subse-

quence converges pointwise almost everywhere in both spaces. Outside a null set, we obtain

$$v(x,y) = \frac{u(x)-u(y)}{\|x-y\|^{\frac{n}{p}+s}}.$$

Completeness of the product proves (a). The same argument, together with reflexivity and separability of the L^p spaces established in Theorem B.7.7, proves (b). For $s = m+\sigma$, apply the argument to weak derivatives of order m and use the fact that the operator $u \mapsto (D^\alpha u)_{|\alpha|\le m}$ has closed graph in the product of $L^p(\Omega)$ spaces.

We prove (c). Choose $\eta \in C_c^\infty(\mathbb{R}^n)$ with $\eta = 1$ on $B_{\mathrm{euc}}(0,1)$ and set $\eta_R(x) = \eta(\frac{x}{R})$. For $0 < s < 1$,

$$\begin{aligned}&|(1-\eta_R(x))u(x) - (1-\eta_R(y))u(y)|\\ &\qquad \le |1-\eta_R(x)|\,|u(x)-u(y)| + |u(y)|\,|\eta_R(x)-\eta_R(y)|.\end{aligned}$$

The first term converges to zero in the weighted product measure by Theorem B.6.14. For the second, use

$$|\eta_R(x)-\eta_R(y)| \le C\min\left\{1, \frac{\|x-y\|}{R}\right\}.$$

After the substitution $h = x-y$,

$$\int_{\mathbb{R}^n} \frac{\min\left\{1, \frac{\|h\|}{R}\right\}^p}{\|h\|^{n+sp}}\,dh = C_{n,s,p}R^{-sp};$$

so the second term tends to zero. We conclude that $\eta_R u \to u$ in $W^{s,p}(\mathbb{R}^n)$.

Now let ρ be a standard mollifier and $u_\varepsilon = \rho_\varepsilon * u$. Theorem B.8.2 and translation invariance give

$$\|u_\varepsilon - u\|_{W^{s,p}(\mathbb{R}^n)} \le \int_{\mathbb{R}^n} \rho(z)\|\tau_{\varepsilon z}u - u\|_{W^{s,p}(\mathbb{R}^n)}\,dz.$$

Translations are continuous in $W^{s,p}(\mathbb{R}^n)$: this follows by applying Proposition B.8.17 both to $u \in L^p(\mathbb{R}^n)$ and to the two-variable function representing its difference quotient in $L^p(\mathbb{R}^{2n})$. Theorem B.6.14 implies $u_\varepsilon \to u$ in $W^{s,p}(\mathbb{R}^n)$. Apply the cutoff first, then regularization; the result belongs to $C_c^\infty(\mathbb{R}^n)$. For $s = m+\sigma$, $0 < \sigma < 1$, also expand the terms produced by the cutoff. If $|\alpha| = m$, the Leibniz rule gives

$$D^\alpha(\eta_R u - u) = (\eta_R - 1)D^\alpha u + \sum_{\substack{\beta\in\mathbb{N}_0^n\\ \beta\le\alpha,\ \beta\ne\alpha}} \binom{\alpha}{\beta} D^{\alpha-\beta}\eta_R\, D^\beta u.$$

The first term converges to zero in $W^{\sigma,p}$ by what has already been proved. For the remaining terms, $D^\beta u \in W^{1,p}$. The increment lemma, whose proof uses only integer-order Sobolev properties, gives

$$\|w\|_{W^{\sigma,p}(\mathbb{R}^n)} \le C\|w\|_{W^{1,p}(\mathbb{R}^n)}, \qquad w \in W^{1,p}(\mathbb{R}^n):$$

in the increment integral, use $\|\tau_h w - w\|_{L^p(\mathbb{R}^n)} \le \|h\|\|\nabla w\|_{L^p(\mathbb{R}^n)}$ for $\|h\| < 1$, and $2\|w\|_{L^p(\mathbb{R}^n)}$ on the complement. If $\gamma = \alpha - \beta \ne 0$, both $\|D^\gamma\eta_R\|_{L^\infty(\mathbb{R}^n)}$ and $\|D(D^\gamma\eta_R)\|_{L^\infty(\mathbb{R}^n)}$ tend to zero. The formula for the difference of a product and these two bounds imply

$$\|D^\gamma\eta_R\, D^\beta u\|_{W^{\sigma,p}(\mathbb{R}^n)} \le C\left(\|D^\gamma\eta_R\|_{L^\infty(\mathbb{R}^n)} + \|D(D^\gamma\eta_R)\|_{L^\infty(\mathbb{R}^n)}\right)\|D^\beta u\|_{W^{\sigma,p}(\mathbb{R}^n)} \longrightarrow 0.$$

Lower-order derivatives are controlled by the same Leibniz rule in L^p. This justifies the cutoff in the full norm. Regularization commutes with each weak derivative, and the continuity of translations already proved applies to the quotients of derivatives of order m. Thus regularization after the cutoff establishes density also at higher orders. □

6.2.1 The Slobodeckij interpolation identity

The Gagliardo seminorm is not an isolated choice: it is exactly the quantity measuring the position of u between $L^p(\mathbb{R}^n)$ and $W^{1,p}(\mathbb{R}^n)$. This interpretation explains both the exponent $n+sp$ and many subsequent properties.

Lemma 6.2.4. (Increments of a Sobolev function) If $w \in W^{1,p}(\mathbb{R}^n)$ and $1 \le p < \infty$, then

$$\|\tau_h w - w\|_{L^p(\mathbb{R}^n)} \le |h| \, \|\nabla w\|_{L^p(\mathbb{R}^n)} \qquad \text{for every } h \in \mathbb{R}^n.$$

Proof. For $w \in C_c^\infty(\mathbb{R}^n)$, Theorem B.6.5 gives

$$w(x+h) - w(x) = \int_0^1 \nabla w(x+th) \cdot h \, dt.$$

Theorem B.8.2 and translation invariance of the $L^p(\mathbb{R}^n)$ norm yield the inequality. Density of $C_c^\infty(\mathbb{R}^n)$ in $W^{1,p}(\mathbb{R}^n)$, Proposition 3.2.10, allows passage to every $w \in W^{1,p}(\mathbb{R}^n)$. □

Theorem 6.2.5. (Slobodeckij as a real interpolation space) Let $0 < s < 1$ and $1 \le p < \infty$. Then

$$\big(L^p(\mathbb{R}^n), W^{1,p}(\mathbb{R}^n)\big)_{s,p} = W^{s,p}(\mathbb{R}^n)$$

and there are constants $c_{n,s,p}, C_{n,s,p} > 0$ such that

$$c_{n,s,p} \|u\|_{W^{s,p}(\mathbb{R}^n)} \le \|u\|_{(L^p(\mathbb{R}^n), W^{1,p}(\mathbb{R}^n))_{s,p}} \le C_{n,s,p} \|u\|_{W^{s,p}(\mathbb{R}^n)}$$

for every $u \in W^{s,p}(\mathbb{R}^n)$.

Proof. Write $K(t,u)$ for the functional of the pair $(L^p(\mathbb{R}^n), W^{1,p}(\mathbb{R}^n))$. If $u = v + w$, with $v \in L^p(\mathbb{R}^n)$ and $w \in W^{1,p}(\mathbb{R}^n)$, Lemma 6.2.4 and the elementary inequality $(a+b)^p \le 2^{p-1}(a^p + b^p)$ give

$$\|\tau_h u - u\|_{L^p(\mathbb{R}^n)}^p \le C_p \big(\|v\|_{L^p(\mathbb{R}^n)} + |h| \|w\|_{W^{1,p}(\mathbb{R}^n)} \big)^p.$$

Taking the infimum and using polar coordinates,

$$[u]_{W^{s,p}(\mathbb{R}^n)}^p \le C \int_{\mathbb{R}^n} \frac{K(|h|,u)^p}{|h|^{n+sp}} \, dh = C |\mathbb{S}^{n-1}| \int_0^\infty \big(t^{-s} K(t,u) \big)^p \, \frac{dt}{t}.$$

The embedding of the interpolated space into $L^p(\mathbb{R}^n) + W^{1,p}(\mathbb{R}^n) = L^p(\mathbb{R}^n)$, proved in Theorem 5.2.4, also controls the $L^p(\mathbb{R}^n)$ norm. This proves one inclusion.

For the converse, take a nonnegative mollifier ρ supported in the unit ball and set $u_t = \rho_t * u$. The decom-

position

$$u = (u - u_t) + u_t$$

is admissible for $K(t,u)$. Proposition B.7.9, with respect to the probability measure $\rho_t(h)\,dh$, gives

$$\|u - u_t\|^p_{L^p(\mathbb{R}^n)} \le Ct^{-n} \int_{\{h\in\mathbb{R}^n \,|\, \|h\|<t\}} \|\tau_h u - u\|^p_{L^p(\mathbb{R}^n)}\,dh.$$

Since $\displaystyle\int_{\mathbb{R}^n} D_i\rho_t(h)\,dh = 0$,

$$D_i u_t(x) = \int_{\mathbb{R}^n} D_i\rho_t(h)\big(u(x-h) - u(x)\big)\,dh,$$

and another application of Proposition B.7.9 gives

$$\|\nabla u_t\|^p_{L^p(\mathbb{R}^n)} \le Ct^{-n-p} \int_{\{h\in\mathbb{R}^n \,|\, \|h\|<t\}} \|\tau_h u - u\|^p_{L^p(\mathbb{R}^n)}\,dh.$$

Moreover, Theorem 4.10.1 gives $\|u_t\|_{L^p(\mathbb{R}^n)} \le \|u\|_{L^p(\mathbb{R}^n)}$. Consequently,

$$K(t,u)^p \le C\left[t^{-n}\int_{\{\|h\|<t\}} \|\tau_h u - u\|^p_{L^p(\mathbb{R}^n)}\,dh + t^p\|u\|^p_{L^p(\mathbb{R}^n)}\right]$$

for $0 < t < 1$. Multiply by t^{-sp}, integrate with respect to dt/t, and apply Theorem B.6.17. The first term gives

$$\int_{\{\|h\|<1\}} \|\tau_h u - u\|^p_{L^p(\mathbb{R}^n)} \left(\int_{\|h\|}^1 t^{-n-sp-1}\,dt\right) dh \le C[u]^p_{W^{s,p}(\mathbb{R}^n)}.$$

The second term is $C\|u\|^p_{L^p(\mathbb{R}^n)} \displaystyle\int_0^1 t^{(1-s)p}\,dt/t$. Apply the two quantified inequalities for the truncated norm in Theorem 5.2.4 and absorb their constants, which depend only on s and p; this gives

$$\|u\|_{(L^p(\mathbb{R}^n),W^{1,p}(\mathbb{R}^n))_{s,p}} \le C\|u\|_{W^{s,p}(\mathbb{R}^n)}.$$

□

Corollary 6.2.6. (Interpolation between consecutive integer orders) Let $m \in \mathbb{N}_0$, $0 < s < 1$, and $1 < p < \infty$. Then

$$\big(W^{m,p}(\mathbb{R}^n), W^{m+1,p}(\mathbb{R}^n)\big)_{s,p} = W^{m+s,p}(\mathbb{R}^n)$$

as sets, and there are constants $c_{n,m,s,p}, C_{n,m,s,p} > 0$ such that

$$c_{n,m,s,p}\|u\|_{W^{m+s,p}(\mathbb{R}^n)} \le \|u\|_{(W^{m,p}(\mathbb{R}^n),W^{m+1,p}(\mathbb{R}^n))_{s,p}} \le C_{n,m,s,p}\|u\|_{W^{m+s,p}(\mathbb{R}^n)}$$

for every $u \in W^{m+s,p}(\mathbb{R}^n)$.

Proof. For $m = 0$, this is the preceding theorem. Assume $m \ge 1$. If $u = v + w$, with $v \in W^{m,p}$ and $w \in W^{m+1,p}$, Lemma 6.2.4 gives, for $\alpha \in \mathbb{N}_0^n$, $|\alpha| = m$,

$$\|\tau_h D^\alpha u - D^\alpha u\|_{L^p(\mathbb{R}^n)} \le 2\|v\|_{W^{m,p}(\mathbb{R}^n)} + C\|h\|\|w\|_{W^{m+1,p}(\mathbb{R}^n)}.$$

Take the infimum over these decompositions and integrate with weight $\|h\|^{-n-sp}$ exactly as in the proof for $m=0$. This controls all seminorms of order $m+s$. Moreover, $W^{m+1,p}\hookrightarrow W^{m,p}$ implies

$$K(1,u;W^{m,p},W^{m+1,p})\ge c\|u\|_{W^{m,p}(\mathbb{R}^n)}.$$

Monotonicity of K and the portion of the interpolation integral corresponding to $1\le t\le 2$ also control this norm. We obtain the first continuous inclusion.

For the converse, fix the mollifier ρ from the preceding proof, supported in the unit ball, and write $u=(u-u_t)+u_t$, where $u_t=\rho_t*u$. If $|\alpha|<m$, the increment lemma gives

$$\|D^\alpha(u-u_t)\|_{L^p(\mathbb{R}^n)}\le Ct\|u\|_{W^{m,p}(\mathbb{R}^n)},\qquad 0<t<1.$$

For $|\alpha|=m$, Minkowski's and Hölder's inequalities give

$$\|D^\alpha(u-u_t)\|_{L^p(\mathbb{R}^n)}^p\le Ct^{-n}\int_{\|h\|<t}\|\tau_hD^\alpha u-D^\alpha u\|_{L^p(\mathbb{R}^n)}^p\,dh.$$

Since $\int_{\mathbb{R}^n}D_\ell\rho_t=0$, also

$$t^p\|D_\ell D^\alpha u_t\|_{L^p(\mathbb{R}^n)}^p\le Ct^{-n}\int_{\|h\|<t}\|\tau_hD^\alpha u-D^\alpha u\|_{L^p(\mathbb{R}^n)}^p\,dh,\qquad \ell\in\{1,\dots,n\}.$$

Derivatives of u_t of order at most m are controlled by Young's inequality, so

$$K(t,u;W^{m,p},W^{m+1,p})^p\le Ct^p\|u\|_{W^{m,p}(\mathbb{R}^n)}^p+Ct^{-n}\int_{\|h\|<t}\sum_{\substack{\alpha\in\mathbb{N}_0^n\\|\alpha|=m}}\|\tau_hD^\alpha u-D^\alpha u\|_{L^p(\mathbb{R}^n)}^p\,dh.$$

Multiply by t^{-sp} and integrate with dt/t over $0<t<1$. The first term is integrable because $s<1$. For the second, Tonelli's theorem and

$$\int_{\|h\|}^1 t^{-n-sp-1}\,dt\le\frac{\|h\|^{-n-sp}}{n+sp},\qquad 0<\|h\|<1,$$

yield the Gagliardo seminorms of derivatives of order m. For $t\ge1$, use the decomposition $u=u+0$; the remaining integral is bounded by $\|u\|_{W^{m,p}(\mathbb{R}^n)}^p/(sp)$. This proves the second inclusion.

The integer-order norms used are the ℓ^p norms of this book. If a sum of norms appears in an estimate, the comparison is explicit: for $r\in\{m,m+1\}$, with $N_r=\#\{\alpha\in\mathbb{N}_0^n\mid|\alpha|\le r\}$,

$$\left(\sum_{\substack{\alpha\in\mathbb{N}_0^n\\|\alpha|\le r}}a_\alpha^p\right)^{1/p}\le\sum_{\substack{\alpha\in\mathbb{N}_0^n\\|\alpha|\le r}}a_\alpha\le N_r^{1-1/p}\left(\sum_{\substack{\alpha\in\mathbb{N}_0^n\\|\alpha|\le r}}a_\alpha^p\right)^{1/p}.$$

The constants therefore depend only on n,m,s,p and the fixed mollifier. The same argument holds for $p=1$. □

6.3 Besov and Triebel–Lizorkin spaces

The Littlewood–Paley decomposition from Chapter 4 allows a distribution to be studied by separating its content into frequency scales. Each block $\Delta_j u$ measures the part of u lying roughly at frequencies of size 2^j, while the block $\Delta_0 u$ collects low frequencies. Once this separation is made, there are two natural ways to combine the information. In the first, one takes the spatial norm of each block and then sums over scales; in the second, one first combines all blocks pointwise and only then takes the spatial norm. The first procedure leads to Besov spaces, the second to Triebel–Lizorkin spaces.

The difference between these two orders of combination is not merely notational. When the indices agree, Tonelli's theorem permits interchange of sum and integral; otherwise, the position of the sequence norm generally changes the resulting space. This distinction will later explain why Sobolev–Slobodeckij spaces are identified with $B^s_{p,p}(\mathbb{R}^n)$, while Bessel potentials are identified with $F^s_{p,2}(\mathbb{R}^n)$. This organization of the scales is the classical Littlewood–Paley description; see, for example, [146, Chapters 1–2] and [126, Chapter 2].

We use the resolution $(\varphi_j)_{j\in\mathbb{N}_0}$ and the blocks Δ_j from Proposition 4.12.1 and Definition 4.12.2. Also choose real radial functions $\widetilde{\varphi}_j \in C_c^\infty(\mathbb{R}^n)$, $j \in \mathbb{N}_0$, equal to one on a neighborhood of $\operatorname{supp}(\varphi_j)$ and having uniform dyadic supports. Write

$$\widetilde{\Delta}_j := \mathcal{F}^{-1}\widetilde{\varphi}_j\mathcal{F}, \qquad j \in \mathbb{N}_0.$$

Then $\widetilde{\Delta}_j\Delta_j = \Delta_j$ for every $j \in \mathbb{N}_0$.

6.3.1 Multiplier tools

The dyadic construction uses two estimates: continuity of certain Fourier multipliers and control of a function by its frequency blocks. Their constants will need to be uniform in the block index.

Theorem 6.3.1. (Mikhlin multipliers) Let $1 < p < \infty$ and let $N \geq n+2$ be an integer. Suppose that $m \in C^N(\mathbb{R}^n \setminus \{0\})$ satisfies

$$M_N(m) := \max_{\substack{\alpha\in\mathbb{N}_0^n \\ |\alpha|\leq N}} \sup_{\xi\in\mathbb{R}^n\setminus\{0\}} \|\xi\|^{|\alpha|}|D^\alpha m(\xi)| < \infty.$$

Then the operator initially defined on $\mathcal{S}(\mathbb{R}^n)$ by

$$T_m f := \mathcal{F}^{-1}(m\widehat{f})$$

extends uniquely to a continuous operator on $L^p(\mathbb{R}^n)$, and

$$\|T_m f\|_{L^p(\mathbb{R}^n)} \leq C_{n,p,N} M_N(m) \|f\|_{L^p(\mathbb{R}^n)}.$$

The same bound holds for a family of symbols with uniform Mikhlin constants.

Proof. If $M_N(m) = 0$, the symbol vanishes. Otherwise, first divide m by $M_N(m)$ and restore this factor at the end. We may thus assume $M_N(m) = 1$. Let $\vartheta \in C_c^\infty(\mathbb{R}^n \setminus \{0\})$ satisfy $\sum_{j\in\mathbb{Z}} \vartheta(2^{-j}\xi) = 1$ for $\xi \neq 0$, and set

$m_j(\xi) = m(\xi)\vartheta(2^{-j}\xi)$. The substitution $\xi = 2^j\zeta$ and the hypotheses show that

$$\max_{\substack{\alpha\in\mathbb{N}_0^n\\ |\alpha|\le N}} \|D^\alpha[m(2^j\cdot)\vartheta]\|_{L^\infty(\mathbb{R}^n)} \le CM_N(m)$$

uniformly in j. Integration by parts in the inverse transform gives, for the kernel $K_j = \mathcal{F}^{-1}m_j$,

$$|K_j(x)| \le CM_N(m)2^{jn}(1+2^j\|x\|)^{-N}$$

and applying the same computation to a derivative gives

$$|\nabla K_j(x)| \le CM_N(m)2^{j(n+1)}(1+2^j\|x\|)^{-N}.$$

The sum $K = \sum_{j\in\mathbb{Z}} K_j$ converges locally uniformly on $\mathbb{R}^n\setminus\{0\}$. Separate indices according to whether $2^j\|x\| \le 1$ or $2^j\|x\| > 1$, and sum the two geometric series; this gives

$$|K(x)| \le CM_N(m)\|x\|^{-n}, \qquad |K(x-h)-K(x)| \le CM_N(m)\frac{\|h\|}{\|x\|^{n+1}}$$

when $\|h\| \le \frac{1}{2}\|x\|$. The operator is bounded on $L^2(\mathbb{R}^n)$ by Theorem 4.11.10, since m is bounded. With the unitary Fourier normalization, the convolution kernel is $(2\pi)^{-n/2}K$. This representation is first verified outside the support of a compactly supported function, where the kernel series converges absolutely; the partial sums of the symbols also converge in L^2 by Plancherel's theorem.

Let $f \in L^1\cap L^2$, let $\lambda > 0$, and apply the Calderón–Zygmund decomposition from Theorem B.8.15:

$$f = g + \sum_{Q\in\mathcal{Q}} b_Q, \qquad \|g\|_{L^2(\mathbb{R}^n)}^2 \le C\lambda\|f\|_{L^1(\mathbb{R}^n)}, \qquad \sum_{Q\in\mathcal{Q}} \|b_Q\|_{L^1(\mathbb{R}^n)} \le C\|f\|_{L^1(\mathbb{R}^n)}.$$

Each b_Q has integral zero and support in Q, and $\sum_{Q\in\mathcal{Q}} |Q| \le C\|f\|_{L^1(\mathbb{R}^n)}/\lambda$. Write $Q^* = 4\sqrt{n}\,Q$, with the same center c_Q. If $x \notin Q^*$ and $y \in Q$, then $\|y-c_Q\| \le \|x-c_Q\|/2$. By cancellation,

$$T_m b_Q(x) = (2\pi)^{-n/2}\int_Q [K(x-y)-K(x-c_Q)]b_Q(y)\,dy,$$

and the kernel estimate implies

$$|T_m b_Q(x)| \le C\frac{\ell(Q)}{\|x-c_Q\|^{n+1}}\|b_Q\|_{L^1(\mathbb{R}^n)}.$$

The integral of $\ell(Q)\|x-c_Q\|^{-n-1}$ outside Q^* is bounded by a dimensional constant. Thus, if $E = \bigcup_{Q\in\mathcal{Q}} Q^*$,

$$|E| \le C\frac{\|f\|_{L^1(\mathbb{R}^n)}}{\lambda}, \qquad \int_{\mathbb{R}^n\setminus E}\sum_{Q\in\mathcal{Q}} |T_m b_Q| \le C\|f\|_{L^1(\mathbb{R}^n)}.$$

Convergence of the decomposition in L^2 identifies this sum outside E with $T_m(f-g)$. Chebyshev's inequality

and the L^2 bound for the good part give

$$|\{x \in \mathbb{R}^n \mid |T_m f(x)| > \lambda\}| \le |E| + \frac{4}{\lambda^2}\|T_m g\|_{L^2(\mathbb{R}^n)}^2 + \frac{2}{\lambda}\int_{\mathbb{R}^n \setminus E} |T_m(f-g)|$$
$$\le C\frac{\|f\|_{L^1(\mathbb{R}^n)}}{\lambda}.$$

Theorem B.8.9 interpolates this weak $(1,1)$ bound with the strong $(2,2)$ bound, yielding continuity on L^p for $1 < p \le 2$. If $p > 2$, apply the preceding argument to the symbol $\overline{m}$ on $L^{p'}$ and use the adjoint identity and duality of L^p. Density of $\mathcal{S}$ in L^p gives a unique continuous extension. Finally, multiplying again by $M_N(m)$ provides the linear bound in the statement and its uniformity. □

Theorem 6.3.2. (Littlewood–Paley square function) Let $1 < p < \infty$. There are constants $c_p, C_p > 0$ such that for every $f \in L^p(\mathbb{R}^n)$,

$$c_p\|f\|_{L^p(\mathbb{R}^n)} \le \left\| \left(\sum_{j \in \mathbb{N}_0} |\Delta_j f|^2 \right)^{\frac{1}{2}} \right\|_{L^p(\mathbb{R}^n)} \le C_p\|f\|_{L^p(\mathbb{R}^n)}.$$

Proof. We first bound the square function by the norm of f. Let $J \subseteq \mathbb{N}_0$ be finite. For each choice of signs $(\varepsilon_j)_{j \in J} \in \{-1,1\}^J$, the symbol

$$m_\varepsilon(\xi) := \sum_{j \in J} \varepsilon_j \varphi_j(\xi)$$

satisfies the hypotheses of Theorem 6.3.1 with constants independent of J and the signs: finite interaction of the supports ensures that at each $\xi \neq 0$ only a uniformly bounded number of terms occur, and after scaling, the derivatives of φ_j have the required bounds. Therefore,

$$\left\| \sum_{j \in J} \varepsilon_j \Delta_j f \right\|_{L^p(\mathbb{R}^n)} \le C_p\|f\|_{L^p(\mathbb{R}^n)}.$$

Take $\varepsilon_j = r_j(t)$, where $(r_j)_{j \in \mathbb{N}_0}$ are the Rademacher functions, integrate in $t \in [0,1]$, and use Khintchine's theorem B.8.8 pointwise in x. Theorem B.6.17 allows the integrals to be interchanged and gives

$$\left\| \left(\sum_{j \in J} |\Delta_j f|^2 \right)^{\frac{1}{2}} \right\|_{L^p(\mathbb{R}^n)} \le C_p\|f\|_{L^p(\mathbb{R}^n)}.$$

Letting J increase to $\mathbb{N}_0$ and applying monotone convergence yields the full upper bound.
For the reverse inequality, first take $f, g \in \mathcal{S}(\mathbb{R}^n)$. Since $\widetilde{\Delta}_j \Delta_j = \Delta_j$ and the dyadic resolution reconstructs the identity in $\mathcal{S}'(\mathbb{R}^n)$,

$$\langle f, g \rangle = \sum_{j \in \mathbb{N}_0} \langle \Delta_j f, \widetilde{\Delta}_j g \rangle.$$

Finite interaction of the supports allows the enlarged blocks to be chosen so that the series converges abso-

lutely for Schwartz functions. Cauchy–Schwarz in $\ell^2(\mathbb{N}_0)$ gives

$$|\langle f, g\rangle| \le \int_{\mathbb{R}^n} \left(\sum_{j\in\mathbb{N}_0} |\Delta_j f(x)|^2\right)^{\frac{1}{2}} \left(\sum_{j\in\mathbb{N}_0} |\widetilde{\Delta}_j g(x)|^2\right)^{\frac{1}{2}} dx.$$

Apply Hölder's inequality with exponents p and p' and the square-function bound already proved, now for the enlarged resolution and $g \in L^{p'}(\mathbb{R}^n)$. Thus,

$$|\langle f, g\rangle| \le C \left\| \left(\sum_{j\in\mathbb{N}_0} |\Delta_j f|^2\right)^{\frac{1}{2}} \right\|_{L^p(\mathbb{R}^n)} \|g\|_{L^{p'}(\mathbb{R}^n)}.$$

Duality from Theorem B.7.7 gives the reverse inequality for $f \in \mathcal{S}(\mathbb{R}^n)$. Finally, density of $\mathcal{S}(\mathbb{R}^n)$ in $L^p(\mathbb{R}^n)$, Proposition 4.8.5, and continuity of the square function extend the equivalence to all of $L^p(\mathbb{R}^n)$. □

For $a > 0$, we shall use the abbreviation

$$\mathcal{M}_a f := \left[\mathcal{M}(|f|^a)\right]^{\frac{1}{a}}.$$

Lemma 6.3.3. (Dyadic multipliers on sequences) Let $0 < p < \infty$, $0 < q \le \infty$, and $0 < a < \min\{p, q\}$, with the convention that q is omitted from this minimum if $q = \infty$. Suppose that $(f_j)_{j\in\mathbb{N}_0} \subseteq \mathcal{S}'(\mathbb{R}^n)$ is a family whose elements are represented by functions and satisfy, for every $j \in \mathbb{N}_0$,

$$\operatorname{supp}(\widehat{f_j}) \subseteq \{\xi \in \mathbb{R}^n \mid \|\xi\| \le A2^j\}.$$

If $T_j f_j = K_j * f_j$, where $K_j(x) = 2^{jn} K^{(j)}(2^j x)$ and

$$\sup_{j\in\mathbb{N}_0} \sup_{x\in\mathbb{R}^n} (1 + \|x\|)^{N+n+1} |K^{(j)}(x)| < \infty$$

for some $N > \frac{n}{a}$, then

$$\left\| \left(\sum_{j\in\mathbb{N}_0} |T_j f_j|^q\right)^{\frac{1}{q}} \right\|_{L^p(\mathbb{R}^n)} \le C \left\| \left(\sum_{j\in\mathbb{N}_0} |f_j|^q\right)^{\frac{1}{q}} \right\|_{L^p(\mathbb{R}^n)},$$

with the usual suprema when $q = \infty$.

Proof. Lemma B.8.16 gives $|T_j f_j| \le C\mathcal{M}_a f_j$ pointwise. If $q < \infty$, apply Theorem B.8.14 to the sequence $(|f_j|^a)_{j\in\mathbb{N}_0}$ with exponents $\frac{p}{a}$ and $\frac{q}{a}$, both greater than one, and raise the result to the power $\frac{1}{a}$. If $q = \infty$, use

$$\sup_{j\in\mathbb{N}_0} \mathcal{M}(|f_j|^a) \le \mathcal{M}\left(\sup_{j\in\mathbb{N}_0} |f_j|^a\right)$$

and continuity of $\mathcal{M}$ on $L^{\frac{p}{a}}(\mathbb{R}^n)$ from Theorem B.8.11. □

Definition 6.3.4. (Besov and Triebel–Lizorkin spaces) Let $s \in \mathbb{R}$ and $1 \le q \le \infty$. In this section, we work in the Banach range of these scales; classical theory extends the definitions to more general quasi-Banach

indices, but these endpoints will not be needed for later results.

(a) If $1 \le p \le \infty$, define

$$B^s_{p,q}(\mathbb{R}^n) := \left\{ u \in \mathcal{S}'(\mathbb{R}^n) \;\middle|\; \|u\|_{B^s_{p,q}(\mathbb{R}^n)} < \infty \right\},$$

where

$$\|u\|_{B^s_{p,q}(\mathbb{R}^n)} := \left\| \left(2^{js} \|\Delta_j u\|_{L^p(\mathbb{R}^n)} \right)_{j \in \mathbb{N}_0} \right\|_{\ell^q(\mathbb{N}_0)}.$$

(b) If $1 \le p < \infty$, define

$$F^s_{p,q}(\mathbb{R}^n) := \left\{ u \in \mathcal{S}'(\mathbb{R}^n) \;\middle|\; \|u\|_{F^s_{p,q}(\mathbb{R}^n)} < \infty \right\},$$

where

$$\|u\|_{F^s_{p,q}(\mathbb{R}^n)} := \left\| \left(\sum_{j \in \mathbb{N}_0} 2^{jsq} |\Delta_j u|^q \right)^{\frac{1}{q}} \right\|_{L^p(\mathbb{R}^n)},$$

and, if $q = \infty$,

$$\|u\|_{F^s_{p,\infty}(\mathbb{R}^n)} := \left\| \sup_{j \in \mathbb{N}_0} 2^{js} |\Delta_j u| \right\|_{L^p(\mathbb{R}^n)}.$$

Definition 6.3.5. (Retraction and coretraction) Let X and Y be Banach spaces. A continuous linear operator $R\colon X \longrightarrow Y$ is a *retraction* if there is a continuous linear operator $S\colon Y \longrightarrow X$ such that

$$RS = I_Y.$$

In that case, S is called a *coretraction* of R or a continuous right inverse. In particular, every retraction is surjective and every coretraction is injective.

We also adopt the convention $F^s_{\infty,\infty}(\mathbb{R}^n) := B^s_{\infty,\infty}(\mathbb{R}^n)$. The usual scale $F^s_{\infty,q}$, with $q < \infty$, is defined through local averages and will not be used in this chapter; see [146, Section 1.5.2].

If $p = q < \infty$, Theorem B.6.17 directly shows that

$$B^s_{p,p}(\mathbb{R}^n) = F^s_{p,p}(\mathbb{R}^n)$$

with the same norm for a fixed resolution. For distinct indices, interchanging $L^p(\mathbb{R}^n)$ and $\ell^q(\mathbb{N}_0)$ generally changes the space.

Reconstruction of a distribution requires retaining information about the frequencies of its summands. The next lemma expresses this condition and also allows treatment of the endpoint $p = 1$.

Lemma 6.3.6. (Synthesis of blocks with controlled spectral support) Let $s \in \mathbb{R}$, $1 \le q \le \infty$, and $0 < c < C$. Suppose that $v_j \in L^p(\mathbb{R}^n)$, $j \in \mathbb{N}_0$, and

$$\operatorname{supp} \widehat{v}_0 \subseteq \{\xi \in \mathbb{R}^n \mid \|\xi\| \le C\}, \qquad \operatorname{supp} \widehat{v}_j \subseteq \{\xi \in \mathbb{R}^n \mid c2^j \le \|\xi\| \le C2^j\} \quad (j \in \mathbb{N}).$$

If $1 \le p \le \infty$, then

$$\left\| \sum_{j \in \mathbb{N}_0} v_j \right\|_{B^s_{p,q}(\mathbb{R}^n)} \le C_1 \left\| \left(2^{js} \|v_j\|_{L^p(\mathbb{R}^n)}\right)_{j \in \mathbb{N}_0} \right\|_{\ell^q}.$$

If $1 \le p < \infty$, also

$$\left\| \sum_{j \in \mathbb{N}_0} v_j \right\|_{F^s_{p,q}(\mathbb{R}^n)} \le C_2 \left\| \left(2^{js} v_j\right)_{j \in \mathbb{N}_0} \right\|_{L^p(\mathbb{R}^n;\ell^q)}.$$

In each assertion, finiteness of the right-hand side ensures convergence of the series in $\mathcal{S}'(\mathbb{R}^n)$.

Proof. Choose multipliers P_j equal to one on the indicated supports, supported on slightly larger annuli when $j \ge 1$. For $\zeta \in \mathcal{S}(\mathbb{R}^n)$ and any $N > 0$,

$$\|P_j \zeta\|_{L^{p'}(\mathbb{R}^n)} \le C_N 2^{-jN} \mathfrak{p}_N(\zeta), \qquad j \in \mathbb{N}_0,$$

where $\mathfrak{p}_N$ is a finite sum of Schwartz seminorms. To obtain this bound, differentiate the product of the symbol of P_j and $\widehat{\zeta}$, use decay of all derivatives of $\widehat{\zeta}$ on the annulus, and integrate by parts in the inversion formula. The number of integrations is chosen greater than n; this simultaneously controls the uniform norm and the integral norm of the result, and the remaining norms follow from Hölder's inequality.
Each sequence norm in the statement dominates $2^{js}\|v_j\|_{L^p(\mathbb{R}^n)}$. Since $\langle v_j, \zeta \rangle = \langle v_j, P_j \zeta \rangle$, Hölder's inequality gives

$$|\langle v_j, \zeta \rangle| \le C_N 2^{-j(N+s)} \mathfrak{p}_N(\zeta) \mathcal{N},$$

where $\mathcal{N}$ is the corresponding right-hand side. Choosing $N > |s|$ proves absolute convergence of the pairing and its continuity on ζ.
The spectral supports imply $\Delta_k v_j = 0$ if $|k - j| > N_0$, for a fixed integer N_0. Young's inequality gives

$$2^{ks} \left\| \Delta_k \sum_{j \in \mathbb{N}_0} v_j \right\|_{L^p(\mathbb{R}^n)} \le C \sum_{\substack{j \in \mathbb{N}_0 \\ |j-k| \le N_0}} 2^{js} \|v_j\|_{L^p(\mathbb{R}^n)}.$$

Proposition B.8.4 proves the Besov bound. For Triebel–Lizorkin, choose $0 < a < 1$, so that $a < p$ and, if $q < \infty$, also $a < q$. Lemma 6.3.3, applied to the blocks v_j, allows the $L^p(\ell^q)$ norm to be taken in the same finite sum of shifts. This gives the second bound. Apply the estimates first to finite sums; distributional convergence identifies each block of the limit, and Fatou's lemma allows passage to the series. For $q = \infty$, use the supremum over $j \in \mathbb{N}_0$. □

Theorem 6.3.7. (Independence of the dyadic resolution) Let $\|\cdot\|_{A,\Delta}$ and $\|\cdot\|_{A,\nabla}$ be the norms constructed from two dyadic resolutions, where $A = B^s_{p,q}$ or $A = F^s_{p,q}$, with the indices in Definition 6.3.4. There are $c_A, C_A > 0$, independent of u, such that

$$c_A \|u\|_{A,\Delta} \le \|u\|_{A,\nabla} \le C_A \|u\|_{A,\Delta}.$$

These spaces are Banach, and their inclusions into $\mathcal{S}'(\mathbb{R}^n)$ are continuous.

Proof. Inserting the enlarged blocks gives

$$\nabla_k u = \sum_{\substack{j\in\mathbb{N}_0\\ |j-k|\le N_0}} \nabla_k \widetilde{\Delta}_j \Delta_j u, \qquad k \in \mathbb{N}_0.$$

The kernels have uniformly bounded integral norms. Young's inequalities for convolutions and sequences prove the Besov bound. For the Triebel–Lizorkin norm, Lemma 6.3.3 applies to $f_j = \Delta_j u$, whose spectral supports are controlled. The sum contains only $2N_0+1$ index shifts and therefore gives the required bound. Interchanging the resolutions proves equivalence.

For completeness, take the sequence spaces

$$b^s_{p,q} := \left\{ (v_j)_{j\in\mathbb{N}_0} \mid \left\| \left(2^{js}\|v_j\|_{L^p(\mathbb{R}^n)}\right)_{j\in\mathbb{N}_0} \right\|_{\ell^q} < \infty \right\},$$

$$f^s_{p,q} := \left\{ (v_j)_{j\in\mathbb{N}_0} \mid \left\| \left(2^{js} v_j\right)_{j\in\mathbb{N}_0} \right\|_{L^p(\mathbb{R}^n;\ell^q(\mathbb{N}_0))} < \infty \right\}.$$

In $L^p(\ell^\infty)$, we mean sequences of measurable functions, identified coordinatewise almost everywhere, with norm $\| \sup_{j\in\mathbb{N}_0} |v_j| \|_{L^p(\mathbb{R}^n)}$. This is a mixed norm; the map taking values in ℓ^∞ need not be strongly measurable in the Bochner sense. Completeness of both sequence spaces follows directly: from a Cauchy sequence, extract a subsequence whose differences have summable norms. The sum of the absolute values of these differences is finite almost everywhere in the corresponding sequence norm. This gives a coordinatewise measurable limit, and the summable-tail inequality proves convergence in norm. For the remaining indices, this agrees with the usual completeness of Lebesgue spaces and Banach sums. In each space, retain only the sequences whose Fourier supports lie in the annuli of the preceding lemma, chosen to contain the supports of φ_j. This subspace is closed: convergence in either norm implies convergence of each coordinate in L^p and hence in $\mathcal{S}'$; a distribution vanishing outside a fixed closed set retains this property in the limit.

On this subspace, define

$$R(v_j)_{j\in\mathbb{N}_0} := \sum_{j\in\mathbb{N}_0} v_j, \qquad Su := (\Delta_j u)_{j\in\mathbb{N}_0}.$$

The lemma proves continuity of R; the definitions of the norms prove continuity of S. Dyadic reconstruction gives $RS = I$. Thus SR is a continuous projection from the sequence subspace onto $S(A)$. Its image is closed and Banach, and S identifies A isometrically with it. The pairing estimate obtained in the lemma, applied to $v_j = \Delta_j u$, also proves continuity of $A \hookrightarrow \mathcal{S}'$. □

For interpolation of Bessel spaces, it will be useful to have synthesis defined on sequences without spectral restrictions.

Lemma 6.3.8. (Synthesis on the full sequence space) The operator

$$\widetilde{R}(v_j)_{j\in\mathbb{N}_0} := \sum_{j\in\mathbb{N}_0} \widetilde{\Delta}_j v_j$$

is continuous from $b^s_{p,q}$ to $B^s_{p,q}$ for $1 \le p,q \le \infty$. It is also continuous from $f^s_{p,q}$ to $F^s_{p,q}$ if $1 < p < \infty$ and $1 \le q \le \infty$. In both cases, $\widetilde{R}S = I$.

Proof. The enlarged blocks have kernels dominated by

$$Ch_j(x), \qquad h_j(x) := 2^{jn}(1 + 2^j\|x\|)^{-n-1}.$$

The Besov bound follows from Young's inequality and the spectral synthesis lemma. For $1 < p < \infty$, $1 < q < \infty$, domination by the maximal operator and Fefferman–Stein control $\|(\widetilde{\Delta}_j v_j)_{j\in\mathbb{N}_0}\|_{L^p(\mathbb{R}^n;\ell^q(\mathbb{N}_0))}$. If $q = \infty$, use

$$\sup_{j\in\mathbb{N}_0} |\widetilde{\Delta}_j v_j| \le C\mathcal{M}\left(\sup_{j\in\mathbb{N}_0} |v_j|\right).$$

For $q = 1$, take a finite family and a function $g \in L^{p'}(\mathbb{R}^n)$, $g \ge 0$. Tonelli's theorem and symmetry of h_j give

$$\begin{aligned}\int_{\mathbb{R}^n} g \sum_{j=0}^{N} |\widetilde{\Delta}_j v_j| &\le C \int_{\mathbb{R}^n} \sum_{j=0}^{N} |v_j|(h_j * g) \\ &\le C \int_{\mathbb{R}^n} \left(\sum_{j=0}^{N} |v_j|\right) \mathcal{M}g \\ &\le C_p \left\| \sum_{j=0}^{N} |v_j| \right\|_{L^p(\mathbb{R}^n)} \|g\|_{L^{p'}(\mathbb{R}^n)}.\end{aligned}$$

Duality of L^p and monotone convergence yield the bound for the full family. Incorporate the weights 2^{js} into v_j. Then apply the spectral synthesis lemma to $\widetilde{\Delta}_j v_j$. □

The requirement $p > 1$ in the second assertion matters: the proof of completeness for $F^s_{1,q}$ uses the subspace with controlled spectral supports from the preceding theorem.

Corollary 6.3.9. (Approximation and loss of regularity) For $p, q < \infty$, $\mathcal{S}(\mathbb{R}^n)$ is dense in $B^s_{p,q}$ and in $F^s_{p,q}$. For any admissible fine index, $1 \le p < \infty$, and $\varepsilon > 0$,

$$A^s_{p,q}(\mathbb{R}^n) \hookrightarrow B^{s-\varepsilon}_{p,p}(\mathbb{R}^n), \qquad A \in \{B, F\}.$$

The dyadic partial sums converge in this latter space.

Proof. If both indices are finite, the tails of the block sequence tend to zero in the corresponding norm by dominated convergence. The spectral synthesis lemma gives the same conclusion for tails of the reconstruction. Each of the finitely many remaining blocks is approximated in L^p by Schwartz functions; applying a multiplier equal to one on its spectral support preserves convergence and keeps the support in a slightly larger annulus. Finite synthesis gives approximation in the norm of the space.
In every case,

$$2^{js}\|\Delta_j u\|_{L^p(\mathbb{R}^n)} \le \|u\|_{A^s_{p,q}}, \qquad j \in \mathbb{N}_0.$$

Multiplying by $2^{-j\varepsilon}$ and summing the pth powers proves the second assertion and convergence of the tails. For $q = \infty$, the asserted convergence takes place in the space of order $s - \varepsilon$. □

6.3.2 Fundamental identifications and interpolation

In this subsection, we use the abstract interpolation results developed in Chapter 5; in particular, we apply the real and complex methods to the Euclidean scales constructed here.

The newly defined scales contain several spaces introduced earlier. Two mechanisms should be distinguished. Identification of Bessel potentials with $F^s_{p,2}(\mathbb{R}^n)$ is a Littlewood–Paley statement and therefore depends on the quadratic combination of frequency blocks. In contrast, identification of noninteger Sobolev–Slobodeckij spaces with $B^s_{p,p}(\mathbb{R}^n)$ comes from real interpolation. The two proofs explain how different extensions of the integer Sobolev scale arise.

Theorem 6.3.10. (Bessel potentials and integer-order Sobolev spaces) Let $1 < p < \infty$ and $s \in \mathbb{R}$.

(a) For every $s \in \mathbb{R}$,

$$H^{s,p}(\mathbb{R}^n) = F^s_{p,2}(\mathbb{R}^n)$$

and there exist $c_{s,p}, C_{s,p} > 0$ such that

$$c_{s,p}\|u\|_{H^{s,p}(\mathbb{R}^n)} \le \|u\|_{F^s_{p,2}(\mathbb{R}^n)} \le C_{s,p}\|u\|_{H^{s,p}(\mathbb{R}^n)}.$$

(b) If $m \in \mathbb{N}_0$, then

$$H^{m,p}(\mathbb{R}^n) = W^{m,p}(\mathbb{R}^n)$$

and there exist $c_{m,p}, C_{m,p} > 0$ such that

$$c_{m,p}\|u\|_{W^{m,p}(\mathbb{R}^n)} \le \|u\|_{H^{m,p}(\mathbb{R}^n)} \le C_{m,p}\|u\|_{W^{m,p}(\mathbb{R}^n)}.$$

The classical identification $F^s_{p,2} = H^{s,p}$ can be found in [146, Chapter 1].

Proof. First extend the Littlewood–Paley criterion to distributions. If $v \in \mathcal{S}'(\mathbb{R}^n)$ and

$$G_v := \left(\sum_{j \in \mathbb{N}_0} |\Delta_j v|^2 \right)^{1/2} \in L^p(\mathbb{R}^n),$$

dyadic reproduction and Cauchy–Schwarz give, for $\zeta \in \mathcal{S}(\mathbb{R}^n)$,

$$\begin{aligned} |\langle v, \zeta \rangle| &= \left| \sum_{j \in \mathbb{N}_0} \langle \Delta_j v, \widetilde{\Delta}_j \zeta \rangle \right| \\ &\le \|G_v\|_{L^p(\mathbb{R}^n)} \left\| \left(\sum_{j \in \mathbb{N}_0} |\widetilde{\Delta}_j \zeta|^2 \right)^{1/2} \right\|_{L^{p'}(\mathbb{R}^n)} \le C\|G_v\|_{L^p(\mathbb{R}^n)} \|\zeta\|_{L^{p'}(\mathbb{R}^n)}. \end{aligned}$$

The sum of pairings converges absolutely by the same inequality. The argument with signs used in Theorem 6.3.2 also applies to the enlarged blocks, since their symbols have the same uniform bounds and finite overlap. Density of $\mathcal{S}$ in $L^{p'}$ and duality of $L^{p'}$ show that v is represented by a function in L^p, with $\|v\|_{L^p(\mathbb{R}^n)} \le C\|G_v\|_{L^p(\mathbb{R}^n)}$. Together with the direct Littlewood–Paley bound, this proves the criterion in both directions for $v \in \mathcal{S}'$.

On the support of φ_j, the weight $\langle\xi\rangle^s$ is comparable to 2^{js} uniformly in $j \in \mathbb{N}_0$. To pass from this comparison of symbols to one of norms, consider

$$m_j(\xi) = 2^{-js}\langle\xi\rangle^s \widetilde{\varphi}_j(\xi), \qquad \widetilde{m}_j(\xi) = 2^{js}\langle\xi\rangle^{-s}\widetilde{\varphi}_j(\xi).$$

After $\xi = 2^j\zeta$, all their derivatives are uniformly bounded on a fixed compact set. Integration by parts shows that their kernels satisfy the hypotheses of Lemma 6.3.3. Applying it with fine index 2, first to the blocks of u and then to those of $J^s u$, yields

$$c\left\|\left(\sum_{j\in\mathbb{N}_0} 2^{2js}|\Delta_j u|^2\right)^{1/2}\right\|_{L^p(\mathbb{R}^n)} \le \left\|\left(\sum_{j\in\mathbb{N}_0} |\Delta_j J^s u|^2\right)^{1/2}\right\|_{L^p(\mathbb{R}^n)} \le C\left\|\left(\sum_{j\in\mathbb{N}_0} 2^{2js}|\Delta_j u|^2\right)^{1/2}\right\|_{L^p(\mathbb{R}^n)}.$$

The preceding distributional criterion states that these quantities are finite exactly when $J^s u \in L^p$, and are then equivalent to $\|J^s u\|_{L^p(\mathbb{R}^n)}$. This proves (a).

For (b), if $\alpha \in \mathbb{N}_0^n$ and $|\alpha| \le m$, the symbol

$$b_\alpha(\xi) = (i\xi)^\alpha \langle\xi\rangle^{-m}$$

satisfies the Mikhlin conditions: each differentiation lowers its order by one, and its initial order is $|\alpha| - m \le 0$. Thus $D^\alpha u = T_{b_\alpha} J^m u$ and

$$\sum_{\substack{\alpha\in\mathbb{N}_0^n \\ |\alpha|\le m}} \|D^\alpha u\|_{L^p(\mathbb{R}^n)} \le C\|J^m u\|_{L^p(\mathbb{R}^n)}.$$

To recover $J^m u$ from the derivatives, introduce the positive polynomial

$$P_m(\xi) = \sum_{\substack{\alpha\in\mathbb{N}_0^n \\ |\alpha|\le m}} \xi^{2\alpha}.$$

We have $c_m\langle\xi\rangle^{2m} \le P_m(\xi) \le C_m\langle\xi\rangle^{2m}$. The upper bound follows by estimating each monomial. For the lower bound, if $\|\xi\| \ge 1$, some coordinate satisfies $|\xi_\ell| \ge \|\xi\|/\sqrt{n}$, and the summand ξ_ℓ^{2m} gives the bound; if $\|\xi\| \le 1$, use the constant term.

For the same multi-indices, define

$$a_\alpha(\xi) = \frac{\langle\xi\rangle^m (-i\xi)^\alpha}{P_m(\xi)}.$$

Differentiating $P_m P_m^{-1} = 1$ and inducting on $|\beta|$ gives

$$|D^\beta(P_m^{-1})(\xi)| \le C_\beta\langle\xi\rangle^{-2m-|\beta|}, \qquad \beta \in \mathbb{N}_0^n.$$

The Leibniz rule then implies $|D^\beta a_\alpha(\xi)| \le C_{\alpha,\beta}\langle\xi\rangle^{|\alpha|-m-|\beta|}$; hence the a_α are also Mikhlin symbols. The algebraic identity

$$\sum_{\substack{\alpha\in\mathbb{N}_0^n \\ |\alpha|\le m}} a_\alpha(\xi)(i\xi)^\alpha = \langle\xi\rangle^m$$

gives, in $\mathcal{S}'$,

$$J^m u = \sum_{\substack{\alpha \in \mathbb{N}_0^n \\ |\alpha| \le m}} T_{a_\alpha} D^\alpha u.$$

Continuity of each multiplier on L^p proves the reverse inequality. The sum norms and the ℓ^p norms for this finite number of derivatives are equivalent, giving exactly the norm of $W^{m,p}$ fixed in this book. □

The preceding theorem allows interpolation methods to be transferred to dyadic scales. For the real method, regularity is encoded in the weight 2^{js} of each block; for the complex method, these weights interpolate geometrically. This difference explains why the real method produces the Besov scale while the complex method preserves the Bessel scale.

Theorem 6.3.11. (Interpolation of the scales) Let $s_0 < s_1$, $0 < \theta < 1$, and $s = (1-\theta)s_0 + \theta s_1$.

(a) If $1 < p < \infty$ and $1 \le q \le \infty$, then

$$(H^{s_0,p}(\mathbb{R}^n), H^{s_1,p}(\mathbb{R}^n))_{\theta,q} = B^s_{p,q}(\mathbb{R}^n)$$

and there exist $c, C > 0$, depending on $n, s_0, s_1, p, q, \theta$ and the fixed resolution, such that

$$c\|u\|_{B^s_{p,q}(\mathbb{R}^n)} \le \|u\|_{(H^{s_0,p}(\mathbb{R}^n), H^{s_1,p}(\mathbb{R}^n))_{\theta,q}} \le C\|u\|_{B^s_{p,q}(\mathbb{R}^n)}.$$

(b) If $1 < p_0, p_1 < \infty$ and

$$\frac{1}{p} = \frac{1-\theta}{p_0} + \frac{\theta}{p_1},$$

then

$$[H^{s_0,p_0}(\mathbb{R}^n), H^{s_1,p_1}(\mathbb{R}^n)]_\theta = H^{s,p}(\mathbb{R}^n)$$

and there exist $c, C > 0$, depending on $n, s_0, s_1, p_0, p_1, \theta$ and the fixed resolution, such that

$$c\|u\|_{H^{s,p}(\mathbb{R}^n)} \le \|u\|_{[H^{s_0,p_0}, H^{s_1,p_1}]_\theta} \le C\|u\|_{H^{s,p}(\mathbb{R}^n)}.$$

(c) In particular, if $m \in \mathbb{N}$ and $0 < \theta < 1$, then

$$(L^p(\mathbb{R}^n), W^{m,p}(\mathbb{R}^n))_{\theta,q} = B^{\theta m}_{p,q}(\mathbb{R}^n),$$

and

$$[L^p(\mathbb{R}^n), W^{m,p}(\mathbb{R}^n)]_\theta = H^{\theta m,p}(\mathbb{R}^n).$$

Remark 6.3.12. (Why p is fixed in the real method) In part (a), p cannot simply be replaced by two distinct exponents p_0, p_1. If $p^{-1} = (1-\theta)p_0^{-1} + \theta p_1^{-1}$, already in the low-frequency block one would obtain

$$(L^{p_0}(\mathbb{R}^n), L^{p_1}(\mathbb{R}^n))_{\theta,q} = L^{p,q}(\mathbb{R}^n),$$

a Lorentz space, rather than $L^p(\mathbb{R}^n)$ except in special cases. Formulas with $p_0 \neq p_1$ lead to Besov–Lorentz scales. The complex method in part (b), in contrast, interpolates smoothness and the spatial exponent

simultaneously within the Bessel scale.

Proof. Define the analysis operator

$$Su := (\Delta_j u)_{j\in\mathbb{N}_0}$$

and the synthesis operator

$$R(v_j)_{j\in\mathbb{N}_0} := \sum_{j\in\mathbb{N}_0} \widetilde{\Delta}_j v_j.$$

Lemma 6.3.8, with $1 < p < \infty$ and fine index 2, proves that both operators are continuous on the scales below and satisfy $RS = I$. Thus the function scales are identified as retracts of the weighted sequence spaces associated with their dyadic blocks.
We prove (a). Write

$$\delta := s_1 - s_0 > 0, \qquad t_k := 2^{-k\delta}, \qquad a_j := \|\Delta_j u\|_{L^p(\mathbb{R}^n)}, \quad j,k \in \mathbb{N}_0.$$

For $k \in \mathbb{N}_0$, separate high and low frequencies by

$$u = u_0^{(k)} + u_1^{(k)},$$

with

$$u_0^{(k)} := \sum_{\substack{j\in\mathbb{N}_0\\ j>k}} \widetilde{\Delta}_j \Delta_j u, \qquad u_1^{(k)} := \sum_{j=0}^{k} \widetilde{\Delta}_j \Delta_j u.$$

Finite interaction of the blocks, the triangle inequality, and the identification $H^{s_i,p}(\mathbb{R}^n) = F^{s_i}_{p,2}(\mathbb{R}^n)$ from Theorem 6.3.10 give

$$K(t_k, u; H^{s_0,p}(\mathbb{R}^n), H^{s_1,p}(\mathbb{R}^n)) \le C \left(\sum_{\substack{j\in\mathbb{N}_0\\ j>k}} 2^{js_0} a_j + t_k \sum_{j=0}^{k} 2^{js_1} a_j \right). \tag{6.3}$$

In the reverse direction, let $u = v_0 + v_1$ with $v_i \in H^{s_i,p}(\mathbb{R}^n)$. Uniform boundedness of the block Δ_j and the description $H^{s_i,p} = F^{s_i}_{p,2}$ imply

$$2^{js_0} a_j \le C \left(\|v_0\|_{H^{s_0,p}(\mathbb{R}^n)} + t_j \|v_1\|_{H^{s_1,p}(\mathbb{R}^n)} \right).$$

Taking the infimum over all decompositions of u gives

$$2^{js} a_j \le C t_j^{-\theta} K(t_j, u; H^{s_0,p}(\mathbb{R}^n), H^{s_1,p}(\mathbb{R}^n)). \tag{6.4}$$

Set $b_j := 2^{js} a_j$. Multiplying (6.3) by $t_k^{-\theta}$ transforms its right-hand side into

$$C \left(\sum_{\substack{j\in\mathbb{N}_0\\ j>k}} 2^{-\theta\delta(j-k)} b_j + \sum_{j=0}^{k} 2^{-(1-\theta)\delta(k-j)} b_j \right).$$

Both coefficient sequences are geometrically summable. Lemma 5.2.5 and the Hardy inequalities from Theorem B.8.5, together with (6.4), give constants $c, C > 0$ such that

$$c\left\|(2^{js}\|\Delta_j u\|_{L^p(\mathbb{R}^n)})_{j\in\mathbb{N}_0}\right\|_{\ell^q(\mathbb{N}_0)} \le \|u\|_{(H^{s_0,p}(\mathbb{R}^n),H^{s_1,p}(\mathbb{R}^n))_{\theta,q}} \le C\left\|(2^{js}\|\Delta_j u\|_{L^p(\mathbb{R}^n)})_{j\in\mathbb{N}_0}\right\|_{\ell^q(\mathbb{N}_0)}.$$

This discretization describes the portion $0 < t \le 1$. For $t \ge 1$, the embedding $H^{s_1,p}(\mathbb{R}^n) \hookrightarrow H^{s_0,p}(\mathbb{R}^n)$ implies that there is $c_0 > 0$, independent of t and u, such that

$$c_0\|u\|_{H^{s_0,p}(\mathbb{R}^n)} \le K(t,u;H^{s_0,p}(\mathbb{R}^n),H^{s_1,p}(\mathbb{R}^n)) \le \|u\|_{H^{s_0,p}(\mathbb{R}^n)}$$

for every $t \ge 1$. This norm is also controlled by the Besov norm. To see this, dyadic reconstruction and the triangle inequality give

$$\|u\|_{H^{s_0,p}(\mathbb{R}^n)} \le C\sum_{j\in\mathbb{N}_0} 2^{js_0}a_j = C\sum_{j\in\mathbb{N}_0} 2^{-j(s-s_0)}b_j.$$

The sequence $(2^{-j(s-s_0)})_{j\in\mathbb{N}_0}$ belongs to $\ell^{q'}(\mathbb{N}_0)$ when $1 < q < \infty$; for $q = 1$ use its uniform bound, and for $q = \infty$ its summability. By Hölder's inequality for sequences, with these endpoint interpretations,

$$\|u\|_{H^{s_0,p}(\mathbb{R}^n)} \le C\|(b_j)_{j\in\mathbb{N}_0}\|_{\ell^q(\mathbb{N}_0)}.$$

Thus the interpolation integral over $[1,\infty)$ is controlled by the same norm, since $t^{-\theta} \in L^q((1,\infty),dt/t)$ for $q < \infty$ and is bounded for $q = \infty$. This proves (a), including the endpoints $q = 1$ and $q = \infty$.
For (b), define, for $i \in \{0,1\}$,

$$\ell^2_{s_i}(\mathbb{N}_0) := \left\{(z_j)_{j\in\mathbb{N}_0} \;\middle|\; \sum_{j\in\mathbb{N}_0} 2^{2js_i}|z_j|^2 < \infty\right\},$$

with its natural norm, and set

$$Y_i := L^{p_i}(\mathbb{R}^n;\ell^2_{s_i}(\mathbb{N}_0)).$$

By Theorem 6.3.10, S and R identify $H^{s_i,p_i}(\mathbb{R}^n)$ with a retract of Y_i. The weights interpolate geometrically,

$$(2^{js_0})^{1-\theta}(2^{js_1})^{\theta} = 2^{js},$$

and the spatial exponent satisfies $p^{-1} = (1-\theta)p_0^{-1} + \theta p_1^{-1}$. Proposition 5.7.12, applied to weighted sequences on $\mathbb{N}_0$ (or equivalently, after extending them by zero to $\mathbb{Z}$), and then to the Bochner spaces, gives

$$[Y_0, Y_1]_\theta = L^p(\mathbb{R}^n;\ell^2_s(\mathbb{N}_0)).$$

Theorem 5.7.5, applied to S and R, preserves the retraction. Finally, the identification

$$H^{s,p}(\mathbb{R}^n) = F^s_{p,2}(\mathbb{R}^n)$$

from Theorem 6.3.10 identifies the resulting retract with $H^{s,p}(\mathbb{R}^n)$ and proves (b).
For (c), use $H^{0,p}(\mathbb{R}^n) = L^p(\mathbb{R}^n)$ and $H^{m,p}(\mathbb{R}^n) = W^{m,p}(\mathbb{R}^n)$, both from Theorem 6.3.10, and apply (a) and (b) with $s_0 = 0$ and $s_1 = m$. □

Corollary 6.3.13. (Real interpolation with different fine indices) Let $s_0 < s_1$, $0 < \theta < 1$, $s = (1-\theta)s_0 + \theta s_1$, $1 < p < \infty$, and $1 \le q, q_0, q_1 \le \infty$. If $A_0, A_1 \in \{B, F\}$, then

$$\big((A_0)^{s_0}_{p,q_0}(\mathbb{R}^n), (A_1)^{s_1}_{p,q_1}(\mathbb{R}^n)\big)_{\theta,q} = B^s_{p,q}(\mathbb{R}^n)$$

with equivalent norms. Here $(A_i)^{s_i}_{p,q_i}$ means $B^{s_i}_{p,q_i}$ or $F^{s_i}_{p,q_i}$ according to the choice of A_i, for $i \in \{0,1\}$.

Proof. The proof of part (a) of the preceding theorem uses two properties of the endpoints $Y_i = H^{s_i,p}$:

$$2^{js_i}\|\Delta_j v\|_{L^p(\mathbb{R}^n)} \le C\|v\|_{Y_i}, \qquad \left\|\sum_{j\in J} v_j\right\|_{Y_i} \le C\sum_{j\in J} 2^{js_i}\|v_j\|_{L^p(\mathbb{R}^n)},$$

where $J \subseteq \mathbb{N}_0$ and the v_j have spectral support in the corresponding annuli. The second assertion includes series when the right-hand side is finite. Both properties also hold for $Y_i = (A_i)^{s_i}_{p,q_i}$: the first follows from the definition, and the second from Lemma 6.3.6 and the triangle inequality.
Thus, with $t_k = 2^{-k(s_1-s_0)}$ and $a_j = \|\Delta_j u\|_{L^p(\mathbb{R}^n)}$, the same frequency splitting yields

$$K(t_k, u; Y_0, Y_1) \le C\left(\sum_{\substack{j\in\mathbb{N}_0\\ j>k}} 2^{js_0}a_j + t_k\sum_{j=0}^{k} 2^{js_1}a_j\right), \qquad 2^{ks}a_k \le Ct_k^{-\theta}K(t_k, u; Y_0, Y_1).$$

Multiplying the first inequality by $t_k^{-\theta}$ produces exactly the two geometric sequences from the preceding proof. Young's inequality and discretization of K compare the Besov norm with the portion of the interpolation norm corresponding to $0 < t \le 1$. If $u \in B^s_{p,q}$, the second property, with $i = 0$, also gives

$$\|u\|_{Y_0} \le C\sum_{j\in\mathbb{N}_0} 2^{-j(s-s_0)}\big(2^{js}a_j\big) \le C'\|u\|_{B^s_{p,q}(\mathbb{R}^n)}.$$

For $t \ge 1$, use $K(t, u; Y_0, Y_1) \le \|u\|_{Y_0}$; integrability of $t^{-\theta}$ completes the bound on that interval. This proves both inclusions. □

The real interpolation formula now identifies the spaces defined through differences with the Besov scale.

Corollary 6.3.14. (Sobolev–Slobodeckij, Besov, and Triebel–Lizorkin) Let $1 < p < \infty$ and $s > 0$, and assume $s \notin \mathbb{N}$. Then

$$W^{s,p}(\mathbb{R}^n) = B^s_{p,p}(\mathbb{R}^n) = F^s_{p,p}(\mathbb{R}^n)$$

and there are constants $c_{n,s,p}, C_{n,s,p} > 0$ such that

$$c_{n,s,p}\|u\|_{W^{s,p}(\mathbb{R}^n)} \le \|u\|_{B^s_{p,p}(\mathbb{R}^n)} = \|u\|_{F^s_{p,p}(\mathbb{R}^n)} \le C_{n,s,p}\|u\|_{W^{s,p}(\mathbb{R}^n)}.$$

The identification through real interpolation is classical; see [146, Chapters 1–2].

Proof. Write $s = m + \sigma$, with $m \in \mathbb{N}_0$ and $0 < \sigma < 1$. Corollary 6.2.6 gives

$$W^{s,p}(\mathbb{R}^n) = (W^{m,p}(\mathbb{R}^n), W^{m+1,p}(\mathbb{R}^n))_{\sigma,p}.$$

By Theorem 6.3.10, the two integer-order spaces in the pair may be replaced by $H^{m,p}(\mathbb{R}^n)$ and $H^{m+1,p}(\mathbb{R}^n)$. Part (a) of Theorem 6.3.11 then gives

$$W^{s,p}(\mathbb{R}^n) = B^s_{p,p}(\mathbb{R}^n).$$

On the other hand, for a fixed dyadic resolution, Theorem B.6.17 allows sum and integral to be interchanged:

$$\begin{aligned} \|u\|^p_{F^s_{p,p}(\mathbb{R}^n)} &= \int_{\mathbb{R}^n} \sum_{j\in\mathbb{N}_0} 2^{jsp} |\Delta_j u(x)|^p \, dx \\ &= \sum_{j\in\mathbb{N}_0} 2^{jsp} \|\Delta_j u\|^p_{L^p(\mathbb{R}^n)} = \|u\|^p_{B^s_{p,p}(\mathbb{R}^n)}. \end{aligned}$$

This yields the identification and equivalence of norms. □

Corollary 6.3.15. (When $H^{s,p}(\mathbb{R}^n)$ and $W^{s,p}(\mathbb{R}^n)$ coincide) Let $s > 0$ and $s \notin \mathbb{N}$, and let $1 < p < \infty$.

(a) If $1 < p \le 2$, then $W^{s,p}(\mathbb{R}^n) \hookrightarrow H^{s,p}(\mathbb{R}^n)$.

(b) If $2 \le p < \infty$, then $H^{s,p}(\mathbb{R}^n) \hookrightarrow W^{s,p}(\mathbb{R}^n)$.

(c) Equality holds if $p = 2$. If $p \ne 2$, the corresponding embedding is strict.

For $s = m \in \mathbb{N}_0$, however,

$$H^{m,p}(\mathbb{R}^n) = W^{m,p}(\mathbb{R}^n)$$

for every $1 < p < \infty$.

Proof. By Corollary 6.3.14 and Theorem 6.3.10, it suffices to compare $F^s_{p,p}$ with $F^s_{p,2}$. The inclusion $\ell^{q_0}(\mathbb{N}_0) \hookrightarrow \ell^{q_1}(\mathbb{N}_0)$, for $q_0 \le q_1$, applied at each point to $(2^{js}|\Delta_j u(x)|)_{j\in\mathbb{N}_0}$, proves the embeddings and equality for $p = 2$.

We construct examples establishing strictness inside any open ball $B \subseteq \mathbb{R}^n$. This will also allow their use on domains. By independence of the resolution, we may choose a radial cutoff χ equal to one when $\|\xi\| \le 1$, zero when $\|\xi\| \ge 3/2$, and nonincreasing in the radius. For $\varphi_j(\xi) = \chi(2^{-j}\xi) - \chi(2^{-j+1}\xi)$, $j \ge 1$, the block equals one when $3/4 < 2^{-j}\|\xi\| < 1$. Take $\xi_* = (7/8, 0, \dots, 0)$, a number $0 < \varepsilon < 1/16$, and

$$j_m = J + 4m, \qquad \lambda_m = 2^{j_m}\xi_*, \qquad m \in \mathbb{N},$$

with $J \in \mathbb{N}$. The balls of center λ_m and radius $\varepsilon 2^{j_m}$ lie in regions where $\varphi_{j_m} = 1$; the other blocks vanish there.

Fix $0 \ne \zeta \in C^\infty_c(B)$ and a cutoff $\omega \in C^\infty_c(B_{\mathrm{euc}}(0,\varepsilon))$ equal to one near the origin. Define

$$\zeta_m = \mathcal{F}^{-1}\big(\omega(2^{-j_m}\cdot)\widehat{\zeta}\big).$$

For any multi-indices $\alpha, \beta \in \mathbb{N}_0^n$ and any $N > 0$, rapid decay of $\widehat{\zeta}$ gives

$$\sup_{x \in \mathbb{R}^n} |x^\alpha D^\beta (\zeta_m - \zeta)(x)| \le C_{\alpha,\beta,N} 2^{-j_m N}. \tag{6.5}$$

Indeed, the symbol $1 - \omega(2^{-j_m}\xi)$ vanishes on a ball of radius comparable to 2^{j_m}. Differentiating in ξ to produce x^α, multiplying by ξ^β, and estimating the inverse transform by its L^1 norm reduces the bound to tail integrals of a Schwartz function. These tails decay with every power of the radius.
Let $(a_m)_{m\in\mathbb{N}}$ be a bounded sequence. Since $s > 0$, the series

$$w = \sum_{m\in\mathbb{N}} a_m 2^{-j_m s} e^{i\langle \lambda_m, x\rangle} \zeta_m(x), \qquad u = \zeta(x) \sum_{m\in\mathbb{N}} a_m 2^{-j_m s} e^{i\langle \lambda_m, x\rangle}$$

converge uniformly and in $\mathcal{S}'$. The second function has support in B. By the choice of frequencies,

$$2^{j_m s} \Delta_{j_m} w = a_m e^{i\langle \lambda_m, x\rangle} \zeta_m(x), \qquad \Delta_j w = 0 \quad \text{if } j \notin \{j_m \mid m \in \mathbb{N}\}.$$

The sequence $(a_m(\zeta_m - \zeta))_{m\in\mathbb{N}}$ belongs to $L^p(\mathbb{R}^n; \ell^q(\mathbb{N}))$ for every $1 \le q \le \infty$: by (6.5), the sum of its L^p norms is finite. On the other hand,

$$\big\| (a_m \zeta)_{m\in\mathbb{N}} \big\|_{L^p(\mathbb{R}^n; \ell^q(\mathbb{N}_0))} = \|\zeta\|_{L^p(\mathbb{R}^n)} \|(a_m)_{m\in\mathbb{N}}\|_{\ell^q}.$$

The triangle inequality, also applied to the difference, shows that

$$w \in F^s_{p,q} \quad \Longleftrightarrow \quad (a_m)_{m\in\mathbb{N}} \in \ell^q(\mathbb{N}).$$

Moreover, $u - w \in \mathcal{S}$. To verify this, differentiate each summand of the difference. A derivative of the exponential produces at most a power of 2^{j_m}, and any polynomial weight in x is absorbed into the seminorm in (6.5). Choosing N larger than these powers makes the series summable in every Schwartz seminorm. Therefore,

$$u \in F^s_{p,q} \quad \Longleftrightarrow \quad (a_m)_{m\in\mathbb{N}} \in \ell^q(\mathbb{N}).$$

If $p < 2$, choose $a_m = m^{-\gamma}$ with $1/2 < \gamma \le 1/p$; then $(a_m) \in \ell^2 \setminus \ell^p$ and $u \in H^{s,p} \setminus W^{s,p}$. If $p > 2$, choose $1/p < \gamma \le 1/2$ to obtain $u \in W^{s,p} \setminus H^{s,p}$. These choices prove strictness, even with compact support in B. The integer-order case follows from Theorem 6.3.10. □

Remark 6.3.16. (Two different extensions of the integer scale) The corollary clarifies a common source of terminological ambiguity. Some texts call both $H^{s,p}(\mathbb{R}^n)$ and $W^{s,p}(\mathbb{R}^n)$ "fractional Sobolev spaces." We shall retain different letters. The scale

$$H^{s,p}(\mathbb{R}^n) = F^s_{p,2}(\mathbb{R}^n)$$

is stable under complex interpolation and suited to multipliers and elliptic operators. The scale

$$W^{s,p}(\mathbb{R}^n) = B^s_{p,p}(\mathbb{R}^n) = F^s_{p,p}(\mathbb{R}^n), \qquad s \notin \mathbb{N},$$

arises from real interpolation and is suited to differences, traces, and nonlocal energies. For $p = 2$, both perspectives come together.

6.4 Multipliers, changes of coordinates, and localization

Euclidean theory can be transferred to a manifold only if two operations are stable: multiplication by a function in a partition of unity and change of coordinates. The next result treats both operations. Uniformity of the constants will be decisive in the chapter on bounded geometry.

Definition 6.4.1. (The spaces BC^j and BUC^j) Let $U \subseteq \mathbb{R}^m$ be an open subset, let F be a Banach space, and let $j \in \mathbb{N}_0$. Adopt the conventions $D^0 f = f$ and $\mathcal{L}^0(\mathbb{R}^m;F) = F$. For $0 \le \ell \le j$, the space $\mathcal{L}^\ell(\mathbb{R}^m;F)$ carries the norm

$$\|A\|_{\mathcal{L}^\ell} := \sup\bigl\{\|A(v_1,\dots,v_\ell)\|_F \mid |v_1| \le 1,\dots,|v_\ell| \le 1\bigr\}.$$

Define

$$BC^j(U,F) := \left\{ f \in C^j(U,F) \,\middle|\, \sum_{\ell=0}^{j} \sup_{x\in U} \|D^\ell f(x)\|_{\mathcal{L}^\ell} < +\infty \right\},$$

with the norm

$$\|f\|_{BC^j(U,F)} := \sum_{\ell=0}^{j} \sup_{x\in U} \|D^\ell f(x)\|_{\mathcal{L}^\ell}.$$

The space $BUC^j(U,F)$ is the subspace of $BC^j(U,F)$ consisting of functions for which

$$D^\ell f \colon U \longrightarrow \mathcal{L}^\ell(\mathbb{R}^m;F)$$

is uniformly continuous for each $0 \le \ell \le j$; it carries the norm induced from $BC^j(U,F)$. In particular, $BC^0(U,F)$ is the space of continuous bounded functions, while $BUC^0(U,F)$ additionally requires uniform continuity.

Now let $Q^m_+ = [0,1)\times(-1,1)^{m-1}$ and let $V \subseteq Q^m_+$ be a relatively open subset. Set

$$V^\circ := V \cap \bigl((0,1)\times(-1,1)^{m-1}\bigr).$$

By $C^j(V,F)$, we mean the space of functions $f\colon V \longrightarrow F$ for which $f\restriction_{V^\circ}$ is of class C^j and each derivative $D^\ell(f\restriction_{V^\circ})$, $0 \le \ell \le j$, admits a continuous extension to V, requiring the order-zero extension to agree with f. The extension is unique because V° is dense in V and is also denoted by $D^\ell f$. Define $BC^j(V,F)$ and its norm by the preceding formulas with V in place of U, and let $BUC^j(V,F)$ be the subspace for which each extended function

$$D^\ell f \colon V \longrightarrow \mathcal{L}^\ell(\mathbb{R}^m;F)$$

is uniformly continuous with respect to the induced Euclidean distance. In particular, if $V = Q^m_+$, each derivative of a function in $BUC^j(Q^m_+,F)$ has a unique continuous extension to the Euclidean closure of Q^m_+. The convention also applies to overlap domains relatively open in a half-box and agrees with the usual notion of regularity up to the face $\{0\}\times(-1,1)^{m-1}$ on a manifold with boundary.

Finally, if Ω is any of the preceding domains,

$$BC^\infty(\Omega,F) := \bigcap_{j\in\mathbb{N}_0} BC^j(\Omega,F), \qquad BUC^\infty(\Omega,F) := \bigcap_{j\in\mathbb{N}_0} BUC^j(\Omega,F),$$

with the families of seminorms $\|\cdot\|_{BC^j}$; no single uniform bound in j is required. For matrix-valued func-

tions and tensor coefficients, use the corresponding finite-dimensional space as codomain, with its operator norm or the tensor norm induced by the Euclidean norm. Thus the bounds hold simultaneously for all components.

This is the sum convention used in Amann's uniform regularity. If one introduces the auxiliary norm $\|f\|_{\max,j} := \max_{\ell\in\{0,\dots,j\}} \sup_{x\in U} \|D^\ell f(x)\|_{\mathcal{L}^\ell}$, then explicitly,

$$\|f\|_{\max,j} \le \|f\|_{BC^j} \le (j+1)\|f\|_{\max,j}.$$

The class of spaces is also independent of the chosen Euclidean norm. Indeed, if $a|v|_1 \le |v|_2 \le b|v|_1$ for every $v \in \mathbb{R}^m$, with $a, b > 0$, then for each ℓ,

$$\|A\|_{\mathcal{L}^\ell,2} \le a^{-\ell}\|A\|_{\mathcal{L}^\ell,1}, \qquad \|A\|_{\mathcal{L}^\ell,1} \le b^\ell \|A\|_{\mathcal{L}^\ell,2}.$$

Consequently,

$$\|f\|_{BC^j,2} \le \max\{1, a^{-j}\}\|f\|_{BC^j,1}, \qquad \|f\|_{BC^j,1} \le \max\{1, b^j\}\|f\|_{BC^j,2}.$$

The two domain metrics are bi-Lipschitz equivalent and therefore determine the same uniform continuity. If F is finite dimensional and the codomain norms satisfy

$$c_F\|w\|_{F,1} \le \|w\|_{F,2} \le C_F\|w\|_{F,1} \qquad (w \in F),$$

then the preceding inequalities become

$$\|f\|_{BC^j,2} \le C_F \max\{1, a^{-j}\}\|f\|_{BC^j,1}, \qquad \|f\|_{BC^j,1} \le c_F^{-1} \max\{1, b^j\}\|f\|_{BC^j,2}.$$

Thus the classes BC^j and BUC^j are independent of these choices.

Estimates for changes of coordinates require control of both frequency separation and spatial decay of the kernel. Write

$$h_{r,D}(x) := 2^{rn}(1 + 2^r\|x\|)^{-D}, \qquad r \in \mathbb{N}_0, \quad D > n,$$

and, for a band-limited function v,

$$P_{r,\lambda}v(x) := \sup_{z\in\mathbb{R}^n} \frac{|v(z)|}{(1 + 2^r\|x - z\|)^\lambda}.$$

Lemma B.8.16 ensures that $P_{r,\lambda}v \le C\mathcal{M}_a v$ when $\lambda > n/a$ and the support of $\widehat{v}$ lies in a ball of radius comparable to 2^r.

Lemma 6.4.2. (Kernel estimate for a change of coordinates) Let $M \in \mathbb{N}$, let $g \in BC^M(\mathbb{R}^n)$, and let ψ be a global diffeomorphism of class C^{M+1}. Suppose that ψ and ψ^{-1} are Lipschitz and that their derivatives of orders $1, \dots, M+1$ are bounded. The kernel $L_{j,r}(x,z)$ of

$$\Delta_j\big[g\,((\widetilde{\Delta}_r v) \circ \psi)\big](x) = \int_{\mathbb{R}^n} L_{j,r}(x,z)v(z)\,dz$$

satisfies, for any $D > n$,

$$|L_{j,r}(x,z)| \le C_{M,D}\,2^{-M|j-r|}h_{\min\{j,r\},D}(\psi(x) - z), \qquad j, r \in \mathbb{N}_0. \tag{6.6}$$

Proof. Denote by K_j and $\widetilde{K}_r$ the real convolution kernels of the blocks, including their Fourier constants. Then

$$L_{j,r}(x,z) = \int_{\mathbb{R}^n} K_j(x-y)g(y)\widetilde{K}_r(\psi(y)-z)\,dy.$$

Positive-index kernels have all moments zero. Moreover, for any multi-index α and any $D_1 > 0$,

$$|D^\alpha K_j(y)| + |D^\alpha \widetilde{K}_j(y)| \le C_{\alpha,D_1} 2^{j(n+|\alpha|)}(1+2^j\|y\|)^{-D_1}.$$

If $j \ge r$ and $j \ge 1$, subtract from $y \mapsto g(y)\widetilde{K}_r(\psi(y)-z)$ its Taylor polynomial at x of degree $M-1$. The polynomial terms vanish upon integration against $K_j(x-y)$. The Leibniz and Faà di Bruno formulas, Theorem 1.1.19, show that derivatives of order M of the remainder are bounded by

$$C2^{r(n+M)}(1+2^r\|\psi(x)-z\|)^{-D}(1+2^r\|x-y\|)^{D}$$

on the segment between x and y. Here we use

$$1+2^r\|\psi(x)-z\| \le C(1+2^r\|\psi(x+t(y-x))-z\|)(1+2^r\|x-y\|), \qquad 0 \le t \le 1.$$

The integral remainder also contains $\|x-y\|^M$. The substitution $w = 2^j(x-y)$, with $D_1 > M+D+n$, gives

$$\int_{\mathbb{R}^n} |K_j(x-y)|\,\|x-y\|^M(1+2^r\|x-y\|)^D\,dy \le C2^{-jM}.$$

This yields (6.6) in this case.
If $r > j$, first make the substitution $w = \psi(y)$. The factor against which $\widetilde{K}_r(w-z)$ acts is

$$K_j(x-\psi^{-1}(w))\,g(\psi^{-1}(w))\,|\det D\psi^{-1}(w)|.$$

Subtract its Taylor polynomial at z of degree $M-1$. Its derivatives of order M require at most $M+1$ derivatives of ψ^{-1} because of the determinant. The same computation, now with $2^{jM}\|w-z\|^M$, gives $2^{-M(r-j)}$. The bi-Lipschitz condition compares $\|x-\psi^{-1}(z)\|$ with $\|\psi(x)-z\|$. When $j = r = 0$, the bound follows directly from the integral of two rapidly decreasing kernels. This also covers equal positive indices.

□

Lemma 6.4.3. (Multipliers and diffeomorphisms on the Sobolev scale) Let $s \in \mathbb{R}$ and $k \in \mathbb{N}$, with $k > |s|+n+1$. For $H^{s,p}$, assume $1 < p < \infty$; for $B^s_{p,q}$, assume $1 \le p,q \le \infty$; and for $F^s_{p,q}$, assume $1 \le p < \infty$, $1 \le q \le \infty$.

(a) If $g \in BC^k(\mathbb{R}^n)$, then

$$\|gu\|_{A^s_{p,q}} \le C\|g\|_{BC^k}\|u\|_{A^s_{p,q}}, \qquad A \in \{B,F\},$$

and the same assertion holds in $H^{s,p}$.

(b) Let $\psi\colon \mathbb{R}^n \longrightarrow \mathbb{R}^n$ be a diffeomorphism of class C^{k+1}, with

$$|\det D\psi(x)| \ge c > 0, \qquad \|D^\alpha\psi\|_{L^\infty(\mathbb{R}^n,\mathbb{R}^n)} \le C_\alpha \quad (1 \le |\alpha| \le k+1).$$

Then $u \mapsto u \circ \psi$ is continuous on the same scales. The constants depend only on the parameters and the indicated bounds.

(c) Let $\psi\colon U \longrightarrow V$ be a diffeomorphism and let $\eta \in C_c^{k+1}(U)$. Suppose that the derivative bounds and bi-Lipschitz conditions of the preceding lemma hold on a neighborhood of the support of η. The operator

$$T_{\eta,\psi}u(x) := \begin{cases} \eta(x)u(\psi(x)), & x \in U, \\ 0, & x \notin U \end{cases}$$

is continuous on the same scales. The bound is uniform for families with the same derivative bounds, bi-Lipschitz constants, an upper bound for the diameters of the supports, and a positive lower bound for their distance from the boundary of these neighborhoods.

Proof. The inverse matrix formula and the lower bound for the determinant control $D\psi^{-1}$. Differentiating $\psi^{-1} \circ \psi = I$ and applying Faà di Bruno, the term containing $D^m\psi^{-1}$ is

$$(D^m\psi^{-1}) \circ \psi\,[D\psi, \dots, D\psi].$$

The other terms contain derivatives of ψ^{-1} of order less than m. Induction on $m = 2, \dots, k+1$, followed by multiplication by $D\psi^{-1}$ in each argument, controls all derivatives of the inverse. Integrating the first derivative along segments proves that both functions are globally Lipschitz.
Choose $0 < a < 1$, $\lambda > n/a$, and an integer $M < k$ so that $M - \lambda > |s|$. This is possible because $k > |s| + n + 1$. Apply (6.6) to $v_r = \Delta_r u$, with $D > n + \lambda$. Peetre's definition gives

$$|v_r(z)| \le P_{r,\lambda}v_r(\psi(x))(1 + 2^r\|\psi(x) - z\|)^{\lambda}.$$

The integral of the second factor against $h_{\min\{j,r\},D}$ is bounded by $C2^{\lambda(r-j)_+}$. Thus,

$$|\Delta_j[g\,((\widetilde{\Delta}_r\Delta_r u) \circ \psi)](x)| \le C2^{-(M-\lambda)|j-r|}\mathcal{M}_a(\Delta_r u)(\psi(x)). \tag{6.7}$$

Multiplication corresponds to $\psi = I$, and composition to $g = 1$.
Multiply by 2^{js} and sum in $r \in \mathbb{N}_0$. The coefficients

$$\left(2^{-(M-\lambda-|s|)|j-r|}\right)_{j-r\in\mathbb{Z}}$$

form a summable sequence. For Besov spaces, scalar boundedness of the maximal operator on $L^{p/a}$, followed by Young's inequality for sequences, gives the bound; if $p = \infty$, use its bound on L^∞ directly. For Triebel–Lizorkin spaces, apply Fefferman–Stein with exponents $p/a > 1$ and $q/a > 1$. If $q = \infty$, use the maximal operator of the supremum, as in Lemma 6.3.3. Change of variables introduces only the bound for $|\det D\psi^{-1}|$. The identity $H^{s,p} = F^s_{p,2}$ gives the assertion for Bessel spaces.
For part (c), reduce the local change to finitely many global changes. Fix x_0 near the support of η and write

$$A_0 = D\psi(x_0), \qquad a_0(x) = \psi(x_0) + A_0(x - x_0).$$

If $B(x_0, 2r)$ lies in the neighborhood under consideration, choose a cutoff χ equal to one on $B(x_0, r)$ and supported in $B(x_0, 2r)$, with $\|D\chi\|_{L^\infty(\mathbb{R}^n)} \le C/r$. The fundamental theorem of calculus, applied to $\psi - a_0$ and

its derivative, gives

$$\|\psi - a_0\|_{L^\infty(B(x_0,2r))} \le Cr^2 \|D^2\psi\|_{L^\infty(B_{\mathrm{euc}}(x_0,2r))}, \qquad \|D(\psi - a_0)\|_{L^\infty(B(x_0,2r))} \le Cr \|D^2\psi\|_{L^\infty(B_{\mathrm{euc}}(x_0,2r))}.$$

Extend $F_0 = \chi(\psi - a_0)$ by zero. By the Leibniz rule, $\|DF_0\|_{L^\infty(B_{\mathrm{euc}}(x_0,2r))} \le Cr\|D^2\psi\|_{L^\infty(B_{\mathrm{euc}}(x_0,2r))}$. Choose $r > 0$, uniformly under the assumptions of this part, so that $\|A_0^{-1}\|\|DF_0\|_{L^\infty(\mathbb{R}^n)} < 1/2$. The function

$$\Psi_0(x) = a_0(x) + F_0(x), \qquad x \in \mathbb{R}^n,$$

agrees with ψ on $B(x_0, r)$ and is bi-Lipschitz. To check surjectivity as well, given $y \in \mathbb{R}^n$, apply the fixed-point theorem to

$$x \longmapsto x_0 + A_0^{-1}\big(y - \psi(x_0) - F_0(x)\big),$$

whose contraction constant is less than $1/2$. Its fixed point is the unique solution of $\Psi_0(x) = y$. The inverse function theorem and the derivative bounds already established give a global diffeomorphism with the bounds required in (b).

Cover the support of η by finitely many of these balls and choose a subordinate smooth partition $(\beta_\ell)_{\ell=1}^N$. Then

$$T_{\eta,\psi}u = \sum_{\ell=1}^{N} \eta\beta_\ell\,(u \circ \Psi_\ell).$$

Applying (a) and (b) to each summand proves (c). The ball radius, the number N, and the cutoff derivatives are controlled by the bounds in the statement, giving the asserted uniformity as well.

We specify the distributional interpretation when $s < 0$ and the coefficients have finite regularity. The pairing estimate in the proof of Lemma 6.3.6, for a test function supported on a compact set K, gives

$$|\langle u, \zeta\rangle| \le C_K \|u\|_{A^s_{p,q}} \max_{\substack{\alpha\in\mathbb{N}_0^n \\ |\alpha|\le m}} \|D^\alpha \zeta\|_{L^\infty(\mathbb{R}^n)},$$

if m is an integer with $|s| + n < m < k$. Thus u also acts continuously on C_c^m functions. Define the operators by

$$\langle gu, \zeta\rangle = \langle u, g\zeta\rangle, \qquad \langle u \circ \psi, \zeta\rangle = \left\langle u, (\zeta \circ \psi^{-1})|\det D\psi^{-1}|\right\rangle.$$

The available derivatives make both pairings legitimate. The dyadic partial sums converge in this sense: approximate the test function C_c^k in C_c^m by smooth functions and use the preceding uniform bound. Thus estimates for finite sums pass to the distributional operator by Fatou's lemma. This argument includes $q = \infty$ without requiring density in the norm of order s. □

To formulate the localization principle, call a family $(\eta_\nu)_{\nu\in I} \subseteq C_c^\infty(\mathbb{R}^n)$ a *uniform localization system* if it satisfies:

(i) $0 \le \eta_\nu \le 1$ and $\displaystyle\sum_{\nu\in I} \eta_\nu = 1$;

(ii) each point belongs to at most N supports;

(iii) support diameters and all $\|\eta_\nu\|_{BC^k(\mathbb{R}^n)}$ norms are uniformly bounded;

(iv) there exist $\chi_\nu \in C_c^\infty(\mathbb{R}^n)$, with $\chi_\nu = 1$ near $\operatorname{supp}(\eta_\nu)$, satisfying the same bounds and the same type of overlap.

Theorem 6.4.4. (Localization principle) Let (η_ν) be a uniform localization system.

(a) If $s \in \mathbb{R}$, $1 < p < \infty$, and $1 \le q \le \infty$, there are constants $c, C > 0$, independent of u, such that

$$c\|u\|_{F^s_{p,q}(\mathbb{R}^n)} \le \left(\sum_{\nu \in I} \|\eta_\nu u\|^p_{F^s_{p,q}(\mathbb{R}^n)} \right)^{\frac{1}{p}} \le C\|u\|_{F^s_{p,q}(\mathbb{R}^n)}.$$

In particular, the formula holds for $H^{s,p}(\mathbb{R}^n) = F^s_{p,2}(\mathbb{R}^n)$ and, if $s > 0$ is not an integer, for $W^{s,p}(\mathbb{R}^n) = F^s_{p,p}(\mathbb{R}^n)$.

(b) For $B^s_{p,q}(\mathbb{R}^n)$ with $q \neq p$, there is in general no analogous equivalence with an outer ℓ^p sum. Such an equivalence does hold when $q = p$, because $B^s_{p,p}(\mathbb{R}^n) = F^s_{p,p}(\mathbb{R}^n)$.

Proof. Omit indices for which $\eta_\nu = 0$ and choose $x_\nu \in \operatorname{supp} \eta_\nu$, $\nu \in I$. The diameter bounds place the supports of η_ν and χ_ν in balls of fixed radius around x_ν. Moreover, there is $r_0 > 0$, independent of ν, such that $\chi_\nu > 1/2$ on $B(x_\nu, r_0)$: simply take

$$r_0 < \frac{1}{2\left(1 + \sup_{\nu \in I} \|D\chi_\nu\|_{L^\infty(\mathbb{R}^n)}\right)}.$$

Since the supports of χ_ν have bounded overlap, comparing the volumes of these balls gives

$$\#\{\nu \in I \mid \|x - x_\nu\| \le R\} \le C(1+R)^n, \qquad x \in \mathbb{R}^n, \quad R > 0.$$

In particular, I is countable and, for $D > n$,

$$\sup_{x \in \mathbb{R}^n} \sum_{\nu \in I} (1 + \|x - x_\nu\|)^{-D} < \infty. \tag{6.8}$$

To verify the last bound, group the centers in $\|x - x_\nu\| \le 1$ and in the annuli $2^m < \|x - x_\nu\| \le 2^{m+1}$, $m \in \mathbb{N}_0$. The resulting series is dominated by $\sum_{m \in \mathbb{N}_0} 2^{m(n-D)}$.

We shall use the preceding kernel estimate with the spatial decay supplied by the cutoffs. For $a_\nu = \eta_\nu$ or $a_\nu = \chi_\nu$, let $L_{\nu,j,r}$ be the kernels of $\Delta_j a_\nu \widetilde{\Delta}_r$. For any $M, D, E > 0$, with $E > n$,

$$|L_{\nu,j,r}(x,z)| \le C_{M,D,E}\, 2^{-M|j-r|}(1 + \|x - x_\nu\|)^{-D} h_{\min\{j,r\},E}(x - z). \tag{6.9}$$

The constant is uniform in ν, j, r.

We explain the spatial factor. In the integral

$$L_{\nu,j,r}(x,z) = \int_{\mathbb{R}^n} K_j(x-y) a_\nu(y) \widetilde{K}_r(y-z)\, dy,$$

y belongs to a ball of fixed radius around x_ν. If x lies in a slightly larger ball, that factor is comparable to one, and Lemma 6.4.2 applies. On the complement, $1 + \|x - x_\nu\| \le C(1 + \|x - y\|)$. For $j \ge r$, decay of $K_j(x-y)$ allows extraction of $(1+\|x-x_\nu\|)^{-D} 2^{-M(j-r)}$; the remaining powers are integrated with $\widetilde{K}_r$. For $r > j$, subtract Taylor polynomials against $\widetilde{K}_r$. Each derivative of $K_j(x-y)a_\nu(y)$ retains the same decay outside the ball and

contributes at most a factor 2^j. Integration of the remainder contributes 2^{-rM}. In both cases, the inequality

$$1 + 2^{\min\{j,r\}}\|x-z\| \le (1 + 2^{\min\{j,r\}}\|x-y\|)(1 + 2^{\min\{j,r\}}\|y-z\|)$$

allows the factor $h_{\min\{j,r\},E}(x-z)$ to be retained. Initially choose decay powers larger than the sum of the extracted powers plus $n+1$, so all remaining integrals are uniformly finite. Only finitely many derivative bounds of the cutoffs are involved.

Fix $0 < a < 1$, $\lambda > n/a$, $D > n$, and $M > |s| + \lambda$. Integrating (6.9) against $\Delta_r u$, as in (6.7), gives

$$2^{js}|\Delta_j(a_\nu u)(x)| \le C w_\nu(x) \sum_{r\in\mathbb{N}_0} 2^{-(M-\lambda-|s|)|j-r|} 2^{rs} P_{r,\lambda}(\Delta_r u)(x),$$

where $w_\nu(x) := (1 + \|x - x_\nu\|)^{-D}$. Take the ℓ^q norm in j, use Young's inequality for sequences, and set

$$G_u(x) := \left\| \left(2^{rs} P_{r,\lambda}(\Delta_r u)(x)\right)_{r\in\mathbb{N}_0} \right\|_{\ell^q}.$$

Peetre control and Fefferman–Stein, with the supremum argument if $q = \infty$, imply

$$\|G_u\|_{L^p(\mathbb{R}^n)} \le C\|u\|_{F^s_{p,q}(\mathbb{R}^n)}.$$

Thus (6.8) and Tonelli's theorem give

$$\sum_{\nu\in I} \|\eta_\nu u\|^p_{F^s_{p,q}(\mathbb{R}^n)} \le C \int_{\mathbb{R}^n} \sum_{\nu\in I} w_\nu(x)^p G_u(x)^p \, dx \le C\|u\|^p_{F^s_{p,q}(\mathbb{R}^n)}.$$

For the reverse inequality, first consider a finite family $(v_\nu)_{\nu\in I}$ and the operator

$$R(v_\nu)_{\nu\in I} := \sum_{\nu\in I} \chi_\nu v_\nu.$$

The same estimate, followed by the triangle inequality in ℓ^q, gives pointwise

$$\left\| \left(2^{js}\Delta_j R(v_\nu)(x)\right)_{j\in\mathbb{N}_0} \right\|_{\ell^q} \le C \sum_{\nu\in I} w_\nu(x) G_{v_\nu}(x).$$

Hölder's inequality for the weighted sum over I implies

$$\left(\sum_{\nu\in I} w_\nu G_{v_\nu}\right)^p \le \left(\sum_{\nu\in I} w_\nu\right)^{p-1} \sum_{\nu\in I} w_\nu G^p_{v_\nu}.$$

Integration yields

$$\|R(v_\nu)\|^p_{F^s_{p,q}(\mathbb{R}^n)} \le C \sum_{\nu\in I} \|v_\nu\|^p_{F^s_{p,q}(\mathbb{R}^n)}.$$

Finite families are dense in the outer ℓ^p sum, so R extends continuously to it. Apply this bound to $v_\nu = \eta_\nu u$. The sum is locally finite in the distributional sense, and $\chi_\nu \eta_\nu = \eta_\nu$, so $R(\eta_\nu u) = u$. This completes (a).

For (b), construct functions with compact spatial support. Choose a smooth partition obtained by lattice translation that equals one on small balls around its centers, and $\zeta \in C^\infty_c(\mathbb{R}^n)$, $\zeta \neq 0$, supported in one of these balls. Choose distinct lattice centers x_m sufficiently far apart that each translate of ζ lies in a region

where only one cutoff equals one.

We may use a dyadic resolution whose annular symbol equals one near some point $\xi_* \neq 0$. Indeed, choose the initial cutoff equal to one on $\|\xi\| \le 1$ and zero for $\|\xi\| \ge 3/2$; its dyadic difference equals one on $3/4 < \|\xi\| < 1$. Fix ξ_* in that annulus. For integers $j_m = J + Lm$, $m \in \mathbb{N}$, set

$$v_m(x) := 2^{-j_m s}\zeta(x - x_m)e^{i2^{j_m}\xi_*\cdot x}, \qquad u_N := \sum_{m=1}^{N} v_m.$$

The integers J, L will be fixed once, independently of N. For any $M > |s|$, regularity of ζ gives

$$2^{ks}\|\Delta_k v_m\|_{L^p(\mathbb{R}^n)} \le C_M 2^{-(M-|s|)|k-j_m|}, \qquad k \in \mathbb{N}_0, \quad m \in \mathbb{N}. \tag{6.10}$$

For $k > j_m$, use M derivatives of $\zeta e^{i2^{j_m}\xi_*\cdot x}$ and the moments of K_k. For $k < j_m$ separated by more than a fixed number of indices, integrate by parts in the direction ξ_* in the convolution formula: each integration contributes 2^{-j_m}, while differentiating the kernel contributes at most 2^k. Derivatives of ζ have fixed L^p norms. The remaining indices are controlled by Young's inequality. These operations prove (6.10) also for $p = 1$ and $p = \infty$.

Moreover,

$$2^{j_m s}e^{-i2^{j_m}\xi_*\cdot x}\Delta_{j_m} v_m(x) \longrightarrow \zeta(x - x_m) \quad \text{in } L^p$$

uniformly in the translations as $j_m \to \infty$. To see this, the modulated kernel has mass one and scale 2^{-j_m}; write the difference using $\zeta(\cdot - y) - \zeta$ and use continuity of translations. For $p = \infty$, use uniform continuity of ζ. Choose J so that the norm of these principal blocks is at least $c_0 > 0$. Then choose L sufficiently large that

$$C_M \sum_{\ell \in \mathbb{Z}\setminus\{0\}} 2^{-(M-|s|)L|\ell|} < c_0/2.$$

The reverse triangle inequality in each block j_m gives $2^{j_m s}\|\Delta_{j_m} u_N\|_{L^p(\mathbb{R}^n)} \ge c_0/2$. The upper bound for all blocks follows by summing (6.10) and applying Young's inequality. Thus,

$$cN^{1/q} \le \|u_N\|_{B^s_{p,q}(\mathbb{R}^n)} \le CN^{1/q}.$$

By the choice of supports, the nonzero localizations of u_N are exactly $v_1, \dots, v_N$, and each has Besov norm between two positive constants. Consequently,

$$cN^{1/p} \le \left\| \left(\|\eta_\nu u_N\|_{B^s_{p,q}(\mathbb{R}^n)} \right)_{\nu \in I} \right\|_{\ell^p} \le CN^{1/p}.$$

We interpret $N^{1/\infty} = 1$. Equivalence of the two norms with constants independent of N would require $p = q$. For $p = q < \infty$, the identity $B^s_{p,p} = F^s_{p,p}$ and (a) give the asserted equivalence. □

Remark 6.4.5. (Besov localization on manifolds) Part (b) does not prevent localization of a Besov function with finitely many charts, but it does prevent using an unchanged ℓ^p sum over an infinite atlas. On a noncompact manifold without boundary and of bounded geometry, one first defines the scale F, which does localize, and then

$$B^s_{p,q}(M) := (F^{s_0}_{p,p}(M), F^{s_1}_{p,p}(M))_{\theta,q}, \qquad s = (1-\theta)s_0 + \theta s_1.$$

In the Euclidean case, Corollary 6.3.13 justifies this formula for any $s_0 < s < s_1$, with $\theta = (s - s_0)/(s_1 - s_0)$. In the construction on the manifold, independence of auxiliary parameters follows by combining localization formulas with reiteration. Uniform bounds on the charts and their transitions are the assumptions controlling the constants over an infinite atlas. The procedure will be revisited in Chapter 13 and agrees with the Große–Schneider construction [72] and Amann's localization principle [6].

6.5 Open subsets, extension operators, and comparison of scales

For $A \in \{B, F\}$, define the restriction space

$$A^s_{p,q}(\Omega) := \{U\restriction_\Omega \mid U \in A^s_{p,q}(\mathbb{R}^n)\}, \qquad \|u\|_{A^s_{p,q}(\Omega)} := \inf_{\substack{U \in A^s_{p,q}(\mathbb{R}^n) \\ U\restriction_\Omega = u}} \|U\|_{A^s_{p,q}(\mathbb{R}^n)}.$$

This convention agrees with Definition 6.1.5 when $A^s_{p,q} = F^s_{p,2}(\mathbb{R}^n) = H^{s,p}(\mathbb{R}^n)$.

Extension must use only values of the distribution inside the domain. To achieve this, we construct kernels supported in a cone that remains within the domain when subtracted from a point of the domain. Cancellation of all moments will allow the same kernels to be used at every regularity order.

Lemma 6.5.1. (Conical reproducing kernels) Let $\omega\colon \mathbb{R}^{n-1} \longrightarrow \mathbb{R}$ be a Lipschitz function with constant L, and set

$$\Omega_\omega := \{(x', x_n) \in \mathbb{R}^n \mid x_n > \omega(x')\}, \qquad \mathcal{K}_L := \{(y', y_n) \in \mathbb{R}^n \mid y_n < -(L+1)\|y'\|\}.$$

There exist $\varphi_0, \varphi, \psi_0, \psi \in \mathcal{S}(\mathbb{R}^n)$ such that, upon defining

$$\varphi_j(x) := 2^{jn}\varphi(2^j x), \qquad \psi_j(x) := 2^{jn}\psi(2^j x), \qquad j \in \mathbb{N},$$

the following properties hold.

(a) The supports of φ_j, ψ_j are contained in $\mathcal{K}_L \cap \{x_n \le -c2^{-j}\}$, with $c > 0$. Moreover,

$$\int_{\mathbb{R}^n} \varphi_0 = \int_{\mathbb{R}^n} \psi_0 = 1, \qquad \int_{\mathbb{R}^n} x^\alpha \varphi(x)\,dx = \int_{\mathbb{R}^n} x^\alpha \psi(x)\,dx = 0 \quad (\alpha \in \mathbb{N}_0^n).$$

(b) Denote by

$$\mathcal{S}'(\Omega_\omega) := \{U\restriction_{\Omega_\omega} \mid U \in \mathcal{S}'(\mathbb{R}^n)\}$$

the space of restrictions of tempered distributions. For u in this space, $\varphi_j * u$ is a well-defined smooth function on Ω_ω, independent of the extension, and

$$u = \sum_{j \in \mathbb{N}_0} \psi_j * (\varphi_j * u) \quad \text{in } \mathcal{D}'(\Omega_\omega). \tag{6.11}$$

(c) For $U \in \mathcal{S}'(\mathbb{R}^n)$, write

$$Q_{j,\lambda}U(x) := \sup_{y \in \mathbb{R}^n} \frac{|(\varphi_j * U)(y)|}{(1 + 2^j\|x - y\|)^\lambda}.$$

If $\lambda > n/a$, where $0 < a < 1$, then

$$\left\| \left(2^{js} \|Q_{j,\lambda} U\|_{L^p(\mathbb{R}^n)}\right)_{j\in\mathbb{N}_0} \right\|_{\ell^q} \le C\|U\|_{B^s_{p,q}(\mathbb{R}^n)}, \tag{6.12}$$

$$\left\| \left(2^{js} Q_{j,\lambda} U\right)_{j\in\mathbb{N}_0} \right\|_{L^p(\mathbb{R}^n;\ell^q(\mathbb{N}_0))} \le C\|U\|_{F^s_{p,q}(\mathbb{R}^n)} \tag{6.13}$$

for the Banach indices defined in this chapter. The first bound also allows $p = \infty$. If $f_j = (\varphi_j * U)\restriction_{\Omega_\omega}$, then for every $N > 0$,

$$|\Delta_k[\psi_j * (\mathbf{1}_{\Omega_\omega} f_j)](x)| \le C_N 2^{-N|j-k|} Q_{j,\lambda} U(x), \qquad j,k \in \mathbb{N}_0. \tag{6.14}$$

Proof. First construct a function $g \in \mathcal{S}(\mathbb{R})$ supported in $[1,\infty)$, with integral one and all positive-order moments zero. Choose $\rho \in C^\infty_c((1,2))$, with $\int_{\mathbb{R}} \rho = 1$. For $0 \le \ell \le N$, the polynomial interpolation formula at the points $2^0,\dots,2^N$, evaluated at zero, gives the coefficients

$$a_{\ell,N} := \prod_{\substack{r\in\{0,\dots,N\}\\ r\ne\ell}} \frac{2^r}{2^r - 2^\ell}.$$

Indeed, the polynomials

$$\prod_{\substack{r\in\{0,\dots,N\}\\ r\ne\ell}} \frac{t - 2^r}{2^\ell - 2^r}$$

equal one at $t = 2^\ell$ and zero at the other points. Their combination with the values of a polynomial of degree at most N agrees with that polynomial, since their difference has $N+1$ roots. In particular,

$$\sum_{\ell=0}^{N} a_{\ell,N} 2^{\ell m} = \begin{cases} 1, & m = 0, \\ 0, & 1 \le m \le N. \end{cases}$$

Separating factors with $r < \ell$ and $r > \ell$ shows that

$$|a_{\ell,N}| \le C 2^{-\ell(\ell+1)/2}.$$

The constant is uniform because $\prod_{r\in\mathbb{N}} (1 - 2^{-r}) > 0$. This last assertion follows by taking logarithms and using $-\log(1-t) \le 2t$ for $0 \le t \le 1/2$. For each ℓ, the products have a limit a_ℓ as $N \to \infty$. The preceding bound allows passage to the limit in every moment sum, even after multiplying by $2^{\ell m}$. Thus,

$$\sum_{\ell\in\mathbb{N}_0} a_\ell 2^{\ell m} = \delta_{m0}, \qquad m \in \mathbb{N}_0.$$

Define

$$g(t) := \sum_{\ell\in\mathbb{N}_0} a_\ell 2^{-\ell} \rho(2^{-\ell} t).$$

The seminorm $\sup_{t\in\mathbb{R}} (1+|t|)^A |D^B g(t)|$, with $A, B \in \mathbb{N}_0$, is dominated by a constant times $\sum_{\ell\in\mathbb{N}_0} |a_\ell| 2^{\ell(A-B-1)}$. All

these series converge. Thus g is Schwartz, has the required support, and its moments can be computed term by term.

Choose an invertible matrix A whose columns lie in a narrow cone around the positive vertical half-axis and whose positive cone lies in $\{y_n > (L+1)\|y'\|\}$. This choice is obtained by taking n linearly independent vectors sufficiently close to the vertical vector. Set $B := -A$ and

$$\vartheta(x) := |\det B|^{-1} \prod_{i=1}^{n} g((B^{-1}x)_i), \qquad \vartheta_j(x) := 2^{jn}\vartheta(2^j x), \quad j \in \mathbb{Z}.$$

The change of variables $x = By$ proves that ϑ has integral one. Every positive-degree monomial in By expands as a sum of monomials in y, each containing a positive-order moment of some factor g. Thus all positive-order moments of ϑ vanish. Its support lies in $\mathcal{K}_L$, separated from the vertex by a plane $x_n = -c$.

Now define

$$\varphi_0 := \vartheta, \qquad \psi_0 := 3\vartheta - 2\vartheta * \vartheta,$$

and, for $j \in \mathbb{N}$,

$$\varphi_j := \vartheta_j - \vartheta_{j-1},$$

$$\psi_j := 3(\vartheta_j + \vartheta_{j-1}) - 2(\vartheta_j * \vartheta_j + \vartheta_j * \vartheta_{j-1} + \vartheta_{j-1} * \vartheta_{j-1}).$$

These are dilations of two fixed functions. Stability of the cone under addition preserves the supports. The convolution moment formula, obtained by expanding $(x+y)^\alpha$, shows that φ_j and ψ_j have all moments zero. In particular, the integral of ψ_j is $6-6=0$.

The polynomial identity

$$(a-b)\big(3(a+b) - 2(a^2+ab+b^2)\big) = (3a^2 - 2a^3) - (3b^2 - 2b^3)$$

yields, in the convolution algebra, the telescoping sum

$$\sum_{j=0}^{N} \psi_j * \varphi_j = 3\vartheta_N * \vartheta_N - 2\vartheta_N * \vartheta_N * \vartheta_N.$$

Since $\int_{\mathbb{R}^n} \vartheta = 1$, $\vartheta_N * \zeta \to \zeta$ in $\mathcal{S}$ for $\zeta \in \mathcal{S}$. This is checked by writing the difference as

$$\int_{\mathbb{R}^n} \vartheta(y)\big(\zeta(\cdot - 2^{-N}y) - \zeta\big)\, dy$$

and using continuity of translations in each Schwartz seminorm, dominated by a power of $1 + \|y\|$. By duality, the telescoping sum converges to the identity in $\mathcal{S}'$. With the unitary Fourier normalization, this is equivalent to

$$\sum_{j \in \mathbb{N}_0} \widehat{\psi}_j(\xi)\widehat{\varphi}_j(\xi) = (2\pi)^{-n}, \qquad \xi \in \mathbb{R}^n. \tag{6.15}$$

If $x \in \Omega_\omega$ and $y \in \mathcal{K}_L$, then

$$x_n - y_n > \omega(x') + (L+1)\|y'\| \geq \omega(x'-y') + \|y'\|.$$

Thus $x - y \in \Omega_\omega$. For a tempered extension U of u, define $(\varphi_j * u)(x) := \langle U, \varphi_j(x - \cdot)\rangle$. The Schwartz function

in the pairing has support inside Ω_ω at a positive distance from its boundary. Approximate it in $\mathcal{S}$ by compact cutoffs whose supports remain in that domain. Two extensions agreeing on Ω_ω act identically on each cutoff and, after passage to the limit, on the whole function. This proves independence. Derivatives with respect to x are taken in the kernel, so the convolution is smooth. The same argument applies to ψ_j, and restriction of the global identity already proved gives (6.11).

We prove the bounds. If κ_k is the kernel of Δ_k, cancellation and Schwartz decay imply, for any $N, \lambda > 0$,

$$\int_{\mathbb{R}^n} |(\kappa_k * \psi_j)(y)|(1 + 2^j\|y\|)^\lambda \, dy \le C_{N,\lambda} 2^{-N|j-k|}. \tag{6.16}$$

If $j > k$, subtract from the kernel at scale 2^{-k} its Taylor polynomial of degree $M-1$ and use the moments of ψ_j. The remainder contributes $2^{-M(j-k)}$; the weight in the integral costs at most $2^{\lambda(j-k)}$. If $k > j$, the moments of κ_k contribute $2^{-M(k-j)}$. In both computations, first integrate the factor $\|y\|^M$ at the scale of the canceling kernel, then the decay of the other kernel. Choosing $M > N + \lambda$ and decay powers larger than $M + \lambda + n + 1$ proves the bound. Zero indices are treated in the same way using cancellation at the positive index; for $j = k = 0$, weighted integrability of two Schwartz functions suffices.

The same estimate holds for $\varphi_j * \widetilde{\kappa}_r$. Inserting the reconstruction of U and comparing weights at scales j and r, we obtain, for any $N > 0$,

$$Q_{j,\lambda} U(x) \le C_N \sum_{r \in \mathbb{N}_0} 2^{-N|j-r|} P_{r,\lambda}(\Delta_r U)(x). \tag{6.17}$$

In detail, bound $|\Delta_r U(z)|$ by $P_{r,\lambda}(\Delta_r U)(x)(1 + 2^r\|x - z\|)^\lambda$. After dividing by the weight at scale j, the triangle inequality for the weights introduces at most $2^{\lambda|j-r|}$. Absorb this factor by taking a higher cancellation order in (6.16). The pairings and sums first converge in $\mathcal{S}'$; the estimate holds with possibly infinite sides and, when the norm of U is finite, controls their pointwise convergence.

Take $N > |s|$. Young's inequality for sequences and control of Peetre's maximal function by $\mathcal{M}_a$ give (6.12) and (6.13). For Besov spaces, use the scalar maximal operator on each block; for Triebel–Lizorkin spaces, use the exponents p/a and q/a, both greater than one. The case $q = \infty$ follows using the maximal operator of the supremum.

Finally,

$$|\varphi_j * U(y)| \le Q_{j,\lambda} U(x)(1 + 2^j\|x - y\|)^\lambda.$$

Inserting this bound into convolution with $\kappa_k * \psi_j$ and using (6.16) proves (6.14). The indicator of the domain only decreases the integral of absolute values. □

This construction realizes Rychkov's conical reproduction [124, Theorem 4.1]. The distinction between $\mathcal{S}'(\Omega)$ and $\mathcal{D}'(\Omega)$, as well as the double-convolution formulation, can also be found in [133, Section 1.1].

The preceding computation gives a property to be used when differentiating the extension. Let η_j, θ_j and $j \in \mathbb{N}$ be dyadic dilations of Schwartz functions with all moments zero. For a measurable set $D \subseteq \mathbb{R}^n$ and $m \ge 0$, define

$$T_m f := \sum_{j \in \mathbb{N}} 2^{-jm} \eta_j * \big(\mathbf{1}_D (\theta_j * f)\big).$$

Estimates (6.16) and (6.17), applied to these two families, prove

$$\|T_m f\|_{A^{s+m}_{p,q}} \le C\|f\|_{A^s_{p,q}}, \qquad A \in \{B, F\}. \tag{6.18}$$

Indeed, after multiplying the output block by $2^{k(s+m)}$, the factor 2^{-jm} leaves

$$2^{k(s+m)}2^{-jm}2^{-N|j-k|} \le 2^{js}2^{-(N-|s+m|)|j-k|}.$$

Choosing $N > |s+m|$ allows the geometric summation in the proof to be repeated. The series converges in $\mathcal{S}'$: a tempered distribution gives $|\theta_j * f(x)| \le C2^{jM_0}(1+\|x\|)^{M_0}$ for some M_0, whereas pairing with $\eta_j(-\cdot) * \zeta$ decays faster than every power of 2^{-j}. This last bound is exactly the preceding Taylor computation applied in Schwartz seminorms. The same justification applies to the series defining the extension operator.

Theorem 6.5.2. (Extension on Lipschitz domains) Let $\Omega \subseteq \mathbb{R}^n$ be a bounded Lipschitz domain. There is a single linear operator E, independent of the parameters, with $Eu\restriction_\Omega = u$, inducing continuous operators

$$E\colon A^s_{p,q}(\Omega) \longrightarrow A^s_{p,q}(\mathbb{R}^n), \qquad A \in \{B, F\}, \quad s \in \mathbb{R},$$

for all indices defined in this chapter. Moreover,

$$E\colon W^{s,p}(\Omega) \longrightarrow W^{s,p}(\mathbb{R}^n) \quad \text{is continuous if } s \ge 0, \quad 1 < p < \infty.$$

If $s > 0$ is not an integer, then

$$W^{s,p}(\Omega) = B^s_{p,p}(\Omega) = F^s_{p,p}(\Omega)$$

with equivalent norms. The constants may depend on the domain and the parameters, but the operator is the same.

Proof. Begin on Ω_ω. For $u \in \mathcal{S}'(\Omega_\omega)$, define

$$E_\omega u := \sum_{j\in\mathbb{N}_0} \psi_j * \big(\mathbf{1}_{\Omega_\omega}(\varphi_j * u)\big).$$

The preceding lemma shows that this formula depends only on u. For a tempered extension U, the functions $\varphi_j * U$ are smooth and of polynomial growth, so their product with the indicator defines a tempered distribution. The justification following (6.18) proves convergence of the series. If the evaluation point lies in Ω_ω, the support of ψ_j allows the indicator to be removed. Conical reproduction then gives $E_\omega u = u$ on that domain.

Multiply (6.14) by 2^{ks}, take $N > |s|$, and apply Young's inequality and the local-means bounds. For any extension U in the scale under consideration, we obtain

$$\|E_\omega u\|_{A^s_{p,q}(\mathbb{R}^n)} \le C\|U\|_{A^s_{p,q}(\mathbb{R}^n)}.$$

Taking the infimum over $U\restriction_{\Omega_\omega} = u$ proves the bound by the quotient norm.

We now relate this norm to the intrinsic norms. First let $0 < \sigma < 1$ and $u \in W^{\sigma,p}(\Omega_\omega)$. Its extension by zero

belongs to $L^p(\mathbb{R}^n)$, so $u \in \mathcal{S}'(\Omega_\omega)$. For $j \geq 1$, cancellation of φ_j gives

$$\varphi_j * u(x) = \int_{K_L} \varphi_j(y)\big(u(x-y) - u(x)\big)\, dy.$$

Both arguments of u remain in the domain. Hölder's inequality with respect to the measure $|\varphi_j(y)|\,dy$ and Tonelli's theorem imply

$$\begin{aligned}\sum_{j\in\mathbb{N}} 2^{j\sigma p}\|\varphi_j * u\|^p_{L^p(\Omega_\omega)} &\leq C \int_{K_L} \left(\sum_{j\in\mathbb{N}} 2^{j\sigma p}|\varphi_j(y)|\right) \int_{\Omega_\omega} |u(x-y)-u(x)|^p\, dx\, dy \\ &\leq C[u]^p_{W^{\sigma,p}(\Omega_\omega)}.\end{aligned}$$

The second inequality uses

$$\sum_{j\in\mathbb{N}} 2^{j\sigma p}|\varphi_j(y)| \leq C\|y\|^{-n-\sigma p}.$$

This bound follows by separating $2^j\|y\| \leq 1$ and $2^j\|y\| > 1$ with a decay exponent greater than $n + \sigma p$. The zero block is controlled by Young's inequality. For Besov synthesis, the unweighted version of (6.16) and Young's inequality suffice, so

$$\|E_\omega u\|_{B^\sigma_{p,p}(\mathbb{R}^n)} \leq C\left(\|u\|_{L^p(\Omega_\omega)} + [u]_{W^{\sigma,p}(\Omega_\omega)}\right).$$

The global identification with $W^{\sigma,p}$ proves extension in this first interval.
To treat higher-order derivatives, construct primitives preserving the cone. With the function g used above, set

$$g_-(t) := \tfrac{1}{2}g(t/2), \qquad d(t) := g(t) - g_-(t).$$

All moments of d vanish. For $m \in \mathbb{N}$,

$$h_m(t) := \frac{1}{(m-1)!}\int_{-\infty}^{t} (t-r)^{m-1} d(r)\, dr$$

satisfies $D^m h_m = d$, is supported in $[1,\infty)$, and is Schwartz. Indeed, the vanishing moments allow the integral to be written as the negative of the integral from t to ∞, proving decay of all its derivatives. Integrating by parts m times gives

$$\int_{\mathbb{R}} t^\ell h_m(t)\, dt = (-1)^m \frac{\ell!}{(\ell+m)!}\int_{\mathbb{R}} t^{\ell+m} d(t)\, dt = 0, \qquad \ell \in \mathbb{N}_0.$$

The telescoping identity for a product gives

$$\prod_{r=1}^{n} g(y_r) - \prod_{r=1}^{n} g_-(y_r) = \sum_{i=1}^{n} \left(\prod_{r=1}^{i-1} g(y_r)\right) d(y_i) \left(\prod_{r=i+1}^{n} g_-(y_r)\right),$$

with the empty product equal to one. Replace d by $D^m h_m$ and make the linear change $x = By$. This gives

functions $\tau_{i,m} \in \mathcal{S}(\mathbb{R}^n)$ supported in the same cone, with all moments zero, such that

$$\varphi = \sum_{i=1}^{n} D_{v_i}^m \tau_{i,m}, \qquad v_i := Be_i.$$

Here D_{v_i} is differentiation in the constant direction v_i. If $\tau_{i,m,j}(x) := 2^{jn}\tau_{i,m}(2^j x)$, then

$$\varphi_j * u = 2^{-jm} \sum_{i=1}^{n} \tau_{i,m,j} * D_{v_i}^m u \quad \text{in } \Omega_\omega.$$

Integration by parts is distributional; the kernel supports remain inside the domain, so no boundary terms appear.

If $u \in W^{m,p}(\Omega_\omega)$, extend each $D_{v_i}^m u$ by zero to a function $f_i \in L^p(\mathbb{R}^n)$. For $|\alpha| \le m$, differentiating the series for $E_\omega u$ gives the zero block and the sums

$$\sum_{j\in\mathbb{N}} 2^{j(|\alpha|-m)} \psi_j^\alpha * \left(\mathbf{1}_{\Omega_\omega}(\tau_{i,m,j} * f_i)\right), \qquad \psi_j^\alpha := 2^{-j|\alpha|} D^\alpha \psi_j.$$

Bound (6.18), with scale $F_{p,2}^0 = L^p$, controls these sums in $F_{p,2}^{m-|\alpha|} \hookrightarrow L^p$. The zero block is controlled by Young's inequality with $D^\alpha \psi_0$. Since directional derivatives are finite combinations of partial derivatives of order m, we conclude

$$\|E_\omega u\|_{W^{m,p}(\mathbb{R}^n)} \le C\|u\|_{W^{m,p}(\Omega_\omega)}.$$

The case $m = 0$ follows directly from the bound in $F_{p,2}^0$, using the extension by zero of u.

If $s = m + \sigma$, $0 < \sigma < 1$, each $D_{v_i}^m u$ belongs to $W^{\sigma,p}(\Omega_\omega)$. The first case of the proof gives an extension f_i in $B_{p,p}^\sigma(\mathbb{R}^n)$ with controlled norm. The same representation, now without differentiating the output kernel, and (6.18) give

$$\|E_\omega u\|_{B_{p,p}^{m+\sigma}(\mathbb{R}^n)} \le C\left(\|u\|_{L^p(\Omega_\omega)} + \sum_{i=1}^{n} \|D_{v_i}^m u\|_{W^{\sigma,p}(\Omega_\omega)}\right) \le C\|u\|_{W^{m+\sigma,p}(\Omega_\omega)}.$$

The global identification $B_{p,p}^{m+\sigma} = W^{m+\sigma,p}$ completes the intrinsic bound at all noninteger orders.

For a bounded Lipschitz domain, choose a finite cover by boundary cylinders and an interior region. After rotations and translations, each boundary portion is the graph of a Lipschitz function. Extend that function to all of $\mathbb{R}^{n-1}$ by $\inf_{y\in D}(\omega(y) + L\|x' - y\|)$, where D is the graph domain; the Lipschitz inequality proves agreement with ω on D. This gives special domains Ω_i agreeing with Ω in smaller cylinders. Choose a smooth partition $\eta_0, \dots, \eta_N$ on a neighborhood of $\overline{\Omega}$, with η_0 supported in Ω, and cutoffs χ_i equal to one near $\operatorname{supp}\eta_i$ and supported in these smaller cylinders. Define

$$E_\Omega u := (\eta_0 u)^0 + \sum_{i=1}^{N} \chi_i E_i(\eta_i u).$$

On each special domain, set $\eta_i u$ equal to zero outside the cylinder; the cutoff vanishes near this artificial boundary. The superscript 0 indicates extension by zero of the interior part. On Ω, the formula equals

$\sum_{i=0}^{N} \eta_i u = u$. Smooth multipliers and finiteness of the cover give the bounds in restriction spaces.

For intrinsic norms, the Leibniz rule controls derivatives of the products. In the Gagliardo quotients, terms crossing an artificial boundary are estimated using the positive distance d from the cutoff support to that boundary and

$$\int_{\{h\in\mathbb{R}^n : \|h\|\geq d\}} \|h\|^{-n-\sigma p}\, dh = C_{n,\sigma,p} d^{-\sigma p}.$$

Interior terms are controlled by the seminorm of u and by $|\eta_i(x)-\eta_i(y)| \leq C\min\{1,\|x-y\|\}$. For higher-order products, the Leibniz rule also produces derivatives of u of order less than m. Gluing at integer orders, which uses only the Leibniz rule, already gives a continuous operator from $W^{1,p}(\Omega)$ to $W^{1,p}(\mathbb{R}^n)$. Each of these lower derivatives belongs to $W^{1,p}(\Omega)$; extend it with this operator and apply the increment lemma to control its $W^{\sigma,p}$ norm. This justifies all fractional terms in the products and preserves the intrinsic bounds under gluing.

Finally, restricting a global function never increases either its derivative norms or its Gagliardo integral. This gives $\|u\|_{W^{s,p}(\Omega)} \leq C\|u\|_{B^s_{p,p}(\Omega)}$. The constructed extension gives the reverse inequality. The identity $B^s_{p,p} = F^s_{p,p}$ passes to the quotients and completes the proof. □

Corollary 6.5.3. (Comparison of H/W on a domain) Let Ω be a bounded Lipschitz domain, let $s > 0$ be noninteger, and let $1 < p < \infty$. Then

$$\begin{cases} W^{s,p}(\Omega) \hookrightarrow H^{s,p}(\Omega), & 1 < p \leq 2, \\ H^{s,p}(\Omega) \hookrightarrow W^{s,p}(\Omega), & 2 \leq p < \infty. \end{cases}$$

Equality holds for $p = 2$ and, if Ω has nonempty interior, the embedding is strict for $p \neq 2$. On an arbitrary open subset, only the embedding of the restriction space $B^s_{p,p}(\Omega)$ into the intrinsic Gagliardo space is always guaranteed; equality, even for $p = 2$, requires an extension property.

Proof. Apply the extension operator from Theorem 6.5.2, the global embedding from Corollary 6.3.15, and restriction to the domain. The identity for $p = 2$ follows in the same way.

For strictness, fix a ball $B \Subset \Omega$. The construction in Corollary 6.3.15 gives a function u supported in B that belongs to the larger scale but not the smaller one on $\mathbb{R}^n$. Its restriction belongs to the larger scale on Ω. If it also belonged to the smaller scale, the extension operator would give an extension V in that global scale. Take $\chi \in C^\infty_c(\Omega)$ equal to one near $\overline{B}$. Since $V = u$ on Ω, we have $\chi V = u$ on $\mathcal{S}'(\mathbb{R}^n)$. Continuity of multiplication by χ would place u in the smaller global scale, a contradiction.

On an arbitrary open subset, restricting a global extension decreases the integrals defining the intrinsic norm. This gives $B^s_{p,p}(\Omega) \hookrightarrow W^{s,p}(\Omega)$. Our proof of the reverse inclusion requires the continuous extension constructed for Lipschitz domains. □

6.6 Sobolev embeddings of real order

The quantity

$$\operatorname{ind}(s,p) := s - \frac{n}{p}$$

is called the differential index. Bernstein's inequalities from Theorem 4.12.4 show that passage from p_0 to a larger exponent p_1 requires losing $n\left(\frac{1}{p_0}-\frac{1}{p_1}\right)$ derivatives. Interpolation explains the same rule starting from integer-order embeddings.

Theorem 6.6.1. (Embeddings between scales) Let $1 < p_0 \le p_1 < \infty$ and $s_0, s_1 \in \mathbb{R}$.

(a) If $s_0 - \frac{n}{p_0} = s_1 - \frac{n}{p_1}$, then

$$B^{s_0}_{p_0,q}(\mathbb{R}^n) \hookrightarrow B^{s_1}_{p_1,q}(\mathbb{R}^n)$$

for $1 \le q \le \infty$, and also

$$F^{s_0}_{p_0,q}(\mathbb{R}^n) \hookrightarrow F^{s_1}_{p_1,q}(\mathbb{R}^n)$$

for the same fine indices.

(b) If $s_0 > s_1$ and p is fixed, then

$$A^{s_0}_{p,q_0}(\mathbb{R}^n) \hookrightarrow A^{s_1}_{p,q_1}(\mathbb{R}^n), \qquad A \in \{B, F\},$$

for any admissible fine indices q_0, q_1.

(c) If $s_0 = s_1$, the embedding within a single scale holds when $q_0 \le q_1$.

Proof. For Besov spaces, Bernstein's inequality gives, for each $j \in \mathbb{N}_0$,

$$2^{js_1}\|\Delta_j u\|_{L^{p_1}(\mathbb{R}^n)} \le C 2^{j(s_1 + n(1/p_0 - 1/p_1))}\|\Delta_j u\|_{L^{p_0}(\mathbb{R}^n)} = C 2^{js_0}\|\Delta_j u\|_{L^{p_0}(\mathbb{R}^n)}.$$

Taking the $\ell^q(\mathbb{N}_0)$ norm proves the first embedding.
For Triebel–Lizorkin spaces, the blocks must be estimated together before integration. If $p_0 = p_1$, then also $s_0 = s_1$, and the assertion is immediate. Assume $p_0 < p_1$ and set

$$d = s_0 - s_1 = n(1/p_0 - 1/p_1), \qquad f_j = 2^{js_0}\Delta_j u, \qquad G(x) = \|(f_j(x))_{j\in\mathbb{N}_0}\|_{\ell^q}.$$

We have $0 < d < n/p_0$. A band-limited reproducing kernel gives $f_j = \widetilde{K}_j * f_j$, where

$$|\widetilde{K}_j(y)| \le C_N 2^{jn}(1 + 2^j\|y\|)^{-N}.$$

By Minkowski's inequality in ℓ^q, with the supremum if $q = \infty$,

$$\begin{aligned}\|(2^{-jd}f_j(x))_{j\in\mathbb{N}_0}\|_{\ell^q} &\le C_N \int_{\mathbb{R}^n} \sup_{j\in\mathbb{N}_0}\left[2^{j(n-d)}(1 + 2^j\|y\|)^{-N}\right] G(x-y)\,dy \\ &\le C\int_{\mathbb{R}^n} \|y\|^{d-n} G(x-y)\,dy =: C I_d G(x).\end{aligned}$$

The second inequality follows because $t^{n-d}(1+t)^{-N}$ is bounded for $t > 0$ if $N > n - d$.
We prove the scalar bound needed for I_d. For $R > 0$, split the integral into $\|y\| < R$ and $\|y\| \ge R$. Decomposing the first region into annuli $2^{-k-1}R \le \|y\| < 2^{-k}R$, $k \in \mathbb{N}_0$, and using the Hardy–Littlewood maximal operator

gives

$$\int_{\|y\|<R} \|y\|^{d-n} G(x-y)\,dy \le CR^d \mathcal{M}G(x) \sum_{k\in\mathbb{N}_0} 2^{-kd} \le C' R^d \mathcal{M}G(x).$$

Hölder's inequality on the second region yields

$$\int_{\|y\|\ge R} \|y\|^{d-n} G(x-y)\,dy \le CR^{d-n/p_0} \|G\|_{L^{p_0}(\mathbb{R}^n)},$$

since $(n-d)p_0' > n$. When $\mathcal{M}G(x) > 0$, choose $R = (\|G\|_{L^{p_0}(\mathbb{R}^n)}/\mathcal{M}G(x))^{p_0/n}$; if the maximal function vanishes, both integrals vanish. This gives

$$I_d G(x) \le C\|G\|_{L^{p_0}(\mathbb{R}^n)}^{dp_0/n} \big(\mathcal{M}G(x)\big)^{1-dp_0/n}.$$

Since $p_1(1-dp_0/n) = p_0$, boundedness of the maximal operator on L^{p_0} implies $\|I_d G\|_{L^{p_1}(\mathbb{R}^n)} \le C\|G\|_{L^{p_0}(\mathbb{R}^n)}$. This inequality and the preceding vector-valued estimate prove $F^{s_0}_{p_0,q} \hookrightarrow F^{s_1}_{p_1,q}$, including $q = \infty$.
For (b), write $\delta = s_0 - s_1 > 0$. If $(b_j)_{j\in\mathbb{N}_0}$ is a nonnegative sequence,

$$\|(2^{-j\delta} b_j)_{j\in\mathbb{N}_0}\|_{\ell^{q_1}} \le \|(2^{-j\delta})_{j\in\mathbb{N}_0}\|_{\ell^{q_1}} \sup_{j\in\mathbb{N}_0} b_j \le C_{\delta,q_1} \|(b_j)_{j\in\mathbb{N}_0}\|_{\ell^{q_0}}.$$

Apply this inequality to $b_j = 2^{js_0}\|\Delta_j u\|_{L^p(\mathbb{R}^n)}$ for Besov spaces and pointwise to $b_j(x) = 2^{js_0}|\Delta_j u(x)|$ for Triebel–Lizorkin spaces. Finally, (c) is the inclusion $\ell^{q_0} \hookrightarrow \ell^{q_1}$ when $q_0 \le q_1$, applied in these same two positions. □

Lemma 6.6.2. (Fractional Morrey estimate for the Gagliardo seminorm) Let $0 < s < 1$, $1 < p < \infty$, and $sp > n$. If $\alpha = s - \frac{n}{p}$, every $u \in W^{s,p}(\mathbb{R}^n)$ has a representative in $C_b^{0,\alpha}(\mathbb{R}^n)$, and

$$\|u\|_{C_b^{0,\alpha}(\mathbb{R}^n)} \le C\|u\|_{W^{s,p}(\mathbb{R}^n)}.$$

Proof. Let $B = B(x,r)$. By Proposition B.7.9 and Theorem B.6.17,

$$\begin{aligned}\int_B |u-u_B|^p &\le \frac{1}{|B|}\int_B\int_B |u(y)-u(z)|^p\,dy\,dz \\ &\le Cr^{-n}(2r)^{n+sp}[u]^p_{W^{s,p}(\mathbb{R}^n)} = Cr^{n+p\alpha}[u]^p_{W^{s,p}(\mathbb{R}^n)}.\end{aligned}$$

We explain the passage from this integral estimate to pointwise continuity. If $B_k = B(x, 2^{-k}r)$, Proposition B.7.9 gives

$$|u_{B_{k+1}} - u_{B_k}| \le C(2^{-k}r)^\alpha [u]_{W^{s,p}(\mathbb{R}^n)}.$$

The geometric series shows that $(u_{B_k})_{k\in\mathbb{N}_0}$ converges. By Theorem B.8.12, its limit agrees with $u(x)$ for almost every x and defines a representative at every point. If $r = \|x-y\|$, compare the averages on $B(x,r)$ and $B(y,r)$ with the average on a ball containing both; the same estimate and the two dyadic telescoping sums give

$$|u(x)-u(y)| \le C\|x-y\|^\alpha [u]_{W^{s,p}(\mathbb{R}^n)}.$$

Finally, Proposition B.7.9 bounds the average on the unit ball by $\|u\|_{L^p(\mathbb{R}^n)}$, which also controls the uniform norm. □

Theorem 6.6.3. (Sobolev, Morrey, and the critical case) Let $s > 0$ and $1 < p < \infty$.

(a) If $sp < n$ and $p_s^* = \dfrac{np}{n-sp}$, then

$$H^{s,p}(\mathbb{R}^n) \hookrightarrow L^{p_s^*}(\mathbb{R}^n).$$

If $s \notin \mathbb{N}$, also

$$W^{s,p}(\mathbb{R}^n) \hookrightarrow L^{p_s^*,p}(\mathbb{R}^n) \hookrightarrow L^{p_s^*}(\mathbb{R}^n).$$

(b) If $sp = n$, both $H^{s,p}(\mathbb{R}^n)$ and $W^{s,p}(\mathbb{R}^n)$ embed into $L^q(\mathbb{R}^n)$ for every $p \le q < \infty$, but not into $L^\infty(\mathbb{R}^n)$ in general. The limiting embedding

$$B^{\frac{n}{p}}_{p,1}(\mathbb{R}^n) \hookrightarrow L^\infty(\mathbb{R}^n)$$

is continuous.

(c) If $sp > n$, the elements have continuous representatives. More precisely, if $k \in \mathbb{N}_0$ and $0 < \alpha < 1$ satisfy $k + \alpha < s - \frac{n}{p}$, then

$$H^{s,p}(\mathbb{R}^n),\ W^{s,p}(\mathbb{R}^n) \hookrightarrow C_b^{k,\alpha}(\mathbb{R}^n).$$

When $0 < s < 1$ and $sp > n$, the Slobodeckij scale reaches the exponent $\alpha = s - \frac{n}{p}$.

The same results hold on a bounded Lipschitz domain after restriction; there, in the critical case, one obtains $L^q(\Omega)$ for every $1 \le q < \infty$.

Proof. We first explain the interpolation mechanism. By Theorem 6.3.10, the embedding of the F scale at constant differential index gives

$$H^{s,p}(\mathbb{R}^n) = F^s_{p,2}(\mathbb{R}^n) \hookrightarrow F^0_{p_s^*,2}(\mathbb{R}^n) = L^{p_s^*}(\mathbb{R}^n).$$

To obtain the Lorentz refinement without varying the spatial exponent in the real interpolation formula, choose

$$0 \le s_0 < s < s_1 < \frac{n}{p}, \qquad s = (1-\theta)s_0 + \theta s_1,$$

and define q_i by $q_i^{-1} = p^{-1} - \frac{s_i}{n}$. The embedding just proved gives $H^{s_i,p}(\mathbb{R}^n) \hookrightarrow L^{q_i}(\mathbb{R}^n)$. Interpolate the identity operator using Theorem 5.3.1 and use Theorems 6.3.11 and 5.8.3:

$$W^{s,p}(\mathbb{R}^n) = (H^{s_0,p}(\mathbb{R}^n), H^{s_1,p}(\mathbb{R}^n))_{\theta,p} \hookrightarrow (L^{q_0}(\mathbb{R}^n), L^{q_1}(\mathbb{R}^n))_{\theta,p} = L^{p_s^*,p}(\mathbb{R}^n).$$

Indeed, $(p_s^*)^{-1} = (1-\theta)q_0^{-1} + \theta q_1^{-1}$. Since $p < p_s^*$, monotonicity of the second index in Lorentz spaces, included in Theorem 5.8.3, implies $L^{p_s^*,p}(\mathbb{R}^n) \hookrightarrow L^{p_s^*}(\mathbb{R}^n)$. This proves (a).
If $sp = n$, apply (a) with any $s - \varepsilon$ and choose ε to obtain the desired finite exponent. On $\mathbb{R}^n$, this covers $q \ge p$; on a domain of finite measure, Proposition B.7.9 also covers $q < p$.
We show explicitly that the critical embedding into $L^\infty(\mathbb{R}^n)$ fails. Choose $\eta \in \mathcal{S}(\mathbb{R}^n)$ with $\eta(0) > 0$ and

$$\operatorname{supp}(\widehat{\eta}) \subseteq \left\{ \xi \in \mathbb{R}^n \,\middle|\, \frac{3}{4} \le \|\xi\| \le \frac{4}{3} \right\},$$

and define

$$u_N(x) := \sum_{j=1}^{N} \frac{1}{j} \eta(2^j x).$$

Finite interaction of the blocks and the change of variable $y = 2^j x$ give

$$\sup_{N\in\mathbb{N}} \|u_N\|_{B^{\frac{n}{p}}_{p,p}(\mathbb{R}^n)} \le C \left(\sum_{j=1}^{\infty} \frac{1}{j^p} \right)^{\frac{1}{p}} < \infty.$$

The critical Triebel–Lizorkin norm is also uniformly bounded. Indeed, on the annulus $2^{-k-1} < \|x\| \le 2^{-k}$, geometric growth for $j \le k$ and Schwartz decay for $j > k$ give

$$\left(\sum_{j=1}^{N} \frac{2^{\frac{2jn}{p}}}{j^2} |\eta(2^j x)|^2 \right)^{\frac{1}{2}} \le C \frac{2^{\frac{kn}{p}}}{1+k}.$$

Use this bound for $1 \le k < N$. Raising to the power p and integrating over these annuli gives $\sum_{k=1}^{N-1} (1+k)^{-p}$. On the ball $\|x\| \le 2^{-N}$, the geometric sum gives a bound $C2^{Nn/p}/N$, whose integral to the power p is at most CN^{-p}. On $\|x\| > 1$, choose $M > n/p$ and use $|\eta(2^j x)| \le C_M 2^{-jM} \|x\|^{-M}$; the sum is bounded by $C_M \|x\|^{-M}$, whose pth power is integrable on that region. The region $1/2 < \|x\| \le 1$ likewise has a uniform bound. Lemma 6.3.6 converts these estimates for the sequence of summands into the norm of u_N. Thus,

$$\sup_{N\in\mathbb{N}} \|u_N\|_{F^{\frac{n}{p}}_{p,2}(\mathbb{R}^n)} < \infty.$$

However, $u_N(0) = \eta(0) \sum_{j=1}^{N} \frac{1}{j} \to \infty$. Theorem 6.3.10 always identifies $H^{\frac{n}{p},p}(\mathbb{R}^n)$ with $F^{\frac{n}{p}}_{p,2}(\mathbb{R}^n)$. If $\frac{n}{p} \notin \mathbb{N}$, Corollary 6.3.14 identifies $W^{\frac{n}{p},p}(\mathbb{R}^n)$ with $B^{\frac{n}{p}}_{p,p}(\mathbb{R}^n)$; if $\frac{n}{p} \in \mathbb{N}$, the same Theorem 6.3.10 gives $W^{\frac{n}{p},p}(\mathbb{R}^n) = H^{\frac{n}{p},p}(\mathbb{R}^n)$. Therefore, in every case, neither $W^{\frac{n}{p},p}(\mathbb{R}^n)$ nor $H^{\frac{n}{p},p}(\mathbb{R}^n)$ embeds into $L^\infty(\mathbb{R}^n)$.
On the other hand, Theorem 4.12.4 and absolute summation give

$$\|u\|_{L^\infty(\mathbb{R}^n)} \le \sum_{j\in\mathbb{N}_0} \|\Delta_j u\|_{L^\infty(\mathbb{R}^n)} \le C \sum_{j\in\mathbb{N}_0} 2^{\frac{jn}{p}} \|\Delta_j u\|_{L^p(\mathbb{R}^n)} = C\|u\|_{B^{\frac{n}{p}}_{p,1}(\mathbb{R}^n)}.$$

If $sp > n$, Theorem 4.12.4, applied block by block, maps the source space into $B^{s-\frac{n}{p}}_{\infty,\infty}(\mathbb{R}^n)$, the Hölder–Zygmund scale. If $k + \alpha < s - \frac{n}{p}$, the uniform block sum and the estimate

$$\|D^k \Delta_j u(\cdot + h) - D^k \Delta_j u\|_{L^\infty(\mathbb{R}^n)} \le C \min\{1, 2^j\|h\|\}\, 2^{jk} \|\Delta_j u\|_{L^\infty(\mathbb{R}^n)}$$

are split into $2^j\|h\| \le 1$ and $2^j\|h\| > 1$; the two geometric series give the modulus $\|h\|^\alpha$. For $W^{s,p}(\mathbb{R}^n)$ with $0 < s < 1$, Lemma 6.6.2 directly provides the limiting exponent $s - \frac{n}{p}$. The extension from Theorem 6.5.2 transfers all embeddings to the domain. □

Theorem 6.6.4. (Rellich–Kondrashov of real order) Let $\Omega \subseteq \mathbb{R}^n$ be a bounded Lipschitz domain, and let $1 < p < \infty$ and $s > t \geq 0$. Then

$$H^{s,p}(\Omega) \hookrightarrow H^{t,p}(\Omega)$$

is compact. If s, t are not integers, the same result holds for $W^{s,p}(\Omega) \hookrightarrow W^{t,p}(\Omega)$; with the usual integer-order interpretations, it holds for all nonnegative orders. Moreover, if $sp < n$ and $1 \leq q < p_s^*$, the embeddings into $L^q(\Omega)$ are compact.

Proof. Let $(u_\nu)_{\nu\in\mathbb{N}}$ be a bounded sequence in one of the spaces of order s. Extend it by Theorem 6.5.2 and multiply by a cutoff $\zeta \in C_c^\infty(\mathbb{R}^n)$ equal to one on a neighborhood of $\overline{\Omega}$. This gives a sequence $(v_\nu)_{\nu\in\mathbb{N}}$ supported in a fixed compact set $K \subset \mathbb{R}^n$ and bounded in the corresponding global space. If

$$P_J := \sum_{j=0}^{J} \Delta_j,$$

the block definition and Proposition B.8.4 give the uniform tail estimate

$$\|(I - P_J)v_\nu\|_{A^t_{p,r}(\mathbb{R}^n)} \leq C 2^{-J(s-t)} \|v_\nu\|_{A^s_{p,r}(\mathbb{R}^n)}, \qquad A \in \{B, F\}.$$

Here take $A = F$, $r = 2$ for the Bessel scale and $A = B$, $r = p$ for the noninteger Slobodeckij scale. We first prove compactness within each of these two scales, then treat integer or mixed orders of $W^{s,p}$.
Fix J. The operator P_J is convolution with a kernel $K_J \in \mathcal{S}(\mathbb{R}^n)$. The sequence $(v_\nu)_{\nu\in\mathbb{N}}$ is bounded in $L^p(\mathbb{R}^n)$ and vanishes outside K. By Theorem 4.10.1 and Proposition B.8.17,

$$\|P_J v_\nu(\cdot + h) - P_J v_\nu\|_{L^p(\mathbb{R}^n)} \leq \|K_J(\cdot + h) - K_J\|_{L^1(\mathbb{R}^n)} \|v_\nu\|_{L^p(\mathbb{R}^n)} \longrightarrow 0$$

uniformly in ν as $\|h\| \to 0$. Moreover, Minkowski's integral inequality from Theorem B.8.2 gives

$$\|P_J v_\nu\|_{L^p(\{x\in\mathbb{R}^n \mid \|x\| > R\})} \leq \|v_\nu\|_{L^1(K)} \sup_{y\in K} \|K_J(\cdot - y)\|_{L^p(\{x\in\mathbb{R}^n \mid \|x\| > R\})} \longrightarrow 0$$

uniformly in ν as $R \to \infty$; we also used $\|v_\nu\|_{L^1(K)} \leq |K|^{\frac{1}{p'}} \|v_\nu\|_{L^p(\mathbb{R}^n)}$. The Fréchet–Kolmogorov criterion from Proposition B.7.19 shows that $(P_J v_\nu)_{\nu\in\mathbb{N}}$ is relatively compact in $L^p(\mathbb{R}^n)$.
Since $P_J v_\nu$ has frequencies in a fixed ball, Theorem 4.12.4 implies

$$\|P_J(v_\nu - v_\mu)\|_{A^t_{p,r}(\mathbb{R}^n)} \leq C_J \|P_J(v_\nu - v_\mu)\|_{L^p(\mathbb{R}^n)}.$$

Write $M_s := \sup_{\nu\in\mathbb{N}} \|v_\nu\|_{A^s_{p,r}(\mathbb{R}^n)} < \infty$. For each $k \in \mathbb{N}$, choose J_k so that

$$2C 2^{-J_k(s-t)} M_s < 2^{-k}.$$

Starting from the original sequence, recursively extract nested subsequences $(v_\nu^{(k)})_\nu$: once the subsequence at level $k-1$ is chosen, compactness of $(P_{J_k} v_\nu^{(k-1)})_\nu$ in $L^p(\mathbb{R}^n)$ and Bernstein's inequality allow us to choose $(v_\nu^{(k)})_\nu$ so that $(P_{J_k} v_\nu^{(k)})_\nu$ converges in $A^t_{p,r}(\mathbb{R}^n)$. Take the diagonal subsequence $w_k := v_k^{(k)}$. For each fixed k_0, the tail $(w_k)_{k\geq k_0}$ is a subsequence of $(v_\nu^{(k_0)})_\nu$; thus $(P_{J_{k_0}} w_k)_{k\geq k_0}$ is Cauchy in the space of order t. Given $\varepsilon > 0$,

choose k_0 with $2^{-k_0} < \frac{\varepsilon}{2}$ and then $N \geq k_0$ so that for $k, \ell \geq N$,

$$\|P_{J_{k_0}}(w_k - w_\ell)\|_{A^t_{p,r}(\mathbb{R}^n)} < \frac{\varepsilon}{2}.$$

The uniform estimate for the two tails then gives

$$\|w_k - w_\ell\|_{A^t_{p,r}(\mathbb{R}^n)} < \varepsilon.$$

Thus (w_k) converges in the space of order t. Restriction to Ω is continuous, proving compactness between orders within each scale.

For integer or mixed orders of $W^{s,p}$, choose two nonintegers a, b with $t < b < a < s$. The strict loss in order allows the fine block index to change. Indeed, if $A_j := 2^{js}\|\Delta_j v\|_{L^p(\mathbb{R}^n)}$, the source norm dominates $\sup_{j\in\mathbb{N}_0} A_j$, both for $B^s_{p,p}$ and for $F^s_{p,2}$. By convergence of the geometric series,

$$\|v\|_{B^a_{p,p}(\mathbb{R}^n)} \leq C\left(\sum_{j=0}^{\infty} 2^{-jp(s-a)} A_j^p\right)^{1/p} \leq C_{s-a}\|v\|_{W^{s,p}(\mathbb{R}^n)}.$$

When s is an integer, use $W^{s,p} = H^{s,p} = F^s_{p,2}$ here, with equivalence of norms. At the target endpoint, the triangle inequality in $L^p(\ell^2)$ and Hölder's inequality for sequences give

$$\|v\|_{F^t_{p,2}(\mathbb{R}^n)} \leq C\sum_{j=0}^{\infty} 2^{jt}\|\Delta_j v\|_{L^p(\mathbb{R}^n)} \leq C_{b-t}\|v\|_{B^b_{p,p}(\mathbb{R}^n)}.$$

If t is not an integer, the inclusion $B^b_{p,p} \hookrightarrow B^t_{p,p}$ follows directly from the weights; if it is an integer, the last estimate and $F^t_{p,2} = W^{t,p}$ give the required inclusion. Applying these estimates to extensions with common support and using the compactness from $B^a_{p,p}$ to $B^b_{p,p}$ just proved gives a subsequence converging in $W^{t,p}(\Omega)$. This includes all nonnegative orders without identifying $B^j_{p,p}$ with $W^{j,p}$ at an integer order.

For the embedding into $L^q(\Omega)$, choose $0 < t < s$ such that $q < p^*_t < p^*_s$ when $q > p$; if $q \leq p$, any $0 < t < s$ and Proposition B.7.9 on the domain of finite measure suffice. In both cases, use

$$A^s_{p,r}(\Omega) \hookrightarrow\hookrightarrow A^t_{p,r}(\Omega) \hookrightarrow L^q(\Omega).$$

The second embedding is Theorem 6.6.3. This completes the proof. □

6.7 Fractional-order traces

Restriction to the hyperplane $\mathbb{R}^{n-1} \times \{0\}$ lowers dimension by one. A function concentrated in a strip of thickness 2^{-j} has a spatial norm containing the factor $2^{-j/p}$; evaluation at the center of the strip loses that factor. This explains the loss of $1/p$ derivatives. In Triebel–Lizorkin spaces, integration in the normal direction also determines the fine index p of the target norm.

Assume $n \geq 2$. When $n = 1$, omit tangential variables and interpret the space on a point as $\mathbb{K}$ with its absolute value; the same arguments give evaluation at the endpoints of an interval.

For a compact smooth hypersurface Σ, define $B^\sigma_{p,q}(\Sigma)$ using a finite atlas, a partition of unity, and the Euclidean

norms of the local expressions. Lemma 6.4.3, applied in dimension $n-1$, compares any two such norms: insert one partition into the other and apply the coordinate-change operators on each overlap. Since there are finitely many terms, both inequalities have constants independent of the distribution. The resulting space is independent of the atlas.

Lemma 6.7.1. (Dyadic trace estimate) Let $1 < p < \infty$ and $j \in \mathbb{N}_0$, and let $v \in L^p(\mathbb{R}^n)$ satisfy

$$\operatorname{supp} \widehat{v} \subseteq \{\xi \in \mathbb{R}^n \mid \|\xi\| \le A2^j\}.$$

Then

$$\|v(\cdot,0)\|_{L^p(\mathbb{R}^{n-1})} \le C_{A,p}\, 2^{j/p} \|v\|_{L^p(\mathbb{R}^n)}. \tag{6.19}$$

Let $s > 1/p$, $1 \le q \le \infty$, $u_j = \Delta_j u$, $j \in \mathbb{N}_0$, and $\sigma = s - 1/p > 0$. If the corresponding right-hand norm is finite, then

$$\left\| \left(2^{\ell\sigma} \left\| \Delta'_\ell \sum_{j\in\mathbb{N}_0} u_j(\cdot,0) \right\|_{L^p(\mathbb{R}^{n-1})} \right)_{\ell\in\mathbb{N}_0} \right\|_{\ell^q} \le C \left\| \left(2^{js}\|u_j\|_{L^p(\mathbb{R}^n)}\right)_{j\in\mathbb{N}_0} \right\|_{\ell^q}, \tag{6.20}$$

and

$$\left(\sum_{\ell\in\mathbb{N}_0} 2^{\ell\sigma p} \left\| \Delta'_\ell \sum_{j\in\mathbb{N}_0} u_j(\cdot,0) \right\|^p_{L^p(\mathbb{R}^{n-1})} \right)^{1/p} \le C \left\| \left(2^{js} u_j\right)_{j\in\mathbb{N}_0} \right\|_{L^p(\mathbb{R}^n;\ell^q(\mathbb{N}_0))}. \tag{6.21}$$

Here Δ'_ℓ are blocks on $\mathbb{R}^{n-1}$. Suprema replace the ℓ^∞ norms. The constant in (6.21) can be chosen independently of $q \in [1,\infty]$.

Proof. Choose a kernel $\eta \in \mathcal{S}(\mathbb{R})$ whose convolution multiplier $(2\pi)^{1/2}\widehat{\eta}$ equals one on $[-A,A]$. Reproduction in the normal variable gives

$$v(x',0) = \int_{\mathbb{R}} 2^j \eta(-2^j t) v(x',t)\, dt.$$

Hölder's inequality in t implies

$$|v(x',0)|^p \le C 2^j \int_{\mathbb{R}} |v(x',t)|^p\, dt.$$

Integration in x' proves (6.19). The formula is first obtained for Schwartz functions, then for v through reproduction by a kernel of enlarged frequency support. This kernel provides the smooth representative of v and allows passage to the limit in L^p.

Set $g_j = u_j(\cdot,0)$. Its tangential Fourier support lies in a ball of radius $C2^j$, although it may contain low tangential frequencies. Thus,

$$\Delta'_\ell \sum_{j\in\mathbb{N}_0} g_j = \sum_{\substack{j\in\mathbb{N}_0 \\ j\ge \ell - N_0}} \Delta'_\ell g_j. \tag{6.22}$$

Young's inequality and (6.19) give

$$2^{\ell\sigma}\|\Delta'_\ell g_j\|_{L^p(\mathbb{R}^{n-1})} \le C 2^{-(j-\ell)\sigma} 2^{js}\|u_j\|_{L^p(\mathbb{R}^n)}, \qquad j \ge \ell - N_0. \tag{6.23}$$

The sequence $\left(2^{-m\sigma}\mathbf{1}_{\{m\ge -N_0\}}\right)_{m\in\mathbb{Z}}$ is summable. Young's inequality for sequences proves (6.20).

For the second estimate, integrate each block over a different strip. Define

$$I_j := (2^{-j}, 2^{1-j}], \qquad j \in \mathbb{N}_0.$$

These intervals are disjoint and have length 2^{-j}. If $t \in I_j$, Peetre's definition implies

$$|u_j(x', 0)| \le 3^{\lambda} P_{j,\lambda} u_j(x', t).$$

Multiply by 2^{jsp} and integrate in I_j and then in x'. Summing in j, disjointness of the intervals gives

$$\begin{aligned}\sum_{j\in\mathbb{N}_0} 2^{j(sp-1)} \|g_j\|_{L^p(\mathbb{R}^{n-1})}^p &\le C \sum_{j\in\mathbb{N}_0} \int_{\mathbb{R}^{n-1}\times I_j} \left(2^{js} P_{j,\lambda} u_j(x)\right)^p dx \\ &\le C \int_{\mathbb{R}^n} \sup_{j\in\mathbb{N}_0} \left(2^{js} P_{j,\lambda} u_j(x)\right)^p dx.\end{aligned}$$

Choose $0 < a < 1$ and $\lambda > n/a$. Peetre control and monotonicity of the maximal operator give

$$\sup_{j\in\mathbb{N}_0} 2^{js} P_{j,\lambda} u_j \le C \left[\mathcal{M}\left(\sup_{j\in\mathbb{N}_0} |2^{js} u_j|^a \right) \right]^{1/a}.$$

Since $p/a > 1$, boundedness of the maximal operator implies

$$\left(\sum_{j\in\mathbb{N}_0} 2^{j\sigma p} \|g_j\|_{L^p(\mathbb{R}^{n-1})}^p \right)^{1/p} \le C \left\| \sup_{j\in\mathbb{N}_0} |2^{js} u_j| \right\|_{L^p(\mathbb{R}^n)} \le C \left\| \left(2^{js} u_j\right)_{j\in\mathbb{N}_0} \right\|_{L^p(\mathbb{R}^n;\ell^q(\mathbb{N}_0))}.$$

Finally, (6.22), Young's convolution inequality, and the same geometric sequence from (6.23) transfer this norm of the g_j to the $B^{\sigma}_{p,p}$ norm of their sum. This proves (6.21) with a constant independent of q.
The trace series converge in $L^p(\mathbb{R}^{n-1})$: in both situations, the sequence $(2^{j\sigma}\|g_j\|_{L^p(\mathbb{R}^{n-1})})_{j\in\mathbb{N}_0}$ is bounded and $\sum_{j\in\mathbb{N}_0} 2^{-j\sigma} < \infty$. Thus all steps for finite families pass to the limit. □

Theorem 6.7.2. (Hyperplane trace and coretraction) Let $1 < p < \infty$, $1 \le q \le \infty$, and $s > 1/p$. Restriction to the hyperplane induces continuous surjective operators

$$\operatorname{tr}\colon B^s_{p,q}(\mathbb{R}^n) \longrightarrow B^{s-1/p}_{p,q}(\mathbb{R}^{n-1}), \qquad \operatorname{tr}\colon F^s_{p,q}(\mathbb{R}^n) \longrightarrow B^{s-1/p}_{p,p}(\mathbb{R}^{n-1}). \tag{6.24}$$

Both have a continuous linear coretraction. In particular,

$$\operatorname{tr}\colon H^{s,p}(\mathbb{R}^n) \longrightarrow B^{s-1/p}_{p,p}(\mathbb{R}^{n-1}) \tag{6.25}$$

is a retraction.

Proof. For each element of the spaces in the statement, define

$$\operatorname{tr} u := \sum_{j\in\mathbb{N}_0} (\Delta_j u)(\cdot, 0).$$

The lemma proves convergence and continuity. This definition agrees with canonical evaluation in the normal direction. Indeed, (6.19) holds on every hyperplane of height t with the same constant, and

$$\sup_{t\in\mathbb{R}} \|(\Delta_j u)(\cdot,t)\|_{L^p(\mathbb{R}^{n-1})} \le C 2^{-j(s-1/p)} \|u\|_{A^s_{p,q}}.$$

Each block is a continuous function of t with values in $L^p(\mathbb{R}^{n-1})$. This follows from one-dimensional reproduction and continuity of translations of its kernel. The series converges uniformly in this space of continuous functions. Its sum represents u as a distribution by dyadic reconstruction, and its value at zero is the defined trace. Thus the trace is independent of the resolution. If u vanishes on the half-space $t > 0$, its continuous representative in t vanishes for $t > 0$ and also at $t = 0$. This observation will give independence from extensions.

Choose $\rho \in \mathcal{S}(\mathbb{R})$ with $\rho(0) = 1$ and compact Fourier support. For data g in the target space, set

$$(\operatorname{ex} g)(x',t) := \sum_{j\in\mathbb{N}_0} \rho(2^j t)\Delta'_j g(x'). \tag{6.26}$$

The summands have spectral support in annuli of $\mathbb{R}^n$ comparable to 2^j, except for the zero block, whose support lies in a ball. Moreover,

$$\|\rho(2^j\cdot)\Delta'_j g\|_{L^p(\mathbb{R}^n)} = 2^{-j/p}\|\rho\|_{L^p(\mathbb{R})}\|\Delta'_j g\|_{L^p(\mathbb{R}^{n-1})}. \tag{6.27}$$

Lemma 6.3.6 gives the Besov bound and distributional convergence.

For Triebel–Lizorkin spaces, we prove the stronger bound with fine index one; the inclusion $\ell^1 \hookrightarrow \ell^q$ will give the other indices. Write

$$b_j(x') := 2^{j(s-1/p)}|\Delta'_j g(x')|, \qquad j \in \mathbb{N}_0.$$

Spectral synthesis and decay of ρ give

$$\|\operatorname{ex} g\|_{F^s_{p,1}(\mathbb{R}^n)} \le C \left\| \sum_{j\in\mathbb{N}_0} 2^{j/p}(1+2^j|t|)^{-M} b_j(x') \right\|_{L^p(\mathbb{R}^{n-1}\times\mathbb{R},\,dx'\,dt)}.$$

Take $M > 1/p$ and split $\mathbb{R}\setminus\{0\}$ into

$$A_m := \{t \in \mathbb{R} \mid 2^{-m-1} < |t| \le 2^{-m}\}, \qquad m \in \mathbb{Z}.$$

Their measure is 2^{-m}. For $t \in A_m$, multiplying the sum by $2^{-m/p}$ bounds it by

$$C \sum_{j\in\mathbb{N}_0} c_{j-m} b_j(x'), \qquad c_\ell := \begin{cases} 2^{\ell/p}, & \ell \le 0, \\ 2^{-\ell(M-1/p)}, & \ell > 0. \end{cases}$$

The sequence $(c_\ell)_{\ell\in\mathbb{Z}}$ belongs to $\ell^1(\mathbb{Z})$. Young's inequality in the indices j, m, followed by Tonelli's theorem in x', yields

$$\|\operatorname{ex} g\|^p_{F^s_{p,q}(\mathbb{R}^n)} \le C \sum_{j\in\mathbb{N}_0} 2^{jp(s-1/p)} \|\Delta'_j g\|^p_{L^p(\mathbb{R}^{n-1})} = C\|g\|^p_{B^{s-1/p}_{p,p}(\mathbb{R}^{n-1})}. \tag{6.28}$$

The constants are independent of the number of summands.

Finally, $s - 1/p > 0$ implies $\sum_{j\in\mathbb{N}_0} \|\Delta'_j g\|_{L^p(\mathbb{R}^{n-1})} < \infty$. The series in (6.26) converges uniformly in t with values in L^p and equals $\sum_{j\in\mathbb{N}_0} \Delta'_j g = g$ at $t = 0$. The canonical interpretation of the trace proves $\operatorname{tr}\operatorname{ex} = I$. □

Theorem 6.7.3. (Fractional trace on smooth domains) Let $\Omega \subseteq \mathbb{R}^n$ be a bounded domain with boundary C^∞, and let $1 < p < \infty$, $1 \le q \le \infty$, and $s > 1/p$. There are continuous surjective operators

$$\operatorname{Tr}\colon B^s_{p,q}(\Omega) \longrightarrow B^{s-1/p}_{p,q}(\partial\Omega), \qquad \operatorname{Tr}\colon F^s_{p,q}(\Omega) \longrightarrow B^{s-1/p}_{p,p}(\partial\Omega).$$

Each has a continuous linear right inverse. In particular,

$$\operatorname{Tr}\colon H^{s,p}(\Omega) \longrightarrow B^{s-1/p}_{p,p}(\partial\Omega)$$

is a retraction; the same holds with $W^{s,p}(\Omega)$ as source space when s is not an integer.

Proof. Choose an extension U of u to $\mathbb{R}^n$, boundary charts $\Phi_i\colon Q \longrightarrow U_i$, $i \in \{1,\dots,N\}$, and subordinate smooth cutoffs η_i whose sum equals one near $\partial\Omega$. The charts satisfy

$$\Phi_i(Q \cap \{t > 0\}) = U_i \cap \Omega, \qquad \Phi_i(Q \cap \{t = 0\}) = U_i \cap \partial\Omega.$$

Choose the cutoffs compactly supported inside each chart. Define

$$\operatorname{Tr}_\Omega u := \sum_{i=1}^{N} \big[\operatorname{tr}\big((\eta_i U) \circ \Phi_i\big)\big] \circ (\Phi_i \restriction_{\{t=0\}})^{-1}, \tag{6.29}$$

with extension by zero of each localized expression. The multiplication and composition lemmas and the hyperplane theorem bound the sum by $C\|U\|_{A^s_{p,q}}$.

If U_1, U_2 extend the same u, the localized expression of $U_1 - U_2$ vanishes on $t > 0$. The final observation about the canonical trace in the preceding theorem shows that its trace is zero. Thus the formula does not depend on the extension. Taking the infimum over all extensions gives the bound by the quotient norm of u.

To compare two systems of charts, fix $0 < \varepsilon < s - 1/p$. Corollary 6.3.9 allows approximation of U, after localization, in $B^{s-\varepsilon}_{p,p}$ by smooth functions. The two trace constructions agree for these functions. Multiplication, composition, and trace are continuous at this lower order, which still exceeds $1/p$. Passing to the limit, the resulting traces agree as distributions on the boundary. Since both already belong to the target space of order $s - 1/p$, this identity is also equality of their elements in that space. The argument covers $q = \infty$.

We now construct a right inverse. Choose cutoffs $\zeta_i \in C^\infty(\partial\Omega)$ supported inside the charts, with $\sum_{i=1}^{N} \zeta_i^2 = 1$ To obtain them, start with cutoffs whose sum is positive and divide each by the square root of the sum of their squares. Given g, express

$$g_i := (\zeta_i g) \circ (\Phi_i \restriction_{\{t=0\}})$$

on $\mathbb{R}^{n-1}$, extending it by zero. Apply ex from (6.26). Choose on Q a cutoff χ_i whose restriction to $t = 0$ is the expression of ζ_i, and extend it smoothly with compact support inside Q. The sum of the functions $\chi_i \operatorname{ex} g_i$

transported by Φ_i^{-1} and restricted to Ω defines a continuous operator. Its trace is

$$\sum_{i=1}^{N} \zeta_i(\zeta_i g) = g.$$

The Bessel and Slobodeckij identifications give the final assertions. □

Remark 6.7.4. (Lipschitz boundaries) On a Lipschitz boundary, coordinate changes do not have the derivatives used in the preceding theorem. The trace formulation at this boundary regularity requires a separate development; in the interval

$$1/p < s < 1 + 1/p$$

the target space has order between zero and one and is described through differences in boundary charts. The corresponding classical theorem can be found in [146, Section 4.4.2]. Boundary charts of the smooth manifolds in this book will be treated using the preceding theorem.

Part III

Nonlinear analysis on Riemannian manifolds

Introduction to Part III

We now return to manifolds with the tools developed in the Euclidean setting. This is one of the central steps in the book. It is not enough to replace partial derivatives with covariant derivatives and repeat the same formulas: working on a manifold requires the Riemannian measure, bundle metrics, connections, supports of sections, and transformations between charts and trivializations. Each of these structures determines how an analytic notion is correctly formulated.

The first chapters construct Sobolev spaces of functions and of sections of vector bundles, and develop the integration-by-parts formulas used to define weak covariant derivatives and formal adjoints. Differential operators on bundles and vector-valued distributions are then introduced. The principal symbol and ellipticity allow regularity to be recovered from the equation. Later, the connection Laplacian and the heat semigroup provide intrinsic scales of fractional regularity.

The final stage of this development requires us to leave behind the convenience of compactness. On a noncompact manifold, a local estimate can be globalized only if its constants remain controlled as the chart moves. Bounded geometry provides precisely this uniform control. Normal and Fermi coordinates, partitions of unity, and uniform trivializations then allow the results to be extended to submanifolds and manifolds with boundary. Throughout these chapters, we will continually alternate between two operations: expressing a geometric object in coordinates in order to calculate, and reconstructing a global, intrinsic statement from local estimates.

Aubin and analysis on manifolds

The development of geometric equations in the twentieth century made it necessary to adapt the tools of functional analysis to spaces whose geometry could not be ignored. Thierry Aubin played a central role in systematizing Sobolev inequalities and variational problems on manifolds, particularly in the study of conformal equations. Subsequently, Hebey, Strichartz, Eichhorn, Grigor'yan, Amann, and many others extended these ideas to complete and noncompact manifolds, manifolds of bounded geometry, manifolds with boundary, and spaces with more general structures. In this part we follow the same course: beginning with the local theory and identifying the geometric hypotheses that turn it into a global theory.

7

Sobolev spaces on Riemannian manifolds

The Dirichlet energy provides an intrinsic starting point for transferring Sobolev spaces to a Riemannian manifold $(M, \mathbf{g})$. For scalar data f, we formally consider

$$\mathcal{E}_{\mathbf{g}}(u) = \frac{1}{2}\int_M |du|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}} - \int_M f u \, d\lambda_{\mathbf{g}}.$$

For smooth u and φ, with interior support or boundary conditions that eliminate the boundary term, the first variation gives

$$\int_M \langle du, d\varphi \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} = \int_M f \varphi \, d\lambda_{\mathbf{g}}.$$

This identity is the weak formulation of $-\Delta_{\mathbf{g}} u = f$ and remains meaningful when u has only one square-integrable weak derivative.

The metric enters both the norm of du and the measure $\lambda_{\mathbf{g}}$, but the definition must be independent of coordinates. Charts allow a function to be compared locally with its Euclidean representative; partitions of unity assemble these comparisons, and covariant derivatives provide a global description of higher orders. On a compact manifold, finiteness of the cover makes the norms obtained from these constructions equivalent.

This chapter will define the spaces $W^{m,p}(M)$, prove their completeness, and establish independence from the relevant auxiliary data. It will then transfer the density, embedding, and Rellich–Kondrashov theorems to the manifold. The following example first shows how the same geometric operator takes different expressions in different charts while still representing the Laplace–Beltrami operator.

Example 7.0.1. (The Laplace–Beltrami operator on the sphere in different coordinates) Let $S^2 \subset \mathbb{R}^3$ be the unit sphere and let $\iota\colon S^2 \hookrightarrow \mathbb{R}^3$ be the canonical inclusion. Denote the Euclidean metric on $\mathbb{R}^3$ by $\overline{\mathbf{g}}$. The Riemannian metric on S^2 is defined as the pullback of $\overline{\mathbf{g}}$ by the inclusion:

$$\mathbf{g} = \iota^* \overline{\mathbf{g}}, \qquad \mathbf{g}_p(X_p, Y_p) = \overline{\mathbf{g}}_{\iota(p)}(d\iota_p(X_p), d\iota_p(Y_p)), \quad X_p, Y_p \in T_p S^2.$$

If (x^1, x^2) are local coordinates induced by a chart $\varphi\colon U \subseteq S^2 \longrightarrow V \subseteq \mathbb{R}^2$, denote by $\Phi := \iota \circ \varphi^{-1}\colon V = \varphi(U) \longrightarrow \mathbb{R}^3$ the composition of the inverse chart with the inclusion. By the definition of the induced

metric,

$$\mathbf{g} = \iota^*\overline{\mathbf{g}}, \qquad \mathbf{g}_p(X_p, Y_p) = \overline{\mathbf{g}}_{\iota(p)}\big(d\iota_p(X_p), d\iota_p(Y_p)\big), \quad X_p, Y_p \in T_pS^2.$$

In particular, for the coordinate vectors

$$\partial_i\big|_p = (d\varphi^{-1})_{\varphi(p)}\left(\partial_i\Big|_{\varphi(p)}\right),$$

we have

$$d\iota_p\left(\partial_i\big|_p\right) = d\iota_p \circ \left((d\varphi^{-1})_{\varphi(p)}\left(\partial_i\Big|_{\varphi(p)}\right)\right) = d(\iota\circ\varphi^{-1})_{\varphi(p)}\left(\partial_i\Big|_{\varphi(p)}\right) = d\Phi_{\varphi(p)}\left(\partial_i\Big|_{\varphi(p)}\right).$$

Thus, evaluating the definition of $\mathbf{g}$ at the point p,

$$g_{ij}(p) = \mathbf{g}_p\left(\partial_i\big|_p, \partial_j\big|_p\right) = \overline{\mathbf{g}}_{\iota(p)}\left(d\Phi_{\varphi(p)}\left(\partial_i\Big|_{\varphi(p)}\right), d\Phi_{\varphi(p)}\left(\partial_j\Big|_{\varphi(p)}\right)\right).$$

Finally, since $d\Phi_{\varphi(p)}\left(\partial_i\Big|_{\varphi(p)}\right)$ agrees with the partial derivative $\dfrac{\partial\Phi}{\partial x_i}(\varphi(p))$ at $\mathbb{R}^3$, we obtain

$$g_{ij}(p) = \left\langle \frac{\partial\Phi}{\partial x^i}(\varphi(p)), \frac{\partial\Phi}{\partial x^j}(\varphi(p)) \right\rangle_{\mathbb{R}^3},$$

where $\langle\cdot,\cdot\rangle_{\mathbb{R}^3}$ is the Euclidean inner product. This identity shows that the local coefficients of the induced metric on S^2 are computed, for each $p \in U$, as the inner products of the partial derivatives of the parametrization $\Phi = \iota\circ\varphi^{-1}$ evaluated at $\varphi(p) \in \mathbb{R}^2$.

We shall use spherical coordinates (θ, φ) with the following convention: θ is the radial angle in the xy plane, $0 < \theta < 2\pi$, and φ is the azimuthal angle measured from the positive z axis, $0 < \varphi < \pi$. The inverse of these coordinates defines a chart on an open subset of S^2. The corresponding map is

$$\Phi(\theta, \varphi) = \big(\sin\varphi\cos\theta,\ \sin\varphi\sin\theta,\ \cos\varphi\big).$$

Its partial derivatives are

$$\partial_\theta\Phi = \big(-\sin\varphi\sin\theta,\ \sin\varphi\cos\theta,\ 0\big), \qquad \partial_\varphi\Phi = \big(\cos\varphi\cos\theta,\ \cos\varphi\sin\theta,\ -\sin\varphi\big).$$

With $\mathbf{g} = \iota^*\overline{\mathbf{g}}$, we obtain pointwise

$$g_{\theta\theta} = \langle\partial_\theta\Phi, \partial_\theta\Phi\rangle_{\mathbb{R}^3} = \sin^2\varphi, \qquad g_{\theta\varphi} = \big\langle\partial_\theta\Phi, \partial_\varphi\Phi\big\rangle_{\mathbb{R}^3} = 0, \qquad g_{\varphi\varphi} = \big\langle\partial_\varphi\Phi, \partial_\varphi\Phi\big\rangle_{\mathbb{R}^3} = 1.$$

Therefore,

$$(g_{ij}) = \begin{pmatrix} \sin^2\varphi & 0 \\ 0 & 1 \end{pmatrix}, \qquad (g^{ij}) = \begin{pmatrix} \csc^2\varphi & 0 \\ 0 & 1 \end{pmatrix}, \qquad \sqrt{\det(\mathbf{g})} = \sin\varphi,$$

and the local Laplace–Beltrami formula is

$$\Delta u = \frac{1}{\sqrt{\det(\mathbf{g})}}\partial_i\big(\sqrt{\det(\mathbf{g})}g^{ij}\partial_j u\big) = \frac{1}{\sin\varphi}\partial_\varphi\big(\sin\varphi\partial_\varphi u\big) + \frac{1}{\sin^2\varphi}\partial_{\theta\theta}u.$$

Now let $N = (0,0,1)$ be the north pole and consider stereographic projection

$$\sigma\colon S^2 \setminus \{N\} \longrightarrow \mathbb{R}^2, \qquad \sigma(x,y,z) = \left(\frac{x}{1-z}, \frac{y}{1-z}\right).$$

Its inverse

$$\sigma^{-1}(x,y) = \left(\frac{2x}{1+x^2+y^2}, \frac{2y}{1+x^2+y^2}, \frac{x^2+y^2-1}{1+x^2+y^2}\right)$$

composed with the inclusion $\iota\colon S^2 \hookrightarrow \mathbb{R}^3$ gives

$$\widetilde{\Phi} = \iota\circ\sigma^{-1}\colon \mathbb{R}^2 \longrightarrow \mathbb{R}^3, \qquad \widetilde{\Phi}(x,y) = \left(\frac{2x}{1+x^2+y^2}, \frac{2y}{1+x^2+y^2}, \frac{x^2+y^2-1}{1+x^2+y^2}\right).$$

Differentiating and taking Euclidean inner products gives

$$g_{xx} = \left\langle \partial_x\widetilde{\Phi}, \partial_x\widetilde{\Phi}\right\rangle_{\mathbb{R}^3} = \frac{4}{\big(1+x^2+y^2\big)^2}, \qquad g_{yy} = \left\langle \partial_y\widetilde{\Phi}, \partial_y\widetilde{\Phi}\right\rangle_{\mathbb{R}^3} = \frac{4}{\big(1+x^2+y^2\big)^2},$$

$$g_{xy} = g_{yx} = \left\langle \partial_x\widetilde{\Phi}, \partial_y\widetilde{\Phi}\right\rangle_{\mathbb{R}^3} = 0,$$

whence

$$(g_{ij}) = \frac{4}{\big(1+x^2+y^2\big)^2}\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}, \qquad (g^{ij}) = \frac{\big(1+x^2+y^2\big)^2}{4}\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}, \qquad \sqrt{\det(\mathbf{g})} = \frac{4}{\big(1+x^2+y^2\big)^2}.$$

In these coordinates,

$$\Delta u = \frac{1}{\sqrt{\det(\mathbf{g})}}\partial_i\big(\sqrt{\det(\mathbf{g})}g^{ij}\partial_j u\big) = \frac{\big(1+x^2+y^2\big)^2}{4}\big(\partial_{xx}u + \partial_{yy}u\big).$$

PDEs on Riemannian manifolds arise inevitably in several fields:

- In **differential geometry**, problems such as the Yamabe problem (existence of metrics of constant scalar curvature in a conformal class) and the study of geometric flows such as Ricci flow (used by Perelman in resolving the Poincaré conjecture) depend essentially on Sobolev inequalities and estimates on manifolds.
- In **mathematical physics**, the equations of general relativity are formulated on Lorentzian manifolds, and analysis of their associated operators requires suitable Sobolev spaces. The positive mass theorem is a paradigmatic example in which geometry, physics, and Sobolev inequalities interact.
- In **global analysis and topology**, the *Hodge theorem* ensures that each differential cohomology class has a harmonic representative, while the *Atiyah–Singer index theorem* relates the index of elliptic operators to topological invariants of the manifold. These results show how analysis of differential operators on manifolds becomes a central tool for understanding their global structure.

Thierry Aubin and Sobolev spaces on manifolds

In 1976, Thierry Aubin published a systematic treatment of Sobolev spaces on Riemannian manifolds and of the inequalities used to study geometric equations [15]. His work helped consolidate an intrinsic approach based on the metric and connection, particularly fruitful in conformal problems and nonlinear equations. Seeley developed spectral tools, and Strichartz extended several constructions to complete manifolds. Contemporary theory combines these ideas with uniform localization, heat kernels, and bounded geometry.

Sobolev spaces on manifolds are more than a generalization of Euclidean tools. They provide the language in which energy, regularity, and geometry can be studied simultaneously.

7.1 Definition and basic properties

We shall adopt an intrinsic definition using covariant derivatives. In a chart, these derivatives are expressed in terms of partial derivatives and Christoffel symbols; globally, the metric allows them to be measured and integrated without privileging coordinates.

For a function $u \in C^\infty(M)$, the information of order m is encoded by $\nabla^m u$. The following results describe its local expression and its relationship with the Riemannian metric.

Proposition 7.1.1. Let M be a smooth manifold with or without boundary. Let ∇ be a connection on TM, let (U,φ) be a chart on M, and let $\{\Gamma_{ij}^k\}$ be the Christoffel symbols of the connection with respect to (U,φ). Given $u \in C^\infty(M)$, $\nabla^m u$ has the following local expression:

$$(\nabla^m u)_{i_1\dots i_m} = \frac{\partial (\nabla^{m-1}u)_{i_2\dots i_m}}{\partial x_{i_1}} - \sum_{l=2}^{m} \Gamma_{i_1 i_l}^k (\nabla^{m-1}u)_{i_2\dots i_{l-1} k i_{l+1}\dots i_m}.$$

That is, according to the convention fixed in Proposition 2.4.29, the new covariant index occupies the first slot.

Proof. Using Proposition 2.4.13 and the convention for the position of the new index, we have

$$\begin{aligned}
(\nabla^m u)_{i_1\dots i_m} &= (\nabla_{\partial_{i_1}}(\nabla^{m-1}u))(\partial_{i_2},\dots,\partial_{i_m}) \\
&= \partial_{i_1}\left((\nabla^{m-1}u)(\partial_{i_2},\dots,\partial_{i_m})\right) \\
&\quad - \sum_{l=2}^{m} (\nabla^{m-1}u)\left(\partial_{i_2},\dots,\partial_{i_{l-1}},\nabla_{\partial_{i_1}}\partial_{i_l},\partial_{i_{l+1}},\dots,\partial_{i_m}\right) \\
&= \frac{\partial (\nabla^{m-1}u)_{i_2\dots i_m}}{\partial x_{i_1}} - \sum_{l=2}^{m} \Gamma_{i_1 i_l}^k (\nabla^{m-1}u)_{i_2\dots i_{l-1} k i_{l+1}\dots i_m}.
\end{aligned}$$

□

Proposition 7.1.2. Let M be a smooth manifold with or without boundary of dimension n, and let ∇ be a

connection on TM. If $u \in C^\infty(M)$ and (U, φ) is a smooth chart on M, then

$$\nabla^m u = \sum_{i_1,\dots,i_m=1}^{n} \sum_{0\le|\alpha|\le m} D^\alpha u P_\alpha^{i_1\dots i_m} \mathbf{d}x^{i_1} \otimes \cdots \otimes \mathbf{d}x^{i_m}$$

on U, where $P_\alpha^{i_1\dots i_m}$ is a polynomial in the Christoffel symbols of ∇ and their derivatives up to order $m-1$.

Proof. We argue by induction on m. For $m = 1$, $\nabla u = \dfrac{\partial u}{\partial x^i}\mathbf{d}x^i$; for $m = 2$,

$$\nabla^2 u = \left(\frac{\partial^2 u}{\partial x^i \partial x^j} - \Gamma_{ij}^k \frac{\partial u}{\partial x^k} \right) \mathbf{d}x^i \otimes \mathbf{d}x^j.$$

Suppose the assertion holds for some $m \ge 2$. By Proposition 7.1.1,

$$(\nabla^{m+1} u)_{i_1\dots i_{m+1}} = \frac{\partial (\nabla^m u)_{i_2\dots i_{m+1}}}{\partial x_{i_1}} - \sum_{l=2}^{m+1} \Gamma_{i_1 i_l}^k (\nabla^m u)_{i_2\dots i_{l-1} k i_{l+1}\dots i_{m+1}}.$$

The induction hypothesis tells us that

$$(\nabla^m u)_{i_2\dots i_{m+1}} = \sum_{0\le|\alpha|\le m} D^\alpha u P_\alpha^{i_2\dots i_{m+1}}.$$

Then

$$\begin{aligned}(\nabla^{m+1} u)_{i_1\dots i_{m+1}} = &\sum_{0\le|\alpha|\le m} \frac{\partial (D^\alpha u)}{\partial x_{i_1}} P_\alpha^{i_2\dots i_{m+1}} \\ &+ \sum_{0\le|\alpha|\le m} D^\alpha u \frac{\partial P_\alpha^{i_2\dots i_{m+1}}}{\partial x_{i_1}} \\ &- \sum_{l=2}^{m+1} \sum_{k=1}^{n} \Gamma_{i_1 i_l}^k \sum_{0\le|\alpha|\le m} D^\alpha u \, P_\alpha^{i_2\dots i_{l-1} k i_{l+1}\dots i_{m+1}}.\end{aligned}$$

The first line contains derivatives of u of order at most $m+1$. In the second, the coefficients are polynomials in the Christoffel symbols and their derivatives up to order m, because we differentiate once a polynomial that, by hypothesis, contains derivatives only up to order $m-1$. In the third line, that polynomial is multiplied by a Christoffel symbol without increasing the maximum order of derivatives of its coefficients. Grouping the terms multiplying each $D^\beta u$, $|\beta| \le m+1$, gives the required polynomials $P_\beta^{i_1\dots i_{m+1}}$. This completes the induction. □

Since $(M, \mathcal{L}_M, \lambda_{\mathbf{g}})$ is a measure space and $\lambda_{\mathbf{g}}$ is a Radon measure, the results of measure theory apply directly and allow us to consider the Lebesgue spaces $L^p(M)$.

If $u \in C^\infty(M)$, Proposition 2.3.3 gives the following local coordinate expression for $|\nabla^k u|_{\mathbf{g}} := \sqrt{\mathbf{g}(\nabla^k u, \nabla^k u)}\colon M \longrightarrow [0,\infty)$:

$$|\nabla^k u|_{\mathbf{g}} = \sqrt{g^{i_1 j_1} \cdots g^{i_k j_k} (\nabla^k u)_{i_1\dots i_k} (\nabla^k u)_{j_1\dots j_k}}.$$

Moreover, this function is at least continuous, and hence measurable. We may consider

$$\int_M |\nabla^k u|_{\mathbf{g}}^p d\lambda_{\mathbf{g}}$$

for each $p \in [1,\infty)$. We can define

$$\|u\|_{W^{m,p}(M)} := \left(\sum_{j=0}^{m} \int_M |\nabla^j u|_{\mathbf{g}}^p d\lambda_{\mathbf{g}} \right)^{\frac{1}{p}}$$

and ask which $u \in C^\infty(M)$ satisfy $\|u\|_{W^{m,p}(M)} < \infty$. This motivates the following definition.

Definition 7.1.3. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary. For an integer $m \geq 0$ and $p \in [1,\infty)$, define

(a) $C^{m,p}(M) := \{u \in C^\infty(M) \mid \|u\|_{W^{m,p}(M)} < \infty\}$

(b) $W^{m,p}(M)$ as the completion of $C^{m,p}(M)$ under the norm $\|\cdot\|_{W^{m,p}(M)}$.

Remark 7.1.4. We have

$$C^{m,p}(M) = \{u \in C^\infty(M) \mid |\nabla^j u|_{\mathbf{g}} \in L^p(M) \text{ for every } j \in \{0,\dots,m\}\}.$$

To see that this definition is consistent, we shall prove that $\left(C^{m,p}(M), \|\cdot\|_{W^{m,p}(M)}\right)$ is a normed space.

Proposition 7.1.5. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $m \in \mathbb{N}_0$ and $1 \leq p < \infty$. Then $\left(C^{m,p}(M), \|\cdot\|_{W^{m,p}(M)}\right)$ is a normed space.

Proof. Let $u \in C^\infty(M)$ satisfy $\|u\|_{W^{m,p}(M)} = 0$. Since $0 \leq \|u\|_{L^p(M)} \leq \|u\|_{W^{m,p}(M)} = 0$, we have $\|u\|_{L^p(M)} = 0$, so $u = 0$ almost everywhere. Moreover, since u is continuous, we conclude that $u \equiv 0$ on M.

Now let $\lambda \in \mathbb{R}$. Then

$$\|\lambda u\|_{W^{m,p}(M)} := \left(\sum_{j=0}^{m} \int_M |\nabla^j(\lambda u)|_{\mathbf{g}}^p d\lambda_{\mathbf{g}} \right)^{\frac{1}{p}} = \left(\sum_{j=0}^{m} \int_M |\lambda \nabla^j(u)|_{\mathbf{g}}^p d\lambda_{\mathbf{g}} \right)^{\frac{1}{p}} = \left(\sum_{j=0}^{m} \int_M |\lambda|^p |\nabla^j u|_{\mathbf{g}}^p d\lambda_{\mathbf{g}} \right)^{\frac{1}{p}}$$

$$= |\lambda| \left(\sum_{j=0}^{m} \int_M |\nabla^j u|_{\mathbf{g}}^p d\lambda_{\mathbf{g}} \right)^{\frac{1}{p}} = |\lambda| \|u\|_{W^{m,p}(M)},$$

where we used $|\lambda \nabla^j u|_{\mathbf{g}} = \sqrt{\mathbf{g}(\lambda \nabla^j u, \lambda \nabla^j u)} = \sqrt{\lambda^2 \mathbf{g}(\nabla^j u, \nabla^j u)} = |\lambda| \sqrt{\mathbf{g}(\nabla^j u, \nabla^j u)} = |\lambda| |\nabla^j u|_{\mathbf{g}}$ for each $j \in \{0,\dots,m\}$.

Let $u, v \in C^{m,p}(M)$. For $w \in C^{m,p}(M)$, define on the measure space

$$X_m := M \times \{0,\dots,m\}, \qquad \mu_m := \lambda_{\mathbf{g}} \otimes \#,$$

the function $A_w(x,j) := |\nabla^j w(x)|_{\mathbf{g}}$, where # is counting measure. Then

$$\|A_w\|_{L^p(X_m,\mu_m)} = \left(\sum_{j=0}^{m} \int_M |\nabla^j w|_{\mathbf{g}}^p \, d\lambda_{\mathbf{g}} \right)^{\frac{1}{p}} = \|w\|_{W^{m,p}(M)}.$$

Since $|\nabla^j(u+v)|_{\mathbf{g}} \le |\nabla^j u|_{\mathbf{g}} + |\nabla^j v|_{\mathbf{g}}$, we have $A_{u+v} \le A_u + A_v$. Monotonicity of the norm and Minkowski's inequality in $L^p(X_m,\mu_m)$, given in Theorem B.7.3, yield

$$\|u+v\|_{W^{m,p}(M)} \le \|A_u + A_v\|_{L^p(X_m,\mu_m)} \le \|u\|_{W^{m,p}(M)} + \|v\|_{W^{m,p}(M)}.$$

In particular, $C^{m,p}(M)$ is closed under addition and multiplication by scalars in $C^\infty(M)$; thus it is a vector space, and $\|\cdot\|_{W^{m,p}(M)}$ is a norm. □

We shall also define the analogue of $W_0^{m,p}(\Omega)$.

Definition 7.1.6. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $m \in \mathbb{N}_0$ and $1 \le p < \infty$. Define

$$W_0^{m,p}(M) := \overline{C_c^\infty(\operatorname{Int} M)}^{W^{m,p}(M)}.$$

Functions in $C_c^\infty(\operatorname{Int} M)$ are viewed as smooth functions on M by extension by zero; this is legitimate because their supports are compactly contained in the interior.

The sum norm defined below is often used in the literature; see, for example, [79] and [1]. The following proposition quantifies its comparison with the norm adopted in this book.

Proposition 7.1.7. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $m \in \mathbb{N}_0$ and $1 \le p < \infty$. For each $u \in C^{m,p}(M)$, define

$$\|u\|_{\widetilde{W}^{m,p}(M)} := \sum_{j=0}^{m} \left(\int_M |\nabla^j u|_{\mathbf{g}}^p \, d\lambda_{\mathbf{g}} \right)^{\frac{1}{p}}.$$

Then, for every $u \in C^{m,p}(M)$,

$$\|u\|_{W^{m,p}(M)} \le \|u\|_{\widetilde{W}^{m,p}(M)} \le (m+1)^{1-\frac{1}{p}} \|u\|_{W^{m,p}(M)}.$$

Proof. Set $x_j := \left(\int_M |\nabla^j u|_{\mathbf{g}}^p \, d\lambda_{\mathbf{g}} \right)^{\frac{1}{p}}$. The inequalities $\|x\|_{\ell^p} \le \|x\|_{\ell^1} \le (m+1)^{1-\frac{1}{p}} \|x\|_{\ell^p}$, obtained by Hölder's inequality on $\mathbb{R}^{m+1}$, are exactly the two asserted inequalities. □

Compact Riemannian manifolds play a particularly important role in the study of Sobolev spaces, since they allow generalizations of the results previously established in Euclidean spaces. If M is closed, then $\operatorname{Int} M = M$ and $C_c^\infty(M) = C^\infty(M)$; consequently, $W_0^{m,p}(M) = W^{m,p}(M)$, and $C^\infty(M)$ is dense in this space. When M has boundary, the relationship between $W_0^{m,p}(M)$ and the trace will be studied in Section 9.4, in the more general setting of sections of vector bundles.

At times, a smooth manifold M may carry two Riemannian metrics, say $\mathbf{g}$ and $\widetilde{\mathbf{g}}$, making it necessary to

distinguish the metric used in the Sobolev norm. In this case, we write $\|u\|_{W^{m,p}(M),\mathbf{g}}$ for the norm associated with $\mathbf{g}$ and $\|u\|_{W^{m,p}(M),\widetilde{\mathbf{g}}}$ for the norm associated with $\widetilde{\mathbf{g}}$.

In the compact case, other useful properties also hold; for example, the Sobolev spaces do not depend on the Riemannian metric. To prove this, we first establish the following results.

Lemma 7.1.8. Let $k,l \in \mathbb{N}_0$ and let M be a compact smooth manifold with or without boundary equipped with two Riemannian metrics $\mathbf{g}$ and $\widetilde{\mathbf{g}}$. Then there exist $c_{k,l}, C_{k,l} > 0$ such that for every $p \in M$ and $v \in T^{(k,l)}(T_pM)$,

$$c_{k,l}|v|_{\mathbf{g}}^2 \le |v|_{\widetilde{\mathbf{g}}}^2 \le C_{k,l}|v|_{\mathbf{g}}^2.$$

Here the norms are those induced on the tensor bundle. In the proof, we shall also write $\mathbf{g}_p(v,v)$ and $\widetilde{\mathbf{g}}_p(v,v)$ for the induced inner products evaluated at (v,v). For $(k,l) = (1,0)$, these are the original metrics on T_pM, and the conclusion is precisely the comparison in Definition 2.1.5.

Proof. Let d be the rank of $T^{(k,l)}(TM)$. If $M = \varnothing$ or $d = 0$, the assertion is immediate. By Proposition 1.2.11, Remark 1.2.10, and compactness of M, there are charts (U_i, φ_i) and compact regular coordinate balls and, if M has boundary, compact regular coordinate half-balls

$$\overline{B}_1, \dots, \overline{B}_N$$

covering M and satisfying $\overline{B}_i \subseteq U_i$. For each i, let

$$\Phi_i \colon T^{(k,l)}(TM) \restriction_{U_i} \longrightarrow U_i \times \mathbb{R}^d$$

be the trivialization induced by the tensor frame of the chart containing $\overline{B}_i$. If $p \in \overline{B}_i$ and $w \in \mathbb{R}^d$, set

$$Q_i(p,w) := \mathbf{g}_p\big(\Phi_i^{-1}(p,w), \Phi_i^{-1}(p,w)\big),$$
$$\widetilde{Q}_i(p,w) := \widetilde{\mathbf{g}}_p\big(\Phi_i^{-1}(p,w), \Phi_i^{-1}(p,w)\big).$$

Both functions are continuous and, for each p, are positive definite quadratic forms in w. Thus,

$$R_i(p,w) := \frac{\widetilde{Q}_i(p,w)}{Q_i(p,w)}$$

is continuous and strictly positive on

$$\overline{B}_i \times S^{d-1}, \qquad S^{d-1} := \{w \in \mathbb{R}^d \mid \|w\|_2 = 1\}.$$

This set is compact, so there exist

$$c_i := \min_{(p,w)\in \overline{B}_i \times S^{d-1}} R_i(p,w) > 0, \qquad C_i := \max_{(p,w)\in \overline{B}_i \times S^{d-1}} R_i(p,w) < \infty.$$

Homogeneity of the two quadratic forms implies

$$c_i Q_i(p,w) \le \widetilde{Q}_i(p,w) \le C_i Q_i(p,w)$$

for every $p \in \overline{B}_i$ and every $w \in \mathbb{R}^d$. Taking

$$c_{k,l} := \min_{1 \le i \le N} c_i > 0, \qquad C_{k,l} := \max_{1 \le i \le N} C_i < \infty,$$

and writing w for the components of $v \in T^{(k,l)}(T_pM)$ in a chart containing p gives the stated inequality. □

The preceding argument uses only continuity and positivity of the inner products on compact subsets of trivializations. It therefore also applies on any compact set $K \subseteq M$, with continuous metrics defined on a neighborhood of K: simply cover K by finitely many of the balls or half-balls used in the proof. The constants may depend on K and on the metrics. The next proposition specifies the bounds obtained when comparison constants on the tangent bundle are already known.

Proposition 7.1.9. (Comparison of dual norms, tensor norms, and volumes) Let $\mathbf{g}$ and $\widetilde{\mathbf{g}}$ be two Riemannian metrics on a manifold M of dimension n, and let $A \subseteq M$. Suppose that $0 < c \le C < \infty$ and

$$c\,\mathbf{g}_p(v,v) \le \widetilde{\mathbf{g}}_p(v,v) \le C\,\mathbf{g}_p(v,v) \qquad (p \in A,\ v \in T_pM).$$

Then the dual metrics satisfy

$$C^{-1}\mathbf{g}_p^{-1}(\xi,\xi) \le \widetilde{\mathbf{g}}_p^{-1}(\xi,\xi) \le c^{-1}\mathbf{g}_p^{-1}(\xi,\xi) \qquad (\xi \in T_p^*M,\ p \in A). \tag{7.1}$$

Moreover, for $k,l \in \mathbb{N}_0$ and $\mathbf{T} \in T^{(k,l)}(T_pM)$,

$$c^{k/2}C^{-l/2}|\mathbf{T}|_{\mathbf{g}} \le |\mathbf{T}|_{\widetilde{\mathbf{g}}} \le C^{k/2}c^{-l/2}|\mathbf{T}|_{\mathbf{g}}. \tag{7.2}$$

In particular, a comparison $K^{-1}\mathbf{g} \le \widetilde{\mathbf{g}} \le K\mathbf{g}$, with $K \ge 1$, gives the constants $K^{-(k+l)/2}$ and $K^{(k+l)/2}$ for the norms of tensors of type (k,l).
The ratio of the volume elements is the positive function

$$\rho(p) = \frac{\sqrt{\det(\widetilde{\mathbf{g}}_p)}}{\sqrt{\det(\mathbf{g}_p)}},$$

where both determinants are computed in the same chart. This function is independent of the chart, satisfies $d\lambda_{\widetilde{\mathbf{g}}} = \rho\, d\lambda_{\mathbf{g}}$, and obeys

$$c^{n/2} \le \rho(p) \le C^{n/2} \qquad (p \in A). \tag{7.3}$$

Consequently, if A is measurable and $f : A \to [0,\infty]$ is measurable, then

$$c^{n/2}\int_A f\, d\lambda_{\mathbf{g}} \le \int_A f\, d\lambda_{\widetilde{\mathbf{g}}} \le C^{n/2}\int_A f\, d\lambda_{\mathbf{g}}.$$

Proof. Fix $p \in A$. There is a unique endomorphism $L_p : T_pM \to T_pM$ such that

$$\widetilde{\mathbf{g}}_p(v,w) = \mathbf{g}_p(L_pv, w) \qquad (v,w \in T_pM).$$

It is obtained by applying the inverse of the isomorphism $w \mapsto \mathbf{g}_p(w,\cdot)$ to the covector $\widetilde{\mathbf{g}}_p(v,\cdot)$. Symmetry of

$\widetilde{\mathbf{g}}_p$ implies that L_p is self-adjoint with respect to $\mathbf{g}_p$, and its positivity implies $\mathbf{g}_p(L_p v, v) > 0$ when $v \neq 0$. The spectral theorem provides a basis $e_1, \dots, e_n$ orthonormal for $\mathbf{g}_p$ and numbers $\lambda_1, \dots, \lambda_n > 0$ such that

$$L_p e_i = \lambda_i e_i, \qquad \mathbf{g}_p(e_i, e_j) = \delta_{ij}, \qquad \widetilde{\mathbf{g}}_p(e_i, e_j) = \lambda_i \delta_{ij}.$$

Applying the hypothesis to $v = e_i$ gives $c \le \lambda_i \le C$ for every i. This basis is chosen in the fixed fiber T_pM; the chosen bases need not vary smoothly with p.

Let $e^1, \dots, e^n$ be the dual basis. The matrices of the dual metrics are the inverses of the matrices of the tangent metrics. Thus, for $\xi = \sum_{i=1}^{n} \xi_i e^i$,

$$\mathbf{g}_p^{-1}(\xi, \xi) = \sum_{i=1}^{n} \xi_i^2, \qquad \widetilde{\mathbf{g}}_p^{-1}(\xi, \xi) = \sum_{i=1}^{n} \lambda_i^{-1} \xi_i^2.$$

Multiplying the inequalities $C^{-1} \le \lambda_i^{-1} \le c^{-1}$ by ξ_i^2 and summing proves (7.1). This explains why the lower and upper constants exchange roles when comparing dual metrics.

Now consider the basis tensors

$$E_{I,J} := e_{i_1} \otimes \cdots \otimes e_{i_k} \otimes e^{j_1} \otimes \cdots \otimes e^{j_l},$$

where $I = (i_1, \dots, i_k)$ and $J = (j_1, \dots, j_l)$ range over the indices from 1 to n. They are orthogonal for both tensor inner products, and

$$|E_{I,J}|_{\mathbf{g}}^2 = 1, \qquad |E_{I,J}|_{\widetilde{\mathbf{g}}}^2 = \lambda_{i_1} \cdots \lambda_{i_k} \lambda_{j_1}^{-1} \cdots \lambda_{j_l}^{-1}.$$

An empty product is interpreted as 1. Each weight in the last expression lies between $c^k C^{-l}$ and $C^k c^{-l}$. If $\mathbf{T} = \sum_{\substack{I \in \{1,\dots,n\}^k \\ J \in \{1,\dots,n\}^l}} T_J^I E_{I,J}$, orthogonality gives

$$|\mathbf{T}|_{\mathbf{g}}^2 = \sum_{\substack{I \in \{1,\dots,n\}^k \\ J \in \{1,\dots,n\}^l}} |T_J^I|^2, \qquad |\mathbf{T}|_{\widetilde{\mathbf{g}}}^2 = \sum_{\substack{I \in \{1,\dots,n\}^k \\ J \in \{1,\dots,n\}^l}} |T_J^I|^2 \lambda_{i_1} \cdots \lambda_{i_k} \lambda_{j_1}^{-1} \cdots \lambda_{j_l}^{-1}.$$

Multiplying the bounds for each weight by $|T_J^I|^2$ and summing yields

$$c^k C^{-l} |\mathbf{T}|_{\mathbf{g}}^2 \le |\mathbf{T}|_{\widetilde{\mathbf{g}}}^2 \le C^k c^{-l} |\mathbf{T}|_{\mathbf{g}}^2.$$

Taking square roots proves (7.2).

In the basis $e_1, \dots, e_n$, the ratio of determinants is $\lambda_1 \cdots \lambda_n$. A simultaneous change of basis multiplies both determinants by the same square of the determinant of the change-of-basis matrix, leaving their ratio unchanged. In particular,

$$\frac{\det(\widetilde{\mathbf{g}}_p)}{\det(\mathbf{g}_p)} = \prod_{i=1}^{n} \lambda_i, \qquad c^n \le \prod_{i=1}^{n} \lambda_i \le C^n.$$

The coordinate formula for Riemannian measure implies $d\lambda_{\widetilde{\mathbf{g}}} = \rho \, d\lambda_{\mathbf{g}}$, and the square roots of the last bounds prove (7.3). Finally,

$$\int_A f \, d\lambda_{\widetilde{\mathbf{g}}} = \int_A f \rho \, d\lambda_{\mathbf{g}}.$$

Multiply (7.3) by $f \geq 0$ and use monotonicity of the integral. The argument also holds when one of the integrals is infinite. □

This proposition compares two norms of the same tensor. In studying Sobolev norms, we must also compare the tensors $\nabla^j u$ and $\widetilde{\nabla}^j u$ when the connection changes. For functions, $\nabla u = \widetilde{\nabla} u = du$; from order two onward, covariant derivatives may differ. The following lemma compares the full collections of derivatives up to order m, including their lower-order terms.

Lemma 7.1.10. Let $m \geq 0$ and let M be a compact smooth manifold with or without boundary, with two Riemannian metrics $\mathbf{g}$ and $\widetilde{\mathbf{g}}$, and let ∇ and $\widetilde{\nabla}$ be two connections on TM. Then there exist $c_m, C_m > 0$ such that

$$c_m \left(\sum_{j=0}^{m} |\nabla^j u|^2_{\mathbf{g}} \right) \leq \sum_{j=0}^{m} |\widetilde{\nabla}^j u|^2_{\widetilde{\mathbf{g}}} \leq C_m \left(\sum_{j=0}^{m} |\nabla^j u|^2_{\mathbf{g}} \right)$$

for every $u \in C^\infty(M)$.

Proof. If $M = \varnothing$, the assertion is immediate. Assume $M \neq \varnothing$. By Definition 1.7.10, we may consider the bundle

$$\mathscr{T}_m := \bigoplus_{j=0}^{m} T^{(0,j)}(TM), \qquad T^{(0,0)}(TM) := M \times \mathbb{R}.$$

For $u \in C^\infty(M)$, write

$$J^m_\nabla u := (u, \nabla u, \dots, \nabla^m u)$$

and, for each $p \in M$, define

$$\mathscr{D}_{\nabla,p} := \{ J^m_\nabla u(p) \mid u \in C^\infty(M) \} \subseteq (\mathscr{T}_m)_p.$$

Linearity of ∇^j implies that $\mathscr{D}_{\nabla,p}$ is a vector subspace of $(\mathscr{T}_m)_p$.
Let (U, φ) be a smooth chart, let $p \in U$, and set $x := \varphi(p)$ and

$$N := \sum_{j=0}^{m} \binom{n+j-1}{j} = \binom{n+m}{m}.$$

With the multi-index notation from Definition 1.1.10, define the linear map

$$F^\varphi_{\nabla,p} \colon \mathscr{D}_{\nabla,p} \longrightarrow \mathbb{R}^N, \qquad F^\varphi_{\nabla,p}(J^m_\nabla u(p)) := \big(D^\alpha (u \circ \varphi^{-1})(x) \big)_{|\alpha| \leq m}.$$

Propositions 7.1.1 and 7.1.2 give, for $j \in \{1, \dots, m\}$,

$$(\nabla^j u)_{i_1 \dots i_j} = \partial_{i_1} \cdots \partial_{i_j} (u \circ \varphi^{-1}) + \sum_{|\alpha| < j} A^\alpha_{i_1 \dots i_j} D^\alpha (u \circ \varphi^{-1}), \tag{7.4}$$

where the coefficients $A^\alpha_{i_1 \dots i_j}$ are smooth on U. By induction on j, the equality $J^m_\nabla u(p) = J^m_\nabla v(p)$ determines first $u(p) = v(p)$ and then all partial derivatives of $u \circ \varphi^{-1}$ and $v \circ \varphi^{-1}$ up to order m. Thus $F^\varphi_{\nabla,p}$ is well defined and injective.

Let $a = (a_\alpha)_{|\alpha|\le m} \in \mathbb{R}^N$. The polynomial

$$P_a(y) := \sum_{|\alpha|\le m} \frac{a_\alpha}{\alpha!}(y-x)^\alpha$$

satisfies $D^\alpha P_a(x) = a_\alpha$ for every $|\alpha| \le m$. Theorem 1.3.7, applied to $P_a \circ \varphi$, provides a function $u \in C^\infty(M)$ agreeing with $P_a \circ \varphi$ on a neighborhood of p. Then $F^\varphi_{\nabla,p}(J^m_\nabla u(p)) = a$, and $F^\varphi_{\nabla,p}$ is an isomorphism.
Let $(e_1,\dots,e_N)$ be the standard basis of $\mathbb{R}^N$. Substituting each e_ν as the prescribed partial jet in (7.4) shows that the components of

$$\sigma_\nu(q) := (F^\varphi_{\nabla,q})^{-1}(e_\nu), \qquad q \in U, \quad \nu \in \{1,\dots,N\},$$

in the coordinate tensor frames are smooth functions. Moreover, $\sigma_1(q),\dots,\sigma_N(q)$ form a basis of $\mathscr{D}_{\nabla,q}$ for each $q \in U$. Lemma 1.7.52 implies that

$$\mathscr{D}_\nabla := \bigcup_{p\in M} \mathscr{D}_{\nabla,p}$$

is a smooth vector subbundle of $\mathscr{T}_m$ of rank N. The same construction applied to $\widetilde{\nabla}$ produces the subbundle $\mathscr{D}_{\widetilde{\nabla}}$ and the isomorphisms $F^\varphi_{\widetilde{\nabla},p} : \mathscr{D}_{\widetilde{\nabla},p} \longrightarrow \mathbb{R}^N$.
Let $(\overline{B},\varphi)$ be a compact regular coordinate ball or half-ball whose coordinate map is the restriction of the preceding chart. For $p \in \overline{B}$ and $v \in \mathbb{R}^N$, define

$$Q(p,v) := \sum_{j=0}^m \left| \left((F^\varphi_{\nabla,p})^{-1}(v)\right)_j \right|^2_{\mathbf{g}},$$

$$\widetilde{Q}(p,v) := \sum_{j=0}^m \left| \left((F^\varphi_{\widetilde{\nabla},p})^{-1}(v)\right)_j \right|^2_{\widetilde{\mathbf{g}}}.$$

The families $\sigma_1,\dots,\sigma_N$ constructed above and their analogues for $\widetilde{\nabla}$ show that Q and $\widetilde{Q}$ are continuous on $\overline{B}\times\mathbb{R}^N$. For each p, both are positive definite quadratic forms in v. Thus the ratio

$$R(p,v) := \frac{\widetilde{Q}(p,v)}{Q(p,v)}$$

is continuous and strictly positive on $\overline{B}\times S^{N-1}$, where $S^{N-1} := \{v \in \mathbb{R}^N \mid \|v\|_2 = 1\}$. Compactness of $\overline{B}\times S^{N-1}$ provides numbers

$$c_{\overline{B},m} := \min_{(p,v)\in\overline{B}\times S^{N-1}} R(p,v) > 0, \qquad C_{\overline{B},m} := \max_{(p,v)\in\overline{B}\times S^{N-1}} R(p,v) < \infty.$$

Since Q and $\widetilde{Q}$ are homogeneous of degree two in v, it follows that

$$c_{\overline{B},m} Q(p,v) \le \widetilde{Q}(p,v) \le C_{\overline{B},m} Q(p,v) \tag{7.5}$$

for every $p \in \overline{B}$ and every $v \in \mathbb{R}^N$; for $v \neq 0$, apply the definitions of $c_{\overline{B},m}$ and $C_{\overline{B},m}$ to $v/\|v\|_2$, and for $v = 0$ the inequality is immediate.

For $p \in \overline{B}$ and $u \in C^\infty(M)$, the definition of the two isomorphisms gives

$$F^{\varphi}_{\nabla,p}(J^m_\nabla u(p)) = \left(D^\alpha(u\circ\varphi^{-1})(\varphi(p))\right)_{|\alpha|\le m} = F^{\varphi}_{\widetilde{\nabla},p}(J^m_{\widetilde{\nabla}} u(p)).$$

Substituting this vector into (7.5) yields

$$c_{\overline{B},m}\sum_{j=0}^m |\nabla^j u(p)|^2_{\mathbf{g}} \le \sum_{j=0}^m |\widetilde{\nabla}^j u(p)|^2_{\widetilde{\mathbf{g}}} \le C_{\overline{B},m}\sum_{j=0}^m |\nabla^j u(p)|^2_{\mathbf{g}}.$$

Compactness of M allows us to choose a finite cover $\overline{B}_1,\dots,\overline{B}_k$ by compact regular coordinate balls or half-balls. Taking

$$c_m := \min_{1\le i\le k} c_{\overline{B}_i,m} > 0, \qquad C_m := \max_{1\le i\le k} C_{\overline{B}_i,m} < \infty,$$

gives the two-sided inequality on all of M. □

We would also like a way to relate integrals with respect to two metrics when M is compact; this can be obtained using Lemma 7.1.8.

Lemma 7.1.11. Let M be a compact smooth manifold with or without boundary equipped with two Riemannian metrics $\mathbf{g}$ and $\widetilde{\mathbf{g}}$. Then there exist $C, c > 0$ such that for every measurable $f : M \longrightarrow [0,\infty]$,

$$c\int_M f\, d\lambda_{\mathbf{g}} \le \int_M f\, d\lambda_{\widetilde{\mathbf{g}}} \le C\int_M f\, d\lambda_{\mathbf{g}}.$$

Proof. Consider a finite family $(\overline{B}_i,\varphi_i)_{i=1}^k$ of compact regular coordinate balls and, where appropriate, half-balls whose relative interiors cover M (this is possible because M is compact). We have $\sqrt{\det(\mathbf{g})}, \sqrt{\det(\widetilde{\mathbf{g}})} > 0$ on $\overline{B}_i$ for every $i \in \{1,\dots,k\}$, since the matrices of both metrics are symmetric and positive definite. We may therefore define $h_i : \overline{B}_i \longrightarrow [0,\infty)$, $h_i(p) = \dfrac{\sqrt{\det(\widetilde{\mathbf{g}}_p)}}{\sqrt{\det(\mathbf{g}_p)}}$. Note that $h_i > 0$. Since $\overline{B}_i$ is compact, there exist $c_i = \min\limits_{p\in\overline{B}_i} h_i(p)$ and $C_i = \max\limits_{p\in\overline{B}_i} h_i(p)$, both positive. Then $c_i\sqrt{\det(\mathbf{g})} \le \sqrt{\det(\widetilde{\mathbf{g}})} \le C_i\sqrt{\det(\mathbf{g})}$ on $\overline{B}_i$. Let $(A_i)_{i=1}^k$ be a family of pairwise disjoint measurable sets as in Definition 2.15.5 for $A = M$. We have $M = \coprod_{i=1}^k A_i$. Let $c := \min\limits_{1\le i\le k} c_i$ and $C := \max\limits_{1\le i\le k} C_i$. We have $f = \sum_{i=1}^k f\mathbf{1}_{A_i}$. Moreover,

$$c_i\int_{A_i} f\, d\lambda_{\mathbf{g}} = c_i\int_{\varphi_i(A_i)} (f\circ\varphi_i^{-1})\sqrt{\det(\mathbf{g})\circ\varphi_i^{-1}}\, d\lambda_n$$

$$\le \int_{\varphi_i(A_i)} (f\circ\varphi_i^{-1})\sqrt{\det(\widetilde{\mathbf{g}})\circ\varphi_i^{-1}}\, d\lambda_n = \int_{A_i} f\, d\lambda_{\widetilde{\mathbf{g}}}.$$

Similarly,

$$\int_{A_i} f\, d\lambda_{\widetilde{\mathbf{g}}} \le C_i\int_{A_i} f\, d\lambda_{\mathbf{g}}.$$

Therefore,

$$c_i \int_M f \mathbf{1}_{A_i} d\lambda_{\mathbf{g}} \le \int_M f \mathbf{1}_{A_i} d\lambda_{\widetilde{\mathbf{g}}} \le C_i \int_M f \mathbf{1}_{A_i} d\lambda_{\mathbf{g}}.$$

Hence

$$c \int_M f \, d\lambda_{\mathbf{g}} = c \sum_{i=1}^{k} \int_M f \mathbf{1}_{A_i} d\lambda_{\mathbf{g}} \le \sum_{i=1}^{k} c_i \int_M f \mathbf{1}_{A_i} d\lambda_{\mathbf{g}} \le \sum_{i=1}^{k} \int_M f \mathbf{1}_{A_i} d\lambda_{\widetilde{\mathbf{g}}} = \int_M f \, d\lambda_{\widetilde{\mathbf{g}}}.$$

Similarly,

$$\int_M f \, d\lambda_{\widetilde{\mathbf{g}}} \le C \int_M f \, d\lambda_{\mathbf{g}}.$$

□

Remark 7.1.12. If $u, v, w \colon M \longrightarrow [0, \infty]$ are measurable and satisfy $u \le v \le w$, then Lemma 7.1.11 gives

$$c \int_M u \, d\lambda_{\mathbf{g}} \le \int_M u \, d\lambda_{\widetilde{\mathbf{g}}} \le \int_M v \, d\lambda_{\widetilde{\mathbf{g}}} \le \int_M w \, d\lambda_{\widetilde{\mathbf{g}}} \le C \int_M w \, d\lambda_{\mathbf{g}},$$

; that is,

$$c \int_M u \, d\lambda_{\mathbf{g}} \le \int_M v \, d\lambda_{\widetilde{\mathbf{g}}} \le C \int_M w \, d\lambda_{\mathbf{g}}.$$

Theorem 7.1.13. Let M be a compact smooth manifold with or without boundary, let $m \in \mathbb{N}_0$, and let $1 \le p < \infty$. If $\mathbf{g}$ and $\widetilde{\mathbf{g}}$ are two Riemannian metrics on M, then the norms $\|\cdot\|_{W^{m,p}(M),\mathbf{g}}$ and $\|\cdot\|_{W^{m,p}(M),\widetilde{\mathbf{g}}}$ are equivalent. In particular, the two completions canonically define the same space $W^{m,p}(M)$.

Proof. Let ∇ and $\widetilde{\nabla}$ be the Levi–Civita connections of $\mathbf{g}$ and $\widetilde{\mathbf{g}}$, respectively. For $u \in C^\infty(M)$ and $q \in M$, set

$$x(q) := \big(|u(q)|, |\nabla u(q)|_{\mathbf{g}}, \dots, |\nabla^m u(q)|_{\mathbf{g}}\big),$$

$$y(q) := \big(|u(q)|, |\widetilde{\nabla} u(q)|_{\widetilde{\mathbf{g}}}, \dots, |\widetilde{\nabla}^m u(q)|_{\widetilde{\mathbf{g}}}\big).$$

By Lemma 7.1.10, there exist $c_m, C_m > 0$ such that

$$\sqrt{c_m}\,\|x(q)\|_2 \le \|y(q)\|_2 \le \sqrt{C_m}\,\|x(q)\|_2 \qquad (q \in M).$$

Since all norms on $\mathbb{R}^{m+1}$ are equivalent, there exist $a_{m,p}, b_{m,p} > 0$ such that

$$a_{m,p}\|z\|_p \le \|z\|_2 \le b_{m,p}\|z\|_p \qquad (z \in \mathbb{R}^{m+1}).$$

Applying these two inequalities first to $x(q)$ and then to $y(q)$ yields, pointwise,

$$\frac{a_{m,p}\sqrt{c_m}}{b_{m,p}}\|x(q)\|_p \le \|y(q)\|_p \le \frac{b_{m,p}\sqrt{C_m}}{a_{m,p}}\|x(q)\|_p.$$

Raise this to the power p. Lemma 7.1.11, applied to the two Riemannian measures, allows us to integrate the outer expressions and gives constants $A, B > 0$, independent of u, for which

$$A\|u\|_{W^{m,p}(M),\mathbf{g}} \le \|u\|_{W^{m,p}(M),\widetilde{\mathbf{g}}} \le B\|u\|_{W^{m,p}(M),\mathbf{g}}.$$

Thus, the identity on $C^\infty(M)$ is bicontinuous for the two norms. By the universal property of completion, it extends uniquely to a bicontinuous isomorphism between the two completions, identifying each smooth function with itself. □

Example 7.1.14. (Dependence of the constants on derivatives of the metric) Comparison of metrics at order zero does not suffice to control the equivalence constants of all Sobolev norms. Consider the compact manifold with boundary $M = [0, 2\pi]$, with $\mathbf{g}_0 = (\mathbf{d}x)^2$, and, for each integer $N \geq 1$, the metric

$$\mathbf{g}_N = e^{2\sin(Nx)}(\mathbf{d}x)^2.$$

For every $x \in M$ and every $v \in T_xM$,

$$e^{-2}\mathbf{g}_0(v,v) \leq \mathbf{g}_N(v,v) \leq e^2\mathbf{g}_0(v,v).$$

The constants are independent of N. However, the only coefficient of the Levi–Civita connection of $\mathbf{g}_N$ is

$$\Gamma^1_{11}(\mathbf{g}_N) = \frac{1}{2}e^{-2\sin(Nx)}\frac{d}{dx}\left(e^{2\sin(Nx)}\right) = N\cos(Nx).$$

For the fixed smooth function $u(x) = x$, we have $u' = 1$, $u'' = 0$, and, by the coordinate formula for the Hessian,

$$(\nabla^{\mathbf{g}_N})^2 u = \left(u'' - \Gamma^1_{11}(\mathbf{g}_N)u'\right)(\mathbf{d}x)^2 = -N\cos(Nx)(\mathbf{d}x)^2.$$

Since $|(\mathbf{d}x)^2|^2_{\mathbf{g}_N} = e^{-4\sin(Nx)}$ and $d\lambda_{\mathbf{g}_N} = e^{\sin(Nx)}\,dx$, we obtain

$$\begin{aligned}\|(\nabla^{\mathbf{g}_N})^2 u\|^2_{L^2(M,\mathbf{g}_N)} &= N^2\int_0^{2\pi}\cos^2(Nx)e^{-3\sin(Nx)}\,dx \\ &\geq e^{-3}N^2\int_0^{2\pi}\cos^2(Nx)\,dx = \pi e^{-3}N^2.\end{aligned}$$

Therefore, $\|u\|_{W^{2,2}(M),\mathbf{g}_N}$ tends to infinity, while $\|u\|_{W^{2,2}(M),\mathbf{g}_0}$ remains fixed. Theorem 7.1.13 does give equivalence for each fixed pair $(\mathbf{g}_0, \mathbf{g}_N)$. What this example rules out is a common constant deduced solely from the bounds e^{-2} and e^2. The additional control of the connections and their derivatives appears in Lemma 7.1.10.

Remark 7.1.15. (Comparison on compact coordinate subsets) The comparisons used in the preceding proof are pointwise on the compact coordinate subsets: they are obtained by bounding the ratio of two positive quadratic forms on a compact sphere and the ratio of the volume elements. They therefore also hold on a coordinate ball or half-ball U whose closure is contained in an ambient chart, for smooth metrics and connections defined on that chart. It suffices to apply the bounds on $\overline{U}$ and integrate over U; $\overline{U}$ need not be a smooth manifold with boundary. This matters for half-balls, whose closures have a corner where the flat and spherical portions meet. In the following formulas, norms of smooth functions on $\overline{U}$ denote these same integrals: the coordinate boundary has zero n-dimensional measure.

7.2 Kato's inequality

We shall prove Rademacher's theorem on Riemannian manifolds in order to establish an important inequality known as *Kato's inequality* for sections of vector bundles. It will be useful in proving the Sobolev embeddings in the next section.

Recall Rademacher's theorem in Euclidean spaces.

Theorem 7.2.1. (Rademacher in Euclidean spaces) Let $U \subseteq \mathbb{R}^n$ be open and let $f\colon U \longrightarrow \mathbb{R}^m$ be a Lipschitz function. Then f is differentiable almost everywhere on U.

This theorem is proved in [80] and allows us to prove a version of Kato's inequality. We shall establish its counterpart on Riemannian manifolds to develop nonlinear analysis on Riemannian manifolds further.

Theorem 7.2.2. (Rademacher on Riemannian manifolds) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary and let $u\colon M \longrightarrow \mathbb{R}$ be a Lipschitz function. Then the first covariant derivative ∇u exists almost everywhere on M.

Proof. By Proposition 1.2.11, M has a countable basis of regular coordinate balls (and if M has boundary, some are regular coordinate half-balls). By the definition of regular coordinate balls (or half-balls), we may assume that there is a countable atlas $\{(B_j, \varphi_j) \mid j \in \mathbb{N}\}$ of regular coordinate balls (or half-balls) such that $\{(\overline{B}_j, \varphi_j) \mid j \in \mathbb{N}\}$ is a family of compact regular coordinate balls (or half-balls), and $M = \bigcup\limits_{j\in\mathbb{N}} B_j = \bigcup\limits_{j\in\mathbb{N}} \overline{B}_j$. Each $\overline{B}_j$ is a compact subset contained in an ambient chart; it need not be viewed as a smooth submanifold with boundary. For each $j \in \mathbb{N}$, let $C_j = \varphi_j(\overline{B}_j)$.

The set B_j admits two Riemannian metrics, $\mathbf{g}$ and $\boldsymbol{\delta} := \varphi_j^*\overline{\mathbf{g}}$, where $\overline{\mathbf{g}}$ denotes the usual metric on $\mathbb{R}^n$. By the pointwise comparison of Lemma 7.1.8 on the compact set $\overline{B}_j$, in the sense of Remark 7.1.15, there is $K_j > 0$ such that for any $p \in B_j$ and $v \in T_pM$, $\mathbf{g}_p(v,v) \leq K_j \boldsymbol{\delta}_p(v,v)$.

We shall prove that $h_j := u \circ \varphi_j^{-1}\colon C_j \longrightarrow \mathbb{R}$ is Lipschitz. Since u is Lipschitz, there is $K > 0$ such that $|u(p) - u(q)| \leq K d_{\mathbf{g}}(p,q)$ for any $p, q \in M$. Let $x = \varphi_j(p), y = \varphi_j(q) \in C_j$. Since C_j is a closed ball (or closed half-ball) in $\mathbb{R}^n$, it is convex, and hence the segment joining x to y remains in C_j. Let $\gamma\colon [0,1] \longrightarrow C_j$ be given by $\gamma(t) = (1-t)x + ty$. Then γ is a smooth curve with $\gamma(0) = x$ and $\gamma(1) = y$. Thus $\widetilde{\gamma}_j := \varphi_j^{-1} \circ \gamma\colon [0,1] \longrightarrow \overline{B}_j$ is a smooth curve with $\widetilde{\gamma}_j(0) = p$ and $\widetilde{\gamma}_j(1) = q$.

We therefore have

$$
\begin{aligned}
|h_j(x) - h_j(y)| = |u(\varphi_j^{-1}(x)) - u(\varphi_j^{-1}(y))| &\leq K d_{\mathbf{g}}(p,q) \leq K L_{\mathbf{g}}(\widetilde{\gamma}_j) \\
&= K \int_0^1 |\widetilde{\gamma}_j'(t)|_{\mathbf{g}} dt = K \int_0^1 \sqrt{\mathbf{g}_{\widetilde{\gamma}_j(t)}(\widetilde{\gamma}_j'(t), \widetilde{\gamma}_j'(t))} dt \\
&\leq K\sqrt{K_j} \int_0^1 \sqrt{\boldsymbol{\delta}_{(\varphi_j^{-1}\circ\gamma)(t)}((\varphi_j^{-1}\circ\gamma)'(t), (\varphi_j^{-1}\circ\gamma)'(t))} dt \\
&= K\sqrt{K_j} \int_0^1 \sqrt{\overline{\mathbf{g}}_{\gamma(t)}(\gamma'(t), \gamma'(t))} dt = K\sqrt{K_j} \int_0^1 \|\gamma'(t)\| dt
\end{aligned}
$$

$$= K\sqrt{K_j}\int_0^1 \|y-x\|dt = K\sqrt{K_j}\|x-y\|,$$

which proves that h_j is Lipschitz. By Rademacher's theorem (Theorem 7.2.1), the derivative of h_j exists almost everywhere on $\operatorname{int}(C_j)$. But C_j is a closed ball or a closed half-ball, so its Euclidean boundary has zero n-dimensional measure. Thus the derivative of h_j exists almost everywhere on C_j; that is, there exists $N_j \subseteq C_j$ such that $\lambda_n(N_j) = 0$ and dh_j exists on $C_j \setminus N_j$. Let $N_j' = \varphi_j^{-1}(N_j)$. Since

$$\lambda_{\mathbf{g}}(N_j') = \int_{\varphi_j(N_j')} (\varphi_j)_* \sqrt{\det(\mathbf{g})} d\lambda_n = \int_{N_j} \sqrt{\det(\mathbf{g})} \circ \varphi_j^{-1} d\lambda_n = 0,$$

we conclude that N_j' has zero Riemann–Lebesgue measure in M.

Let $p \in B_j \setminus N_j'$. Then $\varphi_j(p) \in C_j \setminus N_j$, so $dh_j|_{\varphi_j(p)}$ exists. Since φ_j is smooth, $d\varphi_j|_p$ exists. Because $u|_{B_j} = h_j \circ \varphi_j$, the chain rule shows that $du|_p$ exists. Since the first covariant derivative of a function agrees with its differential, $\nabla u(p)$ exists. Thus ∇u exists on $B_j \setminus N_j'$. But $N = \bigcup_{j\in\mathbb{N}} N_j'$ satisfies $\lambda_{\mathbf{g}}(N) = 0$, and moreover $\nabla u(p)$ exists for every $p \in \bigcup_{j\in\mathbb{N}} B_j \setminus \bigcup_{j\in\mathbb{N}} N_j' = M \setminus N$. Therefore, ∇u exists almost everywhere on M. □

We now show that if $\mathbf{u} \in \Gamma(\mathbf{E})$, then $\nabla|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ exists almost everywhere on M. First, we prove two results.

Proposition 7.2.3. Let $U \subseteq \mathbb{R}^n$ be a convex open subset, let $s \in \mathbb{N} \cup \{0\}$, and let $f : U \longrightarrow \mathbb{R}$ be a function of class C^{s+1}. If there is $M > 0$ such that $\|\nabla^{s+1} f(x)\|_F \leq M$ for every $x \in U$, then

$$\|\nabla^s f(x) - \nabla^s f(y)\|_F \leq M\|x-y\|$$

for any $x, y \in U$, where $\nabla^0 f = f$ and, for $s \geq 1$,

$$\nabla^s f(x) = \frac{\partial^s f}{\partial x_{i_1} \cdots \partial x_{i_s}}\bigg|_x \mathbf{d}x^{i_1} \otimes \cdots \otimes \mathbf{d}x^{i_s}.$$

Proof. If $s = 0$, the following argument is interpreted with $\nabla^0 f = f$. Let $x, y \in U$. Define $\gamma : [0,1] \longrightarrow U$ by $\gamma(t) = x + t(y-x)$. Then $\gamma'(t) = y - x$. We have

$$\begin{aligned}
\nabla^s f(y) - \nabla^s f(x) &= \frac{\partial^s f}{\partial x_{i_1} \cdots \partial x_{i_s}}\bigg|_{\gamma(1)} \mathbf{d}x^{i_1} \otimes \cdots \otimes \mathbf{d}x^{i_s} - \frac{\partial^s f}{\partial x_{i_1} \cdots \partial x_{i_s}}\bigg|_{\gamma(0)} \mathbf{d}x^{i_1} \otimes \cdots \otimes \mathbf{d}x^{i_s} \\
&= \left(\frac{\partial^s f}{\partial x_{i_1} \cdots \partial x_{i_s}}(\gamma(1)) - \frac{\partial^s f}{\partial x_{i_1} \cdots \partial x_{i_s}}(\gamma(0))\right) \mathbf{d}x^{i_1} \otimes \cdots \otimes \mathbf{d}x^{i_s} \\
&= \left(\int_0^1 \frac{d}{dt}\left(\frac{\partial^s f}{\partial x_{i_1} \cdots \partial x_{i_s}}(\gamma(t))\right) dt\right) \mathbf{d}x^{i_1} \otimes \cdots \otimes \mathbf{d}x^{i_s} \\
&= \left(\int_0^1 \left\langle \nabla\left(\frac{\partial^s f}{\partial x_{i_1} \cdots \partial x_{i_s}}\right)_{\gamma(t)}, y - x\right\rangle_{\mathbb{R}^n} dt\right) \mathbf{d}x^{i_1} \otimes \cdots \otimes \mathbf{d}x^{i_s}
\end{aligned}$$

$$= \left(\int_0^1 \sum_{j=1}^n \frac{\partial^{s+1} f}{\partial x_j \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t))(y^j - x^j) dt \right) \mathbf{d}x^{i_1} \otimes \cdots \otimes \mathbf{d}x^{i_s}.$$

Thus,

$$\|\nabla^s f(y) - \nabla^s f(x)\|_F = \sqrt{\sum_{i_1,\ldots,i_s=1}^n \left(\int_0^1 \sum_{j=1}^n \frac{\partial^{s+1} f}{\partial x_j \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t))(y^j - x^j) dt \right)^2}$$

$$\leq \sqrt{\sum_{i_1,\ldots,i_s=1}^n \int_0^1 \left(\sum_{j=1}^n \frac{\partial^{s+1} f}{\partial x_j \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t))(y^j - x^j) \right)^2 dt},$$

where the last inequality follows from Jensen's inequality (Proposition B.7.11) and convexity of $\varphi(x) = x^2$. But

$$\sqrt{\sum_{i_1,\ldots,i_s=1}^n \int_0^1 \left(\sum_{j=1}^n \frac{\partial^{s+1} f}{\partial x_j \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t))(y^j - x^j) \right)^2 dt}$$

$$= \sqrt{\sum_{i_1,\ldots,i_s=1}^n \int_0^1 \left\langle \left(\frac{\partial^{s+1} f}{\partial x_1 \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t)), \ldots, \frac{\partial^{s+1} f}{\partial x_n \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t)) \right), y - x \right\rangle_{\mathbb{R}^n}^2 dt}$$

$$\leq \sqrt{\sum_{i_1,\ldots,i_s=1}^n \int_0^1 \left\| \left(\frac{\partial^{s+1} f}{\partial x_1 \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t)), \ldots, \frac{\partial^{s+1} f}{\partial x_n \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t)) \right) \right\|^2 \|y - x\|^2 dt}$$

$$= \|x - y\| \sqrt{\sum_{i_1,\ldots,i_s=1}^n \int_0^1 \left\| \left(\frac{\partial^{s+1} f}{\partial x_1 \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t)), \ldots, \frac{\partial^{s+1} f}{\partial x_n \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t)) \right) \right\|^2 dt}$$

$$= \|x - y\| \sqrt{\int_0^1 \sum_{i_1,\ldots,i_s=1}^n \left\| \left(\frac{\partial^{s+1} f}{\partial x_1 \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t)), \ldots, \frac{\partial^{s+1} f}{\partial x_n \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t)) \right) \right\|^2 dt}$$

$$= \|x - y\| \sqrt{\int_0^1 \sum_{i_1,\ldots,i_s=1}^n \sum_{j=1}^n \left(\frac{\partial^{s+1} f}{\partial x_j \partial x_{i_1} \cdots \partial x_{i_s}} (\gamma(t)) \right)^2 dt}$$

$$= \|x - y\| \sqrt{\int_0^1 \|\nabla^{s+1} f(\gamma(t))\|_F^2 dt} \leq \|x - y\| \sqrt{\int_0^1 M^2 dt} = M \|x - y\|.$$

□

Lemma 7.2.4. Let $U \subseteq \mathbb{R}^n$ be open with $\overline{B}_{\text{euc}}(0,2) \subseteq U$, and let $f : U \longrightarrow [0,\infty)$ be a function of class C^2. Then the function $\sqrt{f}$ is Lipschitz on $\overline{B}_{\text{euc}}(0,1)$.

Proof. Since f is of class C^2 on the compact set $\overline{B}_{\text{euc}}(0,2)$, its gradient and Hessian matrix are bounded on that set. Let

$$K := 1 + \sup_{z \in \overline{B}_{\text{euc}}(0,2)} \|\nabla f(z)\| + \sup_{z \in \overline{B}_{\text{euc}}(0,2)} \|\nabla^2 f(z)\|_F.$$

Then $K > 0$ and $\|\nabla f(z)\| \leq K$, $\|\nabla^2 f(z)\|_F \leq K$ for every $z \in \overline{B}_{\text{euc}}(0,2)$.

For $\varepsilon > 0$, consider $f_\varepsilon = f + \varepsilon$. Fix $x \in \overline{B}_{\mathrm{euc}}(0,1)$. If $\nabla f(x) = 0$, then $\nabla\sqrt{f_\varepsilon}(x) = 0$. Thus assume $\nabla f(x) \neq 0$ and define

$$v := \frac{\nabla f(x)}{\|\nabla f(x)\|}.$$

Then $\|v\| = 1$ and, since $x \in \overline{B}_{\mathrm{euc}}(0,1)$, we have $x - tv \in \overline{B}_{\mathrm{euc}}(0,2)$ for every $t \in [0,1]$.
Consider the function $g\colon [0,1] \longrightarrow (0,\infty)$ given by $g(t) := f_\varepsilon(x - tv)$. Then

$$g'(0) = -\langle \nabla f(x), v\rangle_{\mathbb{R}^n} = -\|\nabla f(x)\|.$$

Moreover, for every $t \in [0,1]$,

$$g''(t) = \sum_{i,j=1}^{n} \frac{\partial^2 f}{\partial x_i \partial x_j}(x - tv) v_i v_j.$$

The Cauchy–Schwarz inequality from Theorem B.3.2, applied in $\mathbb{R}^{n^2}$, gives

$$|g''(t)| \leq \left(\sum_{i,j=1}^{n} \left| \frac{\partial^2 f}{\partial x_i \partial x_j}(x - tv) \right|^2 \right)^{\frac{1}{2}} \left(\sum_{i,j=1}^{n} |v_i v_j|^2 \right)^{\frac{1}{2}}$$

$$= \|\nabla^2 f(x - tv)\|_F \|v\|^2 \leq K.$$

By Taylor's formula with integral remainder from Theorem 1.4.9, applied in one dimension, for every $t \in [0,1]$,

$$g(t) = g(0) + g'(0)t + \int_0^t (t - r) g''(r)\, dr \leq g(0) - \|\nabla f(x)\| t + \frac{K}{2} t^2.$$

Let $t_0 := \frac{\|\nabla f(x)\|}{K}$. Since $\|\nabla f(x)\| \leq K$, we have $t_0 \in [0,1]$. Moreover, since $f \geq 0$ and $\varepsilon > 0$, we have $g(t_0) = f(x - t_0 v) + \varepsilon \geq \varepsilon > 0$. Therefore,

$$0 < g(t_0) \leq g(0) - \frac{\|\nabla f(x)\|^2}{K} + \frac{K}{2} \frac{\|\nabla f(x)\|^2}{K^2} = g(0) - \frac{\|\nabla f(x)\|^2}{2K}.$$

It follows that $\|\nabla f(x)\|^2 < 2K g(0) = 2K(f(x) + \varepsilon)$ and consequently

$$\|\nabla \sqrt{f_\varepsilon}(x)\| = \frac{\|\nabla f(x)\|}{2\sqrt{f(x) + \varepsilon}} \leq \sqrt{\frac{K}{2}}.$$

This bound holds for every $x \in \overline{B}_{\mathrm{euc}}(0,1)$, and the constant on the right-hand side is independent of x and ε. Since $\sqrt{f_\varepsilon}$ is of class C^1 on the convex open subset $B_{\mathrm{euc}}(0,1)$, Proposition 7.2.3, applied with $s = 0$, implies

$$\left| \sqrt{f(x) + \varepsilon} - \sqrt{f(y) + \varepsilon} \right| \leq \sqrt{\frac{K}{2}} \|x - y\|$$

for any $x, y \in B_{\mathrm{euc}}(0,1)$. By continuity, the inequality also holds for any $x, y \in \overline{B}_{\mathrm{euc}}(0,1)$. Finally, letting $\varepsilon \to 0$, we obtain

$$|\sqrt{f(x)} - \sqrt{f(y)}| \leq \sqrt{\frac{K}{2}} \|x - y\|$$

for any $x, y \in \overline{B}_{\mathrm{euc}}(0,1)$, so $\sqrt{f}$ is Lipschitz on $\overline{B}_{\mathrm{euc}}(0,1)$. □

Lemma 7.2.5. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{E} \to M$ be a smooth real vector bundle equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. If $\mathbf{u} \in \Gamma(\mathbf{E})$, then for every integer $s \geq 0$, the function $|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ is locally Lipschitz on $\mathrm{Int}(M)$. In particular, $\nabla|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ exists almost everywhere on M.

Proof. Since ∂M has measure zero, it suffices to prove that $\nabla|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ exists almost everywhere on $\mathrm{Int}(M)$. Let (V, φ) be a strongly convex regular normal geodesic coordinate ball whose closure is contained in $\mathrm{Int}(M)$. Composing φ with an affine transformation of $\mathbb{R}^n$, we may assume $\overline{B}_{\mathrm{euc}}(0,3) \subseteq \varphi(V)$. Define $B := \varphi^{-1}(\overline{B}_{\mathrm{euc}}(0,1))$.
On V, we have

$$|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}} = \sqrt{g^{i_1 j_1} \cdots g^{i_s j_s} h_{ab} (\nabla^s \mathbf{u})^a_{i_1 \cdots i_s} (\nabla^s \mathbf{u})^b_{j_1 \cdots j_s}} = \sqrt{\langle \nabla^s \mathbf{u}, \nabla^s \mathbf{u} \rangle_{\mathbf{g},\mathbf{h_E}}},$$

where, if $s = 0$, the factors corresponding to $\mathbf{g}^{-1}$ are absent. Since $\langle \nabla^s \mathbf{u}, \nabla^s \mathbf{u} \rangle_{\mathbf{g},\mathbf{h_E}} \circ \varphi^{-1}$ is smooth and $\varphi(V)$ contains $\overline{B}_{\mathrm{euc}}(0,2)$, Lemma 7.2.4 implies that

$$|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \circ \varphi^{-1} = \sqrt{\langle \nabla^s \mathbf{u}, \nabla^s \mathbf{u} \rangle_{\mathbf{g},\mathbf{h_E}} \circ \varphi^{-1}}$$

is Lipschitz on $\overline{B}_{\mathrm{euc}}(0,1)$. Thus there is $C > 0$ such that

$$\left| \left(|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \circ \varphi^{-1}\right)(x) - \left(|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \circ \varphi^{-1}\right)(y) \right| \leq C \|x - y\|$$

for any $x, y \in \overline{B}_{\mathrm{euc}}(0,1)$.
Let $p, q \in B$. Let $\boldsymbol{\delta} := \varphi^* \overline{\mathbf{g}}$ be the Euclidean metric transported to V. Since $\overline{V}$ is compact, Lemma 7.1.8, applied to the metrics $\mathbf{g}$ and $\boldsymbol{\delta}$, provides a constant $K > 0$ such that $|X|_{\boldsymbol{\delta}} \leq K |X|_{\mathbf{g}}$ for every $X \in TV$. Since V is strongly convex, there is a minimizing geodesic $\gamma \colon [0,1] \longrightarrow V$ joining p to q and satisfying $L_{\mathbf{g}}(\gamma) = d_{\mathbf{g}}(p,q)$. The curve $\varphi \circ \gamma$ joins $\varphi(p)$ to $\varphi(q)$, and therefore

$$\|\varphi(p) - \varphi(q)\| \leq L_{\overline{\mathbf{g}}}(\varphi \circ \gamma) = L_{\boldsymbol{\delta}}(\gamma) \leq K L_{\mathbf{g}}(\gamma) = K d_{\mathbf{g}}(p,q).$$

Consequently,

$$\begin{aligned} \left| |\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}(p) - |\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}(q) \right| &\leq C \|\varphi(p) - \varphi(q)\| \\ &\leq C K \, d_{\mathbf{g}}(p,q), \end{aligned}$$

so $|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ is Lipschitz on B.
Since every Riemannian manifold admits a cover by strongly convex normal geodesic coordinate balls, we conclude that $|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ is locally Lipschitz on $\mathrm{Int}(M)$.
By second countability of M, we may extract a countable subcover $(B_j)_{j \in \mathbb{N}}$ consisting of balls of the preceding type. Theorem 7.2.2 implies that $\nabla|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ exists almost everywhere on each B_j. Since the union is countable, it exists almost everywhere on $\mathrm{Int}(M)$ and, because ∂M has measure zero, also almost everywhere on M. □

The preceding results allow us to prove Kato's inequality for sections of vector bundles.

Theorem 7.2.6. (Kato's inequality) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{E} \to M$ be a smooth real vector bundle equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection

$\nabla^{\mathbf{E}}$. For any integer $s \geq 0$ and any $\mathbf{u} \in \Gamma(\mathbf{E})$, we have

$$|\nabla|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}|_{\mathbf{g}} \leq |\nabla^{s+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$$

almost everywhere on M.

Proof. If $|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \neq 0$ at a point, continuity gives a smooth chart (U,φ), with $\varphi = (x^1,\dots,x^n)$, on which this function is positive. Thus $|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}$ is classically differentiable on U, and the chain rule gives

$$\nabla|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}} = \frac{\nabla\langle\nabla^s \mathbf{u}, \nabla^s \mathbf{u}\rangle_{\mathbf{g},\mathbf{h_E}}}{2|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}}.$$

To compute $\nabla\langle\nabla^s \mathbf{u}, \nabla^s \mathbf{u}\rangle_{\mathbf{g},\mathbf{h_E}}$, recall that

$$\left(\nabla\langle\nabla^s \mathbf{u}, \nabla^s \mathbf{u}\rangle_{\mathbf{g},\mathbf{h_E}}\right)_i = \frac{\partial\langle\nabla^s \mathbf{u}, \nabla^s \mathbf{u}\rangle_{\mathbf{g},\mathbf{h_E}}}{\partial x^i}.$$

Since the Levi–Civita connection is compatible with $\mathbf{g}$ and $\nabla^{\mathbf{E}}$ is compatible with $\mathbf{h_E}$, the induced connection on $T^{(0,s)}(TM)\otimes\mathbf{E}$ is compatible with the product metric $\langle\cdot,\cdot\rangle_{\mathbf{g},\mathbf{h_E}}$. Therefore,

$$\begin{aligned}\frac{\partial\langle\nabla^s \mathbf{u}, \nabla^s \mathbf{u}\rangle_{\mathbf{g},\mathbf{h_E}}}{\partial x^i} &= \left\langle\nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u}\right\rangle_{\mathbf{g},\mathbf{h_E}} + \left\langle\nabla^s \mathbf{u}, \nabla_{\partial_i}(\nabla^s \mathbf{u})\right\rangle_{\mathbf{g},\mathbf{h_E}} \\ &= 2\left\langle\nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u}\right\rangle_{\mathbf{g},\mathbf{h_E}}.\end{aligned}$$

Thus,

$$\begin{aligned}\nabla|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}} = \frac{\nabla\langle\nabla^s \mathbf{u}, \nabla^s \mathbf{u}\rangle_{\mathbf{g},\mathbf{h_E}}}{2|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}} &= \frac{2\left\langle\nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u}\right\rangle_{\mathbf{g},\mathbf{h_E}} \mathbf{d}x^i}{2|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}} \\ &= \frac{\left\langle\nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u}\right\rangle_{\mathbf{g},\mathbf{h_E}} \mathbf{d}x^i}{|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h_E}}}.\end{aligned}$$

Consider the square root of $\mathbf{g}^{-1}$, given by Proposition C.1.14, which is positive definite and symmetric, and denote it by (R^{ij}).

Then

$$\begin{aligned}\left|\left\langle\nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u}\right\rangle_{\mathbf{g},\mathbf{h_E}} \mathbf{d}x^i\right|^2_{\mathbf{g}} &= \sum_{1\leq i,j\leq n} g^{ij}\left\langle\nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u}\right\rangle_{\mathbf{g},\mathbf{h_E}}\left\langle\nabla_{\partial_j}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u}\right\rangle_{\mathbf{g},\mathbf{h_E}} \\ &= \sum_{1\leq i,j\leq n}\sum_{m=1}^{n} R^{im}R^{mj}\left\langle\nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u}\right\rangle_{\mathbf{g},\mathbf{h_E}}\left\langle\nabla_{\partial_j}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u}\right\rangle_{\mathbf{g},\mathbf{h_E}} \\ &= \sum_{m=1}^{n}\sum_{1\leq i,j\leq n} R^{im}R^{jm}\left\langle\nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u}\right\rangle_{\mathbf{g},\mathbf{h_E}}\left\langle\nabla_{\partial_j}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u}\right\rangle_{\mathbf{g},\mathbf{h_E}} \\ &= \sum_{m=1}^{n}\left(\sum_{i=1}^{n} R^{im}\left\langle\nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u}\right\rangle_{\mathbf{g},\mathbf{h_E}}\right)^2\end{aligned}$$

$$= \sum_{m=1}^{n} \left(\left\langle \sum_{i=1}^{n} R^{im} \nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u} \right\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \right)^2$$

$$= \sum_{m=1}^{n} \left| \left\langle \sum_{i=1}^{n} R^{im} \nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u} \right\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \right|^2$$

$$\underset{\text{Cauchy–Schwarz}}{\leq} \sum_{m=1}^{n} \left| \sum_{i=1}^{n} R^{im} \nabla_{\partial_i}(\nabla^s \mathbf{u}) \right|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} |\nabla^s \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}}$$

$$= |\nabla^s \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \sum_{m=1}^{n} \left\langle \sum_{i=1}^{n} R^{im} \nabla_{\partial_i}(\nabla^s \mathbf{u}), \sum_{i=1}^{n} R^{im} \nabla_{\partial_i}(\nabla^s \mathbf{u}) \right\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}$$

$$= |\nabla^s \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \sum_{m=1}^{n} \left\langle \sum_{i=1}^{n} R^{im} \nabla_{\partial_i}(\nabla^s \mathbf{u}), \sum_{j=1}^{n} R^{mj} \nabla_{\partial_j}(\nabla^s \mathbf{u}) \right\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}$$

$$= |\nabla^s \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \sum_{m=1}^{n} \left(\sum_{i=1}^{n} R^{im} \sum_{j=1}^{n} R^{mj} \left\langle \nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla_{\partial_j}(\nabla^s \mathbf{u}) \right\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \right)$$

$$= |\nabla^s \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \sum_{m=1}^{n} \left(\sum_{1 \leq i,j \leq n} R^{im} R^{mj} \left\langle \nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla_{\partial_j}(\nabla^s \mathbf{u}) \right\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \right)$$

$$= |\nabla^s \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \sum_{1 \leq i,j \leq n} \sum_{m=1}^{n} R^{im} R^{mj} \left\langle \nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla_{\partial_j}(\nabla^s \mathbf{u}) \right\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}$$

$$= |\nabla^s \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \sum_{1 \leq i,j \leq n} g^{ij} \left\langle \nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla_{\partial_j}(\nabla^s \mathbf{u}) \right\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}$$

$$= |\nabla^s \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} |\nabla(\nabla^s \mathbf{u})|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} = |\nabla^s \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} |\nabla^{s+1} \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}},$$

where we used bilinearity of the induced bundle metric and the Cauchy–Schwarz inequality from Theorem B.3.2 in each fiber of $T^{(0,s)}(TM) \otimes \mathbf{E}$. Thus,

$$|\nabla |\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}|_\mathbf{g} = \frac{\left| \left\langle \nabla_{\partial_i}(\nabla^s \mathbf{u}), \nabla^s \mathbf{u} \right\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \mathbf{d}x^i \right|_\mathbf{g}}{|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}} \leq \frac{|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} |\nabla^{s+1} \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}}{|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}} = |\nabla^{s+1} \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}.$$

Moreover, by Lemma 7.2.5, $\nabla |\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}$ exists almost everywhere on M. If $|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} = 0$ at a point of $\mathrm{Int}(M)$ where $\nabla |\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}$ exists, the nonnegative function $|\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}$ has a global minimum at that point. Its differential therefore vanishes, and consequently $\nabla |\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} = 0$. Hence

$$|\nabla |\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}|_\mathbf{g} = 0 \leq |\nabla^{s+1} \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}.$$

We thus conclude that

$$|\nabla |\nabla^s \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}|_\mathbf{g} \leq |\nabla^{s+1} \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}$$

almost everywhere on M. □

7.3 Sobolev embeddings on compact Riemannian manifolds

Localization in coordinate balls and half-balls allows the Euclidean embeddings to be transferred to a compact Riemannian manifold. We shall use Kato's inequality to pass from first order to higher orders.

Proposition 7.3.1. (Iteration of first-order embeddings) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary. Let $0 \le m < k$ be integers, set $d := k-m$, and consider exponents $p_0,\dots,p_d \in [1,\infty)$. If the inclusions

$$W^{1,p_i}(M) \hookrightarrow L^{p_{i+1}}(M) \qquad (i \in \{0,\dots,d-1\})$$

are continuous, then so is

$$W^{k,p_0}(M) \hookrightarrow W^{m,p_d}(M).$$

Proof. We first show that a continuous embedding $W^{1,p}(M) \hookrightarrow L^q(M)$, with $p,q<\infty$, implies

$$W^{s,p}(M) \hookrightarrow W^{s-1,q}(M) \qquad \text{for every integer } s \ge 1.$$

Let $u \in C^{s,p}(M)$ and fix $0 \le j \le s-1$. Kato's inequality, Theorem 7.2.6, gives

$$\left|\nabla |\nabla^j u|_{\mathbf{g}}\right|_{\mathbf{g}} \le |\nabla^{j+1} u|_{\mathbf{g}} \qquad \text{almost everywhere.}$$

To work with the definition by completion, consider

$$f_\varepsilon := \sqrt{|\nabla^j u|_{\mathbf{g}}^2 + \varepsilon^2} - \varepsilon, \qquad \varepsilon > 0.$$

These functions are smooth and satisfy $0 \le f_\varepsilon \le |\nabla^j u|_{\mathbf{g}}$. Where $|\nabla^j u|_{\mathbf{g}} > 0$, we have

$$\nabla f_\varepsilon = \frac{|\nabla^j u|_{\mathbf{g}}}{\sqrt{|\nabla^j u|_{\mathbf{g}}^2 + \varepsilon^2}} \nabla |\nabla^j u|_{\mathbf{g}}.$$

Where $\nabla^j u = 0$, the differential of its squared norm is zero, so $\nabla f_\varepsilon = 0$. Consequently,

$$|\nabla f_\varepsilon|_{\mathbf{g}} \le |\nabla^{j+1} u|_{\mathbf{g}}.$$

Moreover, $f_\varepsilon \to |\nabla^j u|_{\mathbf{g}}$, and their differentials converge almost everywhere to the differential of that norm: at interior zeros where it exists, the differential vanishes because the point is a minimum. Dominated convergence, applied to the pth powers of the preceding bounds, gives convergence in L^p of the functions and their differentials. Thus (f_ε) is Cauchy in the norm defining $W^{1,p}(M)$ and represents the function $|\nabla^j u|_{\mathbf{g}}$ in its completion. We also obtain

$$\left\| |\nabla^j u|_{\mathbf{g}} \right\|_{W^{1,p}(M)} \le \|\nabla^j u\|_{L^p(M,T^{(0,j)}(TM))} + \|\nabla^{j+1} u\|_{L^p(M,T^{(0,j+1)}(TM))}.$$

Apply the assumed first-order embedding to this function. There is $C_{p,q} > 0$ such that

$$\|\nabla^j u\|_{L^q(M,T^{(0,j)}(TM))} \le C_{p,q} \left(\|\nabla^j u\|_{L^p(M,T^{(0,j)}(TM))} + \|\nabla^{j+1} u\|_{L^p(M,T^{(0,j+1)}(TM))} \right).$$

Summing for $j \in \{0,\dots,s-1\}$ and using Proposition 7.1.7 gives

$$\|u\|_{W^{s-1,q}(M)} \leq C_s \|u\|_{W^{s,p}(M)}.$$

Extension to the completions, Corollary B.2.37, provides the desired embedding. This extension agrees with the canonical inclusion: a smooth sequence converging in $L^p(M)$ to u and in $L^q(M)$ to v converges to both in L^1 on every compact set by Hölder's inequality, so $u = v$ almost everywhere.
For each $i \in \{0,\dots,d-1\}$, apply the preceding argument with $s = k-i$, $p = p_i$, and $q = p_{i+1}$. We obtain

$$\|u\|_{W^{k-i-1,p_{i+1}}(M)} \leq C_i \|u\|_{W^{k-i,p_i}(M)}.$$

The composition of these d embeddings gives

$$\|u\|_{W^{m,p_d}(M)} \leq \left(\prod_{i=0}^{d-1} C_i\right) \|u\|_{W^{k,p_0}(M)},$$

as required. □

Theorem 7.3.2. (Sobolev embedding with finite orders and exponents) Let $(M,\mathbf{g})$ be a compact Riemannian manifold of dimension n, with or without boundary. Let $0 \leq m < k$ be integers and $1 \leq p,q < \infty$ satisfy

$$k - \frac{n}{p} \geq m - \frac{n}{q}.$$

Then the inclusion $W^{k,p}(M) \hookrightarrow W^{m,q}(M)$ is continuous.

Proof. If $n = 0$, compactness implies that M is a finite set, and the assertion follows from equivalence of norms in finite dimensions. Assume $n \geq 1$. We begin with first order. Fix $1 \leq p,q < \infty$ with $1 - \frac{n}{p} \geq -\frac{n}{q}$. Choose a finite cover $(U_i,\varphi_i)_{i=1}^N$ consisting of interior regular coordinate balls and regular coordinate half-balls centered on the boundary. Let $(\psi_i)_{i=1}^N$ be a subordinate smooth partition of unity with $\operatorname{supp}\psi_i \Subset U_i$, and set

$$\Omega_i := \varphi_i\big(U_i \cap \operatorname{Int}(M)\big), \qquad \boldsymbol{\delta}_i := \varphi_i^* \overline{\mathbf{g}},$$

where $\overline{\mathbf{g}}$ is the Euclidean metric.
Let $u \in C^\infty(M)$ and define $v_i := (\psi_i u) \circ \varphi_i^{-1}$ on Ω_i. If U_i is interior, $v_i \in C_c^\infty(\Omega_i)$, and Theorem 3.3.16, with total orders one and zero, gives

$$\|v_i\|_{L^q(\Omega_i)} \leq A_i \|v_i\|_{W^{1,p}(\Omega_i)}.$$

If U_i is a boundary chart, Ω_i is a half-ball. The support of v_i is separated from the spherical portion, so its extension by zero within $\mathbb{R}^n_+$ is smooth up to $x_n = 0$ and has support in the fixed compact set

$$K_i := \varphi_i(\operatorname{supp}\psi_i) \subseteq \overline{\mathbb{R}^n_+}.$$

Theorem 3.6.6, with total orders one and zero, gives the same estimate upon restriction to Ω_i.

Change of variables and the definition of the metric δ_i give

$$\int_{\Omega_i} |v_i|^q \, d\lambda_n = \int_{U_i} |\psi_i u|^q \, d\lambda_{\delta_i}, \qquad \int_{\Omega_i} |dv_i|^p_{\overline{\mathbf{g}}} \, d\lambda_n = \int_{U_i} |d(\psi_i u)|^p_{\delta_i} \, d\lambda_{\delta_i}.$$

Equivalence of norms on $\mathbb{R}^n$, Proposition B.1.2, compares $|dv_i|_{\overline{\mathbf{g}}}$ with $\big(\sum_{a=1}^{n} |D_a v_i|^p\big)^{1/p}$. On the other hand, Remark 7.1.15 allows comparison of the metrics δ_i and $\mathbf{g}$ and their measures on $\overline{U_i}$. Thus there exist $a_i, b_i > 0$, independent of u, such that

$$\|v_i\|_{W^{1,p}(\Omega_i)} \le a_i \|\psi_i u\|_{W^{1,p}(U_i),\mathbf{g}}, \qquad \|\psi_i u\|_{L^q(U_i),\mathbf{g}} \le b_i \|v_i\|_{L^q(\Omega_i)}.$$

The Euclidean estimate then implies

$$\|\psi_i u\|_{L^q(M)} \le a_i b_i A_i \|\psi_i u\|_{W^{1,p}(M)},$$

since $\psi_i u$ and its derivatives vanish outside U_i.
To bound the localization, use $d(\psi_i u) = \psi_i \, du + u \, d\psi_i$ and $0 \le \psi_i \le 1$. Since M is compact, $|d\psi_i|_{\mathbf{g}}$ is bounded and

$$\begin{aligned} \|\psi_i u\|_{W^{1,p}(M)} &\le \|\psi_i u\|_{L^p(M)} + \|d(\psi_i u)\|_{L^p(M,T^*M)} \\ &\le \big(1 + \||d\psi_i|_{\mathbf{g}}\|_{L^\infty(M)}\big) \|u\|_{L^p(M)} + \|du\|_{L^p(M,T^*M)} \\ &\le C_i \|u\|_{W^{1,p}(M)}. \end{aligned}$$

Summing over the finite cover and using $u = \sum_{i=1}^{N} \psi_i u$ gives

$$\|u\|_{L^q(M)} \le \sum_{i=1}^{N} \|\psi_i u\|_{L^q(M)} \le C \|u\|_{W^{1,p}(M)}.$$

The density defining $W^{1,p}(M)$ and Theorem B.2.36 extend this estimate to all of $W^{1,p}(M)$. The limit in L^q is identified with the limit in L^p by uniqueness of the limit in $L^1(M)$.
Now consider the orders $m < k$ and the exponents in the statement. Set $d := k - m$ and define

$$\frac{1}{p_i} := \frac{1}{p} - \frac{i}{d}\left(\frac{1}{p} - \frac{1}{q}\right), \qquad i \in \{0, \dots, d\}.$$

Each p_i is finite and belongs to $[1, \infty)$, since its reciprocal is a convex combination of $1/p$ and $1/q$. Moreover, $p_0 = p$, $p_d = q$, and

$$1 - \frac{n}{p_i} + \frac{n}{p_{i+1}} = 1 - \frac{n}{d}\left(\frac{1}{p} - \frac{1}{q}\right) \ge 0.$$

The first-order part gives $W^{1,p_i}(M) \hookrightarrow L^{p_{i+1}}(M)$ continuously for each $i \in \{0, \dots, d-1\}$. Proposition 7.3.1 then yields $W^{k,p}(M) \hookrightarrow W^{m,q}(M)$ continuously. □

Corollary 7.3.3. (Sobolev embedding and critical exponent) Let $(M, \mathbf{g})$ be a compact Riemannian manifold

of dimension n, with or without boundary. Let $j \geq 0$ and $d \geq 1$ be integers, and let $1 \leq p < n/d$. Then

$$W^{j+d,p}(M) \hookrightarrow W^{j,q}(M) \qquad \text{for every } 1 \leq q \leq p_d^* := \frac{np}{n-dp},$$

and these inclusions are continuous.

Proof. The condition $q \leq p_d^*$ is equivalent to $j + d - \frac{n}{p} \geq j - \frac{n}{q}$. Apply Theorem 7.3.2 with $k = j + d$ and $m = j$. □

7.4 The Rellich–Kondrashov theorem on compact Riemannian manifolds

The Rellich–Kondrashov theorem provides the compact counterpart of the preceding embeddings. The Euclidean version in Theorem 3.4.2 can be transferred to a compact Riemannian manifold $(M, \mathbf{g})$ by means of a finite cover by charts and a partition of unity; in boundary charts, we use the localized half-space version. The following result specifies the orders and exponents for which compactness holds, including the loss of one derivative with any finite exponent. In the range where a finite critical exponent exists, we shall recover the subcritical embeddings from Corollary 7.3.3 as a special case.

Theorem 7.4.1. (Rellich–Kondrashov) Let $(M, \mathbf{g})$ be a compact Riemannian manifold, with or without boundary, of dimension n. For any integers $j \geq 0$ and $m \geq 1$, and any $1 \leq p, q < \infty$ satisfying $j + m - \frac{n}{p} > j - \frac{n}{q}$, the inclusion $W^{j+m,p}(M) \subseteq W^{j,q}(M)$ is compact.

The proof uses the Leibniz rule for the tensor connection, Proposition 2.4.13, iterated while preserving the order of the covariant indices.

Proof. Since M is compact, there is a finite open cover $\{(U_i, \varphi_i) \mid i \in \{1, \dots, N\}\}$ consisting of regular coordinate balls contained in $\mathrm{Int}(M)$ and, when $\partial M \neq \varnothing$, regular coordinate half-balls centered on the boundary. Let $(\psi_i)_{i=1}^N$ be a partition of unity subordinate to this open cover. In both cases, φ_i extends to $\overline{U_i}$, which is compact. Consider again $\boldsymbol{\delta}_i = \varphi_i^* \overline{\mathbf{g}}$.

Let $(u_k)_{k \in \mathbb{N}} \subseteq W^{j+m,p}(M) \cap C^\infty(M)$ be a bounded sequence.

By Remark 7.1.15, the local estimates in Theorem 7.1.13 apply on each $\overline{U_i}$, even when a half-ball has a corner. Thus, for each $i \in \{1, \dots, N\}$, there exist $C_i, c_i > 0$ such that $c_i \|\psi_i u_k\|_{W^{j+m,p}(\overline{U_i}),\boldsymbol{\delta}_i} \leq \|\psi_i u_k\|_{W^{j+m,p}(\overline{U_i}),\mathbf{g}} \leq C_i \|\psi_i u_k\|_{W^{j+m,p}(\overline{U_i}),\boldsymbol{\delta}_i}$, where the constants are independent of the function. Set $v_{i,k} := (\psi_i u_k) \circ \varphi_i^{-1}$. Change of variables gives

$$\|\psi_i u_k\|_{W^{j+m,p}(U_i),\mathbf{g}} \geq c_i \left(\sum_{s=0}^{j+m} \int_{\varphi_i(U_i)} |\nabla^s v_{i,k}|_{\mathbf{g}}^p \, d\lambda_n \right)^{\frac{1}{p}}.$$

For each $s \in \{0, \dots, j+m\}$, Proposition B.1.2 provides $M_s, m_s > 0$ such that $m_s \|\cdot\|_p \leq \|\cdot\|_2 \leq M_s \|\cdot\|_p$ on $\mathbb{R}^{n^s}$, where n^s counts the ordered blocks of s indices. Each multi-index α with $|\alpha| = s$ occurs $s!/\alpha!$ times among

these blocks, with $\alpha! := \alpha_1! \cdots \alpha_n!$. Therefore,

$$\begin{aligned} |\nabla^s v_{i,k}|_{\mathbf{g}}^p &= \left(\sum_{|\alpha|=s} \frac{s!}{\alpha!} |D^\alpha v_{i,k}|^2 \right)^{\frac{p}{2}} \\ &\geq m_s^p \sum_{|\alpha|=s} |D^\alpha v_{i,k}|^p. \end{aligned}$$

Integrating and summing over the orders gives

$$\begin{aligned} \sum_{s=0}^{j+m} \int_{\varphi_i(U_i)} |\nabla^s v_{i,k}|_{\mathbf{g}}^p \, d\lambda_n &\geq \sum_{s=0}^{j+m} m_s^p \sum_{|\alpha|=s} \int_{\varphi_i(U_i)} |D^\alpha v_{i,k}|^p \, d\lambda_n \\ &\geq (m')^p \sum_{|\alpha|\leq j+m} \int_{\varphi_i(U_i)} |D^\alpha v_{i,k}|^p \, d\lambda_n, \end{aligned}$$

where $m' := \min_{0\leq s\leq j+m} m_s > 0$. Taking the pth root and using the definition of the Euclidean Sobolev norm, we conclude that

$$\|\psi_i u_k\|_{W^{j+m,p}(U_i),\mathbf{g}} \geq c_i m' \|v_{i,k}\|_{W^{j+m,p}(\varphi_i(U_i))}.$$

The iterated Leibniz rule expresses $\nabla^s(\psi_i u_k)$ as a sum of terms obtained by distributing the s derivatives between ψ_i and u_k. For each $r \in \{0,\dots,s\}$, there are $\binom{s}{r}$ terms with $s-r$ derivatives on ψ_i and r on u_k. These terms differ by permutations of the covariant indices, which preserve the tensor norm. Proposition 2.3.4 gives

$$|\mathbf{F}\otimes\mathbf{G}|_{\mathbf{g}} = |\mathbf{F}|_{\mathbf{g}}|\mathbf{G}|_{\mathbf{g}} = |\mathbf{G}\otimes\mathbf{F}|_{\mathbf{g}}.$$

Thus, for $0 \leq s \leq j+m$,

$$\begin{aligned} |\nabla^s(\psi_i u_k)|_{\mathbf{g}} &\leq \sum_{r=0}^{s} \binom{s}{r} |\nabla^{s-r}\psi_i|_{\mathbf{g}} |\nabla^r u_k|_{\mathbf{g}} \\ &\leq \sum_{r=0}^{s} \binom{s}{r} \| |\nabla^{s-r}\psi_i|_{\mathbf{g}} \|_{L^\infty(M)} |\nabla^r u_k|_{\mathbf{g}}. \end{aligned}$$

Let

$$A_i := \max_{0\leq s\leq j+m} \| |\nabla^s \psi_i|_{\mathbf{g}} \|_{L^\infty(M)}.$$

Compactness of M implies $A_i < \infty$. Integrating the pointwise estimate and applying Minkowski's inequality gives

$$\|\nabla^s(\psi_i u_k)\|_{L^p(M,T^{(0,s)}(TM))} \leq A_i \sum_{r=0}^{s} \binom{s}{r} \|\nabla^r u_k\|_{L^p(M,T^{(0,r)}(TM))}.$$

Now sum over s and use Proposition 7.1.7:

$$\begin{aligned} \|\psi_i u_k\|_{W^{j+m,p}(M)} &\leq A_i \sum_{s=0}^{j+m} \sum_{r=0}^{s} \binom{s}{r} \|\nabla^r u_k\|_{L^p(M,T^{(0,r)}(TM))} \\ &\leq C_i' \|u_k\|_{W^{j+m,p}(M)}. \end{aligned}$$

The constant C_i' is independent of k. Together with the preceding comparison, this gives

$$\frac{c_i m'}{C_i'}\|v_{i,k}\|_{W^{j+m,p}(\varphi_i(U_i))} \leq \|u_k\|_{W^{j+m,p}(M)}.$$

Thus $(v_{i,k})_k$ is bounded in the corresponding Euclidean space. If U_i is interior, the support of each $v_{i,k}$ is contained in the fixed compact set $\varphi_i(\operatorname{supp}\psi_i) \Subset \varphi_i(U_i)$. Theorem 3.4.2 provides a subsequence converging in $W^{j,q}(\varphi_i(U_i))$.

If U_i is a boundary chart, extend $v_{i,k}$ by zero outside the half-ball, but within $\mathbb{R}^n_+$. Lemma 3.6.8 preserves its Sobolev norm, and the extensions have support contained in the fixed compact set $K_i := \varphi_i(\operatorname{supp}\psi_i) \subseteq \overline{\mathbb{R}^n_+}$. Theorem 3.6.6 gives a subsequence converging in $W^{j,q}(\mathbb{R}^n_+)$ and, upon restriction, a Cauchy subsequence in the Sobolev space on the half-ball.

Since there are finitely many charts, extract successively a subsequence for U_1, then a subsequence of that one for U_2, and so on up to U_N. Relabeling the last subsequence, we may assume without loss of generality that $(\psi_i u_k \circ \varphi_i^{-1})_{k\in\mathbb{N}}$ is Cauchy in $W^{j,q}(\varphi_i(U_i))$ for every $i \in \{1,\dots,N\}$. We shall show that $(\psi_i u_k)_{k\in\mathbb{N}}$ is Cauchy in $W^{j,q}(U_i)$.

Repeating a procedure analogous to the preceding one, if $\widetilde{C_i}, \widetilde{c_i} > 0$ satisfy

$$\widetilde{c_i}\|\psi_i u_k\|_{W^{j,q}(\overline{U_i}),\boldsymbol{\delta}_i} \leq \|\psi_i u_k\|_{W^{j,q}(\overline{U_i}),\mathbf{g}} \leq \widetilde{C_i}\|\psi_i u_k\|_{W^{j,q}(\overline{U_i}),\boldsymbol{\delta}_i}$$

, where the constants are independent of the function, and $\widetilde{M'} = \max_{0\leq s\leq j}\left(\widetilde{M_s}(s!)^{1/q}\right)$, where $\widetilde{M_s}, \widetilde{m_s} > 0$ satisfy $\widetilde{m_s}\|\cdot\|_q \leq \|\cdot\|_2 \leq \widetilde{M_s}\|\cdot\|_q$ on $\mathbb{R}^{n^s}$ with $s \in \{0,\dots,j\}$, use $s!/\alpha! \leq s!$ to compare the sum over blocks with the sum over multi-indices. This includes $j = 0$, with $0! = 1$. Then

$$\|\psi_i u_k - \psi_i u_l\|_{W^{j,q}(U_i),\mathbf{g}} \leq \widetilde{C_i}\widetilde{M'}\|\psi_i u_k \circ \varphi_i^{-1} - \psi_i u_l \circ \varphi_i^{-1}\|_{W^{j,q}(\varphi_i(U_i)),\bar{\mathbf{g}}}.$$

Thus, the sequence $(\psi_i u_k)_{k\in\mathbb{N}}$ is Cauchy in $W^{j,q}(U_i)$. Finally, if $k, l \in \mathbb{N}$, then

$$\|u_k - u_l\|_{W^{j,q}(M),\mathbf{g}} = \left\|\sum_{i=1}^N \psi_i(u_k - u_l)\right\|_{W^{j,q}(M),\mathbf{g}} \leq \sum_{i=1}^N \|\psi_i(u_k - u_l)\|_{W^{j,q}(M),\mathbf{g}}$$

$$= \sum_{i=1}^N \|\psi_i(u_k - u_l)\|_{W^{j,q}(U_i),\mathbf{g}} = \sum_{i=1}^N \|\psi_i u_k - \psi_i u_l\|_{W^{j,q}(U_i),\mathbf{g}}.$$

Hence $(u_k)_{k\in\mathbb{N}}$ is Cauchy in $W^{j,q}(M)$. We have proved that the restricted inclusion $I_0\colon C^{j+m,p}(M) \longrightarrow W^{j,q}(M)$, given by $I_0 u = u$, is compact. Moreover, I_0 is continuous: the compactness just proved maps its unit ball into a relatively compact, and hence bounded, subset of $W^{j,q}(M)$; linearity turns this bound into continuity. Since $C^{j+m,p}(M)$ is dense in $W^{j+m,p}(M)$ by definition and $W^{j,q}(M)$ is a Banach space, Theorem B.2.36 provides a unique compact linear extension $I\colon W^{j+m,p}(M) \longrightarrow W^{j,q}(M)$. This extension agrees with the canonical inclusion. Therefore, the inclusion $W^{j+m,p}(M) \subseteq W^{j,q}(M)$ is compact for all the orders and exponents in the statement. □

Corollary 7.4.2. (Total orders and loss of one derivative) Let $(M, \mathbf{g})$ be a compact Riemannian manifold of dimension n, with possibly empty smooth boundary. If $m > k \geq 0$ are integers and $1 \leq p, q < \infty$ satisfy $m - \frac{n}{p} > k - \frac{n}{q}$, then $W^{m,p}(M) \hookrightarrow W^{k,q}(M)$ is compact. In particular,

$$W^{m,p}(M) \hookrightarrow W^{m-1,p}(M)$$

is compact for every $m \geq 1$ and every $1 \leq p < \infty$.

Proof. Apply the preceding theorem with $j = k$ and a gain of $m - k \geq 1$ derivatives. For the final embedding, take $k = m - 1$ and $q = p$; the strict inequality reduces to $1 > 0$. Thus this case includes $p = 1$ and dimensions $n = 1, 2$ without introducing a critical exponent. □

Corollary 7.4.3. (Subcritical formulation) Under the geometric assumptions of the preceding corollary, if $j \geq 0$, $a \geq 1$, and $ap < n$, the inclusion $W^{j+a,p}(M) \hookrightarrow W^{j,q}(M)$ is compact for $1 \leq q < np/(n - ap)$. At the endpoint $q = np/(n - ap)$, Corollary 7.3.3 gives continuity.

Proof. With $ap < n$, the inequality $j + a - \frac{n}{p} > j - \frac{n}{q}$ is equivalent to $q < np/(n - ap)$, so the general theorem applies. Equality of indices corresponds to the critical exponent in the cited continuous embedding theorem. □

8

Partial differential operators on vector bundles

Differential operators on manifolds naturally act between sections of vector bundles. The gradient, exterior derivative, connections, Hodge operators, and geometric Laplacians are examples of a common structure: their value at a point depends only on finitely many local derivatives of the section.

The intrinsic formulation will allow us to study the order of a differential operator, composition, and commutators with smooth functions without favoring coordinates. The formal adjoint will provide the integration by parts identity needed to define weak covariant derivatives and bundle-valued distributions later. The principal symbol and ellipticity will appear once these two theories have been constructed, so that their consequences can be expressed directly in terms of Sobolev sections and geometric distributions.

From local operators to the language of bundles

For a long time, differential operators were presented through coordinate formulas. Differential geometry showed that the essential feature was not the particular list of coefficients, but the local dependence on finitely many derivatives and the way those expressions change between trivializations. The language of bundles brings operators as seemingly different as the exterior derivative, connections, and Dirac operators together in one theory. Later, the principal symbol will retain precisely the highest-order part of this local information.

8.1 Motivation and basic properties

Before turning to the intrinsic definition, it is helpful to recall the Euclidean case. There, operators are written in terms of partial derivatives of the components; under a change of coordinates, those expressions transform consistently and determine a global map between spaces of sections. The abstract definition will isolate precisely this local dependence on finitely many derivatives.

Consider the Laplacian

$$\Delta\colon C^\infty(\mathbb{R}^n) \longrightarrow C^\infty(\mathbb{R}^n), \qquad \Delta u = \sum_{i=1}^{n} \frac{\partial^2 u}{\partial x_i^2}.$$

This operator can be interpreted as

$$\Delta\colon \Gamma(\underline{\mathbb{R}}) \longrightarrow \Gamma(\underline{\mathbb{R}}),$$

where $\underline{\mathbb{R}}$ denotes the trivial bundle of rank 1 over $\mathbb{R}^n$, that is,

$$\pi\colon \mathbb{R}^n \times \mathbb{R} \longrightarrow \mathbb{R}^n, \qquad \pi(x,v) = x.$$

Another example is the exterior derivative

$$d\colon \Omega^k(\mathbb{R}^n) \longrightarrow \Omega^{k+1}(\mathbb{R}^n),$$

where a k-form $\omega \in \Omega^k(\mathbb{R}^n)$ has, in the standard coordinates, a smooth representative

$$\widetilde{\omega}\colon \mathbb{R}^n \longrightarrow \mathbb{R}^{\binom{n}{k}}.$$

Thus, d can be written as an operator

$$d\colon C^\infty\left(\mathbb{R}^n, \mathbb{R}^{\binom{n}{k}}\right) \longrightarrow C^\infty\left(\mathbb{R}^n, \mathbb{R}^{\binom{n}{k+1}}\right).$$

Remark 8.1.1. In the case of the trivial bundle of rank m over $\mathbb{R}^n$, denoted by $\underline{\mathbb{R}}^m$,

$$\pi\colon \mathbb{R}^n \times \mathbb{R}^m \longrightarrow \mathbb{R}^n,$$

every smooth section σ has the form $\sigma(x) = (x, f(x))$ for a unique function $f\colon \mathbb{R}^n \longrightarrow \mathbb{R}^m$. This gives a natural identification

$$\Gamma(\underline{\mathbb{R}}^m) \cong C^\infty(\mathbb{R}^n, \mathbb{R}^m).$$

More generally, if M is a smooth manifold with or without boundary and we consider the trivial bundle of rank m, again denoted by $\underline{\mathbb{R}}^m$,

$$\pi\colon M \times \mathbb{R}^m \longrightarrow M,$$

the map sending a section $\sigma(p) = (p, f(p))$ to its second component f is linear and bijective, with inverse $f \mapsto [p \mapsto (p, f(p))]$. Therefore,

$$\Gamma(\underline{\mathbb{R}}^m) \cong C^\infty(M, \mathbb{R}^m).$$

In this sense, the exterior derivative may be viewed as

$$d\colon \Gamma\left(\underline{\mathbb{R}}^{\binom{n}{k}}\right) \longrightarrow \Gamma\left(\underline{\mathbb{R}}^{\binom{n}{k+1}}\right).$$

These examples show that many classical differential operators can naturally be described as operators between spaces of sections of vector bundles. This setting can be generalized as follows:

Definition 8.1.2. Let M be a smooth manifold with or without boundary, and let $\pi_1\colon \mathbf{E} \longrightarrow M$, $\pi_2\colon \mathbf{F} \longrightarrow M$ be smooth vector bundles (real or complex) over M. We write

$$\mathbf{Op}(\mathbf{E}, \mathbf{F}) := \{P\colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{F}) \mid P \text{ is } \mathbb{K}\text{-linear}\},$$

where $\mathbb{K} \in \{\mathbb{R}, \mathbb{C}\}$.

The spaces of smooth sections $\Gamma(\mathbf{E})$ and $\Gamma(\mathbf{F})$ are not only $\mathbb{K}$-vector spaces, but also $C^\infty(M)$-modules. Partial differential operators are elements of $\mathbf{Op}$ that interact in a special way with the $C^\infty(M)$-module structure of the spaces of sections.

An element $P \in \mathbf{Op}(\mathbf{E},\mathbf{F})$ is $C^\infty(M)$-linear if $P(f\mathbf{u}) = f(P\mathbf{u})$ for any $\mathbf{u} \in \Gamma(\mathbf{E})$. We define the commutator of $P \in \mathbf{Op}(\mathbf{E},\mathbf{F})$ and $f \in C^\infty(M)$ to be the element $[P,f] \in \mathbf{Op}(\mathbf{E},\mathbf{F})$ such that $[P,f](\mathbf{u}) = P(f\mathbf{u}) - f(P\mathbf{u})$ for every $\mathbf{u} \in \Gamma(\mathbf{E})$.

The operator P is $C^\infty(M)$–linear if and only if $[P,f] = 0$ for any $f \in C^\infty(M)$.

Each function $f \in C^\infty(M)$ defines a map

$$\mathrm{ad}(f)\colon \mathbf{Op}(\mathbf{E},\mathbf{F}) \longrightarrow \mathbf{Op}(\mathbf{E},\mathbf{F}), \qquad \mathrm{ad}(f)(P) = [P,f].$$

We define a partial differential operator recursively as follows:

Definition 8.1.3. Let M be a smooth manifold with or without boundary and let $\mathbf{E},\mathbf{F} \longrightarrow M$ be smooth vector bundles over M.

(a) $\mathbf{PDO}^{(0)}(\mathbf{E},\mathbf{F}) := \{P \in \mathbf{Op}(\mathbf{E},\mathbf{F}) \mid [P,f] = 0, \forall f \in C^\infty(M)\}$.

(b) If $m > 0$,
$$\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F}) := \{P \in \mathbf{Op}(\mathbf{E},\mathbf{F}) \mid [P,f] \in \mathbf{PDO}^{(m-1)}(\mathbf{E},\mathbf{F}), \forall f \in C^\infty(M)\}.$$

(c) $\mathbf{PDO}(\mathbf{E},\mathbf{F}) := \bigcup_{m=0}^{\infty} \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$.

In general, if $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$, we say that P is a partial differential operator of order less than or equal to m.

In terms of the notation ad, this definition can be rewritten more explicitly:

Proposition 8.1.4. Let M be a smooth manifold with or without boundary and let $\mathbf{E},\mathbf{F} \longrightarrow M$ be smooth vector bundles over M.

(a) $\mathbf{PDO}^{(0)}(\mathbf{E},\mathbf{F}) = \bigcap_{f \in C^\infty(M)} \ker(\mathrm{ad}(f))$.

(b) More generally, for $m \geq 1$,
$$\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F}) = \bigcap_{f_0,\ldots,f_m \in C^\infty(M)} \ker\left(\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_m)\right).$$

In particular, $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$ if and only if

$$\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_m)(P) = 0, \qquad \forall f_0,\ldots,f_m \in C^\infty(M).$$

Proof. For the base case $m = 0$ we use the definition; note that $P \in \mathbf{PDO}^{(0)}(\mathbf{E},\mathbf{F})$ if and only if $[P,f] = 0$ for

every $f \in C^\infty(M)$, that is, $\mathrm{ad}(f)(P) = 0$ for every $f \in C^\infty(M)$, which is equivalent to

$$P \in \bigcap_{f \in C^\infty(M)} \ker(\mathrm{ad}(f)).$$

Now suppose that the characterization holds up to $m-1$, that is,

$$\mathbf{PDO}^{(m-1)}(\mathbf{E},\mathbf{F}) = \bigcap_{f_0,\dots,f_{m-1} \in C^\infty(M)} \ker\big(\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_{m-1})\big).$$

We wish to show that the same description holds for m.
By definition,

$$P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F}) \quad \Longleftrightarrow \quad [P, f_m] \in \mathbf{PDO}^{(m-1)}(\mathbf{E},\mathbf{F}) \text{ for every } f_m \in C^\infty(M).$$

Applying the induction hypothesis, this condition is equivalent to

$$\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_{m-1})([P, f_m]) = 0, \qquad \forall f_0,\dots,f_{m-1},f_m \in C^\infty(M).$$

But this holds if and only if

$$\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_{m-1})\,\mathrm{ad}(f_m)(P) = 0, \qquad \forall f_0,\dots,f_m \in C^\infty(M),$$

that is, if and only if

$$P \in \bigcap_{f_0,\dots,f_m \in C^\infty(M)} \ker\big(\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_m)\big).$$

Therefore, the equivalence holds for m, completing the induction. □

Remark 8.1.5. In the literature, one commonly encounters the abbreviation

$$\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F}) = \ker \mathrm{ad}^{m+1},$$

which is to be understood in the preceding sense: not as a power of a single operator, but as the intersection of the kernels of *all* possible compositions of $m+1$ operators of the form $\mathrm{ad}(f)$ with $f \in C^\infty(M)$.

Proposition 8.1.6. Let M be a smooth manifold with or without boundary and let $\mathbf{E},\mathbf{F} \longrightarrow M$ be smooth vector bundles. Let $P, Q \in \mathbf{Op}(\mathbf{E},\mathbf{F})$, $f, g, h \in C^\infty(M)$, and $\alpha, \beta \in \mathbb{K}$. The commutator

$$[P, f](\mathbf{u}) := P(f\mathbf{u}) - fP(\mathbf{u}), \qquad \mathbf{u} \in \Gamma(\mathbf{E}),$$

satisfies the following properties:

(a) $\mathbb{K}$-linearity in the operator:

$$[\alpha P + \beta Q, f] = \alpha\,[P, f] + \beta\,[Q, f].$$

(b) $C^\infty(M)$-linearity in the operator:

$$[hP, f] = h\,[P, f].$$

(c) $\mathbb{K}$-linearity in the function:

$$[P, \alpha f + \beta g] = \alpha\,[P, f] + \beta\,[P, g].$$

(d) Leibniz rule: for every section $\mathbf{u} \in \Gamma(\mathbf{E})$,

$$[P, fg](\mathbf{u}) = [P, f](g\mathbf{u}) + f\,[P, g](\mathbf{u}).$$

If $P \in \mathbf{PDO}^{(1)}(\mathbf{E}, \mathbf{F})$, this identity reduces to

$$[P, fg](\mathbf{u}) = g\,[P, f](\mathbf{u}) + f\,[P, g](\mathbf{u}).$$

(e) If $c \in \mathbb{K}$ is viewed as a constant function, then

$$[P, c] = 0.$$

(f) The operator P is $C^\infty(M)$-linear if and only if

$$[P, f] = 0 \qquad \forall f \in C^\infty(M).$$

Proof. Let $\mathbf{u} \in \Gamma(\mathbf{E})$.
(a) We have

$$[\alpha P + \beta Q, f](\mathbf{u}) = (\alpha P + \beta Q)(f\mathbf{u}) - f(\alpha P + \beta Q)(\mathbf{u}) = \alpha(P(f\mathbf{u}) - fP(\mathbf{u})) + \beta(Q(f\mathbf{u}) - fQ(\mathbf{u})),$$

which is $\alpha[P, f](\mathbf{u}) + \beta[Q, f](\mathbf{u})$.
(b) By definition,

$$[hP, f](\mathbf{u}) = (hP)(f\mathbf{u}) - f(hP)(\mathbf{u}) = hP(f\mathbf{u}) - fhP(\mathbf{u}) = h\big(P(f\mathbf{u}) - fP(\mathbf{u})\big) = h\,[P, f](\mathbf{u}).$$

(c) For $\alpha f + \beta g$,

$$[P, \alpha f + \beta g](\mathbf{u}) = P((\alpha f + \beta g)\mathbf{u}) - (\alpha f + \beta g)P(\mathbf{u}) = \alpha(P(f\mathbf{u}) - fP(\mathbf{u})) + \beta(P(g\mathbf{u}) - gP(\mathbf{u})).$$

(d) For fg,

$$[P, fg](\mathbf{u}) = P(fg\,\mathbf{u}) - fgP(\mathbf{u}).$$

We add and subtract $fP(g\mathbf{u})$ to obtain

$$[P, fg](\mathbf{u}) = \big(P(fg\mathbf{u}) - fP(g\mathbf{u})\big) + f\big(P(g\mathbf{u}) - gP(\mathbf{u})\big) = [P, f](g\mathbf{u}) + f\,[P, g](\mathbf{u}).$$

If $P \in \mathbf{PDO}^{(1)}(\mathbf{E}, \mathbf{F})$, then $[P, f] \in \mathbf{PDO}^{(0)}(\mathbf{E}, \mathbf{F})$ by definition. In particular, $[[P, f], g] = 0$, that is,

$$[P, f](g\mathbf{u}) = g[P, f](\mathbf{u}).$$

Substituting this equality gives the formula for the first-order case.

(e) If c is constant, then

$$[P,c](\mathbf{u}) = P(c\mathbf{u}) - cP(\mathbf{u}) = cP(\mathbf{u}) - cP(\mathbf{u}) = 0.$$

(f) If P is $C^\infty(M)$-linear, then $P(f\mathbf{u}) = fP(\mathbf{u})$, and hence $[P,f] = 0$. Conversely, if $[P,f] = 0$ for every f, then

$$P(f\mathbf{u}) - fP(\mathbf{u}) = 0,$$

for every section $\mathbf{u}$, implying that P is $C^\infty(M)$-linear. □

Proposition 8.1.7. Let M be a smooth manifold with or without boundary and let $\mathbf{E},\mathbf{F} \longrightarrow M$ be smooth vector bundles. For each $f \in C^\infty(M)$ define

$$\operatorname{ad}(f)\colon \mathbf{Op}(\mathbf{E},\mathbf{F}) \longrightarrow \mathbf{Op}(\mathbf{E},\mathbf{F}), \qquad \operatorname{ad}(f)(P) = [P,f].$$

Then $\operatorname{ad}(f)$ satisfies the following properties:

(a) $\mathbb{K}$-linearity:

$$\operatorname{ad}(f)(\alpha P + \beta Q) = \alpha \operatorname{ad}(f)(P) + \beta \operatorname{ad}(f)(Q).$$

(b) $C^\infty(M)$-linearity in the operator:

$$\operatorname{ad}(f)(hP + Q) = h \operatorname{ad}(f)(P) + \operatorname{ad}(f)(Q).$$

(c) $\mathbb{K}$-linearity in the function:

$$\operatorname{ad}(\alpha f + \beta g) = \alpha \operatorname{ad}(f) + \beta \operatorname{ad}(g).$$

(d) If c is constant, then

$$\operatorname{ad}(c) = 0.$$

Proof. (a) This follows from property (a) of Proposition 8.1.6:

$$\operatorname{ad}(f)(\alpha P + \beta Q) = [\alpha P + \beta Q, f] = \alpha[P,f] + \beta[Q,f].$$

(b) Using property (b) of Proposition 8.1.6,

$$\operatorname{ad}(f)(hP + Q) = [hP + Q, f] = [hP, f] + [Q,f] = h[P,f] + \operatorname{ad}(f)(Q).$$

(c) Using property (c) of Proposition 8.1.6,

$$\operatorname{ad}(\alpha f + \beta g)(P) = [P, \alpha f + \beta g] = \alpha[P,f] + \beta[P,g].$$

(d) If c is constant, property (e) of Proposition 8.1.6 implies

$$\operatorname{ad}(c)(P) = [P,c] = 0,$$

for every $P \in \mathbf{Op}(\mathbf{E},\mathbf{F})$. □

Remark 8.1.8. The preceding propositions imply that $\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$ has the structure of an $C^\infty(M)$-module.

We give some simple examples of partial differential operators in the Euclidean case to familiarize the reader with this concept.

Example 8.1.9. Consider $M=\mathbb{R}^n$ and the trivial bundles $\mathbf{E}=\mathbf{F}=\underline{\mathbb{R}}$ of rank 1.

(a) The operator of multiplication by a smooth function is the most elementary example of a partial differential operator. Let M_f be defined by

$$(M_f u)(x) = f(x)u(x), \qquad f \in C^\infty(\mathbb{R}^n).$$

For any $g,u \in C^\infty(\mathbb{R}^n)$ we have

$$[M_f, g](u) = M_f(gu) - g(M_f u) = f\cdot(gu) - g\cdot(fu) = 0.$$

Consequently, $[M_f,g]=0$ for every $g\in C^\infty(\mathbb{R}^n)$, and therefore

$$M_f \in \mathbf{PDO}^{(0)}(\mathbf{E},\mathbf{F}).$$

(b) Now consider the partial derivative operator $P=\partial_i=\dfrac{\partial}{\partial x_i}$. For $u,f\in C^\infty(\mathbb{R}^n)$,

$$[\partial_i, f](u) = \partial_i(fu) - f\,\partial_i u.$$

Applying the product rule,

$$\partial_i(fu) = (\partial_i f)u + f\,\partial_i u,$$

gives

$$[\partial_i, f](u) = (\partial_i f)u.$$

That is, the commutator with f is simply multiplication by the function $\partial_i f$, an operator of order 0. Thus, $[\partial_i,f]\in\mathbf{PDO}^{(0)}(\mathbf{E},\mathbf{F})$, and by definition

$$\partial_i \in \mathbf{PDO}^{(1)}(\mathbf{E},\mathbf{F}).$$

(c) Finally, we analyze second-order partial derivatives. Let $P=\partial_i^2$. For $u\in C^\infty(\mathbb{R}^n)$,

$$[\partial_i^2, f](u) = \partial_i^2(fu) - f\,\partial_i^2 u.$$

Applying the product rule twice:

$$\partial_i^2(fu) = \partial_i\big((\partial_i f)u + f\,\partial_i u\big) = (\partial_i^2 f)u + 2(\partial_i f)\partial_i u + f\,\partial_i^2 u.$$

Subtracting $f\,\partial_i^2 u$ gives

$$[\partial_i^2, f](u) = (\partial_i^2 f)u + 2(\partial_i f)\partial_i u.$$

Taking a second commutator with another function $g \in C^\infty(\mathbb{R}^n)$,

$$[[\partial_i^2, f], g](u) = [M_{\partial_i^2 f} + 2(\partial_i f)\partial_i, g](u).$$

The first term $(\partial_i^2 f)\mathrm{Id}$ commutes with g, since it is multiplication by a smooth function. For the second,

$$[2(\partial_i f)\partial_i, g](u) = 2(\partial_i f)\big(\partial_i(gu) - g\partial_i u\big) = 2(\partial_i f)(\partial_i g)u,$$

which is multiplication by a smooth function, that is, an operator of order 0. Thus,

$[[\partial_i^2, f], g] \in \mathbf{PDO}^{(0)}(\mathbf{E}, \mathbf{F})$, y $\partial_i^2 \in \mathbf{PDO}^{(2)}(\mathbf{E}, \mathbf{F})$.

The example of multiplication by a smooth function generalizes as follows:

Example 8.1.10. Let M be a smooth manifold with or without boundary and let $\mathbf{E} \to M$ be a smooth vector bundle (real or complex). Fixing a function $f \in C^\infty(M)$, consider the operator

$$M_f : \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{E}), \qquad M_f(\mathbf{u}) := f\mathbf{u}.$$

We wish to show that $M_f \in \mathbf{PDO}^{(0)}(\mathbf{E}, \mathbf{E})$. For every function $g \in C^\infty(M)$ and every section $\mathbf{u} \in \Gamma(\mathbf{E})$ we have

$$[M_f, g](\mathbf{u}) = M_f(g\mathbf{u}) - gM_f(\mathbf{u}) = f(g\mathbf{u}) - g(f\mathbf{u}) = (fg)\mathbf{u} - (gf)\mathbf{u} = (fg)\mathbf{u} - (fg)\mathbf{u} = 0.$$

Therefore, $[M_f, g] = 0$ for every $g \in C^\infty(M)$, meaning that

$$M_f \in \mathbf{PDO}^{(0)}(\mathbf{E}, \mathbf{E}).$$

Another example of a partial differential operator is the Laplace–Beltrami operator on a Riemannian manifold:

Example 8.1.11. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary and consider the trivial bundle $\mathbf{E} = \mathbf{F} = \underline{\mathbb{R}}$. The Laplace–Beltrami operator is defined by

$$\Delta_{\mathbf{g}} u := \operatorname{div}(\operatorname{grad} u), \qquad u \in C^\infty(M).$$

We will show that $\Delta_{\mathbf{g}} \in \mathbf{PDO}^{(2)}(\mathbf{E}, \mathbf{F})$ but that $\Delta_{\mathbf{g}} \notin \mathbf{PDO}^{(1)}(\mathbf{E}, \mathbf{F})$.
For every function $f \in C^\infty(M)$, Proposition 2.16.11 gives

$$\Delta_{\mathbf{g}}(fu) = f\Delta_{\mathbf{g}} u + 2\langle \operatorname{grad} f, \operatorname{grad} u\rangle_{\mathbf{g}} + u\Delta_{\mathbf{g}} f,$$

and therefore

$$[\Delta_{\mathbf{g}}, f](u) = \Delta_{\mathbf{g}}(fu) - f\Delta_{\mathbf{g}} u = 2\langle \operatorname{grad} f, \operatorname{grad} u\rangle_{\mathbf{g}} + (\Delta_{\mathbf{g}} f)u.$$

Now let $h \in C^\infty(M)$. By definition of the commutator, for every $u \in C^\infty(M)$ we have

$$[[\Delta_{\mathbf{g}}, f], h](u) = [\Delta_{\mathbf{g}}, f](hu) - h[\Delta_{\mathbf{g}}, f](u).$$

Using the identity

$$[\Delta_{\mathbf{g}}, f](v) = 2\langle \operatorname{grad} f, \operatorname{grad} v\rangle_{\mathbf{g}} + (\Delta_{\mathbf{g}} f)\, v, \qquad v \in C^\infty(M),$$

we obtain

$$[\Delta_{\mathbf{g}}, f](hu) = 2\langle \operatorname{grad} f, \operatorname{grad}(hu)\rangle_{\mathbf{g}} + (\Delta_{\mathbf{g}} f)hu$$

and

$$[\Delta_{\mathbf{g}}, f](u) = 2\langle \operatorname{grad} f, \operatorname{grad} u\rangle_{\mathbf{g}} + (\Delta_{\mathbf{g}} f)\, u.$$

Therefore,

$$[[\Delta_{\mathbf{g}}, f], h](u) = \Big(2\langle \operatorname{grad} f, \operatorname{grad}(hu)\rangle_{\mathbf{g}} + (\Delta_{\mathbf{g}} f)hu\Big) - h\Big(2\langle \operatorname{grad} f, \operatorname{grad} u\rangle_{\mathbf{g}} + (\Delta_{\mathbf{g}} f)u\Big)$$

$$= 2\langle \operatorname{grad} f, \operatorname{grad}(hu)\rangle_{\mathbf{g}} + (\Delta_{\mathbf{g}} f)hu - 2h\langle \operatorname{grad} f, \operatorname{grad} u\rangle_{\mathbf{g}} - h(\Delta_{\mathbf{g}} f)\, u.$$

We now use the Leibniz rule for the gradient (Proposition 2.16.3):

$$\operatorname{grad}(hu) = h \operatorname{grad} u + u \operatorname{grad} h,$$

so that

$$\langle \operatorname{grad} f, \operatorname{grad}(hu)\rangle_{\mathbf{g}} = \big\langle \operatorname{grad} f,\, h \operatorname{grad} u + u \operatorname{grad} h\big\rangle_{\mathbf{g}}$$

$$= h\langle \operatorname{grad} f, \operatorname{grad} u\rangle_{\mathbf{g}} + u\langle \operatorname{grad} f, \operatorname{grad} h\rangle_{\mathbf{g}},$$

where we have used the $C^\infty(M)$–bilinearity of the inner product induced by $\mathbf{g}$. Consequently,

$$2\langle \operatorname{grad} f, \operatorname{grad}(hu)\rangle_{\mathbf{g}} = 2h\langle \operatorname{grad} f, \operatorname{grad} u\rangle_{\mathbf{g}} + 2u\,\langle \operatorname{grad} f, \operatorname{grad} h\rangle_{\mathbf{g}}.$$

Substituting this expression into the formula for $[[\Delta_{\mathbf{g}}, f], h](u)$, we have

$$[[\Delta_{\mathbf{g}}, f], h](u) = \Big(2h\langle \operatorname{grad} f, \operatorname{grad} u\rangle_{\mathbf{g}} + 2u\,\langle \operatorname{grad} f, \operatorname{grad} h\rangle_{\mathbf{g}} + (\Delta_{\mathbf{g}} f)hu\Big)$$

$$-\Big(2h\langle \operatorname{grad} f, \operatorname{grad} u\rangle_{\mathbf{g}} + h(\Delta_{\mathbf{g}} f)\, u\Big).$$

We now simplify term by term. First,

$$2h\langle \operatorname{grad} f, \operatorname{grad} u\rangle_{\mathbf{g}} - 2h\langle \operatorname{grad} f, \operatorname{grad} u\rangle_{\mathbf{g}} = 0.$$

Then, since multiplication of functions is commutative,

$$(\Delta_{\mathbf{g}} f)hu - h(\Delta_{\mathbf{g}} f)\, u = 0.$$

Therefore, only

$$[[\Delta_{\mathbf{g}}, f], h](u) = 2u\,\langle \operatorname{grad} f, \operatorname{grad} h\rangle_{\mathbf{g}}.$$

remains.

In other words, for every $u \in C^\infty(M)$ we have

$$[[\Delta_{\mathbf{g}}, f], h](u) = 2\langle \operatorname{grad} f, \operatorname{grad} h\rangle_{\mathbf{g}}\, u,$$

that is,

$$[[\Delta_{\mathbf{g}}, f], h] = M_{2\langle \operatorname{grad} f, \operatorname{grad} h\rangle_{\mathbf{g}}}.$$

This result is multiplication by the smooth function $2\langle \operatorname{grad} f, \operatorname{grad} h\rangle_{\mathbf{g}}$, so

$$[[\Delta_{\mathbf{g}}, f], h] \in \mathbf{PDO}^{(0)}(\mathbf{E}, \mathbf{F}) \quad \text{for any } f, h \in C^\infty(M).$$

Thus,

$$[\Delta_{\mathbf{g}}, f] \in \mathbf{PDO}^{(1)}(\mathbf{E}, \mathbf{F}) \quad \text{for every } f \in C^\infty(M),$$

and consequently

$$\Delta_{\mathbf{g}} \in \mathbf{PDO}^{(2)}(\mathbf{E}, \mathbf{F}).$$

To show that $\Delta_{\mathbf{g}} \notin \mathbf{PDO}^{(1)}(\mathbf{E}, \mathbf{F})$, it suffices to note that if an operator belongs to $\mathbf{PDO}^{(1)}(\mathbf{E}, \mathbf{F})$, then its second commutators with smooth functions would vanish. However, we have obtained

$$[[\Delta_{\mathbf{g}}, f], h] = M_{2\langle \operatorname{grad} f, \operatorname{grad} h\rangle_{\mathbf{g}}},$$

which is not the zero operator in general. Consequently,

$$\Delta_{\mathbf{g}} \notin \mathbf{PDO}^{(1)}(\mathbf{E}, \mathbf{F}).$$

The preceding example shows that calling these partial differential operators of order less than or equal to m makes sense, since having one of order less than or equal to m does not necessarily imply that it has order less than or equal to $m-1$. Moreover, if it has order less than or equal to m, one can prove that it has order less than or equal to $m+1$, as will be done later in Lemma 8.1.18.

The covariant derivative defined on a smooth vector bundle is another example of a partial differential operator, in this case of order ≤ 1:

Proposition 8.1.12. Let M be a smooth manifold with or without boundary and let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle over M. If

$$\nabla \colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(T^{(0,1)}(TM) \otimes \mathbf{E})$$

is a connection on $\mathbf{E}$, then $\nabla \in \mathbf{PDO}^{(1)}(\mathbf{E}, T^{(0,1)}(TM) \otimes \mathbf{E})$.

Proof. Let $f \in C^\infty(M)$ and $\mathbf{u} \in \Gamma(\mathbf{E})$. Then by Proposition 2.4.25,

$$[\nabla, f](\mathbf{u}) = \nabla(f\mathbf{u}) - f\nabla\mathbf{u} = df \otimes \mathbf{u} + f\nabla\mathbf{u} - f\nabla\mathbf{u} = df \otimes \mathbf{u}.$$

Define $M^{\otimes}_{df} \in \mathbf{Op}(\mathbf{E}, T^{(0,1)}(TM) \otimes \mathbf{E})$ by $M^{\otimes}_{df}(\mathbf{u}) = df \otimes \mathbf{u}$. Let $g \in C^\infty(M)$; then

$$[M^{\otimes}_{df}, g](\mathbf{u}) = M^{\otimes}_{df}(g\mathbf{u}) - gM^{\otimes}_{df}(\mathbf{u}) = df \otimes (g\mathbf{u}) - g(df \otimes \mathbf{u}) = g(df \otimes \mathbf{u}) - g(df \otimes \mathbf{u}) = 0,$$

, so $M^{\otimes}_{df} \in \mathbf{PDO}^{(0)}(\mathbf{E}, T^{(0,1)}(TM) \otimes \mathbf{E})$ and consequently $\nabla \in \mathbf{PDO}^{(1)}(\mathbf{E}, T^{(0,1)}(TM) \otimes \mathbf{E})$. □

To become more familiar with this concept, we study what partial differential operators of order 1 look like on $\underline{\mathbb{R}}$ viewed as a vector bundle over $\mathbb{R}^n$.

Example 8.1.13. Consider again the trivial bundle $\underline{\mathbb{R}}$ over $\mathbb{R}^n$. As we saw earlier, the sections of $\underline{\mathbb{R}}$ are precisely the functions in $C^\infty(\mathbb{R}^n)$. We wish to find $\mathbf{PDO}^{(1)}(\underline{\mathbb{R}},\underline{\mathbb{R}})$. Let $P \in \mathbf{PDO}^{(1)}(\underline{\mathbb{R}},\underline{\mathbb{R}})$ and $u, f \in C^\infty(\mathbb{R}^n)$. Then

$$[P,f]u = \sigma(f)u \quad \text{for some } \sigma(f) \in C^\infty(\mathbb{R}^n),$$

, since $[P,f]$ is $C^\infty(M)$-linear because $P \in \mathbf{PDO}^{(1)}(\underline{\mathbb{R}},\underline{\mathbb{R}})$, and we may take $\sigma(f) = [P,f](1)$. On the other hand, for any $f, g \in C^\infty(\mathbb{R}^n)$,

$$\sigma(fg)u = [P,fg]u = [P,f](gu) + f([P,g]u) = \sigma(f)gu + f\sigma(g)u.$$

Therefore, $\sigma(fg) = \sigma(f)g + f\sigma(g)$, so the map σ is a derivation on $C^\infty(M)$; hence there exists a smooth vector field $\mathbf{X} \in \mathfrak{X}(\mathbb{R}^n)$ such that

$$\sigma(f) = \mathbf{X} \cdot f, \quad \forall f \in C^\infty(\mathbb{R}^n).$$

Then for every $u \in C^\infty(\mathbb{R}^n)$,

$$P(u) = P(u \cdot 1) = [P,u] \cdot 1 + u \cdot P(1) = \mathbf{X} \cdot u + P(1) \cdot u,$$

where $P(1) \in C^\infty(\mathbb{R}^n)$.

Operators of order 0 can be characterized as follows:

Lemma 8.1.14. Let M be a smooth manifold with or without boundary and let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be smooth vector bundles. If $P \in \mathbf{PDO}^{(0)}(\mathbf{E},\mathbf{F})$, then there exists a section $\mathbf{A} \in \Gamma(\mathrm{Hom}(\mathbf{E},\mathbf{F}))$ such that

$$P(\mathbf{u})(p) = \mathbf{A}(p)(\mathbf{u}(p)), \qquad \forall \mathbf{u} \in \Gamma(\mathbf{E}), p \in M.$$

Proof. By definition of a partial differential operator of order 0, the map $P\colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{F})$ is $C^\infty(M)$-linear. Proposition 1.7.31 identifies maps with this property with sections of $\mathrm{Hom}(\mathbf{E},\mathbf{F})$: there is a unique section $\mathbf{A}$ such that $P(\mathbf{u}) = \mathbf{A}(\mathbf{u})$. Evaluating this equality at $p \in M$ gives $P(\mathbf{u})(p) = \mathbf{A}(p)(\mathbf{u}(p))$. □

As a consequence of this lemma, partial differential operators are local.

Proposition 8.1.15. Let M be a smooth manifold with or without boundary and let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be smooth vector bundles. Every $L \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$ is a local operator, that is, $\forall \mathbf{u} \in \Gamma(\mathbf{E})$,

$$\mathrm{supp}(L\mathbf{u}) \subseteq \mathrm{supp}(\mathbf{u}).$$

Proof. The case $m = 0$ follows from Lemma 8.1.14, since if $\mathbf{u}(p) = 0$ then $L(\mathbf{u})(p) = \mathbf{A}(p)(\mathbf{u}(p)) = \mathbf{A}(p)(0) = 0$, so

$$\mathrm{supp}(L\mathbf{u}) \subseteq \mathrm{supp}(\mathbf{u}).$$

Suppose the assertion holds for $m \geq 0$ and let $L \in \mathbf{PDO}^{(m+1)}(\mathbf{E},\mathbf{F})$.
For any $f \in C^\infty(M)$ we have

$$L(f\mathbf{u}) = [L,f]\mathbf{u} + fL(\mathbf{u}).$$

Since $[L,f] \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$, the induction hypothesis gives

$$\begin{aligned} \operatorname{supp} L(f\mathbf{u}) &\subseteq \operatorname{supp}([L,f]\mathbf{u}) \cup \operatorname{supp}(fL(\mathbf{u})) \subseteq \operatorname{supp}(\mathbf{u}) \cup (\operatorname{supp}(f) \cap \operatorname{supp}(L\mathbf{u})) \\ &\subseteq \operatorname{supp}(\mathbf{u}) \cup \operatorname{supp}(f), \quad \forall f \in C^\infty(M). \end{aligned} \tag{8.1}$$

Under these hypotheses, we show that $\operatorname{supp}(L\mathbf{u}) \subseteq \operatorname{supp}(\mathbf{u})$. We argue by contradiction and suppose that there exists $p \in M$ such that $p \in \operatorname{supp}(L\mathbf{u})$ but $p \notin \operatorname{supp}(\mathbf{u})$. Since $\operatorname{supp}(\mathbf{u})$ is closed and M is a regular topological space (in fact, it is metrizable), there is an open set $U \subseteq M$ such that $p \in U$ and $\overline{U} \cap \operatorname{supp}(\mathbf{u}) = \varnothing$, that is, $\operatorname{supp}(\mathbf{u}) \subseteq M \setminus \overline{U}$, where $M \setminus \overline{U}$ is open. By Proposition 1.3.6, there exists $f \in C^\infty(M)$ such that $f \equiv 0$ on $\overline{U}$ and $f \equiv 1$ on $\operatorname{supp}(\mathbf{u})$. The identity $f\mathbf{u} = \mathbf{u}$ holds throughout M, since $f \equiv 1$ on $\operatorname{supp}(\mathbf{u})$, and if a point x lies outside $\operatorname{supp}(\mathbf{u})$, then $\mathbf{u}(x) = 0 = f(x)\mathbf{u}(x)$. Therefore,

$$\operatorname{supp}(L\mathbf{u}) = \operatorname{supp}(L(f\mathbf{u})),$$

, allowing us to conclude that $p \in \operatorname{supp}(L(f\mathbf{u}))$ since we had taken $p \in \operatorname{supp}(L\mathbf{u})$. But this is impossible, because (8.1) would imply $p \in \operatorname{supp}(\mathbf{u}) \cup \operatorname{supp}(f)$, whereas $p \notin \operatorname{supp}(\mathbf{u})$ and $p \notin \operatorname{supp}(f)$ (the latter holds because $f \equiv 0$ on $U \subseteq \overline{U}$, so $U \cap \{x \in M \mid f(x) \neq 0\} = \varnothing$, and thus $p \notin \overline{\{x \in M \mid f(x) \neq 0\}} = \operatorname{supp}(f)$). The contradiction arose from assuming that $p \notin \operatorname{supp}(\mathbf{u})$, so $\operatorname{supp}(L\mathbf{u}) \subseteq \operatorname{supp}(\mathbf{u})$, completing the proof. □

Remark 8.1.16. If $L \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$ and $\mathbf{u},\mathbf{v} \in \Gamma(\mathbf{E})$ are such that there is an open set $U \subseteq M$ with $\mathbf{u} \equiv \mathbf{v}$ on U, and we define $\mathbf{w} := \mathbf{u} - \mathbf{v}$, this shows that $U \cap \operatorname{supp}(\mathbf{w}) = \varnothing$. Proposition 8.1.15 therefore implies that $\operatorname{supp}(L\mathbf{w}) \subseteq \operatorname{supp}(\mathbf{w})$, and consequently $U \cap \operatorname{supp}(L\mathbf{w}) = \varnothing$, from which we conclude that $L\mathbf{u} - L\mathbf{v} = L\mathbf{w} = 0$ on U; that is, $L\mathbf{u}$ and $L\mathbf{v}$ agree on U.
This justifies the word "local" in that proposition, since it tells us that the values of a partial differential operator are completely determined by the values of the section to which it is applied on an open subset of M.

We show that the composition of partial differential operators is again a partial differential operator. For this, we need the following lemmas:

Lemma 8.1.17. Let M be a smooth manifold with or without boundary. Let $\mathbf{E},\mathbf{F},\mathbf{G}$ be smooth vector bundles over M, let $f \in C^\infty(M)$, and let $P\colon \Gamma(\mathbf{F}) \longrightarrow \Gamma(\mathbf{G})$, $Q\colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{F})$ be linear operators. Then, for every $\mathbf{u} \in \Gamma(\mathbf{E})$,

$$[P \circ Q, f](\mathbf{u}) = [P,f]\big(Q(\mathbf{u})\big) + P\big([Q,f](\mathbf{u})\big).$$

Proof. By definition,

$$[P \circ Q, f](\mathbf{u}) = (P \circ Q)(f\mathbf{u}) - f(P \circ Q)(\mathbf{u}) = P\big(Q(f\mathbf{u})\big) - fP\big(Q(\mathbf{u})\big).$$

Add and subtract $P\big(fQ(\mathbf{u})\big)$:

$$\begin{aligned} [P \circ Q, f](\mathbf{u}) &= \Big(P\big(Q(f\mathbf{u})\big) - P\big(fQ(\mathbf{u})\big)\Big) + \Big(P\big(fQ(\mathbf{u})\big) - fP\big(Q(\mathbf{u})\big)\Big) \\ &= P\big(Q(f\mathbf{u}) - fQ(\mathbf{u})\big) + \big(P(fQ(\mathbf{u})) - fP(Q(\mathbf{u}))\big) \\ &= P\big([Q,f](\mathbf{u})\big) + [P,f]\big(Q(\mathbf{u})\big). \end{aligned}$$

□

Also note that if $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$, this should be interpreted as saying that P is a partial differential operator of order less than or equal to m. This tells us that if a partial differential operator has order less than or equal to m, then it has order less than or equal to $m+1$, justifying the initial choice of terminology.

Lemma 8.1.18. Let M be a smooth manifold with or without boundary, let $\mathbf{E},\mathbf{F} \longrightarrow M$ be smooth vector bundles, and let $m \geq 0$. Then

$$\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F}) \subseteq \mathbf{PDO}^{(m+1)}(\mathbf{E},\mathbf{F}).$$

Proof. We prove the assertion by induction on m. If $m = 0$ and $P \in \mathbf{PDO}^{(0)}(\mathbf{E},\mathbf{F})$, then for every $f \in C^\infty(M)$ $[P,f] = 0$, so by the recursive definition of partial differential operators we have $[P,f] = 0 \in \mathbf{PDO}^{(0)}(\mathbf{E},\mathbf{F})$. Suppose as the induction hypothesis that $\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F}) \subseteq \mathbf{PDO}^{(m+1)}(\mathbf{E},\mathbf{F})$. If $P \in \mathbf{PDO}^{(m+1)}(\mathbf{E},\mathbf{F})$, then for every $f \in C^\infty(M)$, $[P,f] \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F}) \subseteq \mathbf{PDO}^{(m+1)}(\mathbf{E},\mathbf{F})$, so $[P,f] \in \mathbf{PDO}^{(m+1)}(\mathbf{E},\mathbf{F})$ $\forall f \in C^\infty(M)$. This allows us to conclude that $P \in \mathbf{PDO}^{(m+2)}(\mathbf{E},\mathbf{F})$. □

We now examine their behavior under composition.

Proposition 8.1.19. Let M be a smooth manifold with or without boundary and let $\mathbf{E},\mathbf{F},\mathbf{G}$ be smooth real or complex vector bundles over M. If $P \in \mathbf{PDO}^{(m)}(\mathbf{F},\mathbf{G})$ and $Q \in \mathbf{PDO}^{(n)}(\mathbf{E},\mathbf{F})$, then $P \circ Q \in \mathbf{PDO}^{(m+n)}(\mathbf{E},\mathbf{G})$.

Proof. Let $k = m+n$. We proceed by induction on k.
For the base case $k = 0$, we have $m = n = 0$, so P,Q are $C^\infty(M)$–linear, and their composition is as well. Therefore, $P \circ Q \in \mathbf{PDO}^{(0)}(\mathbf{E},\mathbf{G})$.
Now suppose as the induction hypothesis that the result holds for any $m,n \geq 0$ such that $m+n = k$; that is, if $P \in \mathbf{PDO}^{(m)}(\mathbf{F},\mathbf{G})$ and $Q \in \mathbf{PDO}^{(n)}(\mathbf{E},\mathbf{F})$ with $m+n = k$, then $P \circ Q \in \mathbf{PDO}^{(k)}(\mathbf{E},\mathbf{G})$. We must prove that the result holds for any $m,n \geq 0$ with $m+n = k+1$.
Let $P \in \mathbf{PDO}^{(m)}(\mathbf{F},\mathbf{G})$ and $Q \in \mathbf{PDO}^{(n)}(\mathbf{E},\mathbf{F})$ with $m+n = k+1$. For $f \in C^\infty(M)$, Lemma 8.1.17 states that

$$[P \circ Q, f] = [P,f] \circ Q + P \circ [Q,f].$$

If $m = 0$, the $C^\infty(M)$–linearity of P gives $[P,f] = 0$; if $m \geq 1$, then $[P,f] \in \mathbf{PDO}^{(m-1)}(\mathbf{F},\mathbf{G})$ and $(m-1)+n = k$, so the induction hypothesis gives $[P,f] \circ Q \in \mathbf{PDO}^{(k)}(\mathbf{E},\mathbf{G})$. For the second summand, if $n = 0$ then $[Q,f] = 0$; if $n \geq 1$, then $[Q,f] \in \mathbf{PDO}^{(n-1)}(\mathbf{E},\mathbf{F})$ and $m+(n-1) = k$, so $P \circ [Q,f] \in \mathbf{PDO}^{(k)}(\mathbf{E},\mathbf{G})$ by the same hypothesis. Consequently, $[P \circ Q, f] \in \mathbf{PDO}^{(k)}(\mathbf{E},\mathbf{G})$ for every $f \in C^\infty(M)$. The recursive definition implies that $P \circ Q \in \mathbf{PDO}^{(k+1)}(\mathbf{E},\mathbf{G}) = \mathbf{PDO}^{(m+n)}(\mathbf{E},\mathbf{G})$. □

As a corollary of the preceding results, the most common differential operators on $\mathbb{R}^n$ defined in terms of partial derivatives are partial differential operators in the sense we have defined.

Corollary 8.1.20. The operator

$$L = \sum_{|\alpha| \leq m} a_\alpha(x) D^\alpha : C^\infty(\mathbb{R}^n) \longrightarrow C^\infty(\mathbb{R}^n)$$

with $a_\alpha \in C^\infty(\mathbb{R}^n)$, is a partial differential operator of order less than or equal to m.

Proof. By Example 8.1.9, each partial derivative ∂_i is a first-order partial differential operator, so Proposition 8.1.19 ensures that L is a partial differential operator of order $\leq m$, since multiplication by a smooth function does not change the order of **PDO**. □

We examine what happens when the ad operators are permuted:

Lemma 8.1.21. Let M be a smooth manifold with or without boundary and let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be smooth vector bundles over M. Then for any $P \in \mathbf{PDO}(\mathbf{E}, \mathbf{F})$ and any $f, g \in C^\infty(M)$

$$(\mathrm{ad}(f) \circ \mathrm{ad}(g))P = (\mathrm{ad}(g) \circ \mathrm{ad}(f))P.$$

Proof. Let $P \in \mathbf{PDO}(\mathbf{E}, \mathbf{F})$, $f, g \in C^\infty(M)$, and $\mathbf{u} \in \Gamma(\mathbf{E})$. Then

$$(\mathrm{ad}(f) \circ \mathrm{ad}(g))(P)(\mathbf{u}) = [[P, g], f](\mathbf{u}) = [P, g](f\mathbf{u}) - f[P, g](\mathbf{u}) = P(gfu) - gP(f\mathbf{u}) - fP(g\mathbf{u}) + fgP(\mathbf{u}).$$

On the other hand,

$$(\mathrm{ad}(g) \circ \mathrm{ad}(f))(P)(\mathbf{u}) = [[P, f], g](\mathbf{u}) = [P, f](g\mathbf{u}) - g[P, f](\mathbf{u}) = P(fgu) - fP(g\mathbf{u}) - gP(f\mathbf{u}) + gfP(\mathbf{u}).$$

Terms of the same color are equal, since we can interchange f and g, so $(\mathrm{ad}(f) \circ \mathrm{ad}(g))P = (\mathrm{ad}(g) \circ \mathrm{ad}(f))P$. □

Remark 8.1.22. The preceding lemma tells us that if $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$, then for any $f_1, \ldots, f_m \in C^\infty(M)$, the bundle homomorphism

$$\mathrm{ad}(f_1) \circ \mathrm{ad}(f_2) \cdots \circ \mathrm{ad}(f_m)P$$

is unchanged when $f_1, \ldots, f_m$ are permuted.

We next characterize iterated commutators using equality of the respective differentials of the functions; to do so, we first prove a lemma.

Lemma 8.1.23. Let M be a smooth manifold with or without boundary. For each $p \in M$, consider the ideals of the ring $C^\infty_p(M)$,

$$\mathbf{m}_p = \{[f] \in C^\infty_p(M) \mid f(p) = 0\}, \qquad \mathcal{I}_p := \{[f] \in C^\infty_p(M) \mid f(p) = 0,\ df(p) = 0\}.$$

Then $\mathcal{I}_p = \mathbf{m}_p^2$; that is, every smooth function f that vanishes at p together with its differential at p can be written, in a neighborhood of p, as

$$f = \sum_{j=1}^{k} g_j h_j, \qquad g_j, h_j \in \mathbf{m}_p.$$

Proof. Let $p \in M$. First observe that $\mathbf{m}_p^2 \subseteq \mathcal{I}_p$. If $g, h \in \mathbf{m}_p$, then $g(p) = h(p) = 0$, and the product rule gives

$$d(gh)(p) = g(p)\,dh(p) + h(p)\,dg(p) = 0.$$

Therefore, $gh \in \mathcal{I}_p$, and every finite combination of such products belongs to $\mathcal{I}_p$.
Now let $f \in \mathcal{I}_p$, so that $f(p) = 0$ and $df(p) = 0$. Take a smooth chart (U, φ) around p, chosen so that $\varphi(U)$ is convex, $\varphi(p) = 0 \in \mathbb{R}^n$, and write

$$\varphi = (x^1, \dots, x^n).$$

Consider the coordinate representation of f given by

$$\tilde{f} := f \circ \varphi^{-1} \colon \varphi(U) \longrightarrow \mathbb{R}.$$

The conditions $f(p) = 0$ and $df(p) = 0$ are equivalent to

$$\tilde{f}(0) = 0, \qquad \frac{\partial \tilde{f}}{\partial x^i}(0) = 0, \quad \forall i \in \{1, \dots, n\}.$$

Taylor's theorem (Theorem 1.4.9) for $k = 1$, applied at the point $a = 0$, gives

$$\tilde{f}(x) = \tilde{f}(0) + \sum_{i=1}^{n} \frac{\partial \tilde{f}}{\partial x^i}(0)\, x^i + \sum_{|\alpha|=2} \frac{2}{\alpha!}\, x^\alpha \int_0^1 (1-t) D^\alpha \tilde{f}(tx)\, dt.$$

The first two terms vanish, so, passing from multi-index notation to the usual Leibniz notation, we obtain

$$\tilde{f}(x) = \sum_{i,j=1}^{n} x^i x^j R_{ij}(x),$$

where

$$R_{ij}(x) := \int_0^1 (1-t) \frac{\partial^2 \tilde{f}}{\partial x^i \partial x^j}(tx)\, dt.$$

Each function R_{ij} is of class C^∞ in a neighborhood of 0 because $\tilde{f}$ is.
Define

$$\tilde{g}_i(x) := \sum_{j=1}^{n} x^j R_{ij}(x),$$

so that

$$\tilde{f}(x) = \sum_{i=1}^{n} x^i \tilde{g}_i(x).$$

Observe that, for each i,

$$\tilde{g}_i(0) = \sum_{j=1}^{n} 0 \cdot R_{ij}(0) = 0.$$

Now let $g_i := \tilde{g}_i \circ \varphi \in C^\infty(U)$. Then, for every $q \in U$ we have

$$f(q) = \sum_{i=1}^{n} x^i(q)\, g_i(q).$$

We can extend x^i, g_i smoothly to M using Theorem 1.3.7 so that this equality holds in a neighborhood $W \subseteq U$ of p.

Therefore,

$$[f] = \left[\sum_{i=1}^{n} x^i g_i\right] = \sum_{i=1}^{n} [x^i][g_i]$$

as germs of functions. Since $x^i(p) = 0$ and $g_i(p) = \tilde{g}_i(0) = 0$, we have $[x^i], [g_i] \in \mathbf{m}_p$ for every $i \in \{1, \dots, n\}$, and therefore

$$[f] \in \mathbf{m}_p^2.$$

We have proved that $\mathcal{I}_p \subseteq \mathbf{m}_p^2$, and together with the reverse inclusion we obtain

$$\mathcal{I}_p = \mathbf{m}_p^2.$$

□

Definition 8.1.24. Let M be a smooth manifold with or without boundary, let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be smooth vector bundles, and let $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$. For $p \in M$ and $f_1, \dots, f_m \in C^\infty(M)$ define

$$\operatorname{ad}(f_1) \cdots \operatorname{ad}(f_m)(P)|_p \colon \mathbf{E}_p \longrightarrow \mathbf{F}_p$$

by

$$\big(\operatorname{ad}(f_1) \cdots \operatorname{ad}(f_m)(P)|_p\big)(v) := \big(\operatorname{ad}(f_1) \cdots \operatorname{ad}(f_m)(P)\big)(\sigma)(p),$$

where $\sigma \in \Gamma(\mathbf{E})$ satisfies $\sigma(p) = v$. Such a section exists by Lemma 1.7.28, and the value does not depend on the choice of σ because the iterated operator has order zero.

Proposition 8.1.25. Let M be a smooth manifold with or without boundary, let $\mathbf{E}, \mathbf{F} \longrightarrow M$ be smooth vector bundles, and let $m \geq 1$. Let also $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$, $f_i, g_i \in C^\infty(M)$ with $i \in \{1, \dots, m\}$ be such that for $p \in M$,

$$df_i(p) = dg_i(p) \in T_p^* M \qquad \forall i \in \{1, \dots, m\},$$

then

$$\operatorname{ad}(f_1) \circ \operatorname{ad}(f_2) \cdots \circ \operatorname{ad}(f_m) P|_p = \operatorname{ad}(g_1) \circ \operatorname{ad}(g_2) \cdots \circ \operatorname{ad}(g_m) P|_p.$$

Proof. By Proposition 8.1.7, $\operatorname{ad}(c) = 0$ for every constant function c. We may replace each g_i by

$$\widehat{g}_i := g_i + f_i(p) - g_i(p).$$

This replacement does not change $\operatorname{ad}(g_i)$ and simultaneously ensures

$$f_i(p) = \widehat{g}_i(p), \qquad df_i(p) = d\widehat{g}_i(p).$$

We again write g_i in place of $\widehat{g}_i$ and set $\varphi_i := f_i - g_i$. Then

$$\varphi_i(p) = 0, \qquad d\varphi_i(p) = 0.$$

By Lemma 8.1.23, the germ of φ_i belongs to $\mathbf{m}_p^2$.
Let $Q \in \mathbf{PDO}^{(1)}(\mathbf{E}, \mathbf{F})$ and let $\varphi \in C^\infty(M)$ with $\varphi(p) = 0$ and $d\varphi(p) = 0$. The same lemma provides, in a

neighborhood of p, functions α_ν, β_ν such that

$$\varphi = \sum_{\nu=1}^{q} \alpha_\nu \beta_\nu, \qquad \alpha_\nu(p) = \beta_\nu(p) = 0.$$

Theorem 1.3.7 allows us to choose global representatives of these germs. By Remark 8.1.16, equality in a neighborhood of p suffices to compute the value at p. The Leibniz rule in Proposition 8.1.6 gives

$$\operatorname{ad}(\varphi)(Q) = \sum_{\nu=1}^{q} \Big(\operatorname{ad}(\alpha_\nu)(Q) \circ M_{\beta_\nu} + M_{\alpha_\nu} \circ \operatorname{ad}(\beta_\nu)(Q) \Big), \tag{8.2}$$

where M_h denotes multiplication by h. Since Q has order at most one, the operators $\operatorname{ad}(\alpha_\nu)(Q)$ and $\operatorname{ad}(\beta_\nu)(Q)$ have order zero. If $\sigma \in \Gamma(\mathbf{E})$, evaluating (8.2) at p gives

$$\big(\operatorname{ad}(\alpha_\nu)(Q)\big)(\beta_\nu \sigma)(p) = 0, \qquad \alpha_\nu(p)\big(\operatorname{ad}(\beta_\nu)(Q)\sigma\big)(p) = 0.$$

Hence,

$$\operatorname{ad}(\varphi)(Q)|_p = 0.$$

For $r \in \{0, \dots, m\}$ define

$$T_r := \operatorname{ad}(g_1) \cdots \operatorname{ad}(g_r) \operatorname{ad}(f_{r+1}) \cdots \operatorname{ad}(f_m)(P),$$

with the convention that an empty product is the identity, and for $r \in \{1, \dots, m\}$ set

$$Q_r := \operatorname{ad}(g_1) \cdots \operatorname{ad}(g_{r-1}) \operatorname{ad}(f_{r+1}) \cdots \operatorname{ad}(f_m)(P).$$

Here exactly $m-1$ commutators have been applied to an operator of order at most m, so Q_r has order at most one. Moreover, the operators $\operatorname{ad}(h)$ commute with one another by Lemma 8.1.21. Also using linearity from Proposition 8.1.7,

$$T_{r-1} - T_r = \operatorname{ad}(f_r - g_r)(Q_r) = \operatorname{ad}(\varphi_r)(Q_r).$$

Equality $\operatorname{ad}(\varphi)(Q)|_p = 0$, applied to $\varphi = \varphi_r$ and $Q = Q_r$, shows that $(T_{r-1} - T_r)|_p = 0$ for every r. Summing telescopically,

$$(T_0 - T_m)|_p = \sum_{r=1}^{m} (T_{r-1} - T_r)|_p = 0.$$

Since T_0 and T_m are, respectively, the two iterated commutators in the statement, the required equality is proved.

□

We will characterize partial differential operators between the trivial vector bundles $\underline{\mathbb{K}}^p$ and $\underline{\mathbb{K}}^q$ explicitly in terms of their local coordinates, giving us a better idea of what a partial differential operator looks like in general.

The ideals in Lemma 8.1.23 and the use of Taylor's theorem in its proof suggest that these ideals are important in characterizing functions in terms of their derivatives. Just as the cotangent bundle captures information about the first derivatives of smooth functions, there are bundles called *jet bundles* that store information about higher-order derivatives of a function. Introducing and studying these bundles will make it easier to characterize partial differential operators locally and to work with related concepts both intrinsically and locally.

Definition 8.1.26. (Jets of order m of smooth functions) Let M be a smooth manifold with or without boundary and let $p \in M$. Denote the ring of germs of smooth functions at p by $C^\infty_p(M)$, and write

$$\mathbf{m}_p = \{[f] \in C^\infty_p(M) \mid f(p) = 0\}$$

which is a maximal ideal.
For $m \geq 0$ define the power

$$\mathbf{m}_p^{m+1} := \left\langle [f_1]\cdots[f_{m+1}] \mid [f_i] \in \mathbf{m}_p,\ i = 1,\dots,m+1 \right\rangle \subset C^\infty_p(M).$$

The *space of jets of order m of smooth functions at p* is defined as the quotient vector space

$$J^m_p(M) = C^\infty_p(M)/\mathbf{m}_p^{m+1}.$$

For $[f] \in C^\infty_p(M)$, denote its class in $J^m_p(M)$ by

$$j^m_p f,$$

and call it the *jet of order m* of f at p.

This definition can be characterized in terms of derivatives, showing the importance of jets.

Lemma 8.1.27. Let M be a smooth manifold with or without boundary. For each $p \in M$, consider the subsets of the ring $C^\infty_p(M)$

$$\mathcal{I}_p^{(m)} := \left\{[f] \in C^\infty_p(M) \mid D^\alpha f(p) = 0 \text{ for every } |\alpha| \leq m\right\}, \qquad \mathbf{m}_p^{m+1} := \left\langle [f_1]\cdots[f_{m+1}] \mid [f_i] \in \mathbf{m}_p \right\rangle.$$

Then $\mathcal{I}_p^{(m)} = \mathbf{m}_p^{m+1}$.

Proof. Let $p \in M$. First we show that $\mathbf{m}_p^{m+1} \subseteq \mathcal{I}_p^{(m)}$. If

$$[f] = [g_1]\cdots[g_{m+1}], \qquad [g_i] \in \mathbf{m}_p,$$

then $g_i(p) = 0$ for every $i \in \{1,\dots,m+1\}$. For any derivative of order $|\alpha| \leq m$, the Leibniz rule in Proposition 1.1.18 gives

$$D^\alpha(g_1\cdots g_{m+1})(p) = \sum_{\alpha_1+\cdots+\alpha_{m+1}=\alpha} \binom{\alpha}{\alpha_1,\dots,\alpha_{m+1}} D^{\alpha_1}g_1(p)\cdots D^{\alpha_{m+1}}g_{m+1}(p),$$

where

$$\binom{\alpha}{\alpha_1,\dots,\alpha_{m+1}} = \frac{\alpha!}{\alpha_1!\cdots\alpha_{m+1}!}$$

is the multinomial coefficient associated with the multi-indices $\alpha, \alpha_1, \dots, \alpha_{m+1}$. Since $|\alpha| \leq m$, in every tuple $\alpha_1,\dots,\alpha_{m+1}$ with sum α at least one of the multi-indices is zero. This implies that in each term of the Leibniz rule, at least one factor $g_i(p)$ is left undifferentiated; since $g_i(p) = 0$, all summands vanish. Therefore,

$$D^\alpha(g_1\cdots g_{m+1})(p) = 0, \qquad \forall\, |\alpha| \leq m,$$

which shows that $[f] \in \mathcal{I}_p^{(m)}$.
Now let $[f] \in \mathcal{I}_p^{(m)}$, so that

$$D^\alpha f(p) = 0, \qquad \forall |\alpha| \le m.$$

Take a smooth chart (U, φ) around p, with $\varphi(U)$ convex and $\varphi(p) = 0$, and write

$$\varphi = (x^1, \dots, x^n).$$

Let

$$\tilde{f} := f \circ \varphi^{-1} \colon \varphi(U) \longrightarrow \mathbb{R}.$$

Then

$$D^\alpha \tilde{f}(0) = 0, \qquad \forall |\alpha| \le m.$$

Taylor's theorem (Theorem 1.4.9) for $k = m$ at the point 0 gives

$$\tilde{f}(x) = \sum_{|\alpha| \le m} \frac{D^\alpha \tilde{f}(0)}{\alpha!} x^\alpha + \sum_{|\alpha| = m+1} \frac{m+1}{\alpha!} x^\alpha \int_0^1 (1-t)^m D^\alpha \tilde{f}(tx)\, dt.$$

The first summand vanishes by hypothesis, so

$$\tilde{f}(x) = \sum_{|\alpha| = m+1} x^\alpha \tilde{g}_\alpha(x),$$

where

$$\tilde{g}_\alpha(x) := \frac{m+1}{\alpha!} \int_0^1 (1-t)^m D^\alpha \tilde{f}(tx)\, dt,$$

and each $\tilde{g}_\alpha$ is of class C^∞ in a neighborhood of 0.
Let $g_\alpha := \tilde{g}_\alpha \circ \varphi \in C^\infty(U)$. Then, for every $q \in U$,

$$f(q) = \sum_{|\alpha| = m+1} x^\alpha(q)\, g_\alpha(q).$$

Using Theorem 1.3.7, extend x^i and g_α to global smooth functions without changing this equality in a neighborhood $W \subseteq U$ of p.
Thus,

$$[f] = \left[\sum_{|\alpha| = m+1} x^\alpha g_\alpha \right] = \sum_{|\alpha| = m+1} [x^\alpha][g_\alpha] \quad \text{in } C_p^\infty(M).$$

Observe that if $|\alpha| = m+1$, then

$$x^\alpha = (x^1)^{\alpha_1} \cdots (x^n)^{\alpha_n}$$

is a product of exactly $m+1$ coordinate functions, all in $\mathbf{m}_p$. Therefore,

$$[x^\alpha] \in \mathbf{m}_p^{m+1}.$$

Finally, since $\mathbf{m}_p^{m+1}$ is an ideal of $C_p^\infty(M)$, multiplying an element of $\mathbf{m}_p^{m+1}$ by any germ $[g_\alpha]$ again yields an

element of $\mathbf{m}_p^{m+1}$. It follows that

$$[f] \in \mathbf{m}_p^{m+1}.$$

This proves that $\mathcal{I}_p^{(m)} \subseteq \mathbf{m}_p^{m+1}$, and together with the reverse inclusion we obtain

$$\mathcal{I}_p^{(m)} = \mathbf{m}_p^{m+1}.$$

□

This allows us to characterize jets at a given point through derivatives and to determine the dimension of the corresponding fibers.

Corollary 8.1.28. Let M be a smooth manifold with or without boundary, let $p \in M$, and let $m \geq 0$. Fix a local chart centered at p and write D^α for derivatives in those coordinates. Then, for any $f, g \in C^\infty(M)$ we have

$$j_p^m f = j_p^m g \quad \Longleftrightarrow \quad D^\alpha f(p) = D^\alpha g(p), \qquad \forall\, |\alpha| \leq m.$$

In particular, the chosen chart determines an isomorphism between the jet space $J_p^m(M)$ and the vector space

$$\mathbb{K}^N, \qquad N := \binom{n+m}{m},$$

through the map

$$J_p^m(M) \longrightarrow \mathbb{K}^N, \qquad j_p^m f \longmapsto \left(D^\alpha f(p)\right)_{|\alpha| \leq m}.$$

Under this identification, $\dim J_p^m(M) = \binom{n+m}{m}$.

Proof. By definition, $j_p^m f = j_p^m g$ if and only if the germs $[f]$ and $[g]$ satisfy

$$[f] - [g] \in \mathbf{m}_p^{m+1}.$$

By Lemma 8.1.27, $\mathbf{m}_p^{m+1} = \mathcal{I}_p^{(m)}$, that is,

$$[f] - [g] \in \mathcal{I}_p^{(m)} \quad \Longleftrightarrow \quad D^\alpha (f-g)(p) = 0,\ \forall\, |\alpha| \leq m.$$

This is equivalent to

$$D^\alpha f(p) = D^\alpha g(p), \qquad \forall\, |\alpha| \leq m,$$

which proves the first assertion.

To establish the isomorphism, use the smooth chart (U, φ) fixed in the statement, with $\varphi(p) = 0$. Define

$$\Psi : J_p^m(M) \longrightarrow \mathbb{K}^N, \qquad \Psi\left(j_p^m f\right) = \left(D^\alpha f(p)\right)_{|\alpha| \leq m}$$

This is well defined by the preceding criterion: if $j_p^m f = j_p^m g$, then $D^\alpha f(p) = D^\alpha g(p)$ for every $|\alpha| \leq m$. It is also linear by linearity of differentiation.

To show that Ψ is injective, Lemma 8.1.27 gives:

$$j_p^m f = j_p^m 0 \iff [f] \in \mathbf{m}_p^{m+1} \iff D^\alpha f(p) = 0,\ \forall |\alpha| \le m \iff \Psi\left(j_p^m f\right) = 0.$$

To show that Ψ is surjective, given a collection of numbers $\{a_\alpha\}_{|\alpha|\le m}$, consider the polynomial

$$P(x) = \sum_{|\alpha|\le m} \frac{a_\alpha}{\alpha!} x^\alpha,$$

which satisfies $D^\alpha P(0) = a_\alpha$ for every multi-index $|\alpha| \le m$. Define $f := P \circ \varphi \colon U \longrightarrow \mathbb{K}$. Since $p \in U$ and $f \in C^\infty(U)$, Theorem 1.3.7 gives an open set $W \subseteq M$ such that $p \in W \subseteq \overline{W} \subseteq U$ and a function $\widetilde{f} \in C^\infty(M)$ such that $\widetilde{f}\restriction_W = f$. Since $D^\alpha f(p) = D^\alpha (f \circ \varphi^{-1})|_{\varphi(p)} = D^\alpha P(0)$ and $D^\alpha \widetilde{f}(p) = D^\alpha f(p)$, we then have

$$\left(D^\alpha \widetilde{f}(p)\right)_{|\alpha|\le m} = (a_\alpha)_{|\alpha|\le m}.$$

with $\widetilde{f} \in C^\infty(M)$.
Therefore, Ψ is a linear isomorphism and the dimension of $J_p^m(M)$ is the number of multi-indices $\alpha \in \mathbb{N}_0^n$ with $|\alpha| \le m$, namely,

$$\dim J_p^m(M) = \binom{n+m}{m}.$$

□

To gain more practice with differential operators between vector bundles, we extend the concept of a partial derivative to local sections of smooth vector bundles.

Lemma 8.1.29. Let $\pi_{\mathbf{E}} \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle of rank r over a smooth manifold M with or without boundary, and let (U, φ) be a chart with local coordinates $\varphi = (x^1, \dots, x^n)$ such that U is the domain of a local trivialization

$$\tau_{\mathbf{E}} \colon \mathbf{E}\restriction_U \longrightarrow U \times \mathbb{K}^r.$$

For each multi-index $\beta \in \mathbb{N}_0^n$ define $D^\beta \colon \Gamma(\mathbf{E}\restriction_U) \longrightarrow \Gamma(\mathbf{E}\restriction_U)$ by

$$(D^\beta \mathbf{u})(p) := \tau_{\mathbf{E}}^{-1}\left(p, D^\beta\left((\pi_2 \circ \tau_{\mathbf{E}} \circ \mathbf{u})\right)(p)\right), \qquad \mathbf{u} \in \Gamma(\mathbf{E}\restriction_U),\ p \in U,$$

where D^β on the right-hand side is the partial derivative of order $|\beta|$ applied componentwise to the function

$$\pi_2 \circ \tau_{\mathbf{E}} \circ \mathbf{u} \colon U \longrightarrow \mathbb{K}^r.$$

Then, for every multi-index β with $|\beta| \ge 1$, we have

$$[D^\beta, f](\mathbf{u}) = \tau_{\mathbf{E}}^{-1}\left(p, \sum_{0<\gamma\le\beta} \binom{\beta}{\gamma} (D^\gamma f)(p)\, D^{\beta-\gamma}\left((\pi_2 \circ \tau_{\mathbf{E}} \circ \mathbf{u})\right)(p)\right),$$

for every $f \in C^\infty(U)$ and every $\mathbf{u} \in \Gamma(\mathbf{E}\restriction_U)$.

Proof. Let $\mathbf{u} \in \Gamma(\mathbf{E} \restriction_U)$. Its local representation is given by the function

$$\widetilde{u} := \pi_2 \circ \tau_{\mathbf{E}} \circ \mathbf{u} \colon U \longrightarrow \mathbb{K}^r,$$

so that

$$\tau_{\mathbf{E}}(\mathbf{u}(p)) = (p, \widetilde{u}(p)), \qquad p \in U.$$

In these coordinates, D^β acts componentwise on $\widetilde{u}$.

The commutator is defined by

$$[D^\beta, f]\mathbf{u} = D^\beta(f\mathbf{u}) \; - \; f\, D^\beta \mathbf{u}.$$

Applying $\pi_2 \circ \tau_{\mathbf{E}}$ gives

$$(\pi_2 \circ \tau_{\mathbf{E}} \circ [D^\beta, f]\mathbf{u})(p) = D^\beta\big(f\,\widetilde{u}\big)(p) - f(p)\, D^\beta \widetilde{u}(p). \tag{8.3}$$

By the Leibniz rule (Proposition 1.1.17), for every $p \in U$,

$$D^\beta(f\,\widetilde{u})(p) = \sum_{\gamma \le \beta} \binom{\beta}{\gamma} (D^\gamma f)(p)\, D^{\beta-\gamma}\widetilde{u}(p). \tag{8.4}$$

The term with $\gamma = 0$ is

$$(D^0 f)(p)\, D^\beta \widetilde{u}(p) = f(p)\, D^\beta \widetilde{u}(p).$$

Substituting (8.4) into (8.3) and subtracting the term $\gamma = 0$ gives

$$(\pi_2 \circ \tau_{\mathbf{E}} \circ [D^\beta, f]\mathbf{u})(p) = \sum_{0 < \gamma \le \beta} \binom{\beta}{\gamma} (D^\gamma f)(p)\, D^{\beta-\gamma}\widetilde{u}(p). \tag{8.5}$$

Finally, to recover the bundle section from its representation in $\mathbb{K}^r$, apply the inverse of the trivialization:

$$[D^\beta, f]\mathbf{u}(p) = \tau_{\mathbf{E}}^{-1}\Big(p, (\pi_2 \circ \tau_{\mathbf{E}} \circ [D^\beta, f]\mathbf{u})(p)\Big).$$

Substituting (8.5) gives

$$[D^\beta, f]\mathbf{u} = \tau_{\mathbf{E}}^{-1}\left(p, \sum_{0 < \gamma \le \beta} \binom{\beta}{\gamma} (D^\gamma f)(p)\, D^{\beta-\gamma}\widetilde{u}(p)\right),$$

which is the desired formula. □

We continue with a lemma that will help characterize PDOs locally using what we have already established about jets.

Lemma 8.1.30. (Vanishing on germs of order $\ge m{+}1$) Let M be a smooth manifold with or without boundary and let $p \in M$. Consider the trivial bundle

$$\underline{\mathbb{K}}^r = M \times \mathbb{K}^r, \qquad \underline{\mathbb{K}}^s = M \times \mathbb{K}^s,$$

and let

$$P \in \mathbf{PDO}^{(m)}\big(\underline{\mathbb{K}}^r, \underline{\mathbb{K}}^s\big).$$

Define the map

$$L_p\colon \ \big(C_p^\infty(M)\big)^r \longrightarrow \mathbb{K}^s, \qquad L_p([u]) := (P(u))(p),$$

which is well defined by locality (Remark 8.1.16).
We write

$$\mathbf{m}_p^{m+1}\big(C_p^\infty(M)\big)^r := \left\{ \sum_{j=1}^{N} [f_j][u_j] \;\middle|\; [f_j] \in \mathbf{m}_p^{m+1},\ [u_j] \in \big(C_p^\infty(M)\big)^r,\ N \in \mathbb{N} \right\},$$

Here we recall that $(C_p^\infty(M))^r$ has the structure of a module over the ring $C_p^\infty(M)$, and note that $\mathbf{m}_p^{m+1}\big(C_p^\infty(M)\big)^r$ is an $C_p^\infty(M)$–submodule of $(C_p^\infty(M))^r$, so the quotient

$$\big(C_p^\infty(M)\big)^r / \mathbf{m}_p^{m+1}\big(C_p^\infty(M)\big)^r$$

has the structure of an $C_p^\infty(M)$–module. Since the field $\mathbb{K}$ can be regarded as a subset of $C_p^\infty(M)$, this space also inherits an $\mathbb{K}$–vector space structure.
With this notation and these hypotheses,

$$L_p\big(\mathbf{m}_p^{m+1}(C_p^\infty(M))^r\big) = \{0\} \subset \mathbb{K}^s,$$

and therefore L_p induces a well-defined $\mathbb{K}$–linear map

$$\overline{L}_p\colon \ \big(C_p^\infty(M)\big)^r / \mathbf{m}_p^{m+1}\big(C_p^\infty(M)\big)^r \longrightarrow \mathbb{K}^s.$$

Proof. Let $[u] \in \big(C_p^\infty(M)\big)^r$. By $\mathbb{K}$–linearity of P, it suffices to prove that

$$L_p\big([f][u]\big) = 0 \qquad \text{for every } [f] \in \mathbf{m}_p^{m+1}.$$

By Lemma 8.1.27,

$$\mathbf{m}_p^{m+1} = \mathcal{I}_p^{(m)} = \big\{[f] \in C_p^\infty(M) \ \mid\ D^\alpha f(p) = 0,\ |\alpha| \le m\big\}.$$

Take a smooth chart (U, φ) with $p \in U$, $\varphi(U)$ convex, $\varphi(p) = 0$, and coordinate functions $x^1, \dots, x^n$. Let $\tilde{f} := f \circ \varphi^{-1}$. The conditions $D^\alpha f(p) = 0$ are equivalent to $D^\alpha \tilde{f}(0) = 0$ for every $|\alpha| \le m$.
Taylor's theorem gives the identity

$$\tilde{f}(x) = \sum_{|\alpha|=m+1} x^\alpha\, \tilde{g}_\alpha(x), \qquad \tilde{g}_\alpha \in C^\infty(\varphi(U)).$$

Let

$$g_\alpha := \tilde{g}_\alpha \circ \varphi \in C^\infty(U), \qquad |\alpha| = m+1.$$

Then on U

$$f = \sum_{|\alpha|=m+1} x^\alpha g_\alpha.$$

We now extend all these functions simultaneously: by Theorem 1.3.7 there exist an open set

$$p \in W \subseteq \overline{W} \subseteq U$$

and smooth functions defined on M

$$\tilde{x}^i,\ \tilde{g}_\alpha^M \in C^\infty(M)$$

such that

$$\tilde{x}^i \restriction_W = x^i \restriction_W, \qquad \tilde{g}_\alpha^M \restriction_W = g_\alpha \restriction_W .$$

Therefore, on W,

$$f = \sum_{|\alpha|=m+1} x^\alpha g_\alpha = \sum_{|\alpha|=m+1} \tilde{x}^\alpha \tilde{g}_\alpha^M,$$

and passing to germs at p gives

$$[f] = \sum_{|\alpha|=m+1} [\tilde{x}^\alpha][\tilde{g}_\alpha^M] \qquad \text{in } C_p^\infty(M).$$

Now let

$$v_\alpha := \tilde{g}_\alpha^M u \in (C^\infty(M))^r.$$

By linearity, it suffices to prove that

$$L_p\big([\tilde{x}^\alpha][v_\alpha]\big) = 0.$$

We write

$$\tilde{x}^\alpha = (\tilde{x}^1)^{\alpha_1} \cdots (\tilde{x}^n)^{\alpha_n}.$$

Define inductively, for $k \geq 1$,

$$\mathrm{ad}(f)^k(P) := \mathrm{ad}(f)\big(\mathrm{ad}(f)^{k-1}(P)\big), \qquad \mathrm{ad}(f)^0(P) := P.$$

Apply the identity

$$P(fw) = f\,P(w) + [P, f](w), \qquad f \in C^\infty(M),$$

successively $|\alpha| = m+1$ times, always using the global functions $\tilde{x}^i$. Upon evaluation at p, all terms retaining any factor $\tilde{x}^i$ vanish because $\tilde{x}^i(p) = 0$, and only the term accumulating a commutator at each step survives. Thus we obtain

$$P\big(\tilde{x}^\alpha v_\alpha\big)(p) = \Big(\mathrm{ad}(\tilde{x}^1)^{\alpha_1} \cdots \mathrm{ad}(\tilde{x}^n)^{\alpha_n} P\Big)\big(v_\alpha\big)(p).$$

But this is an iterated commutator of length

$$\alpha_1 + \cdots + \alpha_n = |\alpha| = m+1,$$

and vanishes by Proposition 8.1.4. In particular,

$$L_p\big([\tilde{x}^\alpha][v_\alpha]\big) = P\big(\tilde{x}^\alpha v_\alpha\big)(p) = 0.$$

Therefore,

$$L_p([f][u]) = 0 \qquad \forall\, [f] \in \mathbf{m}_p^{m+1}.$$

Now let

$$L_p \colon \left(C_p^\infty(M)\right)^r \longrightarrow \mathbb{K}^s.$$

Since

$$L_p\left(\mathbf{m}_p^{m+1}(C_p^\infty(M))^r\right) = \{0\},$$

if $[u]$ and $[w]$ represent the same class in the quotient, then $[u]-[w] \in \mathbf{m}_p^{m+1}(C_p^\infty(M))^r$ and therefore

$$L_p([u]) - L_p([w]) = L_p([u]-[w]) = 0.$$

We therefore define

$$\overline{L}_p([u]) := L_p([u]) = (P(u))(p).$$

The definition is independent of the representative, and the $\mathbb{K}$–linearity of L_p shows that $\overline{L}_p$ is $\mathbb{K}$–linear. □

Remark 8.1.31. Lemma 8.1.30 expresses the fact that a differential operator of order $\leq m$ between trivial bundles depends only on the m-jet of the germ evaluated at the point. Consequently, germs of order $\geq m+1$ are invisible to any differential operator of order $\leq m$ at the pointwise level, as the following example shows.

Example 8.1.32. Let $M = \mathbb{R}$, $p = 0$, and consider the operator

$$P = \frac{d^2}{dx^2} \in \mathbf{PDO}^{(2)}(\underline{\mathbb{R}}, \underline{\mathbb{R}}).$$

Let $f(x) = x^3$, so that

$$f(0) = f'(0) = f''(0) = 0, \text{ so that } [f] \in \mathbf{m}_0^3.$$

Let $u(x) = \sin x$. Then

$$P(fu) = \frac{d^2}{dx^2}(x^3 \sin x),$$

and we obtain

$$(x^3 \sin x)'' = 6x \sin x + 6x^2 \cos x - x^3 \sin x.$$

Evaluating at $p = 0$ gives

$$P(fu)(0) = 0.$$

Therefore,

$$L_0\left([f][u]\right) = (P(fu))(0) = 0,$$

which illustrates Lemma 8.1.30: every germ vanishing to order $m+1$ is invisible to a differential operator of order $\leq m$ when evaluated at the point.

Theorem 8.1.33. (Local characterization of partial differential operators in the trivial case) Let M be a

smooth manifold with or without boundary and consider the trivial bundles

$$\mathbf{E} = \underline{\mathbb{K}}^r = M \times \mathbb{K}^r, \qquad \mathbf{F} = \underline{\mathbb{K}}^s = M \times \mathbb{K}^s.$$

Let

$$P\colon C^\infty(M,\mathbb{K}^r) \longrightarrow C^\infty(M,\mathbb{K}^s)$$

be an $\mathbb{K}$–linear map. Fix $m \geq 0$. The following are equivalent:

(a) $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$.

(b) For every smooth chart (U,φ) with local coordinates $\varphi = (x^1,\dots,x^n)$ there exist smooth functions

$$a_\alpha\colon U \longrightarrow \mathrm{Hom}(\mathbb{K}^r,\mathbb{K}^s), \qquad |\alpha| \leq m,$$

such that, for every function $u \in C^\infty(M,\mathbb{K}^r)$ and every $p \in U$,

$$(Pu)(p) = \sum_{|\alpha|\leq m} a_\alpha(p)\, D^\alpha u(p),$$

where $D^\alpha u(p) \in \mathbb{K}^r$ denotes the vector of partial derivatives of order $|\alpha|$ of the components of u in the chart (U,φ).

Proof. $(b) \Rightarrow (a)$: Suppose that (b) holds. This means that, for each smooth chart (U,φ), there is a collection of smooth coefficients a_α such that, for every function $u \in C^\infty(M,\mathbb{K}^r)$, the restriction of Pu to U satisfies

$$(Pu)\restriction_U = \sum_{|\alpha|\leq m} a_\alpha\, D^\alpha(u\restriction_U).$$

Denote by P_U the differential operator defined on the open set U by this local expression:

$$P_U\colon C^\infty(U,\mathbb{K}^r) \longrightarrow C^\infty(U,\mathbb{K}^s), \qquad v \longmapsto \sum_{|\alpha|\leq m} a_\alpha\, D^\alpha v.$$

We know that, on the domain U, each term D^α is a differential operator of order $|\alpha|$ (Corollary 8.1.20), and multiplication by a_α has order 0. By Proposition 8.1.19, we conclude that P_U is a partial differential operator of order $\leq m$ on U; that is,

$$P_U \in \mathbf{PDO}^{(m)}(\mathbf{E}\restriction_U, \mathbf{F}\restriction_U).$$

To prove that the global operator P belongs to $\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$, we use the recursive definition based on commutators and adjoints. We must check that for any $m+1$ global smooth functions $f_0,\dots,f_m \in C^\infty(M)$, the iterated commutator vanishes:

$$\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_m)(P) = 0.$$

Consider $u \in C^\infty(M,\mathbb{K}^r)$. Since we explicitly know the behavior of Pu on U, for any $f \in C^\infty(M)$ we have the identity:

$$(\mathrm{ad}(f)(P)u)\restriction_U = ([P,f]u)\restriction_U = P_U((fu)\restriction_U) - f\restriction_U P_U(u\restriction_U) = (\mathrm{ad}(f\restriction_U)(P_U))(u\restriction_U).$$

Applying this recursively to the iterated commutators gives, in each chart (U,φ):

$$\big(\big(\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_m)(P)\big)(u)\big)\restriction_U = \big(\mathrm{ad}(f_0\restriction_U)\cdots\mathrm{ad}(f_m\restriction_U)(P_U)\big)(u\restriction_U).$$

Since P_U is a differential operator of order $\le m$ on U, its commutator with $m+1$ functions vanishes identically on U. Therefore,

$$\big(\big(\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_m)(P)\big)(u)\big)\restriction_U = 0.$$

Since we can choose an open cover of M consisting of chart domains, and the function

$$\big(\big(\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_m)(P)\big)(u)\big)\restriction_U$$

vanishes on each of those domains,

$$\big(\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_m)(P)\big)(u) = 0 \quad \text{throughout } M.$$

Since u was arbitrary, the operator $\mathrm{ad}(f_0)\dots\mathrm{ad}(f_m)(P)$ is the zero operator. This proves that $P\in\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$.

$(a)\Rightarrow(b)$: Now suppose that $P\in\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$. In particular, by Remark 8.1.16, P is local. Since $\mathbf{E}$ and $\mathbf{F}$ are trivial bundles, a section of $\mathbf{E}$ can be viewed as a function $u\colon M\longrightarrow\mathbb{K}^r$ and a section of $\mathbf{F}$ as a function $v\colon M\longrightarrow\mathbb{K}^s$. For each $p\in M$ consider the map

$$L_p\colon\ (C^\infty_p(M))^r\longrightarrow\mathbb{K}^s,\qquad L_p([u]) := (Pu)(p),$$

where $[u]$ denotes the germ of u at p. Locality of P ensures that L_p is well defined.
By Lemma 8.1.30, applied to M, the point p, and the operator P, we have

$$L_p\big(\mathbf{m}_p^{m+1}(C^\infty_p(M))^r\big) = \{0\}.$$

Therefore, L_p induces a well-defined $\mathbb{K}$–linear map

$$\overline{L}_p\colon\ (C^\infty_p(M))^r\big/\mathbf{m}_p^{m+1}(C^\infty_p(M))^r\longrightarrow\mathbb{K}^s.$$

We now justify in some detail the structure of the quotient

$$(C^\infty_p(M))^r\big/\mathbf{m}_p^{m+1}(C^\infty_p(M))^r.$$

By definition of the submodule

$$\mathbf{m}_p^{m+1}(C^\infty_p(M))^r = \left\{\sum_{j=1}^{N}[f_j][u_j]\;\middle|\;[f_j]\in\mathbf{m}_p^{m+1},\ [u_j]\in(C^\infty_p(M))^r,\ N\in\mathbb{N}\right\},$$

two germs $[u],[v]\in(C^\infty_p(M))^r$, with coordinates

$$u=(u^1,\dots,u^r),\qquad v=(v^1,\dots,v^r),$$

represent the same class in the quotient if and only if their difference belongs to that submodule, that is, if

and only if

$$[u^j] - [v^j] \in \mathbf{m}_p^{m+1} \qquad \text{for each } j \in \{1,\dots,r\}.$$

In other words,

$$[u] = [v] \text{ in } (C_p^\infty(M))^r / \mathbf{m}_p^{m+1}(C_p^\infty(M))^r \iff [u^j] = [v^j] \text{ in } C_p^\infty(M)/\mathbf{m}_p^{m+1},\ \forall j \in \{1,\dots,r\}.$$

It follows that the quotient, viewed as a vector space,

$$(C_p^\infty(M))^r / \mathbf{m}_p^{m+1}(C_p^\infty(M))^r$$

is isomorphic to the product of vector spaces

$$\left(C_p^\infty(M)/\mathbf{m}_p^{m+1}\right)^r.$$

Now take a smooth chart (U,φ) with $p \in U$ and coordinates $\varphi = (x^1,\dots,x^n)$. By Definition 8.1.26, the space of jets of order m at p is

$$J_p^m(M) := C_p^\infty(M)/\mathbf{m}_p^{m+1},$$

and Corollary 8.1.28 states that each class $j_p^m f$ is determined exactly by the derivatives

$$\left(D^\alpha f(p)\right)_{|\alpha|\le m},$$

in coordinates $x^1,\dots,x^n$, and that the map

$$J_p^m(M) \longrightarrow \mathbb{K}^N, \qquad j_p^m f \longmapsto \left(D^\alpha f(p)\right)_{|\alpha|\le m},$$

is an isomorphism of vector spaces, where $N = \binom{n+m}{m}$.
Combining these observations, we obtain a chain of isomorphisms

$$(C_p^\infty(M))^r / \mathbf{m}_p^{m+1}(C_p^\infty(M))^r \ \cong\ \left(C_p^\infty(M)/\mathbf{m}_p^{m+1}\right)^r \ \cong\ \left(J_p^m(M)\right)^r \ \cong\ \mathbb{K}^{r\binom{n+m}{m}},$$

where the last identification sends the class of

$$u = (u^1,\dots,u^r)$$

to the finite collection of partial derivatives

$$\left(D^\alpha u^j(p)\right)_{|\alpha|\le m,\ 1\le j\le r}.$$

In particular, under this isomorphism the functional $\overline{L}_p$ corresponds to a linear transformation

$$\mathbb{K}^{r\binom{n+m}{m}} \longrightarrow \mathbb{K}^s,$$

uniquely determined by a collection of linear transformations

$$a_\alpha(p) \in \operatorname{Hom}(\mathbb{K}^r,\mathbb{K}^s), \qquad |\alpha| \le m,$$

such that, for every germ $[u] \in (C^\infty_p(M))^r$,

$$\overline{L}_p([u]) = \sum_{|\alpha| \le m} a_\alpha(p)\, D^\alpha u(p),$$

where $D^\alpha u(p) \in \mathbb{K}^r$ is the vector of partial derivatives of order $|\alpha|$ of the components of u in the chart (U, φ). By definition of $\overline{L}_p$ and L_p, if $u \in C^\infty(M, \mathbb{K}^r)$, the germ $[u]$ at p satisfies

$$(Pu)(p) = L_p([u]) = \overline{L}_p([u]) = \sum_{|\alpha| \le m} a_\alpha(p)\, D^\alpha u(p).$$

This proves the local formula in (b) in the chart (U, φ):

$$(Pu)(p) = \sum_{|\alpha| \le m} a_\alpha(p)\, D^\alpha u(p), \qquad p \in U.$$

It remains to check that the coefficients a_α depend smoothly on the point. This property is local. Fix $p_0 \in U$ and choose open sets $V \Subset W \Subset U$ with $p_0 \in V$, together with a function $\chi \in C^\infty_c(U)$ equal to one on W. For each vector in the standard basis $e_j \in \mathbb{K}^r$ and each multi-index γ with $|\gamma| \le m$, extend the function

$$u_{\gamma,j}(x) := \chi(x)(x^1)^{\gamma_1} \cdots (x^n)^{\gamma_n} e_j.$$

globally. On V, the cutoff function contributes to none of the derivatives. The formula already obtained, applied first to $u_{0,j}$, shows that $a_0(\cdot)e_j = P(u_{0,j})$ on V and therefore that a_0 is smooth there. Suppose by induction that a_β is smooth on V for every $|\beta| < \ell$. If $|\gamma| = \ell$, then

$$P(u_{\gamma,j}) = \gamma!\, a_\gamma e_j + \sum_{|\beta| < \ell} a_\beta D^\beta u_{\gamma,j} \qquad \text{on } V.$$

Indeed, the derivatives of order ℓ of the monomial x^γ vanish except for the one corresponding to γ, which equals $\gamma!$. Thus,

$$a_\gamma e_j = \frac{1}{\gamma!}\left(P(u_{\gamma,j}) - \sum_{|\beta| < \ell} a_\beta D^\beta u_{\gamma,j} \right) \qquad \text{on } V,$$

and the right-hand side is smooth by the induction hypothesis. Running through the standard basis and the orders $\ell = 0, \dots, m$, we conclude that all the a_α are smooth near p_0. Since p_0 was arbitrary, they are smooth throughout U. □

Finally, we give the local characterization of partial differential operators on a smooth real or complex vector bundle.

Theorem 8.1.34. (Local characterization of partial differential operators on vector bundles) Let M be a smooth manifold with or without boundary. Let $\pi_{\mathbf{E}} \colon \mathbf{E} \longrightarrow M$ and $\pi_{\mathbf{F}} \colon \mathbf{F} \longrightarrow M$ be smooth vector bundles of ranks r and s (real or complex), and let $m \ge 0$. For an $\mathbb{K}$–linear map

$$P \colon \Gamma(\mathbf{E}) \longrightarrow \Gamma(\mathbf{F}),$$

the following are equivalent:

(a) $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$.

(b) For every smooth chart (U,φ) with local trivializations

$$\tau_{\mathbf{E}}\colon \mathbf{E}\restriction_U \longrightarrow U\times\mathbb{K}^r, \qquad \tau_{\mathbf{F}}\colon \mathbf{F}\restriction_U \longrightarrow U\times\mathbb{K}^s,$$

there exist smooth functions

$$a_\alpha\colon U \longrightarrow \mathrm{Hom}(\mathbb{K}^r,\mathbb{K}^s), \qquad |\alpha|\le m,$$

such that, for every section $\mathbf{u}\in\Gamma(\mathbf{E})$ with local representation in U given by

$$\widetilde{u} := \pi_2\circ\tau_{\mathbf{E}}\circ(\mathbf{u}\restriction_U)\in C^\infty(U,\mathbb{K}^r),$$

we have, for each $p\in U$,

$$P(\mathbf{u})(p) = \tau_{\mathbf{F}}^{-1}\left(p,\ \sum_{|\alpha|\le m} a_\alpha(p)\,D^\alpha\widetilde{u}(p)\right).$$

Proof. Fix a smooth chart (U,φ) with coordinates $\varphi=(x^1,\dots,x^n)$ and local trivializations $\tau_{\mathbf{E}}$ and $\tau_{\mathbf{F}}$ defined on U. Given a global section $\mathbf{u}\in\Gamma(\mathbf{E})$, denote by $\widetilde{u}\in C^\infty(U,\mathbb{K}^r)$ the local representation of $\mathbf{u}$

$$\widetilde{u} := \pi_2\circ\tau_{\mathbf{E}}\circ(\mathbf{u}\restriction_U).$$

Given a global section $\mathbf{v}\in\Gamma(\mathbf{F})$, its representation in the trivialization of $\mathbf{F}$ is, by definition, $\widetilde{v} := \pi_2\circ\tau_{\mathbf{F}}\circ(\mathbf{v}\restriction_U)$.

$(b)\Rightarrow(a)$: Suppose that (b) holds. Define an auxiliary operator $\widetilde{P}_U$ on the space of vector-valued functions on the open set U by the explicit expression in the hypothesis:

$$\widetilde{P}_U\colon C^\infty(U,\mathbb{K}^r)\longrightarrow C^\infty(U,\mathbb{K}^s), \qquad \widetilde{P}_U(w)=\sum_{|\alpha|\le m} a_\alpha\,D^\alpha w.$$

By Theorem 8.1.33, the operator $\widetilde{P}_U$ is a partial differential operator of order $\le m$ between the trivial bundles over U. Hypothesis (b) states that the global operator P and this local operator $\widetilde{P}_U$ are related through the trivializations. Specifically, for every global section $\mathbf{u}\in\Gamma(\mathbf{E})$:

$$P(\mathbf{u})\restriction_U = \tau_{\mathbf{F}}^{-1}\left(\cdot\ ,\ \sum_{|\alpha|\le m} a_\alpha D^\alpha\widetilde{u}\right),$$

so, composing with $\tau_{\mathbf{F}}$ and then projecting onto the second coordinate,

$$\pi_2\circ\tau_{\mathbf{F}}\circ(P(\mathbf{u})\restriction_U) = \widetilde{P}_U(\widetilde{u}).$$

To check that $P\in\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$, it suffices to prove that

$$\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_m)(P)=0, \qquad \forall\, f_0,\dots,f_m\in C^\infty(M).$$

Let $\mathbf{u} \in \Gamma(\mathbf{E})$ and fix arbitrary functions $f_0, \dots, f_m \in C^\infty(M)$. We work in the chart (U, φ) with the chosen trivializations.

Given $f \in C^\infty(M)$ and $\mathbf{u} \in \Gamma(\mathbf{E})$, first observe that the pointwise action of f passes to the local representation through the identity

$$\widetilde{f\mathbf{u}} = \pi_2 \circ \tau_{\mathbf{E}}\big((f\mathbf{u}) \restriction_U\big) = (f \restriction_U)\,\widetilde{u}. \tag{8.6}$$

This equality follows directly from linearity of the trivialization $\tau_{\mathbf{E}}$ on each fiber.

Now apply $\pi_2 \circ \tau_{\mathbf{F}}$ to the commutator $\mathrm{ad}(f)(P)$:

$$\begin{aligned}
\pi_2 \circ \tau_{\mathbf{F}} \circ \big(\mathrm{ad}(f)(P)(\mathbf{u})\big) \restriction_U &= \pi_2 \circ \tau_{\mathbf{F}}\Big(P(f\mathbf{u}) \restriction_U - (fP(\mathbf{u})) \restriction_U\Big) \\
&= \widetilde{P}_U\big(\widetilde{f\mathbf{u}}\big) - (f \restriction_U)\,\widetilde{P}_U(\widetilde{u}) \\
&\overset{(8.6)}{=} \widetilde{P}_U\big((f \restriction_U)\,\widetilde{u}\big) - (f \restriction_U)\,\widetilde{P}_U(\widetilde{u}) \\
&= \big[\widetilde{P}_U, f \restriction_U\big](\widetilde{u}) \\
&= \big(\mathrm{ad}(f \restriction_U)(\widetilde{P}_U)\big)(\widetilde{u}).
\end{aligned}$$

Repeating this argument $m+1$ times and using at each step identity (8.6) together with the compatibility between P and $\widetilde{P}_U$ provided by the trivializations gives

$$\pi_2 \circ \tau_{\mathbf{F}} \circ \big(\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_m)(P)(\mathbf{u})\big) \restriction_U = \big(\mathrm{ad}(f_0 \restriction_U)\cdots\mathrm{ad}(f_m \restriction_U)(\widetilde{P}_U)\big)(\widetilde{u}).$$

By Theorem 8.1.33, the operator $\widetilde{P}_U$ is a partial differential operator of order $\le m$ on the trivial bundle over U. By Proposition 8.1.4, every iterated commutator of length $m+1$ with smooth functions on U vanishes:

$$\mathrm{ad}(f_0 \restriction_U)\cdots\mathrm{ad}(f_m \restriction_U)(\widetilde{P}_U) = 0.$$

Therefore, the right-hand side of the preceding equality is 0 for every $\widetilde{u}$, and consequently

$$\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_m)(P)(\mathbf{u}) = 0 \qquad \text{on } U.$$

Since M admits an open cover by charts that are trivialization domains for $\mathbf{E}$ and $\mathbf{F}$, and the preceding identity holds on each of them, we conclude that

$$\mathrm{ad}(f_0)\cdots\mathrm{ad}(f_m)(P) = 0 \qquad \text{throughout } M.$$

This proves that $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$.

$(a) \Rightarrow (b)$:
Now suppose that $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$. First, P is a local operator (Remark 8.1.16). This means that if two global sections agree on an open set, their images under P agree on that open set. This locality allows us to define the version of the operator in each trivialization.
We define an operator $\widetilde{P}\colon C^\infty(U, \mathbb{K}^r) \longrightarrow C^\infty(U, \mathbb{K}^s)$ transferring the structure of P to U through a pointwise construction. Let $w \in C^\infty(U, \mathbb{K}^r)$ and $p \in U$. To evaluate $\widetilde{P}(w)$ at p, we need to transfer w to a global section

on which P can act. Choose an open set $V \subseteq M$ such that $p \in V$ and $\overline{V} \subseteq U$. By Proposition 1.3.6 (existence of cutoff functions), there exists a smooth function $\psi\colon M \longrightarrow \mathbb{R}$ such that $\psi \equiv 1$ on $\overline{V}$ and $\operatorname{supp}(\psi) \subseteq U$. Construct a global extension $\widehat{\mathbf{w}} \in \Gamma(\mathbf{E})$ defined by:

$$\widehat{\mathbf{w}}(q) := \begin{cases} \tau_{\mathbf{E}}^{-1}(q, \psi(q)w(q)) & \text{if } q \in U, \\ 0 & \text{if } q \in M \setminus U. \end{cases} \tag{8.7}$$

We then define the value of $\widetilde{P}(w)$ at the point p by:

$$\widetilde{P}(w)(p) := \pi_2 \circ \tau_{\mathbf{F}}\big(P(\widehat{\mathbf{w}})(p)\big).$$

By locality of P, this value is independent of the choice of cutoff function ψ and open set V, since any other extension would agree with $\widehat{\mathbf{w}}$ on a neighborhood of p. Therefore, $\widetilde{P}$ is well defined as a linear operator between sections of the trivial bundles.

To apply Theorem 8.1.33, we must prove that $\widetilde{P}$ is a partial differential operator of order $\leq m$ between the trivial bundles over U. That is, we must show that for any $g_0, \cdots, g_m \in C^\infty(U)$ we have:

$$\operatorname{ad}(g_0)\cdots\operatorname{ad}(g_m)(\widetilde{P}) = 0.$$

Let $p \in U$ be arbitrary. Choose an open set $V \subseteq U$ such that $\overline{V} \subseteq U$ and a smooth function $\psi\colon M \longrightarrow \mathbb{R}$ with $\psi \equiv 1$ on $\overline{V}$ and $\operatorname{supp}(\psi) \subseteq U$. This choice fixes a uniform procedure for extending scalar functions and sections defined on U.

Given a function $g \in C^\infty(U)$, define its global extension $\widehat{g} \in C^\infty(M, \mathbb{K})$ by

$$\widehat{g}(q) = \begin{cases} \psi(q)\, g(q), & q \in U, \\ 0, & q \in M \setminus U. \end{cases}$$

By construction, $\widehat{g} \restriction_V = g \restriction_V$ and $\operatorname{supp}(\widehat{g}) \subseteq U$. Likewise, given a vector-valued function $w \in C^\infty(U, \mathbb{K}^r)$, define its global extension $\widehat{\mathbf{w}} \in \Gamma(\mathbf{E})$ as in (8.7):

$$\widehat{\mathbf{w}}(q) = \begin{cases} \tau_{\mathbf{E}}^{-1}(q, \psi(q)\, w(q)), & q \in U, \\ 0, & q \in M \setminus U. \end{cases}$$

In particular, $\widehat{\mathbf{w}} \restriction_V = \tau_{\mathbf{E}}^{-1}(\cdot, w(\cdot))$.

With these extensions fixed, we relate the commutators of $\widetilde{P}$ to those of P. We begin with the case of a single commutator. Let $g \in C^\infty(U)$ and let $\widehat{g} \in C^\infty(M)$ be its global extension defined above. Let $w \in C^\infty(U, \mathbb{K}^r)$, and let $\widehat{\mathbf{w}} \in \Gamma(\mathbf{E})$ be its global extension. By definition of $\widetilde{P}$,

$$\widetilde{P}(w)(q) = \pi_2 \circ \tau_{\mathbf{F}}\big(P(\widehat{\mathbf{w}})(q)\big), \qquad q \in V.$$

Now fix $q \in V$. Since $\psi \equiv 1$ on V, we have

$$\widehat{g}(q) = g(q), \qquad \widehat{\mathbf{w}}(q) = \tau_{\mathbf{E}}^{-1}(q, w(q)).$$

Let $\widehat{\mathbf{w}}_g$ be the global extension of the vector-valued function gw, constructed using the same function ψ:

$$\widehat{\mathbf{w}}_g(q') = \begin{cases} \tau_{\mathbf{E}}^{-1}\big(q', \psi(q')\, g(q') w(q')\big), & q' \in U, \\ 0, & q' \notin U. \end{cases}$$

For $q' \in V$,

$$\widehat{\mathbf{w}}_g(q') = \tau_{\mathbf{E}}^{-1}\big(q', g(q') w(q')\big) = \widehat{g}(q')\, \widehat{\mathbf{w}}(q'),$$

where the last equality is scalar multiplication in the fiber.
Since $\widehat{\mathbf{w}}_g$ and $\widehat{g}\,\widehat{\mathbf{w}}$ agree on a neighborhood of q, locality of P implies

$$P(\widehat{\mathbf{w}}_g)(q) = P(\widehat{g}\,\widehat{\mathbf{w}})(q).$$

Therefore,

$$\begin{aligned} \big(\mathrm{ad}(g)(\widetilde{P})w\big)(q) &= \widetilde{P}(gw)(q) - g(q)\,\widetilde{P}(w)(q) \\ &= \pi_2 \circ \tau_{\mathbf{F}}\big(P(\widehat{\mathbf{w}}_g)(q)\big) - \widehat{g}(q)\,\pi_2 \circ \tau_{\mathbf{F}}\big(P(\widehat{\mathbf{w}})(q)\big) \\ &= \pi_2 \circ \tau_{\mathbf{F}}\big(P(\widehat{g}\,\widehat{\mathbf{w}})(q) - \widehat{g}(q)\,P(\widehat{\mathbf{w}})(q)\big) \\ &= \pi_2 \circ \tau_{\mathbf{F}}\big(\mathrm{ad}(\widehat{g})(P)(\widehat{\mathbf{w}})(q)\big). \end{aligned}$$

Thus, for every $q \in V$,

$$\big(\mathrm{ad}(g)(\widetilde{P})w\big)(q) = \pi_2 \circ \tau_{\mathbf{F}}\big(\mathrm{ad}(\widehat{g})(P)(\widehat{\mathbf{w}})(q)\big).$$

Applying the same reasoning inductively gives, for any $g_0, \dots, g_m \in C^\infty(U)$ and their extensions $\widehat{g}_0, \dots, \widehat{g}_m$,

$$\big(\mathrm{ad}(g_0)\cdots\mathrm{ad}(g_m)(\widetilde{P})w\big)(q) = \pi_2 \circ \tau_{\mathbf{F}}\big(\mathrm{ad}(\widehat{g}_0)\cdots\mathrm{ad}(\widehat{g}_m)(P)(\widehat{\mathbf{w}})\big)(q), \qquad q \in V.$$

Since by hypothesis $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$, $\mathrm{ad}(\hat{g}_0)\cdots\mathrm{ad}(\widehat{g}_m)(P)$ is the zero operator on M. In particular, $\big(\mathrm{ad}(\widehat{g}_0)\cdots\mathrm{ad}(\widehat{g}_m)(P)(\widehat{\mathbf{w}})\big)(q) = 0$ and therefore $\big(\big(\mathrm{ad}(g_0)\cdots\mathrm{ad}(g_m)(\widetilde{P})\big)(w)\big)(q) = 0$. Taking $q = p$, $\big(\big(\mathrm{ad}(g_0)\cdots\mathrm{ad}(g_m)(\widetilde{P})\big)(w)\big)(p) = 0$, and using the fact that p and w were arbitrary, we conclude that

$$\mathrm{ad}(g_0)\cdots\mathrm{ad}(g_m)(\widetilde{P}) = 0 \quad \text{throughout } U.$$

Therefore, $\widetilde{P} \in \mathbf{PDO}^{(m)}(\underline{\mathbb{K}}^r, \underline{\mathbb{K}}^s)$, where $\underline{\mathbb{K}}^r$ and $\underline{\mathbb{K}}^s$ are the trivial bundles of ranks r and s, respectively, over U. Applying Theorem 8.1.33 to the operator $\widetilde{P}$ ensures the existence of smooth functions $a_\alpha \colon U \longrightarrow \mathrm{Hom}(\mathbb{K}^r, \mathbb{K}^s)$ such that, for every $w \in C^\infty(U, \mathbb{K}^r)$ and every $p \in U$:

$$\widetilde{P}(w)(p) = \sum_{|\alpha| \le m} a_\alpha(p)\, D^\alpha w(p).$$

Finally, consider a global section $\mathbf{u} \in \Gamma(\mathbf{E})$. Let $\widetilde{u} \in C^\infty(U, \mathbb{K}^r)$ be its local representation. For any $p \in U$, $\mathbf{u}$ itself serves as a global extension of its local behavior. By definition of $\widetilde{P}$, we have for every $p \in U$:

$$\pi_2 \circ \tau_{\mathbf{F}}\big(P(\mathbf{u})(p)\big) = \widetilde{P}(\widetilde{u})(p) = \sum_{|\alpha| \le m} a_\alpha(p)\, D^\alpha \widetilde{u}(p).$$

Applying $\tau_{\mathbf{F}}^{-1}(p,\cdot)$ to both sides gives

$$P(\mathbf{u})(p) = \tau_{\mathbf{F}}^{-1}\left(p,\ \sum_{|\alpha|\le m} a_\alpha(p)\, D^\alpha \widetilde{u}(p)\right).$$

□

Corollary 8.1.35. (Local expression of a PDO using local frames) Let M be a smooth manifold with or without boundary. Let $\pi_{\mathbf{E}}\colon \mathbf{E} \longrightarrow M$ and $\pi_{\mathbf{F}}\colon \mathbf{F} \longrightarrow M$ be smooth vector bundles of ranks r and s. Under the hypotheses of Theorem 8.1.34, for a continuous linear operator

$$P \in \mathbf{Op}(\mathbf{E},\mathbf{F})$$

and an integer $m \ge 0$, the following are equivalent:

(a) $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$.

(b) For every smooth chart (U,φ) and every pair of smooth local frames

$$\{\mathbf{e}_1,\dots,\mathbf{e}_r\} \text{ in } \mathbf{E}\restriction_U, \qquad \{\mathbf{f}_1,\dots,\mathbf{f}_s\} \text{ in } \mathbf{F}\restriction_U,$$

there exist smooth functions

$$(a_\alpha)_{ij}\colon U \longrightarrow \mathbb{K}, \qquad 1 \le i \le r,\ 1 \le j \le s,\ |\alpha| \le m,$$

such that every section written in components as

$$\mathbf{u} = \sum_{i=1}^{r} u^i \mathbf{e}_i, \qquad u^i \in C^\infty(U,\mathbb{K}),$$

satisfies the identity

$$P(\mathbf{u}) = \sum_{j=1}^{s}\left(\sum_{|\alpha|\le m}\sum_{i=1}^{r} (a_\alpha)_{ij}\, D^\alpha u^i\right)\mathbf{f}_j.$$

on U.

Proof. (a)⇒(b). Fix a chart (U,φ) and local frames $\{\mathbf{e}_i\}$ in $\mathbf{E}\restriction_U$ and $\{\widehat{\mathbf{e}}_j\}$ in $\mathbf{F}\restriction_U$. Recall that, by Proposition 1.7.18, a smooth local frame determines a smooth local trivialization

$$\boldsymbol{\tau}_{\mathbf{E}}\colon \mathbf{E}\restriction_U \longrightarrow U\times\mathbb{K}^r, \qquad \boldsymbol{\tau}_{\mathbf{F}}\colon \mathbf{F}\restriction_U \longrightarrow U\times\mathbb{K}^s,$$

characterized by

$$\boldsymbol{\tau}_{\mathbf{E}}(\mathbf{e}_i(p)) = (p, e_i^0), \qquad \boldsymbol{\tau}_{\mathbf{F}}(\widehat{\mathbf{e}}_j(p)) = (p, \widehat{e}_j^{\,0}),$$

where $\{e_i^0\}$ and $\{\widehat{e}_j^{\,0}\}$ are the standard bases of $\mathbb{K}^r$ and $\mathbb{K}^s$, respectively.

Applying Theorem 8.1.34 to these trivializations, there exist smooth maps

$$a_\alpha : U \longrightarrow \mathrm{Hom}(\mathbb{K}^r, \mathbb{K}^s), \qquad |\alpha| \le m,$$

such that, for the local representation

$$\widetilde{u} := \pi_2 \circ \boldsymbol{\tau}_{\mathbf{E}} \circ \mathbf{u} \in C^\infty(U, \mathbb{K}^r),$$

we have

$$\pi_2 \circ \boldsymbol{\tau}_{\mathbf{F}}\big(P(\mathbf{u})\big) = \sum_{|\alpha| \le m} a_\alpha \, D^\alpha \widetilde{u}.$$

To obtain the component expression, write the action of $a_\alpha(p)$ on the standard basis:

$$a_\alpha(p)(e_i^0) = \sum_{j=1}^{s} (a_\alpha)_{ij}(p)\, \widehat{e}_j^0.$$

This defines smooth functions $(a_\alpha)_{ij}$, which are precisely the matrix entries of $a_\alpha(p)$.

If $\mathbf{u} = \sum_{i=1}^{r} u^i \mathbf{e}_i$, then, for each $p \in U$,

$$\mathbf{u}(p) = \sum_{i=1}^{r} u^i(p)\, \mathbf{e}_i(p).$$

The trivialization induced by the local frame $\{\mathbf{e}_1, \dots, \mathbf{e}_r\}$ is given by

$$\boldsymbol{\tau}_{\mathbf{E}}(\mathbf{e}_i(p)) = (p, e_i^0),$$

where (e_i^0) is the standard basis of $\mathbb{K}^r$. By linearity on each fiber,

$$\boldsymbol{\tau}_{\mathbf{E}}(\mathbf{u}(p)) = \boldsymbol{\tau}_{\mathbf{E}}\left(\sum_{i=1}^{r} u^i(p)\mathbf{e}_i(p)\right) = \left(p, \sum_{i=1}^{r} u^i(p) e_i^0\right) = \big(p, (u^1(p), \dots, u^r(p))\big).$$

Thus, the local representation

$$\widetilde{u} = \pi_2 \circ \boldsymbol{\tau}_{\mathbf{E}} \circ \mathbf{u} : U \longrightarrow \mathbb{K}^r$$

is explicitly given by

$$\widetilde{u}(p) = (u^1(p), \dots, u^r(p)).$$

Therefore,

$$a_\alpha(p)\, D^\alpha \widetilde{u}(p) = \left(\sum_{i=1}^{r} (a_\alpha)_{i1}(p) D^\alpha u^i(p), \dots, \sum_{i=1}^{r} (a_\alpha)_{is}(p) D^\alpha u^i(p)\right).$$

The local representation of $P(\mathbf{u})$ is

$$\pi_2 \circ \boldsymbol{\tau}_{\mathbf{F}}\big(P(\mathbf{u})\big)(p) = \left(\sum_{|\alpha| \le m} \sum_{i=1}^{r} (a_\alpha)_{i1}(p) D^\alpha u^i(p), \dots, \sum_{|\alpha| \le m} \sum_{i=1}^{r} (a_\alpha)_{is}(p) D^\alpha u^i(p)\right).$$

Since $\boldsymbol{\tau}_{\mathbf{F}}(\mathbf{f}_j(p)) = (p, f_j^0)$, inverting $\boldsymbol{\tau}_{\mathbf{F}}$ gives

$$P(\mathbf{u})(p) = \sum_{j=1}^{s} \left(\sum_{|\alpha|\le m} \sum_{i=1}^{r} (a_\alpha)_{ij}(p) D^\alpha u^i(p) \right) \widehat{\mathbf{e}}_j(p),$$

and therefore on U

$$P(\mathbf{u}) = \sum_{j=1}^{s} \left(\sum_{|\alpha|\le m} \sum_{i=1}^{r} (a_\alpha)_{ij} D^\alpha u^i \right) \widehat{\mathbf{e}}_j.$$

(b)⇒(a). Suppose that (b) holds. We must prove that $P \in \mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$ in the sense of Theorem 8.1.34. Let (U,φ) be an arbitrary smooth chart of M and take arbitrary smooth local trivializations

$$\boldsymbol{\tau}_{\mathbf{E}} \colon \mathbf{E} \restriction_U \longrightarrow U \times \mathbb{K}^r, \qquad \boldsymbol{\tau}_{\mathbf{F}} \colon \mathbf{F} \restriction_U \longrightarrow U \times \mathbb{K}^s.$$

By Proposition 1.7.18, each of these trivializations induces a smooth local frame over U. More precisely, there exists a smooth local frame $\{\mathbf{e}_1,\dots,\mathbf{e}_r\}$ in $\mathbf{E} \restriction_U$ associated with $\boldsymbol{\tau}_{\mathbf{E}}$, characterized by

$$\mathbf{e}_i(p) = \boldsymbol{\tau}_{\mathbf{E}}^{-1}(p, e_i^0), \qquad 1 \le i \le r,$$

where $\{e_i^0\}$ is the standard basis of $\mathbb{K}^r$. The trivialization $\boldsymbol{\tau}_{\mathbf{F}}$ induces the smooth local frame $\{\widehat{\mathbf{e}}_1,\dots,\widehat{\mathbf{e}}_s\}$ in $\mathbf{F} \restriction_U$ given by

$$\widehat{\mathbf{e}}_j(p) = \boldsymbol{\tau}_{\mathbf{F}}^{-1}(p, \widehat{e}_j^0), \qquad 1 \le j \le s,$$

where $\{\widehat{e}_j^0\}$ is the standard basis of $\mathbb{K}^s$.
Since by hypothesis (b) holds for every pair of local frames, in particular for the frames $\{\mathbf{e}_i\}$ and $\{\widehat{\mathbf{e}}_j\}$ associated with these trivializations, there exist smooth functions

$$(a_\alpha)_{ij} \colon U \longrightarrow \mathbb{K}, \qquad 1 \le i \le r,\ 1 \le j \le s,\ |\alpha| \le m,$$

such that, for every section

$$\mathbf{u} = \sum_{i=1}^{r} u^i \mathbf{e}_i, \qquad u^i \in C^\infty(U,\mathbb{K}),$$

the identity

$$P(\mathbf{u}) = \sum_{j=1}^{s} \left(\sum_{|\alpha|\le m} \sum_{i=1}^{r} (a_\alpha)_{ij}\, D^\alpha u^i \right) \widehat{\mathbf{e}}_j.$$

holds on U.
Now define, for each multi-index α, a map

$$a_\alpha \colon U \longrightarrow \operatorname{Hom}(\mathbb{K}^r, \mathbb{K}^s)$$

as follows: for each $p \in U$ and each vector $v = (v^1,\dots,v^r) \in \mathbb{K}^r$, set

$$a_\alpha(p)(v) := \left(\sum_{i=1}^{r} (a_\alpha)_{i1}(p) v^i, \dots, \sum_{i=1}^{r} (a_\alpha)_{is}(p) v^i \right) \in \mathbb{K}^s.$$

In other words, the matrix of $a_\alpha(p)$ in the standard bases $\{e_i^0\}$ and $\{\widehat{e}_j^0\}$ is precisely

$$\big((a_\alpha)_{ij}(p)\big)_{1\le i\le r,\ 1\le j\le s}.$$

Since the functions $(a_\alpha)_{ij}$ are smooth, it follows that a_α is a smooth map with values in $\mathrm{Hom}(\mathbb{K}^r,\mathbb{K}^s)$.
We show that these a_α provide the local expression of P in the trivializations $\boldsymbol{\tau}_{\mathbf{E}}$ and $\boldsymbol{\tau}_{\mathbf{F}}$. Let $\mathbf{u}\in\Gamma(\mathbf{E})$ and write on U

$$\mathbf{u}=\sum_{i=1}^{r} u^i\mathbf{e}_i,\qquad u^i\in C^\infty(U,\mathbb{K}).$$

By construction of $\boldsymbol{\tau}_{\mathbf{E}}$ from the frame $\{\mathbf{e}_i\}$, the local representation of $\mathbf{u}$ is

$$\widetilde{u}:=\pi_2\circ\boldsymbol{\tau}_{\mathbf{E}}\circ\mathbf{u}\colon U\longrightarrow\mathbb{K}^r,\qquad \widetilde{u}(p)=(u^1(p),\dots,u^r(p)).$$

In particular,

$$D^\alpha\widetilde{u}(p)=\big(D^\alpha u^1(p),\dots,D^\alpha u^r(p)\big).$$

On the other hand, using the formula in (b) for $P(\mathbf{u})$ and applying $\boldsymbol{\tau}_{\mathbf{F}}$ gives

$$\boldsymbol{\tau}_{\mathbf{F}}\big(P(\mathbf{u})(p)\big)=\left(p,\ \sum_{j=1}^{s}\left(\sum_{|\alpha|\le m}\sum_{i=1}^{r}(a_\alpha)_{ij}(p)\,D^\alpha u^i(p)\right)\widehat{e}_j^0\right).$$

By definition of $a_\alpha(p)$, the vector in $\mathbb{K}^s$ whose jth component is

$$\sum_{|\alpha|\le m}\sum_{i=1}^{r}(a_\alpha)_{ij}(p)\,D^\alpha u^i(p)$$

is precisely

$$\sum_{|\alpha|\le m}a_\alpha(p)\,D^\alpha\widetilde{u}(p).$$

Thus,

$$\pi_2\circ\boldsymbol{\tau}_{\mathbf{F}}\big(P(\mathbf{u})\big)(p)=\sum_{|\alpha|\le m}a_\alpha(p)\,D^\alpha\widetilde{u}(p),\qquad\forall\,p\in U.$$

Since (U,φ) and the trivializations $\boldsymbol{\tau}_{\mathbf{E}},\boldsymbol{\tau}_{\mathbf{F}}$ were arbitrary, we have checked that, in every smooth chart and for every pair of local trivializations, there is a family of smooth maps

$$a_\alpha\colon U\longrightarrow\mathrm{Hom}(\mathbb{K}^r,\mathbb{K}^s),\qquad|\alpha|\le m,$$

providing the expression

$$\pi_2\circ\boldsymbol{\tau}_{\mathbf{F}}\big(P(\mathbf{u})\big)(p)=\sum_{|\alpha|\le m}a_\alpha(p)\,D^\alpha\big(\pi_2\circ\boldsymbol{\tau}_{\mathbf{E}}\circ\mathbf{u}\big)(p)$$

for every $\mathbf{u}\in\Gamma(\mathbf{E})$ and every $p\in U$. By Theorem 8.1.34, we conclude that

$$P\in\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F}).$$

□

Proposition 8.1.36. (Conjugation of differential operators) Let M be a smooth manifold with or without boundary. Let $\mathbf{E},\mathbf{F}\to M$ be complex vector bundles and let

$$P\colon \Gamma(\mathbf{E})\longrightarrow\Gamma(\mathbf{F})$$

be a complex-linear operator. Define

$$\overline{P}\colon \Gamma(\overline{\mathbf{E}})\longrightarrow\Gamma(\overline{\mathbf{F}}),\qquad \overline{P}(\overline{\mathbf{u}}):=\overline{P\mathbf{u}}.$$

Then:

(a) $\overline{P}$ is well defined and complex-linear;

(b) if $P\in\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$, then $\overline{P}\in\mathbf{PDO}^{(m)}(\overline{\mathbf{E}},\overline{\mathbf{F}})$;

(c) if, in a chart and with respect to local frames $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ and $(\mathbf{f}_1,\dots,\mathbf{f}_s)$, the expression for P is

$$(P\mathbf{u})^{\sim}=\sum_{|\alpha|\le m}A_\alpha D^\alpha\widetilde{u},\qquad A_\alpha\colon U\longrightarrow M_{s\times r}(\mathbb{C}),$$

then, with respect to the conjugate frames $(\overline{\mathbf{e}}_1,\dots,\overline{\mathbf{e}}_r)$ and $(\overline{\mathbf{f}}_1,\dots,\overline{\mathbf{f}}_s)$,

$$(\overline{P}\mathbf{z})^{\sim}=\sum_{|\alpha|\le m}\overline{A_\alpha}\,D^\alpha\widetilde{z};$$

(d) conjugation commutes with restrictions and satisfies

$$\overline{Q\circ P}=\overline{Q}\circ\overline{P},\qquad \overline{\mathrm{id}_{\mathbf{E}}}=\mathrm{id}_{\overline{\mathbf{E}}}.$$

In particular, if P is invertible, then $\overline{P^{-1}}=(\overline{P})^{-1}$.

Proof. Conjugation of sections is an antilinear bijection, so every section of $\overline{\mathbf{E}}$ is uniquely expressible as $\overline{\mathbf{u}}$. If $\lambda\in\mathbb{C}$, the scalar structure of $\overline{\mathbf{E}}$ gives $\lambda\overline{\mathbf{u}}=\overline{\overline{\lambda}\mathbf{u}}$; therefore,

$$\overline{P}(\lambda\overline{\mathbf{u}})=\overline{P(\overline{\lambda}\mathbf{u})}=\overline{\overline{\lambda}P\mathbf{u}}=\lambda\overline{P\mathbf{u}}.$$

Additivity is checked in the same way.

For the local formula, write $\mathbf{z}=\sum_{j=1}^{r}z^j\overline{\mathbf{e}}_j$. Then $\mathbf{z}=\overline{\mathbf{u}}$ for $\mathbf{u}=\sum_{j=1}^{r}\overline{z^j}\mathbf{e}_j$. Conjugating the local expression for $P\mathbf{u}$ gives

$$(\overline{P}\mathbf{z})^{\sim}=\overline{\sum_{|\alpha|\le m}A_\alpha D^\alpha(\widetilde{\overline{z}})}=\sum_{|\alpha|\le m}\overline{A_\alpha}D^\alpha\widetilde{z}.$$

The local characterization of differential operators then shows that $\overline{P}$ has order at most m. Compatibility with restrictions is immediate from the same formula. Finally, for every $\mathbf{u}\in\Gamma(\mathbf{E})$,

$$\overline{Q\circ P}(\overline{\mathbf{u}})=\overline{Q(P\mathbf{u})}=(\overline{Q}\circ\overline{P})(\overline{\mathbf{u}}),$$

and the assertions about identities and inverses follow from this equality. □

8.2 Formal Hermitian adjoints

Throughout the complex case, we use Hermitian metrics linear in the first variable and conjugate-linear in the second. All integrals are taken with respect to the Riemann–Lebesgue measure $\lambda_{\mathbf{g}}$ constructed in Definition 2.15.5; in particular, no orientation of M is required.

Definition 8.2.1. (Formal Hermitian adjoint) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $\mathbf{E},\mathbf{F}\to M$ be real vector bundles with bundle metrics if $\mathbb{K}=\mathbb{R}$, or Hermitian bundles if $\mathbb{K}=\mathbb{C}$. For $P\in\mathbf{PDO}(\mathbf{E},\mathbf{F})$, an operator

$$P_h^*\in\mathbf{PDO}(\mathbf{F},\mathbf{E})$$

is called a *formal Hermitian adjoint* of P if

$$\int_M \mathbf{h}_{\mathbf{F}}(P\mathbf{u},\mathbf{v})\,d\lambda_{\mathbf{g}}=\int_M \mathbf{h}_{\mathbf{E}}(\mathbf{u},P_h^*\mathbf{v})\,d\lambda_{\mathbf{g}}$$

for every $\mathbf{u}\in\Gamma_c(\mathbf{E})$ and every $\mathbf{v}\in\Gamma_c(\mathbf{F})$. In the real case, this is the usual real notion.

Lemma 8.2.2. (Uniqueness) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $\mathbf{E},\mathbf{F}\to M$ be real vector bundles with bundle metrics or Hermitian bundles. A differential operator $P\in\mathbf{PDO}(\mathbf{E},\mathbf{F})$ admits at most one formal Hermitian adjoint.

Proof. Let $S_1,S_2\in\mathbf{PDO}(\mathbf{F},\mathbf{E})$ be two adjoints and fix $\mathbf{v}\in\Gamma_c(\mathbf{F})$. Locality implies that $\mathbf{w}:=(S_1-S_2)\mathbf{v}$ belongs to $\Gamma_c(\mathbf{E})$. Taking $\mathbf{u}=\mathbf{w}$ in the difference of the two adjunction identities gives

$$0=\int_M \mathbf{h}_{\mathbf{E}}(\mathbf{w},\mathbf{w})\,d\lambda_{\mathbf{g}},$$

and, by positivity, $\mathbf{w}=0$. Thus, $S_1\mathbf{v}=S_2\mathbf{v}$ for every compactly supported section. Now given $\mathbf{v}\in\Gamma(\mathbf{F})$ and $x\in M$, choose $\chi\in C_c^\infty(M)$ equal to one on a neighborhood of x. By locality, $(S_1-S_2)\mathbf{v}=(S_1-S_2)(\chi\mathbf{v})$ near x, and the last expression is zero. Since x was arbitrary, $S_1=S_2$. □

Theorem 8.2.3. (Existence and local formula for the Hermitian adjoint) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $\mathbf{E},\mathbf{F}\to M$ be real vector bundles with bundle metrics or Hermitian bundles. Let $P\in\mathbf{PDO}^{(m)}(\mathbf{E},\mathbf{F})$. Then there exists a unique $P_h^*\in\mathbf{PDO}^{(m)}(\mathbf{F},\mathbf{E})$.
More precisely, let $\varphi\colon U\to\Omega\subseteq\mathbb{R}^n$ be a chart, with coordinate functions $(x^1,\dots,x^n)$, and choose orthonormal local frames (unitary in the complex case) $\mathbf{e}_1,\dots,\mathbf{e}_r$ and $\mathbf{f}_1,\dots,\mathbf{f}_s$ for $\mathbf{E}$ and $\mathbf{F}$, respectively. For a scalar function $a\in C^\infty(U,\mathbb{K})$ write

$$D^\alpha_\varphi a:=\left[D^\alpha(a\circ\varphi^{-1})\right]\circ\varphi.$$

If the functions $a^{\,j}_{\alpha i}\in C^\infty(U,\mathbb{K})$ are determined by

$$P\left(\sum_{i=1}^{r}u^i\mathbf{e}_i\right)=\sum_{j=1}^{s}\left(\sum_{i=1}^{r}\sum_{|\alpha|\le m}a^{\,j}_{\alpha i}D^\alpha_\varphi u^i\right)\mathbf{f}_j,\tag{8.8}$$

and $g_{ab} := \mathbf{g}(\partial_a, \partial_b)$ are the coordinate coefficients of the metric, then the expression for P_h^* with respect to the same frames is

$$P_h^*\left(\sum_{j=1}^{s} v^j \mathbf{f}_j\right) = \frac{1}{\sqrt{\det(\mathbf{g})}} \sum_{i=1}^{r} \left[\sum_{j=1}^{s} \sum_{|\alpha|\le m} (-1)^{|\alpha|} D_\varphi^\alpha \left(\sqrt{\det(\mathbf{g})}\, \overline{a_{\alpha i}^j}\, v^j\right)\right] \mathbf{e}_i. \tag{8.9}$$

In the real case, the bar does not alter the coefficient. If the coefficients are grouped into the matrix-valued map

$$A_\alpha = (a_{\alpha i}^j) \colon U \longrightarrow M_{s\times r}(\mathbb{K}),$$

its pointwise conjugate transpose is denoted by $A_\alpha^* = \overline{A_\alpha}^T$.

Proof. Fix a chart $\varphi \colon U \to \Omega$ and orthonormal local frames $\mathbf{e}_1, \dots, \mathbf{e}_r$ and $\mathbf{f}_1, \dots, \mathbf{f}_s$ for $\mathbf{E}$ and $\mathbf{F}$, respectively. The expression on the right-hand side of (8.9) defines an operator

$$Q_U : \Gamma(\mathbf{F}|_U) \longrightarrow \Gamma(\mathbf{E}|_U).$$

Indeed, $\det(\mathbf{g})$ is smooth and strictly positive. Expanding each term using the Leibniz rule for multi-indices, $Q_U \mathbf{v}$ depends on the coordinate derivatives of the functions v^j of order at most m. The local characterization in Corollary 8.1.35 therefore implies that $Q_U \in \mathbf{PDO}^{(m)}(\mathbf{F}|_U, \mathbf{E}|_U)$.
We prove the local adjunction identity. Let $\mathbf{u} \in \Gamma_c(\mathbf{E}|_U)$ and let $\mathbf{v} \in \Gamma(\mathbf{F}|_U)$, and write

$$\mathbf{u} = \sum_{i=1}^{r} u^i \mathbf{e}_i, \qquad \mathbf{v} = \sum_{j=1}^{s} v^j \mathbf{f}_j.$$

The image $\varphi(\operatorname{supp}\mathbf{u})$ is a compact set contained in Ω. Since the frames are orthonormal and the Hermitian metric is linear in the first variable, the local formula for the Riemann–Lebesgue measure and (8.8) give

$$\begin{aligned}
&\int_U \mathbf{h}_{\mathbf{F}}(P\mathbf{u}, \mathbf{v})\, d\lambda_{\mathbf{g}} \\
&\quad = \sum_{i=1}^{r} \sum_{j=1}^{s} \sum_{|\alpha|\le m} \int_\Omega \left(a_{\alpha i}^j \circ \varphi^{-1}\right) D^\alpha \left(u^i \circ \varphi^{-1}\right) \overline{\left(v^j \circ \varphi^{-1}\right)} \left(\sqrt{\det(\mathbf{g})} \circ \varphi^{-1}\right) d\lambda_n.
\end{aligned}$$

Fix i, j, and $\alpha = (\alpha_1, \dots, \alpha_n)$. We can integrate α_a times with respect to x^a, for each a, because $u^i \circ \varphi^{-1}$ has compact support in Ω. No boundary term appears, and each integration introduces a minus sign. Therefore,

$$\begin{aligned}
&\int_\Omega \left(a_{\alpha i}^j \circ \varphi^{-1}\right) D^\alpha \left(u^i \circ \varphi^{-1}\right) \overline{\left(v^j \circ \varphi^{-1}\right)} \left(\sqrt{\det(\mathbf{g})} \circ \varphi^{-1}\right) d\lambda_n \\
&\quad = (-1)^{|\alpha|} \int_\Omega \left(u^i \circ \varphi^{-1}\right) D^\alpha \left[\left(a_{\alpha i}^j\, \overline{v^j} \sqrt{\det(\mathbf{g})}\right) \circ \varphi^{-1}\right] d\lambda_n.
\end{aligned}$$

All coordinate derivatives are real and $\sqrt{\det(\mathbf{g})}$ is real. Consequently,

$$D^\alpha \left[\left(a_{\alpha i}^j\, \overline{v^j} \sqrt{\det(\mathbf{g})}\right) \circ \varphi^{-1}\right] = \overline{D^\alpha \left[\left(\overline{a_{\alpha i}^j}\, v^j \sqrt{\det(\mathbf{g})}\right) \circ \varphi^{-1}\right]}.$$

This equality includes the real case, in which conjugation is the identity. Substituting it, summing over i, j, and α, and inserting the factor $\bigl(\sqrt{\det(\mathbf{g})}\bigr)^{-1}\sqrt{\det(\mathbf{g})}$ gives

$$\begin{aligned}
&\int_U \mathbf{h}_{\mathbf{F}}(P\mathbf{u},\mathbf{v})\,d\lambda_{\mathbf{g}} \\
&\quad= \int_\Omega \sum_{i=1}^{r}\bigl(u^i\circ\varphi^{-1}\bigr)\,\overline{\left[\frac{1}{\sqrt{\det(\mathbf{g})}}\sum_{j=1}^{s}\sum_{|\alpha|\le m}(-1)^{|\alpha|}D_\varphi^\alpha\Bigl(\sqrt{\det(\mathbf{g})}\,\overline{a^j_{\alpha i}}\,v^j\Bigr)\right]}\circ\varphi^{-1}\,\bigl(\sqrt{\det(\mathbf{g})}\circ\varphi^{-1}\bigr)\,d\lambda_n \\
&\quad= \int_U \mathbf{h}_{\mathbf{E}}(\mathbf{u},Q_U\mathbf{v})\,d\lambda_{\mathbf{g}}.
\end{aligned}$$

We have proved a slightly stronger identity than required: only $\mathbf{u}$ needs to have compact support in U; the section $\mathbf{v}$ may be any smooth section over U.

We now show that the local operators are compatible. Let U and V be two coordinate domains with orthonormal frames as above, and let $W = U\cap V$. For $\mathbf{u}\in\Gamma_c(\mathbf{E}|_W)$ and $\mathbf{v}\in\Gamma_c(\mathbf{F}|_W)$, the two formulas already proved give

$$\int_W \mathbf{h}_{\mathbf{E}}\bigl(\mathbf{u},(Q_U|_W)\mathbf{v}\bigr)\,d\lambda_{\mathbf{g}} = \int_W \mathbf{h}_{\mathbf{F}}(P\mathbf{u},\mathbf{v})\,d\lambda_{\mathbf{g}} = \int_W \mathbf{h}_{\mathbf{E}}\bigl(\mathbf{u},(Q_V|_W)\mathbf{v}\bigr)\,d\lambda_{\mathbf{g}}.$$

Thus, $Q_U|_W$ and $Q_V|_W$ are formal adjoints of the same operator $P|_W$. Lemma 8.2.2, applied to the Riemannian manifold W, implies that $Q_U|_W = Q_V|_W$. In particular, the equality is not assumed from the coordinate expressions; it follows from the integral identity both satisfy.

We can cover M by a locally finite family $\{U_\ell\}_{\ell\in L}$ of coordinate domains over which $\mathbf{E}$ and $\mathbf{F}$ admit orthonormal frames. Compatibility on intersections allows us to define, for $\mathbf{v}\in\Gamma(\mathbf{F})$, a section $P_h^*\mathbf{v}$ by

$$(P_h^*\mathbf{v})|_{U_\ell} := Q_{U_\ell}(\mathbf{v}|_{U_\ell}).$$

The sections on the right-hand side agree on overlaps, so they define a unique global smooth section. Since the order of a differential operator can be checked locally, the formulas for the Q_{U_ℓ} show that

$$P_h^*\in\mathbf{PDO}^{(m)}(\mathbf{F},\mathbf{E}).$$

It remains to check the global identity. Let $\{\chi_\ell\}_{\ell\in L}$ be a smooth partition of unity subordinate to $\{U_\ell\}_{\ell\in L}$, and let $\mathbf{u}\in\Gamma_c(\mathbf{E})$ and $\mathbf{v}\in\Gamma_c(\mathbf{F})$. The family $\{\operatorname{supp}(\chi_\ell)\}_{\ell\in L}$ is locally finite. Thus each point of the compact set $\operatorname{supp}(\mathbf{u})$ has a neighborhood meeting only finitely many of those supports; a finite subcover by such neighborhoods shows that the set

$$L_{\mathbf{u}} := \{\ell\in L \mid \operatorname{supp}(\mathbf{u})\cap\operatorname{supp}(\chi_\ell)\neq\varnothing\}$$

is finite. Consequently,

$$\mathbf{u} = \sum_{\ell\in L_{\mathbf{u}}}\chi_\ell\mathbf{u}.$$

Moreover, $\chi_\ell\mathbf{u}$ has compact support contained in U_ℓ. Locality of P implies

$$\operatorname{supp}\bigl(P(\chi_\ell\mathbf{u})\bigr)\subseteq\operatorname{supp}(\chi_\ell\mathbf{u})\subseteq U_\ell.$$

We can apply on U_ℓ the local identity in which the first section has compact support and the second is $\mathbf{v}|_{U_\ell}$.

Thus,

$$\begin{aligned}\int_M \mathbf{h}_{\mathbf{F}}(P\mathbf{u},\mathbf{v})\,d\lambda_{\mathbf{g}} &= \sum_{\ell\in L_{\mathbf{u}}}\int_{U_\ell}\mathbf{h}_{\mathbf{F}}\big(P(\chi_\ell\mathbf{u}),\mathbf{v}\big)\,d\lambda_{\mathbf{g}}\\ &= \sum_{\ell\in L_{\mathbf{u}}}\int_{U_\ell}\mathbf{h}_{\mathbf{E}}\big(\chi_\ell\mathbf{u},P_h^*\mathbf{v}\big)\,d\lambda_{\mathbf{g}}\\ &= \int_M \mathbf{h}_{\mathbf{E}}(\mathbf{u},P_h^*\mathbf{v})\,d\lambda_{\mathbf{g}}.\end{aligned}$$

Therefore, P_h^* is a formal Hermitian adjoint of P. Its uniqueness is that of Lemma 8.2.2. □

Remark 8.2.4. (Formal adjoint in the presence of a boundary) If M has smooth boundary and the coefficients of P, the bundle metrics, and the base metric are smooth up to it, the same local formula defines a differential operator P_h^* smooth up to the boundary. Indeed, in a boundary chart the determinant of the metric remains positive, and all derivatives of the coefficients in (8.9) are smooth up to the flat part. On overlaps, the expressions agree first in the interior by the uniqueness already proved, and then on the boundary by continuity. The identity characterizing this formal adjoint is required for test sections with compact support contained in $\operatorname{Int}(M)$.

When the sections reach the boundary, integration by parts may produce additional terms, such as those we will calculate for covariant derivatives. The formal differential operator is determined before boundary conditions are chosen. Its realization as an unbounded operator on L^2, and the domain of its Hilbert space adjoint, require specifying a domain of sections; they are not identified by the differential formula alone.

Proposition 8.2.5. (Rules for the formal Hermitian adjoint) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, let $\mathbf{E},\mathbf{F},\mathbf{G}\to M$ be real vector bundles with bundle metrics or Hermitian bundles, and let $P\in\mathbf{PDO}(\mathbf{E},\mathbf{F})$ and $Q\in\mathbf{PDO}(\mathbf{F},\mathbf{G})$. Then:

(a) $(Q\circ P)_h^* = P_h^*\circ Q_h^*$;

(b) for $R\in\mathbf{PDO}(\mathbf{E},\mathbf{F})$ and $\lambda\in\mathbb{K}$,

$$(P+\lambda R)_h^* = P_h^* + \overline{\lambda}\,R_h^*,$$

where $\overline{\lambda}=\lambda$ in the real case;

(c) if M_f denotes multiplication by $f\in C^\infty(M,\mathbb{K})$, then $(M_f)_h^* = M_{\overline{f}}$;

(d) for every open set $U\subseteq M$,

$$(P|_U)^*_{h|_U} = (P_h^*)|_U;$$

(e) if $\mathbf{E},\mathbf{F}$ are complex and $\overline{\mathbf{E}},\overline{\mathbf{F}}$ are equipped with the conjugate metrics, then

$$(\overline{P})^*_{\overline{h}} = \overline{P_h^*}.$$

Proof. The first identity follows by successively transferring Q and P in the integral; supports remain compact by locality. For the second, linearity in the first variable and conjugate-linearity in the second give

$$\mathbf{h}_{\mathbf{E}}(\mathbf{u},\overline{\lambda}R_h^*\mathbf{v}) = \lambda\mathbf{h}_{\mathbf{E}}(\mathbf{u},R_h^*\mathbf{v}).$$

The third is proved in the same way. The fourth follows by applying the integral identity to compactly supported sections in U and using uniqueness.
For the last assertion, write the conjugate metrics as $\mathbf{h}_{\overline{\mathbf{E}}}(\overline{\mathbf{u}},\overline{\mathbf{w}}) = \overline{\mathbf{h}_{\mathbf{E}}(\mathbf{u},\mathbf{w})}$ and $\mathbf{h}_{\overline{\mathbf{F}}}(\overline{\mathbf{v}},\overline{\mathbf{z}}) = \overline{\mathbf{h}_{\mathbf{F}}(\mathbf{v},\mathbf{z})}$. Then

$$\begin{aligned}\int_M \mathbf{h}_{\overline{\mathbf{F}}}(\overline{P}\,\overline{\mathbf{u}},\overline{\mathbf{v}})\,d\lambda_{\mathbf{g}} &= \overline{\int_M \mathbf{h}_{\mathbf{F}}(P\mathbf{u},\mathbf{v})\,d\lambda_{\mathbf{g}}}\\ &= \overline{\int_M \mathbf{h}_{\mathbf{E}}(\mathbf{u},P_h^*\mathbf{v})\,d\lambda_{\mathbf{g}}}\\ &= \int_M \mathbf{h}_{\overline{\mathbf{E}}}(\overline{\mathbf{u}},\overline{P_h^*}\,\overline{\mathbf{v}})\,d\lambda_{\mathbf{g}},\end{aligned}$$

and uniqueness completes the proof. □

Exercise 8.2.6. Check the rule $(P+\lambda R)_h^* = P_h^* + \overline{\lambda} R_h^*$ directly and explain why the bar is indispensable when $\mathbb{K} = \mathbb{C}$.

Definition 8.2.7. (Formally self-adjoint operator) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $\mathbf{E} \to M$ be a real vector bundle with a bundle metric or a Hermitian bundle. An operator $P \in \mathbf{PDO}(\mathbf{E},\mathbf{E})$ is *formally self-adjoint* if $P = P_h^*$.

We conclude this section with examples illustrating the concept of a formal Hermitian adjoint. We begin with the directional covariant derivative.

Proposition 8.2.8. (Formal adjoint of $\nabla_{\mathbf{X}}$) Let $(M,\mathbf{g})$ be a Riemannian manifold (with or without boundary ∂M) and let ∇ be the Levi–Civita connection. Let $\mathbf{X} \in \mathfrak{X}(M)$ be a fixed smooth vector field. Then the operator

$$\nabla_{\mathbf{X}} \colon \mathfrak{X}(M) \longrightarrow \mathfrak{X}(M), \qquad \mathbf{Y} \longmapsto \nabla_{\mathbf{X}}\mathbf{Y},$$

is a partial differential operator of order 1, that is,

$$\nabla_{\mathbf{X}} \in \mathbf{PDO}^{(1)}(TM,TM).$$

Moreover, for any vector fields $\mathbf{Y},\mathbf{Z} \in \mathfrak{X}_c(M)$ we have

$$\int_M \mathbf{g}(\nabla_{\mathbf{X}}\mathbf{Y},\mathbf{Z})\,d\lambda_{\mathbf{g}} = -\int_M \mathbf{g}\big(\mathbf{Y},\nabla_{\mathbf{X}}\mathbf{Z}\big)\,d\lambda_{\mathbf{g}} - \int_M (\operatorname{div}\mathbf{X})\,\mathbf{g}(\mathbf{Y},\mathbf{Z})\,d\lambda_{\mathbf{g}} + \int_{\partial M} \mathbf{g}(\mathbf{Y},\mathbf{Z})\,\mathbf{g}(\mathbf{X},\boldsymbol{\nu})\,d\lambda_{\tilde{\mathbf{g}}}, \tag{8.10}$$

where, if $\partial M \neq \varnothing$, $\boldsymbol{\nu}$ is the outward unit normal to ∂M.

Proof. First we check that $\nabla_{\mathbf{X}}$ is a partial differential operator of order 1 in the commutator sense.
Let $f \in C^\infty(M)$ and $\mathbf{Y} \in \mathfrak{X}(M)$. Using the Leibniz rule for the connection gives

$$\nabla_{\mathbf{X}}(f\mathbf{Y}) = \mathbf{X}(f)\,\mathbf{Y} + f\,\nabla_{\mathbf{X}}\mathbf{Y}.$$

Therefore,

$$[\nabla_{\mathbf{X}}, f]\mathbf{Y} = \nabla_{\mathbf{X}}(f\mathbf{Y}) - f\,\nabla_{\mathbf{X}}\mathbf{Y} = \mathbf{X}(f)\mathbf{Y}.$$

This depends only on $\mathbf{Y}$ and not on its derivatives, so the operator $[\nabla_{\mathbf{X}}, f]$ is $C^\infty(M)$-linear. Consequently, $\nabla_{\mathbf{X}} \in \mathbf{PDO}^{(1)}(TM, TM)$.

We now prove the integration by parts identity. Let $\mathbf{Y}, \mathbf{Z} \in \mathfrak{X}_c(M)$ and define

$$f := \mathbf{g}(\mathbf{Y}, \mathbf{Z}), \qquad \mathbf{V} := f\mathbf{X}.$$

By the Leibniz rule for divergence (Proposition 2.16.6),

$$\operatorname{div}(f\mathbf{X}) = \mathbf{X}(f) + f \operatorname{div}\mathbf{X}.$$

Since the Levi–Civita connection is compatible with the metric,

$$\mathbf{X}(f) = \mathbf{X}\big(\mathbf{g}(\mathbf{Y}, \mathbf{Z})\big) = \mathbf{g}(\nabla_{\mathbf{X}}\mathbf{Y}, \mathbf{Z}) + \mathbf{g}(\mathbf{Y}, \nabla_{\mathbf{X}}\mathbf{Z}).$$

Consequently,

$$\operatorname{div}(f\mathbf{X}) = \mathbf{g}(\nabla_{\mathbf{X}}\mathbf{Y}, \mathbf{Z}) + \mathbf{g}(\mathbf{Y}, \nabla_{\mathbf{X}}\mathbf{Z}) + (\operatorname{div}\mathbf{X})\mathbf{g}(\mathbf{Y}, \mathbf{Z}).$$

Integrate over M and apply the divergence theorem:

$$\int_M \operatorname{div}(f\mathbf{X})\, d\lambda_{\mathbf{g}} = \int_{\partial M} \mathbf{g}(f\mathbf{X}, \boldsymbol{\nu})\, d\lambda_{\tilde{\mathbf{g}}} = \int_{\partial M} \mathbf{g}(\mathbf{Y}, \mathbf{Z})\, \mathbf{g}(\mathbf{X}, \boldsymbol{\nu})\, d\lambda_{\tilde{\mathbf{g}}}.$$

Rearranging the terms gives (8.10). □

Remark 8.2.9. (Formal adjoint of $\nabla_{\mathbf{X}}$) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and let $\mathbf{X} \in \mathfrak{X}(M)$. For $\mathbf{Y}, \mathbf{Z} \in \mathfrak{X}_c(M)$, identity (8.10) takes the form

$$\int_M \mathbf{g}(\nabla_{\mathbf{X}}\mathbf{Y}, \mathbf{Z})\, d\lambda_{\mathbf{g}} = \int_M \mathbf{g}\big(\mathbf{Y}, -\nabla_{\mathbf{X}}\mathbf{Z} - (\operatorname{div}\mathbf{X})\mathbf{Z}\big)\, d\lambda_{\mathbf{g}}.$$

In this sense, the formal adjoint of the partial differential operator

$$\nabla_{\mathbf{X}} \colon \mathfrak{X}(M) \longrightarrow \mathfrak{X}(M)$$

is given by

$$\nabla_{\mathbf{X}}^* \mathbf{Z} = -\nabla_{\mathbf{X}}\mathbf{Z} - (\operatorname{div}\mathbf{X})\mathbf{Z}.$$

This operator should be distinguished from the global formal adjoint

$$\nabla^* \colon \Gamma(T^*M \otimes TM) \longrightarrow \mathfrak{X}(M),$$

corresponding to the covariant derivative viewed as a first-order differential operator between vector bundles. Later we will derive an integration by parts formula allowing us to compute ∇^* explicitly.

Having introduced the formal adjoint of the covariant derivative, we can define a second-order operator fundamental to Riemannian geometry.

Definition 8.2.10. (Bochner Laplacian) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and let $\pi_{\mathbf{E}} : \mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. We define the Bochner Laplacian of a section $\mathbf{u} \in \Gamma(\mathbf{E})$ by

$$\Delta_B \mathbf{u} := \nabla^{\mathbf{E}*} \nabla^{\mathbf{E}} \mathbf{u},$$

where $\nabla^{\mathbf{E}*}$ denotes the formal adjoint of

$$\nabla^{\mathbf{E}} : \Gamma(\mathbf{E}) \longrightarrow \Gamma(T^*M \otimes \mathbf{E}).$$

Remark 8.2.11. The Bochner Laplacian is formally self-adjoint, as shown by the identity

$$(\nabla^{\mathbf{E}*} \nabla^{\mathbf{E}})^* = (\nabla^{\mathbf{E}})^* (\nabla^{\mathbf{E}*})^* = \nabla^{\mathbf{E}*} \nabla^{\mathbf{E}},$$

since $(\nabla^{\mathbf{E}*})^* = \nabla^{\mathbf{E}}$.

Besides the Bochner Laplacian, there are other important Laplacians, such as the Hodge–de Rham Laplacian, defined on spaces of differential forms:

Definition 8.2.12. (Space of differential forms) Let M be a smooth manifold with or without boundary of dimension n. Recall that the space of differential k-forms is defined by

$$\Omega^k(M) := \Gamma\left(\Lambda^k T^*M\right), \qquad k \in \{0, \dots, n\}.$$

We also define the graded space of all forms as the finite direct sum of $C^\infty(M)$-modules

$$\Omega^\bullet(M) := \bigoplus_{k=0}^{n} \Omega^k(M).$$

Now let $(M, \mathbf{g})$ be an oriented Riemannian manifold without boundary. The Riemannian metric induces a pointwise inner product on each exterior bundle $\Lambda^k T^*M$, denoted by $\langle \cdot, \cdot \rangle_{\mathbf{g}}$, and the Riemannian measure $d\lambda_{\mathbf{g}}$ allows us to define the global inner product

$$\langle \boldsymbol{\alpha}, \boldsymbol{\beta} \rangle_{L^2(M, \Lambda^k T^*M)} := \int_M \langle \boldsymbol{\alpha}, \boldsymbol{\beta} \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}}, \qquad \boldsymbol{\alpha}, \boldsymbol{\beta} \in \Omega^k_c(M).$$

Recall that the exterior derivative

$$d : \Omega^k(M) \longrightarrow \Omega^{k+1}(M)$$

is a partial differential operator of order 1.

If $f \in C^\infty(M)$ and $\boldsymbol{\alpha} \in \Omega^k(M)$, the Leibniz rule gives

$$d(f\boldsymbol{\alpha}) = df \wedge \boldsymbol{\alpha} + f \, d\boldsymbol{\alpha},$$

and therefore

$$[d, f]\boldsymbol{\alpha} = d(f\boldsymbol{\alpha}) - f \, d\boldsymbol{\alpha} = df \wedge \boldsymbol{\alpha}.$$

This depends only on α and not on its derivatives, so the operator $[d, f]$ is $C^\infty(M)$-linear. Consequently,

$$d \in \mathbf{PDO}^{(1)}\big(\Lambda^k T^*M, \Lambda^{k+1} T^*M\big).$$

Definition 8.2.13. (Codifferential) Let $(M, \mathbf{g})$ be an oriented Riemannian manifold without boundary of dimension n. The formal adjoint of the exterior derivative

$$d \colon \Omega^k(M) \longrightarrow \Omega^{k+1}(M)$$

is denoted by

$$\delta \colon \Omega^{k+1}(M) \longrightarrow \Omega^k(M)$$

and is called the codifferential.
In terms of the Hodge star operator $*$, it is given on $\Omega^{k+1}(M)$ by

$$\delta = (-1)^{k+1} \, *^{-1} \, d \, *.$$

This formal adjoint is determined by the rule

$$\int_M \langle d\alpha, \beta \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} = \int_M \langle \alpha, \delta\beta \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}},$$

for $\alpha \in \Omega^k_c(M)$ and $\beta \in \Omega^{k+1}_c(M)$.

Definition 8.2.14. (Hodge–de Rham Laplacian) Let $(M, \mathbf{g})$ be an oriented Riemannian manifold without boundary. We define the Hodge–de Rham Laplacian to be the second-order operator

$$\Delta := d\delta + \delta d \colon \Omega^\bullet(M) \longrightarrow \Omega^\bullet(M).$$

Proposition 8.2.15. Let $(M, \mathbf{g})$ be an oriented Riemannian manifold without boundary. The Hodge–de Rham Laplacian Δ is formally self-adjoint.

Proof. We have

$$(d\delta)^* = \delta^* d^* = d\delta, \qquad (\delta d)^* = d^* \delta^* = \delta d,$$

since $\delta = d^*$ and $(d^*)^* = d$. Therefore,

$$\Delta^* = (d\delta + \delta d)^* = d\delta + \delta d = \Delta.$$

□

The classical exterior differential operator extends naturally to the setting of vector bundles.

Let M be a smooth manifold with or without boundary of dimension n. The space of smooth differential k-forms is defined by

$$\Omega^k(M) := \Gamma\Big(\Lambda^k T^*M\Big),$$

that is, the space of smooth sections of the bundle $\Lambda^k T^*M$. The full space of forms is defined as the direct sum of

$C^\infty(M)$-modules

$$\Omega^\bullet(M) := \bigoplus_{k=0}^{n} \Omega^k(M).$$

If $(x^1, \dots, x^n)$ are local coordinates, we use the notation of increasing multi-indices

$$I = (i_1, \dots, i_k), \qquad 1 \le i_1 < \cdots < i_k \le n,$$

and write

$$\mathbf{d}x^I := \mathbf{d}x^{i_1} \wedge \cdots \wedge \mathbf{d}x^{i_k}.$$

With this notation, a k-form can locally be expressed as

$$\omega = \sum_{1 \le i_1 < \cdots < i_k \le n} \omega_I \, \mathbf{d}x^I,$$

and the classical exterior derivative takes the form

$$d\left(\sum_{1 \le i_1 < \cdots < i_k \le n} \omega_I \, \mathbf{d}x^I \right) = \sum_{1 \le i_1 < \cdots < i_k \le n} d\omega_I \wedge \mathbf{d}x^I.$$

Now let $\pi_{\mathbf{E}} \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle of rank r. This allows us to generalize the concept of a differential form by considering forms with values in $\mathbf{E}$.

Definition 8.2.16. (Bundle-valued differential forms) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let $k \ge 0$. Define

$$\Omega^k(M, \mathbf{E}) := \Gamma\left(\Lambda^k T^*M \otimes \mathbf{E}\right).$$

The full space is defined as the direct sum of $C^\infty(M)$-modules

$$\Omega^\bullet(M, \mathbf{E}) := \bigoplus_{k=0}^{n} \Omega^k(M, \mathbf{E}).$$

Observe that if $\mathbf{E} = M \times \mathbb{R}$ is the trivial bundle, the classical case is recovered:

$$\Omega^k(M, \mathbf{E}) \cong \Omega^k(M).$$

To define an exterior derivative in this setting, a connection on the bundle $\mathbf{E}$ is needed.

Definition 8.2.17. (Induced connection) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let $\nabla^{\mathbf{E}}$ be a connection on $\mathbf{E}$. Also fix an auxiliary connection ∇^M on TM, and use the same notation for its induced connections on the tensor bundles constructed from TM and T^*M. The product connection ∇ on $\Lambda^k T^*M \otimes \mathbf{E}$ is defined for each vector field $\mathbf{X} \in \mathfrak{X}(M)$ by the Leibniz rule

$$\nabla_{\mathbf{X}}(\boldsymbol{\alpha} \otimes \mathbf{s}) = \nabla^M_{\mathbf{X}} \boldsymbol{\alpha} \otimes \mathbf{s} + \boldsymbol{\alpha} \otimes \nabla^{\mathbf{E}}_{\mathbf{X}} \mathbf{s},$$

for $\boldsymbol{\alpha} \in \Omega^k(M)$ and $\mathbf{s} \in \Gamma(\mathbf{E})$.

The alternation operator will relate the product connection to the exterior derivative defined next.

Definition 8.2.18. (Alternation operator) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let

$$\mathbf{T} \in \Gamma\left(T^{(0,k+1)}(TM) \otimes \mathbf{E}\right).$$

Define

$$\operatorname{Alt}(\mathbf{T}) \in \Gamma\left(\Lambda^{k+1} T^*M \otimes \mathbf{E}\right)$$

by

$$\operatorname{Alt}(\mathbf{T})(\mathbf{X}_1, \dots, \mathbf{X}_{k+1}) := \frac{1}{(k+1)!} \sum_{\sigma \in S_{k+1}} \operatorname{sgn}(\sigma)\, \mathbf{T}(\mathbf{X}_{\sigma(1)}, \dots, \mathbf{X}_{\sigma(k+1)}),$$

for vector fields $\mathbf{X}_1, \dots, \mathbf{X}_{k+1} \in \mathfrak{X}(M)$.

Definition 8.2.19. (Bundle-valued exterior derivative) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle over $\mathbb{K}$, and let $\nabla^{\mathbf{E}}$ be a connection on $\mathbf{E}$. For each $k \geq 0$ define

$$d^{\mathbf{E}} \colon \Omega^k(M, \mathbf{E}) \longrightarrow \Omega^{k+1}(M, \mathbf{E})$$

to be the $\mathbb{K}$-linear operator determined locally by the rule

$$d^{\mathbf{E}}(\boldsymbol{\alpha} \otimes \mathbf{s}) = d\boldsymbol{\alpha} \otimes \mathbf{s} + (-1)^k \boldsymbol{\alpha} \wedge \nabla^{\mathbf{E}} \mathbf{s},$$

for every smooth scalar k-form $\boldsymbol{\alpha}$ and every smooth section $\mathbf{s}$ of $\mathbf{E}$ defined on the same open set. Here the wedge product with an $\mathbf{E}$-valued form is obtained by linearity from

$$\boldsymbol{\alpha} \wedge (\boldsymbol{\beta} \otimes \mathbf{s}) = (\boldsymbol{\alpha} \wedge \boldsymbol{\beta}) \otimes \mathbf{s}.$$

If $\mathbb{K} = \mathbb{C}$, scalar forms may be complex and d extends by $\mathbb{C}$-linearity. In degree zero, we recover the connection, $d^{\mathbf{E}}\mathbf{s} = \nabla^{\mathbf{E}}\mathbf{s}$, and in degree $n = \dim M$ the operator takes values in $\Omega^{n+1}(M, \mathbf{E}) = \{0\}$.

We check that this rule determines a global operator without choosing a connection on TM. For a smooth scalar function f, the Leibniz rules for d and $\nabla^{\mathbf{E}}$ give

$$d(f\boldsymbol{\alpha}) \otimes \mathbf{s} + (-1)^k (f\boldsymbol{\alpha}) \wedge \nabla^{\mathbf{E}} \mathbf{s} = f\, d\boldsymbol{\alpha} \otimes \mathbf{s} + (df \wedge \boldsymbol{\alpha}) \otimes \mathbf{s} + (-1)^k f \boldsymbol{\alpha} \wedge \nabla^{\mathbf{E}} \mathbf{s},$$

$$d\boldsymbol{\alpha} \otimes (f\mathbf{s}) + (-1)^k \boldsymbol{\alpha} \wedge \nabla^{\mathbf{E}}(f\mathbf{s}) = f\, d\boldsymbol{\alpha} \otimes \mathbf{s} + (-1)^k (\boldsymbol{\alpha} \wedge df) \otimes \mathbf{s} + (-1)^k f \boldsymbol{\alpha} \wedge \nabla^{\mathbf{E}} \mathbf{s}.$$

Since $df \wedge \boldsymbol{\alpha} = (-1)^k \boldsymbol{\alpha} \wedge df$, the two expressions agree. The rule therefore respects the relation $(f\boldsymbol{\alpha}) \otimes \mathbf{s} = \boldsymbol{\alpha} \otimes (f\mathbf{s})$.

On an open set U with a frame $(\mathbf{e}_a)_{a=1}^r$, every form $\boldsymbol{\omega} \in \Omega^k(U, \mathbf{E})$ has a unique expression $\boldsymbol{\omega} = \sum_{a=1}^{r} \boldsymbol{\alpha}^a \otimes \mathbf{e}_a$. Define its derivative by applying the rule to each summand. If $\mathbf{s} = \sum_{a=1}^{r} f^a \mathbf{e}_a$, the preceding identity and additivity show that the operator thus defined satisfies the same rule on $\boldsymbol{\alpha} \otimes \mathbf{s}$. When we change to another frame, each of its elements is a smooth combination of the $\mathbf{e}_a$; applying that rule to each term of the new representation therefore gives the same result. The construction also commutes with restrictions, because d and $\nabla^{\mathbf{E}}$ do. The local operators consequently agree on intersections and define a unique global smooth form $d^{\mathbf{E}}\boldsymbol{\omega}$. This construction proves the

stated existence, uniqueness, and $\mathbb{K}$-linearity, without assuming that the bundle admits a global frame.

In local coordinates, if $(\mathbf{e}_a)_{a=1}^r$ is a frame for $\mathbf{E}$ and

$$\boldsymbol{\omega} = \sum_{1\le i_1<\cdots<i_k\le n} \sum_{a=1}^{r} \omega_I^a \, \mathbf{d}x^I \otimes \mathbf{e}_a,$$

then

$$d^{\mathbf{E}}\boldsymbol{\omega} = \sum_{1\le i_1<\cdots<i_k\le n} \sum_{a=1}^{r} \left(d\omega_I^a + \sum_{b=1}^{r} \theta_b^a \, \omega_I^b \right) \wedge \mathbf{d}x^I \otimes \mathbf{e}_a,$$

where the connection 1-forms are given by

$$\nabla^{\mathbf{E}} \mathbf{e}_b = \sum_{a=1}^{r} \theta_b^a \otimes \mathbf{e}_a.$$

Indeed, $d(\mathbf{d}x^I) = 0$ and $(-1)^k \mathbf{d}x^I \wedge \theta_b^a = \theta_b^a \wedge \mathbf{d}x^I$; applying the definition to each term of $\boldsymbol{\omega}$ gives exactly this expression.

We now relate this definition to alternation. If the auxiliary connection ∇^M is torsion-free and ∇ is the product connection of Definition 8.2.17, then

$$d^{\mathbf{E}}\boldsymbol{\omega} = (k+1)\,\mathrm{Alt}(\nabla\boldsymbol{\omega}).$$

To prove this, first observe that $\nabla\boldsymbol{\omega}$ is alternating in its last k entries. In the definition of Alt, grouping permutations by the first entry leaves $k!$ equal summands in each group. Hence,

$$(k+1)\,\mathrm{Alt}(\nabla\boldsymbol{\omega})(\mathbf{X}_0,\dots,\mathbf{X}_k) = \sum_{i=0}^{k} (-1)^i (\nabla_{\mathbf{X}_i}\boldsymbol{\omega})(\mathbf{X}_0,\dots,\widehat{\mathbf{X}_i},\dots,\mathbf{X}_k),$$

where the hat indicates omission of that entry.

For a scalar form $\boldsymbol{\alpha}$, this sum is $d\boldsymbol{\alpha}$ when ∇^M is torsion-free. We make the cancellation justifying this explicit. In coordinates, write $\nabla^M_{\partial_\ell}\partial_i = \sum_{j=1}^{n} \Gamma_{\ell i}^j \partial_j$; since $[\partial_\ell, \partial_i] = 0$, vanishing torsion gives $\Gamma_{\ell i}^j = \Gamma_{i\ell}^j$. The dual connection satisfies

$$\nabla^M_{\partial_\ell} \mathbf{d}x^j = -\sum_{i=1}^{n} \Gamma_{\ell i}^j \mathbf{d}x^i.$$

Upon differentiating $\boldsymbol{\alpha} = \sum_{I\in\mathcal{J}_{n,k}} \alpha_I \mathbf{d}x^I$, where $\mathcal{J}_{n,k} := \{(i_1,\dots,i_k) \in \{1,\dots,n\}^k \mid i_1 < \cdots < i_k\}$, the terms differentiating the coefficients produce $\sum_{I\in\mathcal{J}_{n,k}} d\alpha_I \wedge \mathbf{d}x^I$. In the terms differentiating one of the factors $\mathbf{d}x^j$, alternation combines, up to the sign of the position of that factor, the sum

$$\sum_{\ell,i=1}^{n} \Gamma_{\ell i}^j \, \mathbf{d}x^\ell \wedge \mathbf{d}x^i = \frac{1}{2} \sum_{\ell,i=1}^{n} (\Gamma_{\ell i}^j - \Gamma_{i\ell}^j)\, \mathbf{d}x^\ell \wedge \mathbf{d}x^i = 0.$$

Therefore,

$$(k+1)\,\mathrm{Alt}(\nabla^M\boldsymbol{\alpha}) = \sum_{I\in\mathcal{J}_{n,k}} d\alpha_I \wedge \mathbf{d}x^I = d\boldsymbol{\alpha}.$$

In degree zero, there are no covector factors to differentiate, and the same identity is simply $\nabla^M f = df$.

Now apply the product connection to $\alpha \otimes \mathbf{s}$, and write locally $\nabla^{\mathbf{E}}\mathbf{s} = \sum_{a=1}^{r} \eta^a \otimes \mathbf{e}_a$. By the preceding argument, the terms differentiating α give $d\alpha \otimes \mathbf{s}$. By the alternating sum formula, those differentiating $\mathbf{s}$ give

$$\sum_{a=1}^{r} (\eta^a \wedge \alpha) \otimes \mathbf{e}_a = (-1)^k \alpha \wedge \nabla^{\mathbf{E}}\mathbf{s}.$$

Consequently,

$$(k+1)\operatorname{Alt}\big(\nabla(\alpha \otimes \mathbf{s})\big) = d\alpha \otimes \mathbf{s} + (-1)^k \alpha \wedge \nabla^{\mathbf{E}}\mathbf{s} = d^{\mathbf{E}}(\alpha \otimes \mathbf{s}).$$

Every $\mathbf{E}$-valued form is locally a finite sum of these tensors, so the identity holds for any $\omega \in \Omega^k(M, \mathbf{E})$. In particular, the result of alternation does not depend on the chosen auxiliary torsion-free connection. For example, one may take the Levi–Civita connection of an auxiliary Riemannian metric, but that metric is not part of the data defining $d^{\mathbf{E}}$. The vanishing torsion condition is imposed only on ∇^M, not on the bundle connection $\nabla^{\mathbf{E}}$.

Proposition 8.2.20. Let M be a smooth manifold with or without boundary and let $\mathbf{E} \to M$ be a smooth vector bundle with a connection. The operator

$$d^{\mathbf{E}} \colon \Omega^k(M, \mathbf{E}) \longrightarrow \Omega^{k+1}(M, \mathbf{E})$$

is a partial differential operator of order at most 1.

Proof. The rule defining $d^{\mathbf{E}}$ and the Leibniz rule for d imply, first on simple tensors and then by linearity, that

$$d^{\mathbf{E}}(f\omega) = df \wedge \omega + f\, d^{\mathbf{E}}\omega.$$

Thus, $[d^{\mathbf{E}}, f](\omega) = df \wedge \omega$. This commutator is $C^\infty(M)$-linear and hence has order 0. The recursive definition of a differential operator shows that $d^{\mathbf{E}} \in \mathbf{PDO}^{(1)}$, as desired. □

The composition of $d^{\mathbf{E}}$ with itself is controlled by the curvature of the connection.

Definition 8.2.21. (Curvature of a connection) Let M be a smooth manifold with or without boundary, let $\mathbf{E} \to M$ be a smooth vector bundle, and let $\nabla^{\mathbf{E}}$ be a connection on $\mathbf{E}$. We define its curvature to be the tensor field

$$\mathbf{R}^{\mathbf{E}} \in \Gamma\big(\Lambda^2 T^*M \otimes \operatorname{End}(\mathbf{E})\big)$$

given by

$$\mathbf{R}^{\mathbf{E}}(\mathbf{X}, \mathbf{Y}) := \nabla^{\mathbf{E}}_{\mathbf{X}} \nabla^{\mathbf{E}}_{\mathbf{Y}} - \nabla^{\mathbf{E}}_{\mathbf{Y}} \nabla^{\mathbf{E}}_{\mathbf{X}} - \nabla^{\mathbf{E}}_{[\mathbf{X},\mathbf{Y}]},$$

for vector fields $\mathbf{X}, \mathbf{Y}$.

Lemma 8.2.22. (Covariant derivative of curvature) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary and let $\mathbf{E} \to M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$. The product connection on $\Lambda^2 T^*M \otimes \operatorname{End}(\mathbf{E})$ determines the covariant derivative of $\mathbf{R}^{\mathbf{E}}$. For any $\mathbf{X}, \mathbf{Y}, \mathbf{Z} \in \mathfrak{X}(M)$,

$$(\nabla_{\mathbf{Z}} \mathbf{R}^{\mathbf{E}})(\mathbf{X}, \mathbf{Y}) = \nabla^{\operatorname{End}(\mathbf{E})}_{\mathbf{Z}}\big(\mathbf{R}^{\mathbf{E}}(\mathbf{X}, \mathbf{Y})\big) - \mathbf{R}^{\mathbf{E}}(\nabla^M_{\mathbf{Z}}\mathbf{X}, \mathbf{Y}) - \mathbf{R}^{\mathbf{E}}(\mathbf{X}, \nabla^M_{\mathbf{Z}}\mathbf{Y}). \tag{8.11}$$

Consequently, for every section $\mathbf{v} \in \Gamma(\mathbf{E})$,

$$\begin{aligned}\nabla^{\mathbf{E}}_{\mathbf{Z}}\big(\mathbf{R}^{\mathbf{E}}(\mathbf{X},\mathbf{Y})\mathbf{v}\big) &= (\nabla_{\mathbf{Z}}\mathbf{R}^{\mathbf{E}})(\mathbf{X},\mathbf{Y})\mathbf{v} + \mathbf{R}^{\mathbf{E}}(\nabla^{M}_{\mathbf{Z}}\mathbf{X},\mathbf{Y})\mathbf{v} \\ &\quad + \mathbf{R}^{\mathbf{E}}(\mathbf{X},\nabla^{M}_{\mathbf{Z}}\mathbf{Y})\mathbf{v} + \mathbf{R}^{\mathbf{E}}(\mathbf{X},\mathbf{Y})\nabla^{\mathbf{E}}_{\mathbf{Z}}\mathbf{v}.\end{aligned} \tag{8.12}$$

Proof. The first identity is the formula for the induced connection on an 2-covariant tensor with values in $\operatorname{End}(\mathbf{E})$. For the second, apply the Leibniz rule to the parallel evaluation

$$\operatorname{End}(\mathbf{E}) \otimes \mathbf{E} \longrightarrow \mathbf{E}, \qquad (A,\mathbf{v}) \longmapsto A\mathbf{v},$$

and then substitute (8.11). □

Proposition 8.2.23. (Curvature of tensor bundles and the Ricci identity) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary with Levi–Civita connection ∇^{M}, and let $\mathbf{E} \to M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$. For $q \in \mathbb{N}_0$, set

$$\mathbf{F}_q := T^{(0,q)}(TM) \otimes \mathbf{E}$$

and equip $\mathbf{F}_q$ with the induced product connection. If $\mathbf{T} \in \Gamma(\mathbf{F}_q)$, then, for any $\mathbf{X},\mathbf{Y},\mathbf{Z}_1,\dots,\mathbf{Z}_q \in \mathfrak{X}(M)$,

$$\begin{aligned}\big(\mathbf{R}^{\mathbf{F}_q}(\mathbf{X},\mathbf{Y})\mathbf{T}\big)(\mathbf{Z}_1,\dots,\mathbf{Z}_q) &= \mathbf{R}^{\mathbf{E}}(\mathbf{X},\mathbf{Y})\big(\mathbf{T}(\mathbf{Z}_1,\dots,\mathbf{Z}_q)\big) \\ &\quad - \sum_{a=1}^{q} \mathbf{T}(\mathbf{Z}_1,\dots,\mathbf{R}^{M}(\mathbf{X},\mathbf{Y})\mathbf{Z}_a,\dots,\mathbf{Z}_q).\end{aligned} \tag{8.13}$$

When $q = 0$, the sum is understood to be empty and $\mathbf{R}^{\mathbf{F}_0} = \mathbf{R}^{\mathbf{E}}$.
Moreover, the first two entries of the second covariant derivative satisfy the Ricci identity

$$\begin{aligned}&(\nabla^2\mathbf{T})(\mathbf{X},\mathbf{Y},\mathbf{Z}_1,\dots,\mathbf{Z}_q) - (\nabla^2\mathbf{T})(\mathbf{Y},\mathbf{X},\mathbf{Z}_1,\dots,\mathbf{Z}_q) \\ &\quad = \big(\mathbf{R}^{\mathbf{F}_q}(\mathbf{X},\mathbf{Y})\mathbf{T}\big)(\mathbf{Z}_1,\dots,\mathbf{Z}_q).\end{aligned} \tag{8.14}$$

In particular, if $\mathbf{A} \in \Gamma(T^*M \otimes \mathbf{E})$, then

$$\big(\mathbf{R}^{T^*M\otimes\mathbf{E}}(\mathbf{X},\mathbf{Y})\mathbf{A}\big)(\mathbf{Z}) = \mathbf{R}^{\mathbf{E}}(\mathbf{X},\mathbf{Y})\mathbf{A}(\mathbf{Z}) - \mathbf{A}\big(\mathbf{R}^{M}(\mathbf{X},\mathbf{Y})\mathbf{Z}\big). \tag{8.15}$$

Proof. We begin with the curvature of a tensor product. If $\mathbf{G},\mathbf{H} \to M$ are bundles with connections and $\mathbf{s} \in \Gamma(\mathbf{G})$, $\mathbf{t} \in \Gamma(\mathbf{H})$, applying the Leibniz rule twice to the definition of curvature gives

$$\mathbf{R}^{\mathbf{G}\otimes\mathbf{H}}(\mathbf{X},\mathbf{Y})(\mathbf{s}\otimes\mathbf{t}) = \mathbf{R}^{\mathbf{G}}(\mathbf{X},\mathbf{Y})\mathbf{s}\otimes\mathbf{t} + \mathbf{s}\otimes\mathbf{R}^{\mathbf{H}}(\mathbf{X},\mathbf{Y})\mathbf{t}.$$

The mixed terms cancel in pairs. Since simple tensor sections locally generate $\Gamma(\mathbf{G}\otimes\mathbf{H})$, the identity holds for every section.
For the induced connection on the dual, the definition and the Leibniz rule for evaluation imply

$$\big(\mathbf{R}^{\mathbf{G}^*}(\mathbf{X},\mathbf{Y})\boldsymbol{\alpha}\big)(\mathbf{s}) = -\boldsymbol{\alpha}\big(\mathbf{R}^{\mathbf{G}}(\mathbf{X},\mathbf{Y})\mathbf{s}\big).$$

Apply these two formulas to each factor of $T^{(0,q)}(TM) = (T^*M)^{\otimes q}$. The curvature $\mathbf{R}^{\mathbf{E}}$ acts on the factor $\mathbf{E}$,

whereas the curvature of each factor T^*M acts with a negative sign on the corresponding entry. This gives exactly (8.13).

We now prove (8.14). By the formula for the second covariant derivative in Proposition 2.4.29, now applied to the section $\mathbf{T}$ of the bundle $\mathbf{F}_q$, we have

$$(\nabla^2\mathbf{T})(\mathbf{X},\mathbf{Y}) = \nabla^{\mathbf{F}_q}_{\mathbf{X}}\nabla^{\mathbf{F}_q}_{\mathbf{Y}}\mathbf{T} - \nabla^{\mathbf{F}_q}_{\nabla^M_{\mathbf{X}}\mathbf{Y}}\mathbf{T}.$$

Therefore,

$$\begin{aligned}(\nabla^2\mathbf{T})(\mathbf{X},\mathbf{Y}) - (\nabla^2\mathbf{T})(\mathbf{Y},\mathbf{X}) = {}& \nabla^{\mathbf{F}_q}_{\mathbf{X}}\nabla^{\mathbf{F}_q}_{\mathbf{Y}}\mathbf{T} \\ & - \nabla^{\mathbf{F}_q}_{\mathbf{Y}}\nabla^{\mathbf{F}_q}_{\mathbf{X}}\mathbf{T} \\ & - \nabla^{\mathbf{F}_q}_{\nabla^M_{\mathbf{X}}\mathbf{Y}-\nabla^M_{\mathbf{Y}}\mathbf{X}}\mathbf{T}.\end{aligned}$$

The Levi–Civita connection is torsion-free, so $\nabla^M_{\mathbf{X}}\mathbf{Y} - \nabla^M_{\mathbf{Y}}\mathbf{X} = [\mathbf{X},\mathbf{Y}]$. Consequently, the right-hand side is

$$\nabla^{\mathbf{F}_q}_{\mathbf{X}}\nabla^{\mathbf{F}_q}_{\mathbf{Y}}\mathbf{T} - \nabla^{\mathbf{F}_q}_{\mathbf{Y}}\nabla^{\mathbf{F}_q}_{\mathbf{X}}\mathbf{T} - \nabla^{\mathbf{F}_q}_{[\mathbf{X},\mathbf{Y}]}\mathbf{T} = \mathbf{R}^{\mathbf{F}_q}(\mathbf{X},\mathbf{Y})\mathbf{T}.$$

Evaluating this equality on $\mathbf{Z}_1,\dots,\mathbf{Z}_q$ proves (8.14). Finally, (8.15) is the case $q = 1$ of (8.13). □

Proposition 8.2.24. (Skew-adjointness of the curvature of a metric connection) Let M be a smooth manifold with or without boundary, let $(\mathbf{E},\mathbf{h}_\mathbf{E}) \to M$ be a vector bundle with a bundle metric, and let $\nabla^\mathbf{E}$ be a connection compatible with $\mathbf{h}_\mathbf{E}$. Then, for any $\mathbf{X},\mathbf{Y} \in \mathfrak{X}(M)$ and $\mathbf{u},\mathbf{v} \in \Gamma(\mathbf{E})$,

$$\Big\langle \mathbf{R}^\mathbf{E}(\mathbf{X},\mathbf{Y})\mathbf{u},\mathbf{v}\Big\rangle_{\mathbf{h}_\mathbf{E}} + \Big\langle \mathbf{u},\mathbf{R}^\mathbf{E}(\mathbf{X},\mathbf{Y})\mathbf{v}\Big\rangle_{\mathbf{h}_\mathbf{E}} = 0. \tag{8.16}$$

In particular, $\mathbf{R}^\mathbf{E}(\mathbf{X},\mathbf{Y})\colon \mathbf{E}_x \longrightarrow \mathbf{E}_x$ is skew-adjoint on each fiber.

Proof. Metric compatibility gives

$$\mathbf{X}\langle \mathbf{u},\mathbf{v}\rangle_{\mathbf{h}_\mathbf{E}} = \langle \nabla^\mathbf{E}_\mathbf{X}\mathbf{u},\mathbf{v}\rangle_{\mathbf{h}_\mathbf{E}} + \langle \mathbf{u},\nabla^\mathbf{E}_\mathbf{X}\mathbf{v}\rangle_{\mathbf{h}_\mathbf{E}}.$$

Apply this identity successively with $\mathbf{X}$ and $\mathbf{Y}$, subtract the two resulting expressions, and subtract the derivative in the direction $[\mathbf{X},\mathbf{Y}]$. The mixed terms cancel, and the left-hand side is

$$\big(\mathbf{XY} - \mathbf{YX} - [\mathbf{X},\mathbf{Y}]\big)\langle \mathbf{u},\mathbf{v}\rangle_{\mathbf{h}_\mathbf{E}} = 0.$$

The right-hand side is precisely

$$\langle \mathbf{R}^\mathbf{E}(\mathbf{X},\mathbf{Y})\mathbf{u},\mathbf{v}\rangle_{\mathbf{h}_\mathbf{E}} + \langle \mathbf{u},\mathbf{R}^\mathbf{E}(\mathbf{X},\mathbf{Y})\mathbf{v}\rangle_{\mathbf{h}_\mathbf{E}}.$$

This proves (8.16). □

The expression for curvature in a synchronous frame admits an integral formula that will be useful when studying bundles over manifolds of bounded geometry.

Proposition 8.2.25. (Curvature formula in a synchronous frame) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, let $p \in M$, let U be a normal neighborhood of p, and let $\mathbf{e} = (\mathbf{e}_1,\dots,\mathbf{e}_r)$ be a synchronous frame centered at p. In normal coordinates $x = (x^1,\dots,x^n)$, write

$$\nabla^{\mathbf{E}} = d + \mathbf{A}, \qquad \mathbf{A} = \sum_{\mu=1}^{n} A_\mu \, \mathbf{d}x^\mu,$$

and represent the curvature by

$$\mathbf{R}^{\mathbf{E}} = \frac{1}{2} \sum_{\nu,\mu=1}^{n} F_{\nu\mu} \, \mathbf{d}x^\nu \wedge \mathbf{d}x^\mu.$$

Then, for each $\mu \in \{1,\dots,n\}$ and each x in the chart domain,

$$A_\mu(x) = \int_0^1 t \sum_{\nu=1}^{n} x^\nu F_{\nu\mu}(tx)\, dt. \tag{8.17}$$

Proof. If $\mathbf{u} = \sum_{a=1}^{r} u^a \mathbf{e}_a$ and $\widehat{u} = (u^1,\dots,u^r)^T$ is its column of components, then

$$(\nabla^{\mathbf{E}}_{\partial_\mu} \mathbf{u})^\wedge = \partial_\mu \widehat{u} + A_\mu \widehat{u}.$$

Expanding the definition of $\mathbf{R}^{\mathbf{E}}$ on coordinate vector fields gives

$$F_{\nu\mu} = \partial_\nu A_\mu - \partial_\mu A_\nu + [A_\nu, A_\mu]. \tag{8.18}$$

By Proposition 2.7.17, the frame satisfies the radial condition

$$\sum_{\nu=1}^{n} x^\nu A_\nu(x) = 0.$$

Differentiating it with respect to x^μ gives

$$\sum_{\nu=1}^{n} x^\nu \partial_\mu A_\nu(x) = -A_\mu(x),$$

and the same condition makes $\sum_{\nu=1}^{n} x^\nu [A_\nu, A_\mu]$ vanish. Contracting (8.18) with the radial vector field gives

$$\sum_{\nu=1}^{n} x^\nu F_{\nu\mu}(x) = \sum_{\nu=1}^{n} x^\nu \partial_\nu A_\mu(x) + A_\mu(x).$$

Applied at the point tx, this identity is equivalent to

$$\frac{d}{dt}\big[t A_\mu(tx)\big] = t \sum_{\nu=1}^{n} x^\nu F_{\nu\mu}(tx).$$

Since $tA_\mu(tx)$ tends to zero as $t \to 0^+$, integration from 0 to 1 proves (8.17). □

Proposition 8.2.26. (Uniform bounds for families of synchronous frames) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary. Let $r_0 > 0$ and let

$$(\widehat{U}_i, \varphi_i, p_i)_{i \in I}$$

be a family of normal neighborhoods centered at p_i such that $\varphi_i(\widehat{U}_i) = B_{\mathrm{euc}}(0, 3r_0)$. Set

$$U_i := \varphi_i^{-1}\big(B_{\mathrm{euc}}(0, 2r_0)\big).$$

Suppose that the metric matrices in these charts are uniformly elliptic and that, for every multi-index α, their derivatives of order $|\alpha|$ are bounded by a constant independent of i. Also suppose that all derivatives of the coordinate changes $\varphi_j \circ \varphi_i^{-1}$ and their inverses are uniformly bounded on overlaps.
Let $\mathbf{E} \to M$ be a vector bundle of rank $r_{\mathbf{E}}$, equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. On $\Lambda^2 T^*M \otimes \mathrm{End}(\mathbf{E})$ we use the product connection induced by the Levi–Civita connection and $\nabla^{\mathbf{E}}$. Suppose that, for each $k \in \mathbb{N}_0$, there exists $C_k^{\mathbf{E}} > 0$ such that

$$\sup_{i \in I} \sup_{x \in \widehat{U}_i} \Big| \big(\nabla^{\Lambda^2 T^*M \otimes \mathrm{End}(\mathbf{E})}\big)^k \mathbf{R}^{\mathbf{E}}(x) \Big|_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}} \leq C_k^{\mathbf{E}}.$$

On each $\widehat{U}_i$, construct a synchronous frame $\mathbf{e}_i = (\mathbf{e}_{i,1}, \dots, \mathbf{e}_{i,r_{\mathbf{E}}})$ from an orthonormal basis of $\mathbf{E}_{p_i}$ and write, in coordinates φ_i,

$$\nabla^{\mathbf{E}} = d + \mathbf{A}_i, \qquad \mathbf{A}_i = \sum_{\mu=1}^{n} A_{i,\mu}\, \mathbf{d}x^\mu.$$

Then, for every multi-index α, there exists $C_\alpha > 0$, independent of i, such that

$$\sup_{x \in B_{\mathrm{euc}}(0, 2r_0)} \big\| D^\alpha A_{i,\mu}(x) \big\|_{\mathrm{op}, \mathbb{K}^{r_{\mathbf{E}}}} \leq C_\alpha, \qquad \mu \in \{1, \dots, n\}. \tag{8.19}$$

where the Euclidean operator norm is used on the matrices written in the orthonormal synchronous frame. If G_{ij} is the transition matrix determined on $U_i \cap U_j$ by $u_i = G_{ij} u_j$, then G_{ij}, G_{ij}^{-1}, and all their derivatives, expressed in either of the two charts, satisfy bounds independent of i and j.

Proof. The frames $\mathbf{e}_i$ are smooth and orthonormal by Proposition 2.7.17. Represent the curvature in the frame $\mathbf{e}_i$ by

$$\mathbf{R}^{\mathbf{E}} = \frac{1}{2} \sum_{\nu, \mu = 1}^{n} F_{i, \nu\mu}\, \mathbf{d}x^\nu \wedge \mathbf{d}x^\mu.$$

Formula (8.17) applies in each chart and gives

$$A_{i,\mu}(x) = \int_0^1 t \sum_{\nu=1}^{n} x^\nu F_{i,\nu\mu}(tx)\, dt. \tag{8.20}$$

Uniform equivalence between $\mathbf{g}$ and the Euclidean metric, together with the bound on $\mathbf{R}^{\mathbf{E}}$, controls the components $F_{i,\nu\mu}$ at order zero. The preceding formula then provides the uniform bound for $\mathbf{A}_i$ at order

zero.

To obtain the higher orders, let $\mathbf{T}$ be a tensor with values in $\operatorname{End}(\mathbf{E})$. In coordinates φ_i and the frame $\mathbf{e}_i$, the product connection satisfies schematically

$$\partial \mathbf{T} = \nabla \mathbf{T} + \Gamma_i * \mathbf{T} + \mathbf{A}_i * \mathbf{T} - \mathbf{T} * \mathbf{A}_i, \tag{8.21}$$

where $*$ represents a finite sum of tensor products and contractions. The hypotheses on the metric uniformly bound the Christoffel symbols and all their derivatives. Suppose the ordinary derivatives of the matrices $F_{i,\nu\mu}$ and $A_{i,\mu}$ are controlled up to order $k-1$. Differentiating (8.21) and using the Leibniz rule expresses the derivatives of order k of $F_{i,\nu\mu}$ in terms of the components of $(\nabla^{\mathbf{E}})^j \mathbf{R}^{\mathbf{E}}$, with $j \le k$, and quantities already controlled. Differentiating (8.20) under the integral sign yields the order k bounds for $A_{i,\mu}$. Induction proves (8.19).

On an overlap, set $y = \varphi_j \circ \varphi_i^{-1}(x)$. Compatibility of the two local expressions for the connection and the equality $u_i = G_{ij} u_j$ imply

$$\partial_{x^\mu} G_{ij}(x) = \sum_{\nu=1}^{n} G_{ij}(x) A_{j,\nu}(y) \frac{\partial y^\nu}{\partial x^\mu}(x) - A_{i,\mu}(x) G_{ij}(x). \tag{8.22}$$

The matrices G_{ij} are orthogonal or unitary, so $\|G_{ij}\|_{\mathrm{op},\mathbb{K}^{r_{\mathbf{E}}}} = \|G_{ij}^{-1}\|_{\mathrm{op},\mathbb{K}^{r_{\mathbf{E}}}} = 1$. The preceding equation and the bounds already proved control the first derivative. After applying D^α to (8.22), the Leibniz rule expresses the derivatives of order $|\alpha|+1$ of G_{ij} in terms of derivatives of order at most $|\alpha|$ of G_{ij} and uniformly bounded quantities. An induction completes the estimate for all derivatives. For the inverse, use $G_{ij}^{-1} = G_{ij}^{*}$. □

Curvature acts naturally on bundle-valued forms through the exterior product in the differential-form factor and composition in the bundle factor.

Proposition 8.2.27. Let M be a smooth manifold with or without boundary and let $\mathbf{E} \to M$ be a smooth vector bundle with connection $\nabla^{\mathbf{E}}$. For every $\omega \in \Omega^k(M, \mathbf{E})$ we have

$$(d^{\mathbf{E}})^2 \omega = \mathbf{R}^{\mathbf{E}} \wedge \omega.$$

In particular, $(d^{\mathbf{E}})^2 = 0$ as a graded operator on $\Omega^\bullet(M, \mathbf{E})$ if and only if the connection is flat.

Proof. The identity is local. Fix a frame $\mathbf{e} = (\mathbf{e}_1, \dots, \mathbf{e}_r)$ for $\mathbf{E}$ and write

$$\nabla^{\mathbf{E}} = d + \mathbf{A}, \qquad \mathbf{A} = (\theta^a{}_b)_{a,b=1}^{r}.$$

A form $\omega \in \Omega^k(M, \mathbf{E})$ is represented in this frame by the column $\widehat{\omega} = (\omega^1, \dots, \omega^r)^T$ of scalar k-forms. The local formula for $d^{\mathbf{E}}$ is equivalent to

$$\widehat{d^{\mathbf{E}} \omega} = d\widehat{\omega} + \mathbf{A} \wedge \widehat{\omega}.$$

Apply $d^{\mathbf{E}}$ again. Since $\mathbf{A}$ has degree one, the graded Leibniz rule gives

$$\begin{aligned}\widehat{(d^{\mathbf{E}})^2\omega} &= d\big(d\widehat{\omega} + \mathbf{A}\wedge\widehat{\omega}\big) + \mathbf{A}\wedge\big(d\widehat{\omega} + \mathbf{A}\wedge\widehat{\omega}\big)\\ &= d\mathbf{A}\wedge\widehat{\omega} - \mathbf{A}\wedge d\widehat{\omega} + \mathbf{A}\wedge d\widehat{\omega} + \mathbf{A}\wedge\mathbf{A}\wedge\widehat{\omega}\\ &= \big(d\mathbf{A} + \mathbf{A}\wedge\mathbf{A}\big)\wedge\widehat{\omega}.\end{aligned}$$

By the local curvature formula,

$$\widehat{\mathbf{R}^{\mathbf{E}}} = d\mathbf{A} + \mathbf{A}\wedge\mathbf{A};$$

in components, this equality is exactly

$$F_{\nu\mu} = \partial_\nu A_\mu - \partial_\mu A_\nu + [A_\nu, A_\mu].$$

Therefore,

$$(d^{\mathbf{E}})^2\omega = \mathbf{R}^{\mathbf{E}}\wedge\omega.$$

If the connection is flat, the right-hand side vanishes in every degree. Conversely, suppose that $(d^{\mathbf{E}})^2 = 0$ as a graded operator. In particular, it vanishes on $\Omega^0(M,\mathbf{E}) = \Gamma(\mathbf{E})$. Given $p\in M$, $v\in\mathbf{E}_p$, and $X, Y\in T_pM$, choose a smooth section $\mathbf{s}$ with $\mathbf{s}(p) = v$ and smooth extensions of X, Y. Then

$$0 = \big((d^{\mathbf{E}})^2\mathbf{s}\big)_p(X,Y) = \mathbf{R}^{\mathbf{E}}_p(X,Y)v.$$

Since p, v, X, Y are arbitrary, $\mathbf{R}^{\mathbf{E}} = 0$; that is, the connection is flat. □

This construction generalizes the Hodge–de Rham exterior operator to bundle-valued forms. It defines a complex only when the connection is flat; if $\mathbf{R}^{\mathbf{E}}\neq 0$, the preceding identity measures exactly the defect. Later, introducing the formal adjoint of $d^{\mathbf{E}}$ will lead to the $\mathbf{E}$-valued Hodge Laplacian, which is related to the Bochner Laplacian through Weitzenböck-type identities.

Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary and let $\pi_{\mathbf{E}}\colon\mathbf{E}\longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. Recall that we have already defined the operator

$$d^{\mathbf{E}}\colon\Omega^k(M,\mathbf{E})\longrightarrow\Omega^{k+1}(M,\mathbf{E}).$$

The Riemannian metric and bundle metric naturally induce a pointwise inner product on $\Lambda^k T^*M\otimes\mathbf{E}$. Integrating with respect to the Riemannian measure gives a global inner product

$$\langle\alpha,\beta\rangle_{L^2(M,\Lambda^kT^*M\otimes\mathbf{E})} := \int_M \langle\alpha,\beta\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}}, \qquad \alpha,\beta\in\Omega^k_c(M,\mathbf{E}).$$

Definition 8.2.28. (Formal adjoint of $d^{\mathbf{E}}$) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $\mathbf{E}\to M$ be a vector bundle with a bundle metric and a compatible connection. We define the formal adjoint of

$$d^{\mathbf{E}}\colon\Omega^k(M,\mathbf{E})\longrightarrow\Omega^{k+1}(M,\mathbf{E})$$

to be the operator

$$\delta^{\mathbf{E}}\colon\Omega^{k+1}(M,\mathbf{E})\longrightarrow\Omega^k(M,\mathbf{E})$$

characterized by the identity

$$\int_M \langle d^{\mathbf{E}}\boldsymbol{\alpha}, \boldsymbol{\beta}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}} = \int_M \langle \boldsymbol{\alpha}, \delta^{\mathbf{E}}\boldsymbol{\beta}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}}$$

for all

$$\boldsymbol{\alpha} \in \Omega_c^k(M,\mathbf{E}), \qquad \boldsymbol{\beta} \in \Omega_c^{k+1}(M,\mathbf{E}).$$

Observe that this operator exists and is unique by Theorem 8.2.3.

If M is also oriented, the formal adjoint can be expressed through the Hodge operator. We briefly recall this construction.

Definition 8.2.29. (Hodge operator) Let $(M,\mathbf{g})$ be an oriented Riemannian manifold with or without boundary and let $n = \dim M$. The Hodge operator is the bundle isomorphism

$$*\colon \Lambda^k T^*M \longrightarrow \Lambda^{n-k} T^*M$$

characterized by the identity

$$\alpha \wedge *\beta = \langle \alpha, \beta\rangle_{\mathbf{g}}\, dV_{\mathbf{g}},$$

for all $\alpha, \beta \in \Lambda^k T_x^*M$, where $dV_{\mathbf{g}}$ denotes the Riemannian volume form. This operator extends naturally to $\mathbf{E}$-valued forms by

$$*(\alpha \otimes s) := (*\alpha) \otimes s.$$

With this notation, we obtain the classical expression for the formal adjoint.

Proposition 8.2.30. Let $(M,\mathbf{g})$ be an oriented Riemannian manifold without boundary and let $\mathbf{E} \to M$ be a vector bundle with a bundle metric and a compatible connection. Then

$$\delta^{\mathbf{E}} = (-1)^{k+1}\, *^{-1}\, d^{\mathbf{E}} *$$

on $\Omega^{k+1}(M,\mathbf{E})$.

Proof. Let $\boldsymbol{\alpha} \in \Omega_c^k(M,\mathbf{E})$ and $\boldsymbol{\beta} \in \Omega_c^{k+1}(M,\mathbf{E})$. The bundle metric induces a pairing between $\mathbf{E}$-valued forms: in an orthonormal local frame, if $\boldsymbol{\eta} = \sum_{a=1}^{r} \eta^a \otimes \mathbf{e}_a$ and $\boldsymbol{\zeta} = \sum_{a=1}^{r} \zeta^a \otimes \mathbf{e}_a$, set

$$\mathbf{h}_{\mathbf{E}}(\boldsymbol{\eta} \wedge \boldsymbol{\zeta}) := \sum_{a=1}^{r} \eta^a \wedge \overline{\zeta^a},$$

omitting conjugation in the real case. Unitary invariance of this expression shows that it is independent of the frame. Compatibility of $\nabla^{\mathbf{E}}$ with $\mathbf{h}_{\mathbf{E}}$ and the graded Leibniz rule give

$$\begin{aligned} d\,\mathbf{h}_{\mathbf{E}}\big(\boldsymbol{\alpha} \wedge *\boldsymbol{\beta}\big) &= \mathbf{h}_{\mathbf{E}}\big(d^{\mathbf{E}}\boldsymbol{\alpha} \wedge *\boldsymbol{\beta}\big) \\ &\quad + (-1)^k \mathbf{h}_{\mathbf{E}}\big(\boldsymbol{\alpha} \wedge d^{\mathbf{E}}(*\boldsymbol{\beta})\big). \end{aligned}$$

The form on the left-hand side has compact support. Since M is oriented and has no boundary, Stokes'

theorem implies

$$\int_M \mathbf{h}_{\mathbf{E}}\left(d^{\mathbf{E}}\boldsymbol{\alpha}\wedge *\boldsymbol{\beta}\right) = (-1)^{k+1}\int_M \mathbf{h}_{\mathbf{E}}\left(\boldsymbol{\alpha}\wedge d^{\mathbf{E}}(*\boldsymbol{\beta})\right).$$

By definition of the Hodge operator,

$$\mathbf{h}_{\mathbf{E}}\left(d^{\mathbf{E}}\boldsymbol{\alpha}\wedge *\boldsymbol{\beta}\right) = \langle d^{\mathbf{E}}\boldsymbol{\alpha},\boldsymbol{\beta}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\, dV_{\mathbf{g}},$$

whereas

$$\mathbf{h}_{\mathbf{E}}\left(\boldsymbol{\alpha}\wedge d^{\mathbf{E}}(*\boldsymbol{\beta})\right) = \left\langle \boldsymbol{\alpha}, *^{-1}d^{\mathbf{E}}(*\boldsymbol{\beta})\right\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}} dV_{\mathbf{g}}.$$

Therefore,

$$\int_M \langle d^{\mathbf{E}}\boldsymbol{\alpha},\boldsymbol{\beta}\rangle\, d\lambda_{\mathbf{g}} = \int_M \left\langle \boldsymbol{\alpha}, (-1)^{k+1} *^{-1} d^{\mathbf{E}} * \boldsymbol{\beta}\right\rangle d\lambda_{\mathbf{g}}.$$

Uniqueness of the formal adjoint implies that $\delta^{\mathbf{E}} = (-1)^{k+1} *^{-1} d^{\mathbf{E}} *$ on $\Omega^{k+1}(M,\mathbf{E})$. □

From these operators, we can define the bundle-valued Hodge Laplacian.

Definition 8.2.31. (**E**-valued Hodge Laplacian) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $\mathbf{E}\to M$ be a vector bundle with a bundle metric and a compatible connection. Define the operator

$$\Delta^{\mathbf{E}}_{\mathbf{H}}\colon \Omega^k(M,\mathbf{E}) \longrightarrow \Omega^k(M,\mathbf{E})$$

by

$$\Delta^{\mathbf{E}}_{\mathbf{H}} := d^{\mathbf{E}}\delta^{\mathbf{E}} + \delta^{\mathbf{E}}d^{\mathbf{E}}.$$

This operator is formally self-adjoint and has order 2.

On the other hand, recall that the connection induces a covariant derivative on $\Lambda^k T^*M\otimes\mathbf{E}$, allowing us to define the Bochner Laplacian on bundle-valued forms.

Definition 8.2.32. (Bochner Laplacian on bundle-valued forms) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $\mathbf{E}\to M$ be a vector bundle with a bundle metric and a compatible connection. Define

$$\Delta^{\mathbf{E}}_{B} := \nabla^*\nabla,$$

where

$$\nabla\colon \Omega^k(M,\mathbf{E}) \longrightarrow \Gamma(T^*M\otimes\Lambda^k T^*M\otimes\mathbf{E})$$

is the induced connection and ∇^* its formal adjoint.

These two operators are related by a fundamental identity involving the curvature of the connection and the Riemannian curvature.

Theorem 8.2.33. (Weitzenböck identity) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary and let $\mathbf{E}\to M$ be a vector bundle with compatible connection $\nabla^{\mathbf{E}}$. Then, on $\Omega^k(M,\mathbf{E})$, we have

$$\Delta^{\mathbf{E}}_{\mathbf{H}} = \Delta^{\mathbf{E}}_{B} - \sum_{i,j=1}^{n} \varepsilon(\mathbf{e}^i)\iota(\mathbf{e}_j)\mathbf{R}^{\Lambda^k T^*M\otimes\mathbf{E}}(\mathbf{e}_i,\mathbf{e}_j), \tag{8.23}$$

where $(\mathbf{e}_1,\dots,\mathbf{e}_n)$ is any orthonormal local frame and $\varepsilon(\mathbf{e}^i)$ denotes exterior multiplication. The last summand is a zeroth-order endomorphism and includes both the Riemannian curvature on $\Lambda^k T^*M$ and $\mathbf{R}^{\mathbf{E}}$ on the factor $\mathbf{E}$.

Proof. Fix $p \in M$ and choose a frame orthonormal and synchronous at p; thus $\nabla \mathbf{e}_i(p) = 0$ and $[\mathbf{e}_i, \mathbf{e}_j](p) = 0$. At that point,

$$d^{\mathbf{E}} = \sum_{i=1}^{n} \varepsilon(\mathbf{e}^i)\nabla_{\mathbf{e}_i}, \qquad \delta^{\mathbf{E}} = -\sum_{j=1}^{n} \iota(\mathbf{e}_j)\nabla_{\mathbf{e}_j}.$$

Using $\iota(\mathbf{e}_j)\varepsilon(\mathbf{e}^i) + \varepsilon(\mathbf{e}^i)\iota(\mathbf{e}_j) = \delta_{ij} I$ and grouping compositions in the order in which they appear gives

$$\begin{aligned} d^{\mathbf{E}}\delta^{\mathbf{E}} + \delta^{\mathbf{E}} d^{\mathbf{E}} = &- \sum_{i=1}^{n} \nabla_{\mathbf{e}_i}\nabla_{\mathbf{e}_i} \\ &- \sum_{i,j=1}^{n} \varepsilon(\mathbf{e}^i)\iota(\mathbf{e}_j)\big(\nabla_{\mathbf{e}_i}\nabla_{\mathbf{e}_j} - \nabla_{\mathbf{e}_j}\nabla_{\mathbf{e}_i}\big). \end{aligned}$$

The first summand is $\nabla^*\nabla$ at p, and the expression in parentheses is $\mathbf{R}^{\Lambda^k T^*M \otimes \mathbf{E}}(\mathbf{e}_i, \mathbf{e}_j)$. The resulting identity is tensorial; since p was arbitrary, it holds globally. □

In particular, the Hodge Laplacian and the Bochner Laplacian differ only by the algebraic curvature term in (8.23). For $k = 1$ and $\mathbf{E}$ trivial, that term is $\mathrm{Ric}^\sharp$; for $k = 0$ it vanishes. If the connection is not flat, one must also distinguish

$$(d^{\mathbf{E}} + \delta^{\mathbf{E}})^2 = \Delta_{\mathbf{H}}^{\mathbf{E}} + (d^{\mathbf{E}})^2 + (\delta^{\mathbf{E}})^2;$$

therefore, the square of the odd operator agrees with $\Delta_{\mathbf{H}}^{\mathbf{E}}$ only in the flat case.

This identity relates the analytical properties of solutions of differential equations to the curvature of the manifold and the bundle.

8.3 Operators associated with Clifford connections

Section 2.17 constructed Clifford modules, multiplication c, and compatible connections without yet associating an operator with them. Now that the general theory of differential operators on bundles has been defined, we can perform the contraction producing the Dirac operator. No symbols or pseudodifferential operators are used in this section.

Definition 8.3.1. (Dirac-type operator) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary and let $(\mathbf{S}, c, \nabla^{\mathbf{S}})$ be a Hermitian Clifford module with a Clifford connection, in the sense of Definition 2.17.14. Clifford contraction is the bundle homomorphism

$$C\colon T^*M \otimes \mathbf{S} \longrightarrow \mathbf{S}, \qquad C(\xi \otimes s) = c(\xi)s.$$

The associated *Dirac-type operator* is

$$D := C \circ \nabla^{\mathbf{S}} \colon \Gamma(\mathbf{S}) \longrightarrow \Gamma(\mathbf{S}). \tag{8.24}$$

When $\mathbf{S} = \Sigma M$ is the spinor bundle of a spin structure, it is called the *spin Dirac operator*.

Theorem 8.3.2. (Differential nature and Green's identity) Let $(\mathbf{S}, c, \nabla^{\mathbf{S}})$ be as in the preceding definition and let $(\mathbf{e}_1, \dots, \mathbf{e}_n)$ be an orthonormal local frame, with coframe $(\mathbf{e}^1, \dots, \mathbf{e}^n)$. Then

$$D\mathbf{s} = \sum_{j=1}^{n} c(\mathbf{e}^j) \nabla^{\mathbf{S}}_{\mathbf{e}_j} \mathbf{s}. \tag{8.25}$$

The expression is independent of the frame and defines a differential operator of order at most one. More precisely,

$$[D, f]\mathbf{s} = c(df)\mathbf{s}, \qquad f \in C^\infty(M), \quad \mathbf{s} \in \Gamma(\mathbf{S}). \tag{8.26}$$

If $\dim M > 0$, its order is exactly one. For $\mathbf{s}, \mathbf{t} \in \Gamma_c(\mathbf{S})$, Green's identity holds:

$$\begin{aligned} &\int_M \big(\langle D\mathbf{s}, \mathbf{t} \rangle_{\mathbf{S}} - \langle \mathbf{s}, D\mathbf{t} \rangle_{\mathbf{S}} \big)\, d\lambda_{\mathbf{g}} \\ &\qquad = \int_{\partial M} \langle c(\boldsymbol{\nu}^\flat)\mathbf{s}, \mathbf{t} \rangle_{\mathbf{S}}\, d\lambda_{\tilde{\mathbf{g}}}, \end{aligned} \tag{8.27}$$

where the right-hand side is interpreted as zero if the boundary is empty and $\boldsymbol{\nu}$ is the outward unit normal otherwise. In particular, on a manifold without boundary, $D_h^* = D$.

Proof. The local formula follows by writing $\nabla^{\mathbf{S}}\mathbf{s} = \sum_{j=1}^{n} \mathbf{e}^j \otimes \nabla^{\mathbf{S}}_{\mathbf{e}_j}\mathbf{s}$. The connection is an intrinsically defined differential operator on sections, whereas C is a bundle homomorphism. Their composition therefore does not depend on the frame. The Leibniz rule gives

$$D(f\mathbf{s}) = c(df)\mathbf{s} + f D\mathbf{s},$$

which proves (8.26) and, by the commutator characterization, shows that $D \in \mathbf{PDO}^{(1)}(\mathbf{S}, \mathbf{S})$. If $\dim M > 0$, given $x \in M$ and $0 \neq \xi \in T^*_x M$, there locally exists f with $df_x = \xi$; since $c(\xi)^2 = -|\xi|^2 I$, the commutator does not vanish at x, so D does not have order zero.

For the integral identity, define the complex vector field $\mathbf{V}$ by

$$\mathbf{g}(\mathbf{V}, \mathbf{X}) = \langle c(\mathbf{X}^\flat)\mathbf{s}, \mathbf{t} \rangle_{\mathbf{S}}.$$

At a point, choose an orthonormal synchronous frame. Compatibility of the Clifford connection and the identity $c(\xi)^* = -c(\xi)$, using the convention that the Hermitian product is linear in the first variable, give

$$\operatorname{div} \mathbf{V} = \langle D\mathbf{s}, \mathbf{t} \rangle_{\mathbf{S}} - \langle \mathbf{s}, D\mathbf{t} \rangle_{\mathbf{S}}.$$

The divergence theorem yields (8.27). If $\partial M = \varnothing$, the equality is precisely the formal symmetry of D. □

Proposition 8.3.3. (Grading and the Hodge–de Rham example) If $\mathbf{S} = \mathbf{S}^+ \oplus \mathbf{S}^-$ is a graded Clifford module,

then D is odd and is written as

$$D = \begin{pmatrix} 0 & D^- \\ D^+ & 0 \end{pmatrix}, \qquad D^\pm \colon \Gamma(\mathbf{S}^\pm) \longrightarrow \Gamma(\mathbf{S}^\mp).$$

In the absence of a boundary, $(D^+)_h^* = D^-$. Under the same hypothesis, for the module $\mathbf{S} = \Lambda^\bullet T^*M \otimes \mathbb{C}$ of Example 2.17.15,

$$D = d + \delta, \qquad D^2 = \Delta_{\mathbf{H}}. \tag{8.28}$$

Proof. The connection preserves the grading and multiplication by a covector reverses it, so the first assertion is immediate. The relation between the blocks follows from formal symmetry. For forms, in an orthonormal synchronous frame,

$$d = \sum_{j=1}^n \varepsilon(\mathbf{e}^j)\nabla_{\mathbf{e}_j}, \qquad \delta = -\sum_{j=1}^n \iota_{\mathbf{e}_j}\nabla_{\mathbf{e}_j}.$$

Since $c(\mathbf{e}^j) = \varepsilon(\mathbf{e}^j) - \iota_{\mathbf{e}_j}$, we obtain $D = d + \delta$; the identities $d^2 = \delta^2 = 0$ give the second equality. □

8.3.1 Bochner and Lichnerowicz formulas

For the rest of this section, we assume that M has no boundary, in accordance with the global definition of the formal adjoint and the connection Laplacian. The resulting identities are also local identities of differential expressions in the interior of a manifold with boundary.

Recall that the curvature of $\nabla^{\mathbf{S}}$ is

$$\mathbf{R}^{\mathbf{S}}(\mathbf{X}, \mathbf{Y}) = [\nabla^{\mathbf{S}}_{\mathbf{X}}, \nabla^{\mathbf{S}}_{\mathbf{Y}}] - \nabla^{\mathbf{S}}_{[\mathbf{X},\mathbf{Y}]}.$$

Proposition 8.3.4. (Bochner formula for a Clifford module) For every Clifford module with connection,

$$D^2 = (\nabla^{\mathbf{S}})^*\nabla^{\mathbf{S}} + \frac{1}{2}\sum_{i,j=1}^n c(\mathbf{e}^i)c(\mathbf{e}^j)\mathbf{R}^{\mathbf{S}}(\mathbf{e}_i, \mathbf{e}_j). \tag{8.29}$$

Here the connection Laplacian is given locally by

$$(\nabla^{\mathbf{S}})^*\nabla^{\mathbf{S}} = -\sum_{i=1}^n \left(\nabla^{\mathbf{S}}_{\mathbf{e}_i}\nabla^{\mathbf{S}}_{\mathbf{e}_i} - \nabla^{\mathbf{S}}_{\nabla_{\mathbf{e}_i}\mathbf{e}_i}\right). \tag{8.30}$$

Proof. Fix $x \in M$ and choose an orthonormal synchronous frame at x. Clifford compatibility implies $\nabla_{\mathbf{e}_i} c(\mathbf{e}^j) = 0$ at that point. Hence,

$$D^2 = \sum_{i,j=1}^n c(\mathbf{e}^i)c(\mathbf{e}^j)\nabla^{\mathbf{S}}_{\mathbf{e}_i}\nabla^{\mathbf{S}}_{\mathbf{e}_j}.$$

The diagonal terms are $-\sum_{i=1}^{n} \nabla^{\mathbf{S}}_{\mathbf{e}_i}\nabla^{\mathbf{S}}_{\mathbf{e}_i}$. Grouping the terms with $i<j$ and using $c(\mathbf{e}^i)c(\mathbf{e}^j) = -c(\mathbf{e}^j)c(\mathbf{e}^i)$ leaves

$$\sum_{1\le i<j\le n} c(\mathbf{e}^i)c(\mathbf{e}^j)[\nabla^{\mathbf{S}}_{\mathbf{e}_i}, \nabla^{\mathbf{S}}_{\mathbf{e}_j}],$$

which is the curvature term in (8.29) because $[\mathbf{e}_i, \mathbf{e}_j](x) = 0$. In the same frame, (8.30) agrees with the diagonal term. The equality is intrinsic and x was arbitrary. □

Lemma 8.3.5. (Spinor curvature and its contraction) On the spinor bundle of a spin manifold, we have

$$\mathbf{R}^{\Sigma}(\mathbf{X},\mathbf{Y}) = \frac{1}{4}\sum_{a,b=1}^{n} \mathbf{g}\big(\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{e}_a, \mathbf{e}_b\big)c(\mathbf{e}^a)c(\mathbf{e}^b), \tag{8.31}$$

and

$$\frac{1}{2}\sum_{i,j=1}^{n} c(\mathbf{e}^i)c(\mathbf{e}^j)\mathbf{R}^{\Sigma}(\mathbf{e}_i,\mathbf{e}_j) = \frac{1}{4}R_{\mathbf{g}} I. \tag{8.32}$$

Proof. The local formula (2.115) identifies the spinor connection form with the image of the Levi–Civita form under $A = (A_{ab}) \mapsto \frac{1}{4}\sum_{a,b=1}^{n} A_{ab}c(\mathbf{e}^a)c(\mathbf{e}^b)$. Applying the same homomorphism to the curvature form gives (8.31).

Set $R_{ijab} = \mathbf{g}(\mathbf{R}(\mathbf{e}_i,\mathbf{e}_j)\mathbf{e}_a,\mathbf{e}_b)$. Substituting the first formula into the left-hand side of the second produces

$$\frac{1}{8}\sum_{i,j,a,b=1}^{n} R_{ijab}c(\mathbf{e}^i)c(\mathbf{e}^j)c(\mathbf{e}^a)c(\mathbf{e}^b).$$

The antisymmetries of R_{ijab}, symmetry under interchange of pairs, and the first Bianchi identity cancel the terms with distinct indices. Using $c(\mathbf{e}^i)^2 = -I$, the remaining terms reduce to

$$\frac{1}{4}\sum_{i,j=1}^{n} \mathbf{g}(\mathbf{R}(\mathbf{e}_i,\mathbf{e}_j)\mathbf{e}_j,\mathbf{e}_i)I = \frac{1}{4}R_{\mathbf{g}} I,$$

by definition of scalar curvature. □

Theorem 8.3.6. (Lichnerowicz formula) The spin Dirac operator satisfies

$$D^2 = (\nabla^{\Sigma})^*\nabla^{\Sigma} + \frac{1}{4}R_{\mathbf{g}} I. \tag{8.33}$$

If M is closed and $R_{\mathbf{g}} > 0$, then $\ker D = \{0\}$.

Proof. The identity follows from Proposition 8.3.4 and Lemma 8.3.5. If $D\psi = 0$, formal symmetry and (8.33) give

$$0 = \|D\psi\|^2_{L^2(M,\Sigma)} = \|\nabla^{\Sigma}\psi\|^2_{L^2(M,T^*M\otimes\Sigma)} + \frac{1}{4}\int_M R_{\mathbf{g}}|\psi|^2\, d\lambda_{\mathbf{g}}.$$

Both summands are nonnegative, and the second can vanish only if $\psi = 0$. □

8.3.2 Twisted operators and Spin^c

Definition 8.3.7. (Twisted Dirac operator) Let M be spin and let $\mathbf{E} \to M$ be a Hermitian bundle with unitary connection $\nabla^{\mathbf{E}}$. On $\mathbf{S} = \Sigma M \otimes \mathbf{E}$ consider

$$c_{\mathbf{E}}(\xi) = c(\xi) \otimes I_{\mathbf{E}}, \qquad \nabla^{\mathbf{S}} = \nabla^{\Sigma} \otimes I + I \otimes \nabla^{\mathbf{E}}.$$

This is a Clifford module with connection. Its associated operator is the *twisted Dirac operator*

$$D_{\mathbf{E}} = \sum_{j=1}^{n} c(\mathbf{e}^j) \otimes I_{\mathbf{E}} \nabla^{\mathbf{S}}_{\mathbf{e}_j}. \tag{8.34}$$

In even dimensions, it is odd and determines the blocks $D^{\pm}_{\mathbf{E}}$.

Theorem 8.3.8. (Weitzenböck formula for the twisted Dirac operator) With the preceding notation,

$$D^2_{\mathbf{E}} = (\nabla^{\mathbf{S}})^* \nabla^{\mathbf{S}} + \frac{1}{4} R_{\mathbf{g}} I + \frac{1}{2} \sum_{i,j=1}^{n} c(\mathbf{e}^i) c(\mathbf{e}^j) \otimes \mathbf{R}^{\mathbf{E}}(\mathbf{e}_i, \mathbf{e}_j). \tag{8.35}$$

Proof. The curvature of the product connection is

$$\mathbf{R}^{\mathbf{S}} = \mathbf{R}^{\Sigma} \otimes I + I \otimes \mathbf{R}^{\mathbf{E}}.$$

Substitute this identity into (8.29); the spinor part is contracted using (8.32), and the $\mathbf{E}$ part produces the last summand. □

Proposition 8.3.9. (Spin^c operators) Let M be a Spin^c manifold with determinant line $\mathbf{L}$, as in Definition 2.17.17, and choose a unitary connection on $\mathbf{L}$. The induced Clifford connection on $\Sigma^c M$ defines an operator $D_{\mathbf{L}} = c \circ \nabla^{\Sigma^c}$. If $F_{\mathbf{L}} \in \Omega^2(M; i\mathbb{R})$ is the curvature of the connection and

$$c(F_{\mathbf{L}}) := \frac{1}{2} \sum_{i,j=1}^{n} F_{\mathbf{L}}(\mathbf{e}_i, \mathbf{e}_j) c(\mathbf{e}^i) c(\mathbf{e}^j),$$

then

$$D^2_{\mathbf{L}} = (\nabla^{\Sigma^c})^* \nabla^{\Sigma^c} + \frac{1}{4} R_{\mathbf{g}} I + \frac{1}{2} c(F_{\mathbf{L}}). \tag{8.36}$$

In even dimensions, $D_{\mathbf{L}}$ interchanges $\Sigma^{c,+} M$ and $\Sigma^{c,-} M$.

Proof. The infinitesimal homomorphism of Spin$^c(n)$ on spinors is the spin representation on the $\mathfrak{so}(n)$ component and half the representation of the determinant line on the $i\mathbb{R}$ component. Hence,

$$\mathbf{R}^{\Sigma^c}(\mathbf{X}, \mathbf{Y}) = \mathbf{R}^{\Sigma}(\mathbf{X}, \mathbf{Y}) + \frac{1}{2} F_{\mathbf{L}}(\mathbf{X}, \mathbf{Y}) I$$

in any local spinor trivialization. The general Bochner formula and (8.32) give (8.36). The graded assertion follows from the fact that the connection preserves chirality and Clifford multiplication is odd. □

9

Sobolev spaces on vector bundles: an intrinsic approach

From functions to sections

Passing from functions to sections does not merely repeat the Euclidean theory component by component. Components depend on the frame, and ordinary derivatives of them produce additional terms under a change of trivialization. A connection organizes these terms and makes it possible to define weak derivatives taking values in a specific tensor bundle. The integration-by-parts formula will bring these two perspectives together: it is computed locally, yet expresses an intrinsic identity and allows the regularity of a section to be recognized without choosing a global frame.

9.1 Weak covariant derivatives and Sobolev spaces on vector bundles

The preceding construction of Sobolev spaces on manifolds started with smooth sections and completed that space in a covariant norm. There is another description, closer to the Euclidean case: require a section in L^p to possess weak covariant derivatives through the order under consideration. This chapter develops that formulation on a vector bundle and proves its compatibility with the construction by completion.

For compactly supported smooth sections, the identity

$$\int_M \langle \nabla^{\mathbf{E}} \mathbf{u}, \mathbf{\Phi} \rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}} \, d\lambda_{\mathbf{g}} = \int_M \langle \mathbf{u}, (\nabla^{\mathbf{E}})^* \mathbf{\Phi} \rangle_{\mathbf{h}_{\mathbf{E}}} \, d\lambda_{\mathbf{g}}$$

transfers the derivative from $\mathbf{u}$ to a test section. The right-hand side still makes sense for $\mathbf{u} \in L^p(M, \mathbf{E})$ provided $(\nabla^{\mathbf{E}})^* \mathbf{\Phi}$ belongs to the appropriate dual space. This observation leads to the weak covariant derivative and allows elliptic systems on bundles to be formulated without choosing global components.

We work with a smooth vector bundle $\mathbf{E} \longrightarrow M$ equipped with a bundle metric and a smooth connection $\nabla^{\mathbf{E}}$. On tensor factors constructed from TM and T^*M, we use the Levi–Civita connection of $\mathbf{g}$. The definitions of weak covariant derivative and $W^{m,p}(M, \mathbf{E})$ do not require $\nabla^{\mathbf{E}}$ to be compatible with the bundle metric; whenever compatibility is needed for an integration-by-parts formula, an identification of the formal adjoint, or a subsequent

estimate, it will be explicitly included in the hypotheses. The notation $W^{m,p}(M,\mathbf{E})$ denotes the space of sections of $L^p(M,\mathbf{E})$ whose weak covariant derivatives through order m belong to the corresponding L^p spaces of $\mathbf{E}$-valued tensors. This choice retains the notation used in the Euclidean case and treats functions, differential forms, tensor fields, and sections of general bundles uniformly.

To formulate the definition, we first need to construct iterated covariant derivatives and the induced bundle metrics on $T^{(0,s)}(TM)\otimes\mathbf{E}$. We then prove completeness, density of smooth sections, and equivalence with local descriptions. These results give an intrinsic version of the Meyers–Serrin theorem and prepare the embedding, trace, and compactness theorems.

Definition 9.1.1. Let M be a smooth manifold with or without boundary, let $\mathbf{E}\to M$ be a smooth vector bundle with a connection $\nabla^{\mathbf{E}}$, and let ∇^{TM} be a connection on TM. For $s\in\mathbb{N}$, define the sth covariant derivative of $\mathbf{u}\in\Gamma(\mathbf{E})$ as the section $\nabla^s\mathbf{u}\in\Gamma\big(T^{(0,s)}(TM)\otimes\mathbf{E}\big)$ defined recursively as follows: $\nabla^0\mathbf{u}:=\mathbf{u}$ and, for $s\geq 0$,

$$\nabla^{s+1}\mathbf{u}:=\nabla^{T^{(0,s)}(TM)\otimes\mathbf{E}}(\nabla^s\mathbf{u}),$$

where we identify $T^*M\otimes(T^{(0,s)}(TM)\otimes\mathbf{E})$ with $T^{(0,s+1)}(TM)\otimes\mathbf{E}$ by placing the new factor T^*M first. The connection on the right-hand side is the product connection induced by ∇^{TM} and $\nabla^{\mathbf{E}}$.
Schematically,

$$\begin{array}{ccc}
\Gamma(\mathbf{E}) & \xrightarrow{\ \nabla^{\mathbf{E}}\ } & \Gamma\big(T^{(0,1)}(TM)\otimes\mathbf{E}\big) \\
 & & \Big\downarrow{\scriptstyle \nabla^{T^{(0,1)}(TM)\otimes\mathbf{E}}} \\
\Gamma\big(T^{(0,3)}(TM)\otimes\mathbf{E}\big) & \xleftarrow[\ \nabla^{T^{(0,2)}(TM)\otimes\mathbf{E}}\ ]{} & \Gamma\big(T^{(0,2)}(TM)\otimes\mathbf{E}\big) \\
\Big\downarrow{\scriptstyle \nabla^{T^{(0,3)}(TM)\otimes\mathbf{E}}} & & \\
\cdots & \xrightarrow{\ \nabla^{T^{(0,s-1)}(TM)\otimes\mathbf{E}}\ } & \Gamma\big(T^{(0,s)}(TM)\otimes\mathbf{E}\big)
\end{array}$$

Equivalently,

$$(\nabla^{s+1}\mathbf{u})(\mathbf{X}_0,\dots,\mathbf{X}_s):=\big(\nabla_{\mathbf{X}_0}(\nabla^s\mathbf{u})\big)(\mathbf{X}_1,\dots,\mathbf{X}_s).$$

In a chart $(x^1,\dots,x^n)$, with $\partial_i=\partial/\partial x^i$, write

$$(\nabla^s\mathbf{u})_{i_1\cdots i_s}:=(\nabla^s\mathbf{u})(\partial_{i_1},\dots,\partial_{i_s}).$$

In particular,

$$(\nabla^2\mathbf{u})_{ij}=\nabla^{\mathbf{E}}_{\partial_i}\big(\nabla^{\mathbf{E}}_{\partial_j}\mathbf{u}\big)-\Gamma^k_{ij}\nabla^{\mathbf{E}}_{\partial_k}\mathbf{u}. \tag{9.1}$$

This is a component of the tensor $\nabla^2\mathbf{u}$, rather than the mere directional composition: it includes the Christoffel term. At higher orders, we will primarily use $\nabla^s\mathbf{u}$ and its components $(\nabla^s\mathbf{u})_{i_1\cdots i_s}$, according to the same recursion.

The section $\nabla^s\mathbf{u}$ takes values in $T^{(0,s)}(TM)\otimes\mathbf{E}$. To measure it pointwise, we need the bundle metric induced by the Riemannian metric on M and the metric on $\mathbf{E}$.

The same construction defines a bundle metric on every bundle $T^{(k,l)}(TM)\otimes\mathbf{E}$.

Proposition 9.1.2. Let $(M,\mathbf{g})$ be a Riemannian manifold (with or without boundary), and let $\mathbf{E}\to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$. Then there is a unique smooth bundle metric

$\langle\cdot,\cdot\rangle_{\mathbf{g},\mathbf{h_E}}$ on each $\mathbf{E}$-valued tensor bundle, $T^{(k,l)}(TM)\otimes\mathbf{E}$, such that, for simple tensor fields

$$\boldsymbol{\alpha}_1\otimes\cdots\otimes\boldsymbol{\alpha}_k\otimes\boldsymbol{\omega}_1\otimes\cdots\otimes\boldsymbol{\omega}_l\otimes\mathbf{u},\quad \boldsymbol{\beta}_1\otimes\cdots\otimes\boldsymbol{\beta}_k\otimes\boldsymbol{\eta}_1\otimes\cdots\otimes\boldsymbol{\eta}_l\otimes\mathbf{v},$$

with $\boldsymbol{\alpha}_r,\boldsymbol{\beta}_r\in\mathfrak{X}(M)$, $\boldsymbol{\omega}_s,\boldsymbol{\eta}_s\in\Omega^1(M)$, and $\mathbf{u},\mathbf{v}\in\Gamma(\mathbf{E})$, we have

$$\left\langle\boldsymbol{\alpha}_1\otimes\cdots\otimes\boldsymbol{\alpha}_k\otimes\boldsymbol{\omega}_1\otimes\cdots\otimes\boldsymbol{\omega}_l\otimes\mathbf{u},\boldsymbol{\beta}_1\otimes\cdots\otimes\boldsymbol{\beta}_k\otimes\boldsymbol{\eta}_1\otimes\cdots\otimes\boldsymbol{\eta}_l\otimes\mathbf{v}\right\rangle_{\mathbf{g},\mathbf{h_E}}=\left(\prod_{s=1}^{k}\langle\boldsymbol{\alpha}_s,\boldsymbol{\beta}_s\rangle_{\mathbf{g}}\right)\left(\prod_{t=1}^{l}\langle\boldsymbol{\omega}_t,\boldsymbol{\eta}_t\rangle_{\mathbf{g}}\right)\langle\mathbf{u},\mathbf{v}\rangle_{\mathbf{h_E}}.$$

Moreover, if $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ is a smooth local frame of TM, with dual coframe $(\varepsilon^1,\dots,\varepsilon^n)$, $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ is a local frame of $\mathbf{E}$, all defined on $U\subseteq M$, and

$$\mathbf{F}=F^{i_1\dots i_k a}_{j_1\dots j_l}\mathbf{E}_{i_1}\otimes\cdots\otimes\mathbf{E}_{i_k}\otimes\varepsilon^{j_1}\otimes\cdots\otimes\varepsilon^{j_l}\otimes\mathbf{e}_a,$$

$$\mathbf{G}=G^{r_1\dots r_k b}_{s_1\dots s_l}\mathbf{E}_{r_1}\otimes\cdots\otimes\mathbf{E}_{r_k}\otimes\varepsilon^{s_1}\otimes\cdots\otimes\varepsilon^{s_l}\otimes\mathbf{e}_b,$$

then

$$\langle\mathbf{F},\mathbf{G}\rangle_{\mathbf{g},\mathbf{h_E}}=g_{i_1r_1}\cdots g_{i_kr_k}g^{j_1s_1}\cdots g^{j_ls_l}h_{ab}F^{i_1\dots i_k a}_{j_1\dots j_l}\overline{G^{r_1\dots r_k b}_{s_1\dots s_l}}.$$

In the real case, the bar is omitted. In the complex case, it appears because the Hermitian convention fixed in Definition 2.5.1 is linear in the first argument and antilinear in the second. When no confusion is possible, we write simply $\langle\mathbf{F},\mathbf{G}\rangle_{\mathbf{g},\mathbf{h_E}}=\langle\mathbf{F},\mathbf{G}\rangle_{\mathbf{h_E}}$. We use the notation $|\mathbf{F}|_{\mathbf{h_E}}:=\sqrt{\langle\mathbf{F},\mathbf{F}\rangle_{\mathbf{h_E}}}$.

Proof. At each point $p\in M$, the metric $\mathbf{g}_p$ induces the dual inner product $\mathbf{g}_p^{-1}$ on T_p^*M. The tensor product of k copies of $\mathbf{g}_p$, l copies of $\mathbf{g}_p^{-1}$, and one copy of $(\mathbf{h_E})_p$ defines a positive-definite form on

$$T_p^{(k,l)}(T_pM)\otimes\mathbf{E}_p.$$

The formula on simple tensors is precisely the definition of this tensor product. Since simple tensors span the fiber, sesquilinearity determines the form uniquely on the entire fiber.
In the frames of the statement, the inner-product matrices of the factors are, respectively,

$$(g_{ir}),\qquad (g^{js}),\qquad (h_{ab}).$$

Expanding $\mathbf{F}$ and $\mathbf{G}$ in the tensor basis and using linearity of the Hermitian product in the first variable and antilinearity in the second gives

$$\langle\mathbf{F},\mathbf{G}\rangle_{\mathbf{g},\mathbf{h_E}}=g_{i_1r_1}\cdots g_{i_kr_k}g^{j_1s_1}\cdots g^{j_ls_l}h_{ab}F^{i_1\dots i_k a}_{j_1\dots j_l}\overline{G^{r_1\dots r_k b}_{s_1\dots s_l}}.$$

In the real case, the same calculation is bilinear and involves no conjugation. The coefficients g_{ir}, g^{js}, and h_{ab} are smooth in every local frame; hence the resulting family of forms varies smoothly with p. Their definition through tensor products shows that expressions in different frames agree on overlaps. This gives a global smooth bundle metric, and the fiberwise uniqueness already proved completes the proof. □

With these definitions and conventions, we can define what it means for a section to be an L^p-section.

Definition 9.1.3. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $1 \le p \le \infty$, and let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h_E}$. We say that a function $\mathbf{u}\colon M \longrightarrow \mathbf{E}$ is an L^p-section if

(a) $\mathbf{u}$ is measurable, that is, for every open subset $U \subseteq \mathbf{E}$ we have $\mathbf{u}^{-1}(U) \in \mathcal{L}_M$.

(b) $(\pi \circ \mathbf{u})(x) = x$ for almost every $x \in M$.

(c) $|\mathbf{u}|_{\mathbf{h_E}} \in L^p(M, d\lambda_{\mathbf{g}})$.

Write

$$\widetilde{L}^p(\mathbf{E}) := \{\mathbf{u}\colon M \longrightarrow \mathbf{E} \mid \mathbf{u} \text{ is an } L^p \text{ section of } \mathbf{E}\}.$$

Define an equivalence relation $\sim$ on $\widetilde{L}^p(\mathbf{E})$ by

$$\mathbf{u} \sim \mathbf{v} \quad \Longleftrightarrow \quad \mathbf{u}(x) = \mathbf{v}(x) \text{ for almost every } x \in M.$$

Finally, define $L^p(M, \mathbf{E}) := \widetilde{L}^p(\mathbf{E}) \big/ \sim$. Likewise, define

$$L^p_{\mathrm{loc}}(M, \mathbf{E}) := \left\{ \mathbf{u}\colon M \longrightarrow \mathbf{E} \;\middle|\; \begin{array}{l} \mathbf{u} \text{ is measurable, } (\pi \circ \mathbf{u})(x) = x \text{ for almost every } x \in M, \\ \forall K \subseteq M \text{ compact, } \displaystyle\int_K |\mathbf{u}|^p_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} < \infty \end{array} \right\} \Big/ \sim,$$

where $\sim$ again denotes equality almost everywhere on M.

These spaces can be equipped with norms or seminorms as appropriate:

Definition 9.1.4. (L^p norms and local seminorms) Let $(M, \mathbf{g})$ be a smooth Riemannian manifold with or without boundary, let $1 \le p \le \infty$, and let $\mathbf{E} \to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h_E}$.

(a) *Global case.*

(a) If $1 \le p < \infty$ and $\mathbf{u} \in L^p(M, \mathbf{E})$, define

$$\|\mathbf{u}\|_{L^p(M,\mathbf{E})} := \left(\int_M |\mathbf{u}|^p_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \right)^{\frac{1}{p}}.$$

(b) If $p = \infty$ and $\mathbf{u} \in L^\infty(M, \mathbf{E})$, define

$$\|\mathbf{u}\|_{L^\infty(M,\mathbf{E})} := \operatorname*{ess\,sup}_{x \in M} |\mathbf{u}(x)|_{\mathbf{h_E}}.$$

(b) *Local case.*

(a) If $1 \le p < \infty$ and $\mathbf{u} \in L^p_{\mathrm{loc}}(M, \mathbf{E})$, for each compact set $K \subseteq M$ define the seminorm

$$\|\mathbf{u}\|_{L^p(K,\mathbf{E})} := \left(\int_K |\mathbf{u}|^p_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \right)^{\frac{1}{p}}.$$

(b) If $p=\infty$ and $\mathbf{u}\in L^{\infty}_{\mathrm{loc}}(M,\mathbf{E})$, for each compact set $K\subseteq M$ define

$$\|\mathbf{u}\|_{L^{\infty}(K,\mathbf{E})}:=\operatorname*{ess\,sup}_{x\in K}|\mathbf{u}(x)|_{\mathbf{h_E}}.$$

The spaces $L^{p}_{\mathrm{loc}}(M,\mathbf{E})$ are equipped with the family of seminorms $\{\|\cdot\|_{L^p(K,\mathbf{E})}\}_{K\subseteq M\text{ compact}}$.

Our definition of weak derivative uses the formal Hermitian adjoint developed in the preceding chapter. Throughout this chapter, $(\nabla^s)^*_h$ denotes that adjoint; when a previously established formula abbreviates it as $(\nabla^s)^*$, the abbreviation has exactly the same meaning and never denotes the bilinear transpose $(\nabla^s)'$.

Definition 9.1.5. Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E}$ be a smooth vector bundle over M equipped with a bundle metric $\mathbf{h_E}$ and a smooth connection $\nabla^{\mathbf{E}}$. In constructing ∇^s, use the product connection induced by the Levi–Civita connection of $\mathbf{g}$ and by $\nabla^{\mathbf{E}}$. Let $\mathbf{u}\in L^1_{\mathrm{loc}}(M,\mathbf{E})$. We say that $\mathbf{v}\in L^1_{\mathrm{loc}}(M,T^{(0,s)}(TM)\otimes\mathbf{E})$ is the sth weak covariant derivative of $\mathbf{u}$ if, for every $\boldsymbol{\sigma}\in\Gamma_c(T^{(0,s)}(TM)\otimes\mathbf{E})$,

$$\int_M\langle\mathbf{v},\boldsymbol{\sigma}\rangle_{\mathbf{g},\mathbf{h_E}}\,d\lambda_{\mathbf{g}}=\int_M\langle\mathbf{u},(\nabla^s)^*_h\boldsymbol{\sigma}\rangle_{\mathbf{h_E}}\,d\lambda_{\mathbf{g}}.$$

The weak derivative of a section $\mathbf{u}\in L^1_{\mathrm{loc}}(M,\mathbf{E})$ will be unique, as a consequence of a result analogous to Proposition B.6.20.

Lemma 9.1.6. (Localization) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, $\mathbf{E}$ a smooth vector bundle with bundle metric $\mathbf{h_E}$, and $\mathbf{v}\in L^1_{\mathrm{loc}}(M,\mathbf{E})$ such that

$$\int_M\langle\mathbf{v},\boldsymbol{\sigma}\rangle_{\mathbf{h_E}}\,d\lambda_{\mathbf{g}}=0,\qquad\forall\boldsymbol{\sigma}\in\Gamma_c(\mathbf{E}).$$

Then $\mathbf{v}\equiv 0$ almost everywhere on M.

Proof. Consider an open subset $U\subseteq M$ such that (U,ψ) is a smooth chart of M and U is also the domain of a smooth local orthonormal frame of $\mathbf{E}$ over U, say $(\mathbf{e}_1,\dots,\mathbf{e}_r)$.
Given a section $\boldsymbol{\sigma}\in\Gamma_c(\mathbf{E}\restriction_U)$, extend it by zero outside U to obtain $\widetilde{\boldsymbol{\sigma}}\in\Gamma_c(\mathbf{E})$. Applying the hypothesis gives

$$0=\int_M\langle\mathbf{v},\widetilde{\boldsymbol{\sigma}}\rangle_{\mathbf{h_E}}\,d\lambda_{\mathbf{g}}=\int_U\langle\mathbf{v},\boldsymbol{\sigma}\rangle_{\mathbf{h_E}}\,d\lambda_{\mathbf{g}}.$$

Since $\mathbf{v}\in L^1_{\mathrm{loc}}(M,\mathbf{E})$, we can write $\mathbf{v}=\sum_{i=1}^{r}v^i\mathbf{e}_i$ with $v^i\in L^1_{\mathrm{loc}}(U)$ and $\boldsymbol{\sigma}=\sum_{j=1}^{r}\sigma^j\mathbf{e}_j$ with $\sigma^j\in C^\infty_c(U)$. Orthonormality of the frame and the convention of linearity in the first variable give

$$0=\int_U\sum_{i=1}^{r}v^i\overline{\sigma^i}\,d\lambda_{\mathbf{g}}.$$

Now fix $j\in\{1,\dots,r\}$ and take $\boldsymbol{\sigma}:=f\mathbf{e}_j$ with $f\in C^\infty_c(U)$, obtaining

$$\int_U v^j\overline{f}\,d\lambda_{\mathbf{g}}=0,\qquad\forall f\in C^\infty_c(U).$$

Passing to local coordinates gives

$$\int_{\psi(U)} (v^j \circ \psi^{-1})\overline{(f \circ \psi^{-1})}\big(\sqrt{\det(\mathbf{g})} \circ \psi^{-1}\big) d\lambda_n = 0, \qquad \forall f \in C_c^\infty(U).$$

Given arbitrary $\varphi \in C_c^\infty(\psi(U))$, define

$$f := \left(\overline{\frac{\varphi}{\sqrt{\det(\mathbf{g})} \circ \psi^{-1}}}\right) \circ \psi \in C_c^\infty(U).$$

The function is well defined and smooth because $\sqrt{\det(\mathbf{g})} \circ \psi^{-1}$ is smooth and strictly positive. Moreover,

$$\operatorname{supp}(f) \subseteq \psi^{-1}\left(\operatorname{supp}\left(\frac{\varphi}{\sqrt{\det(\mathbf{g})} \circ \psi^{-1}}\right)\right),$$

, and the set on the right is compact: the support inside ψ^{-1} is compact in $\psi(U)$, and ψ is a homeomorphism. Substituting this choice yields

$$\int_{\psi(U)} (v^j \circ \psi^{-1})\varphi \, d\lambda_n = 0, \qquad \forall \varphi \in C_c^\infty(\psi(U)).$$

By Proposition B.6.20, we conclude that $v^j \circ \psi^{-1} = 0$ almost everywhere on $\psi(U)$, and hence $v^j = 0$ almost everywhere on U. Since $j \in \{1, \dots, r\}$ was arbitrary, it follows that $\mathbf{v} = 0$ almost everywhere on U.
Finally, since M is Lindelöf, it can be covered by countably many open subsets of this kind, on each of which $\mathbf{v} = 0$ almost everywhere. It follows that $\mathbf{v} \equiv 0$ almost everywhere on M. □

Corollary 9.1.7. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle with a bundle metric. If $\mathbf{u} \in L^1_{\mathrm{loc}}(M, \mathbf{E})$ has an sth weak covariant derivative, it is unique, and we denote it by $\nabla^s_w \mathbf{u}$, where w stands for "weak."

Proof. Suppose $\mathbf{v}_1$ and $\mathbf{v}_2$ are two sth weak covariant derivatives of $\mathbf{u}$. For every $\sigma \in \Gamma_c(T^{(0,s)}(TM) \otimes \mathbf{E})$, their two defining identities have the same right-hand side. Subtraction gives

$$\int_M \langle \mathbf{v}_1 - \mathbf{v}_2, \sigma \rangle_{\mathbf{g}, \mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} = 0.$$

Lemma 9.1.6, applied to the bundle $T^{(0,s)}(TM) \otimes \mathbf{E}$ with its induced bundle metric, implies that $\mathbf{v}_1 - \mathbf{v}_2 = 0$ almost everywhere. Therefore $\mathbf{v}_1 = \mathbf{v}_2$ almost everywhere. □

The weak covariant derivative is a local operator, just like its classical counterpart:

Proposition 9.1.8. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary and $\mathbf{E} \longrightarrow M$ a smooth vector bundle with bundle metric $\mathbf{h}_\mathbf{E}$. Let $\mathbf{u} \in L^1_{\mathrm{loc}}(M, \mathbf{E})$ be such that $\mathbf{u}$ has an sth weak covariant derivative $\nabla^s_w \mathbf{u} \in L^1_{\mathrm{loc}}(M, T^{(0,s)}(TM) \otimes \mathbf{E})$. Let $U \subseteq M$ be open. If $\mathbf{u} \equiv 0$ almost everywhere on U, then $\nabla^s_w \mathbf{u} \equiv 0$ almost everywhere on U.

Proof. Let $\sigma \in \Gamma_c(T^{(0,s)}(TU)\otimes \mathbf{E}\restriction_U)$. We can define $\widetilde{\sigma} \in \Gamma_c(T^{(0,s)}(TM)\otimes\mathbf{E})$ by

$$\widetilde{\sigma}(p) = \begin{cases} \sigma(p) & \text{if } p \in U \\ 0_{\mathbf{E}_p} & \text{if } p \notin U \end{cases}.$$

Since U is open and $\operatorname{supp}(\sigma) \subseteq U$, $\widetilde{\sigma}$ is smooth, so $\widetilde{\sigma} \in \Gamma_c(T^{(0,s)}(TM)\otimes\mathbf{E})$. By the definition of weak covariant derivative, we have

$$\int_M \langle \nabla^s_w \mathbf{u}, \widetilde{\sigma}\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} d\lambda_\mathbf{g} = \int_M \langle \mathbf{u}, (\nabla^s)^*\widetilde{\sigma}\rangle_{\mathbf{h}_\mathbf{E}} d\lambda_\mathbf{g}.$$

Since $\operatorname{supp}(\widetilde{\sigma}) = \operatorname{supp}(\sigma) \subseteq U$ and by Proposition 8.1.15 ($(\nabla^s)^*$ is a local operator), we have $\operatorname{supp}((\nabla^s)^*\widetilde{\sigma}) \subseteq \operatorname{supp}(\widetilde{\sigma}) \subseteq U$. Then

$$\int_U \langle \nabla^s_w \mathbf{u}, \widetilde{\sigma}\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} d\lambda_\mathbf{g} = \int_M \langle \nabla^s_w \mathbf{u}, \widetilde{\sigma}\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} d\lambda_\mathbf{g} = \int_M \langle \mathbf{u}, (\nabla^s)^*\widetilde{\sigma}\rangle_{\mathbf{h}_\mathbf{E}} d\lambda_\mathbf{g} = \int_U \langle \mathbf{u}, (\nabla^s)^*\widetilde{\sigma}\rangle_{\mathbf{h}_\mathbf{E}} d\lambda_\mathbf{g} = 0,$$

where the last equality holds because $\mathbf{u} \equiv 0$ on U. Therefore Lemma 9.1.6 gives $\nabla^s_w \mathbf{u} \equiv 0$ on U. □

With these definitions, we can define Sobolev spaces by weak covariant derivatives on any smooth vector bundle.

Definition 9.1.9. (Global and local Sobolev spaces) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $\pi\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_\mathbf{E}$ and a smooth connection $\nabla^\mathbf{E}$. Let $m \in \mathbb{N}_0$ and $1 \le p \le \infty$.

(a) *Global Sobolev spaces.* Define

$$W^{m,p}(M,\mathbf{E}) := \left\{ \mathbf{u} \in L^1_{\mathrm{loc}}(M,\mathbf{E}) \;\middle|\; \nabla^s_w \mathbf{u} \in L^p\big(M, T^{(0,s)}(TM)\otimes\mathbf{E}\big) \text{ for every } s \in \{0,\dots,m\} \right\}.$$

The space $W^{m,p}(M,\mathbf{E})$ is a Banach space with norm

$$\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} := \begin{cases} \left(\displaystyle\sum_{s=0}^m \int_M |\nabla^s_w \mathbf{u}|^p_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \right)^{\frac{1}{p}}, & 1 \le p < \infty, \\ \displaystyle\max_{0\le s\le m} \operatorname*{ess\,sup}_{x\in M} |\nabla^s_w \mathbf{u}(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}}, & p = \infty. \end{cases}$$

(b) *Local Sobolev spaces.* Define

$$W^{m,p}_{\mathrm{loc}}(M,\mathbf{E}) := \left\{ \mathbf{u} \in L^1_{\mathrm{loc}}(M,\mathbf{E}) \;\middle|\; \nabla^s_w \mathbf{u} \in L^p_{\mathrm{loc}}\big(M, T^{(0,s)}(TM)\otimes\mathbf{E}\big) \text{ for every } s \in \{0,\dots,m\} \right\}.$$

For each compact set $K \subseteq M$, equip $W^{m,p}_{\mathrm{loc}}(M,\mathbf{E})$ with the local *seminorm*

$$\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E};K)} := \begin{cases} \left(\displaystyle\sum_{s=0}^m \int_K |\nabla^s_w \mathbf{u}|^p_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \right)^{\frac{1}{p}}, & 1 \le p < \infty, \\ \displaystyle\max_{0\le s\le m} \operatorname*{ess\,sup}_{x\in K} |\nabla^s_w \mathbf{u}(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}}, & p = \infty. \end{cases}$$

The space $W^{m,p}_{\mathrm{loc}}(M,\mathbf{E})$ is equipped with the family of seminorms $\{\|\cdot\|_{W^{m,p}(M,\mathbf{E};K)}\}_{K\subseteq M \text{ compact}}$.

Exercise 9.1.10. Under the hypotheses of the preceding definition, where M is a smooth manifold with or without boundary, prove that $(W^{m,p}(M,\mathbf{E}),\|\cdot\|_{W^{m,p}(M,\mathbf{E})})$ is a normed space.

Remark 9.1.11. In the trivial case $\mathbf{E} = M\times\mathbb{R}$, there is a natural bundle isomorphism

$$T^{(0,s)}(TM)\otimes(M\times\mathbb{R}) \cong T^{(0,s)}(TM),$$

given fiberwise by $v\otimes\alpha \mapsto \alpha v$. (More explicitly, considering $v_p \in T^{(0,s)}(T_pM)$, $(p,\alpha)\in\{p\}\times\mathbb{R},$, the assignment is $v_p\otimes(p,\alpha)\mapsto \alpha v_p \in T^{(0,s)}(T_pM)$.) Under this identification, the Sobolev spaces reduce to the usual spaces for functions

$$W^{m,p}(M) := \Big\{u\in L^1_{\mathrm{loc}}(M)\,|\,\nabla^s_w u\in L^p\big(M,T^{(0,s)}(TM)\big)\text{for every } s\in\{0,\dots,m\}\Big\}.$$

9.1.1 Fundamental properties: uniform convexity, reflexivity, and separability

We now prove the fundamental properties of Sobolev spaces on vector bundles, which will be analogous to their Euclidean counterparts. First, we show that $W^{m,p}(M,\mathbf{E})$ is a Banach space. The following lemma is particularly useful for this purpose:

Lemma 9.1.12. Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E}\longrightarrow M$ be a smooth vector bundle with a bundle metric $\mathbf{h_E}$ and a connection $\nabla^{\mathbf{E}}$. Let $1\le p\le\infty$. If $(\mathbf{u}_k)_{k\in\mathbb{N}}\subseteq W^{m,p}(M,\mathbf{E})$ is such that $\mathbf{u}_k\to\mathbf{u}$ in $L^p(M,\mathbf{E})$ and $\nabla^j_w\mathbf{u}_k\to\mathbf{v}_j$ in $L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})$ as $k\to\infty$ for every $j\in\{1,\dots,m\}$, then $\mathbf{u}\in W^{m,p}(M,\mathbf{E})$ and $\nabla^j_w\mathbf{u}=\mathbf{v}_j$ for every $j\in\{1,\dots,m\}$.

Proof. Let $j\in\{1,\dots,m\}$ be arbitrary and let $\boldsymbol{\sigma}\in\Gamma_c\big(T^{(0,j)}(TM)\otimes\mathbf{E}\big)$. Since $\mathbf{u}_k\in W^{m,p}(M,\mathbf{E})$, the definition of weak covariant derivative of order j gives

$$\int_M\langle\nabla^j_w\mathbf{u}_k,\boldsymbol{\sigma}\rangle_{\mathbf{g},\mathbf{h_E}}\,d\lambda_{\mathbf{g}} = \int_M\langle\mathbf{u}_k,(\nabla^j)^*\boldsymbol{\sigma}\rangle_{\mathbf{h_E}}\,d\lambda_{\mathbf{g}}.$$

By Hölder's inequality (Proposition B.7.9), with p' conjugate to p, we have

$$\left|\int_M\langle\mathbf{u}_k-\mathbf{u},(\nabla^j)^*\boldsymbol{\sigma}\rangle_{\mathbf{h_E}}\,d\lambda_{\mathbf{g}}\right| \le \|\mathbf{u}_k-\mathbf{u}\|_{L^p(M,\mathbf{E})}\,\|(\nabla^j)^*\boldsymbol{\sigma}\|_{L^{p'}(M,\mathbf{E})},$$

and, since $\mathbf{u}_k\to\mathbf{u}$ in $L^p(M,\mathbf{E})$, it follows that

$$\int_M\langle\mathbf{u}_k,(\nabla^j)^*\boldsymbol{\sigma}\rangle_{\mathbf{h_E}}\,d\lambda_{\mathbf{g}}\longrightarrow\int_M\langle\mathbf{u},(\nabla^j)^*\boldsymbol{\sigma}\rangle_{\mathbf{h_E}}\,d\lambda_{\mathbf{g}}.$$

Likewise, Hölder's inequality (Proposition B.7.9) gives

$$\left|\int_M\langle\nabla^j_w\mathbf{u}_k-\mathbf{v}_j,\boldsymbol{\sigma}\rangle_{\mathbf{g},\mathbf{h_E}}\,d\lambda_{\mathbf{g}}\right| \le \|\nabla^j_w\mathbf{u}_k-\mathbf{v}_j\|_{L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})}\,\|\boldsymbol{\sigma}\|_{L^{p'}(M,T^{(0,j)}(TM)\otimes\mathbf{E})},$$

and, since $\nabla_w^j \mathbf{u}_k \to \mathbf{v}_j$ in $L^p(M, T^{(0,j)}(TM)\otimes\mathbf{E})$, we obtain

$$\int_M \langle \nabla_w^j \mathbf{u}_k, \sigma\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \longrightarrow \int_M \langle \mathbf{v}_j, \sigma\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

Passing to the limit in the initial identity yields

$$\int_M \langle \mathbf{v}_j, \sigma\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} = \int_M \langle \mathbf{u}, (\nabla^j)^*\sigma\rangle_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \qquad \forall\, \sigma \in \Gamma_c\big(T^{(0,j)}(TM)\otimes\mathbf{E}\big).$$

By the definition of weak covariant derivative of order j, this implies that $\mathbf{u}$ admits a weak covariant derivative of order j and that $\nabla_w^j \mathbf{u} = \mathbf{v}_j$.
Since $j \in \{1,\dots,m\}$ was arbitrary, we conclude that $\mathbf{u} \in W^{m,p}(M,\mathbf{E})$ and $\nabla_w^j \mathbf{u} = \mathbf{v}_j$ for every $j \in \{1,\dots,m\}$. □

To show that the spaces $W^{m,p}(M,\mathbf{E})$ are Banach, we will, as the reader may expect, use the preceding lemma; first, however, we need to show that $L^p(M,\mathbf{E})$ is a Banach space.

Theorem 9.1.13. Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $\pi_{\mathbf{E}}\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h_E}$. If $1 \le p \le \infty$, then $L^p(M,\mathbf{E})$ is a Banach space.

Proof. Let $(\mathbf{s}_n)_{n\in\mathbb{N}}$ be a Cauchy sequence in $L^p(M,\mathbf{E})$.
First consider the case $1 \le p < \infty$. There is a subsequence $(\mathbf{s}_{n_k})_{k\in\mathbb{N}}$ such that

$$\|\mathbf{s}_{n_{k+1}} - \mathbf{s}_{n_k}\|_{L^p(M,\mathbf{E})} < \frac{1}{2^k} \qquad \text{for every } k \in \mathbb{N}.$$

Define

$$G_K(x) := \sum_{k=1}^{K} |\mathbf{s}_{n_{k+1}}(x) - \mathbf{s}_{n_k}(x)|_{\mathbf{h_E}}.$$

Then (G_K) is increasing and, by Minkowski's inequality in $L^p(M)$ (Theorem B.7.3),

$$\|G_K\|_{L^p(M)} \le \sum_{k=1}^{K} \|\mathbf{s}_{n_{k+1}} - \mathbf{s}_{n_k}\|_{L^p(M,\mathbf{E})} < 1.$$

By Theorem B.6.11, there exists $G \in L^p(M)$ such that $G_K \to G$ pointwise and $G(x) < \infty$ almost everywhere.
For each k, there exists a null set $Z_k \subset M$ such that $\pi_{\mathbf{E}}(\mathbf{s}_{n_k}(x)) = x$ for every $x \in M \setminus Z_k$. Define

$$Z := \{x \in M \mid G(x) = \infty\} \cup \bigcup_{k=1}^{\infty} Z_k.$$

Then Z is a null set, and for every $x \in M \setminus Z$ we have $G(x) < \infty$ and $\pi_{\mathbf{E}}(\mathbf{s}_{n_k}(x)) = x$ for every k.
For $x \in M \setminus Z$, the series

$$\sum_{k=1}^{\infty} (\mathbf{s}_{n_{k+1}}(x) - \mathbf{s}_{n_k}(x))$$

converges absolutely in the fiber $\mathbf{E}_x$, since the sum of the norms is $G(x) < \infty$. Since $\mathbf{E}_x$ is finite dimensional, it is complete, and the series converges to a well-defined vector in $\mathbf{E}_x$.

Define

$$\mathbf{s}(x) := \begin{cases} \mathbf{s}_{n_1}(x) + \displaystyle\sum_{k=1}^{\infty} (\mathbf{s}_{n_{k+1}}(x) - \mathbf{s}_{n_k}(x)), & x \in M \setminus Z, \\ 0_x, & x \in Z, \end{cases}$$

where 0_x denotes the zero vector of the fiber $\mathbf{E}_x$.
For $x \in M \setminus Z$, the sum telescopes, giving

$$\mathbf{s}_{n_{k+1}}(x) \to \mathbf{s}(x) \qquad \text{a.e. on } M.$$

Each $\mathbf{s}_{n_k}$ is measurable, so $\mathbf{s}$ is measurable as the almost-everywhere pointwise limit of measurable functions. Moreover, by construction $\pi_{\mathbf{E}}(\mathbf{s}(x)) = x$ for every $x \in M$, so $\mathbf{s}$ is a measurable section of $\mathbf{E}$.
Let $\varepsilon > 0$. Since $(\mathbf{s}_n)$ is Cauchy, there exists N such that

$$\|\mathbf{s}_n - \mathbf{s}_m\|_{L^p(M,\mathbf{E})} < \varepsilon \qquad \text{for every } n, m \geq N.$$

For fixed $n \geq N$, we have

$$|\mathbf{s}_n(x) - \mathbf{s}_{n_k}(x)|^p_{\mathbf{h}_\mathbf{E}} \to |\mathbf{s}_n(x) - \mathbf{s}(x)|^p_{\mathbf{h}_\mathbf{E}} \qquad \text{a.e.}$$

Since $n_k \longrightarrow \infty$, there exists $k_0 \in \mathbb{N}$ such that $n_k \geq N$ for every $k \geq k_0$. Applying Fatou's lemma (Lemma B.6.12), since the functions are nonnegative and measurable,

$$\int_M |\mathbf{s}_n - \mathbf{s}|^p_{\mathbf{h}_\mathbf{E}} \, d\lambda_{\mathbf{g}} \leq \liminf_{k\to\infty} \int_M |\mathbf{s}_n - \mathbf{s}_{n_k}|^p_{\mathbf{h}_\mathbf{E}} \, d\lambda_{\mathbf{g}} \leq \varepsilon^p.$$

Therefore $\|\mathbf{s}_n - \mathbf{s}\|_{L^p(M,\mathbf{E})} \leq \varepsilon$ for every $n \geq N$, and we conclude that $\mathbf{s}_n \to \mathbf{s}$ in $L^p(M,\mathbf{E})$. Taking a fixed index n_0,

$$\|\mathbf{s}\|_{L^p(M,\mathbf{E})} \leq \|\mathbf{s}_{n_0}\|_{L^p(M,\mathbf{E})} + \|\mathbf{s} - \mathbf{s}_{n_0}\|_{L^p(M,\mathbf{E})} < \infty,$$

so $\mathbf{s} \in L^p(M,\mathbf{E})$.
Now consider the case $p = \infty$. By the definition of the essential supremum norm, for each pair $n, m \in \mathbb{N}$ there is a null set $Z_{n,m} \subset M$ such that

$$|\mathbf{s}_n(x) - \mathbf{s}_m(x)|_{\mathbf{h}_\mathbf{E}} \leq \|\mathbf{s}_n - \mathbf{s}_m\|_{L^\infty(M,\mathbf{E})} \qquad \text{for every } x \in M \setminus Z_{n,m}.$$

In addition, for each $n \in \mathbb{N}$ there is a null set $W_n \subset M$ such that $\pi_{\mathbf{E}}(\mathbf{s}_n(x)) = x$ for every $x \in M \setminus W_n$. Define

$$Z := \left(\bigcup_{n,m=1}^{\infty} Z_{n,m} \right) \cup \left(\bigcup_{n=1}^{\infty} W_n \right).$$

Then Z is a null set and, for every $x \in M \setminus Z$ and every $n, m \in \mathbb{N}$,

$$|\mathbf{s}_n(x) - \mathbf{s}_m(x)|_{\mathbf{h}_\mathbf{E}} \leq \|\mathbf{s}_n - \mathbf{s}_m\|_{L^\infty(M,\mathbf{E})}.$$

Since $(\mathbf{s}_n)$ is Cauchy in $L^\infty(M,\mathbf{E})$, the preceding inequality implies that, for each $x \in M \setminus Z$, the sequence

$(\mathbf{s}_n(x))_{n\in\mathbb{N}}$ is Cauchy in $\mathbf{E}_x$. Since $\mathbf{E}_x$ is finite dimensional, it is complete, and there exists $\mathbf{s}(x) \in \mathbf{E}_x$ such that

$$\mathbf{s}_n(x) \longrightarrow \mathbf{s}(x) \qquad \text{as } n \to \infty.$$

Define

$$\mathbf{s}(x) := \begin{cases} \lim\limits_{n\to\infty} \mathbf{s}_n(x), & x \in M \setminus Z, \\ 0_x, & x \in Z, \end{cases}$$

where 0_x denotes the zero vector of the fiber $\mathbf{E}_x$. By construction, $\pi_{\mathbf{E}}(\mathbf{s}(x)) = x$ for every $x \in M \setminus Z$, and also for $x \in Z$ because $\pi_{\mathbf{E}}(0_x) = x$. Moreover, $\mathbf{s}$ is measurable as the almost-everywhere pointwise limit of the measurable sections $\mathbf{s}_n$.
Let $\varepsilon > 0$. Since $(\mathbf{s}_n)$ is Cauchy in $L^\infty(M,\mathbf{E})$, there exists $N \in \mathbb{N}$ such that

$$\|\mathbf{s}_n - \mathbf{s}_m\|_{L^\infty(M,\mathbf{E})} < \varepsilon \qquad \text{for every } n, m \geq N.$$

By the construction of Z, for every $x \in M \setminus Z$ and every $n, m \geq N$ we have

$$|\mathbf{s}_n(x) - \mathbf{s}_m(x)|_{\mathbf{h}_\mathbf{E}} \leq \|\mathbf{s}_n - \mathbf{s}_m\|_{L^\infty(M,\mathbf{E})} < \varepsilon.$$

For fixed $n \geq N$, taking the limit as $m \to \infty$ and using $\mathbf{s}_m(x) \to \mathbf{s}(x)$ for $x \in M \setminus Z$ gives

$$|\mathbf{s}_n(x) - \mathbf{s}(x)|_{\mathbf{h}_\mathbf{E}} \leq \varepsilon \qquad \text{for every } x \in M \setminus Z.$$

Therefore

$$\|\mathbf{s}_n - \mathbf{s}\|_{L^\infty(M,\mathbf{E})} \leq \varepsilon \qquad \text{for every } n \geq N,$$

, and we conclude that $\mathbf{s}_n \to \mathbf{s}$ in $L^\infty(M,\mathbf{E})$. In particular, taking $n = N$ gives $\|\mathbf{s} - \mathbf{s}_N\|_{L^\infty(M,\mathbf{E})} \leq \varepsilon$, and since $\mathbf{s}_N \in L^\infty(M,\mathbf{E})$, we deduce that $\mathbf{s} \in L^\infty(M,\mathbf{E})$.

We conclude that every Cauchy sequence in $L^p(M,\mathbf{E})$ converges to an element of $L^p(M,\mathbf{E})$. Therefore $L^p(M,\mathbf{E})$ is complete for every $1 \leq p \leq \infty$. □

A section together with its weak covariant derivatives can be viewed as an element of a product of L^p spaces. The resulting embedding is isometric and transfers functional properties of the product to the Sobolev space.

Theorem 9.1.14. (Isometric embedding into L^p) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle with a bundle metric $\mathbf{h}_\mathbf{E}$ and a smooth connection $\nabla^\mathbf{E}$. Let $m \in \mathbb{N}_0$ and $1 \leq p \leq \infty$. Then the operator $J_m \colon W^{m,p}(M,\mathbf{E}) \subseteq L^p(M,\mathbf{E}) \longrightarrow \prod_{j=0}^{m} L^p(M, T^{(0,j)}(TM) \otimes \mathbf{E})$ given by $J_m(\mathbf{u}) = \left(\nabla^j_w \mathbf{u}\right)_{j=0}^{m}$ is an isometry onto its image. Moreover, $J_m(W^{m,p}(M,\mathbf{E}))$ is closed, and therefore $W^{m,p}(M,\mathbf{E})$ is a Banach space.

Proof. By the definition of the Sobolev norm, if $1 \le p < \infty$ we have

$$\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} = \left(\sum_{j=0}^{m} \|\nabla_w^j \mathbf{u}\|^p_{L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})} \right)^{\frac{1}{p}},$$

whereas for $p = \infty$ we have

$$\|\mathbf{u}\|_{W^{m,\infty}(M,\mathbf{E})} = \max_{0\le j\le m} \|\nabla_w^j \mathbf{u}\|_{L^\infty(M,T^{(0,j)}(TM)\otimes\mathbf{E})}.$$

Equip the product $\prod_{j=0}^{m} L^p(M, T^{(0,j)}(TM)\otimes\mathbf{E})$ with the ℓ^p norm if $1 \le p < \infty$ and the maximum norm if $p = \infty$. Then, for every $\mathbf{u} \in W^{m,p}(M,\mathbf{E})$,

$$\|J_m(\mathbf{u})\|_{\ell^p} = \left\| (\nabla_w^j \mathbf{u})_{j=0}^m \right\|_{\ell^p} = \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})},$$

showing that J_m is an isometry onto its image.
Now prove that $J_m(W^{m,p}(M,\mathbf{E}))$ is closed. Let

$$J_m(\mathbf{u}_k) = \left(\nabla_w^j \mathbf{u}_k\right)_{j=0}^m \in J_m(W^{m,p}(M,\mathbf{E}))$$

be a sequence such that

$$J_m(\mathbf{u}_k) \longrightarrow (\mathbf{w}_j)_{j=0}^m \quad \text{in} \quad \prod_{j=0}^{m} L^p(M, T^{(0,j)}(TM)\otimes\mathbf{E}).$$

In particular,

$$\mathbf{u}_k \to \mathbf{w}_0 \text{ in } L^p(M,\mathbf{E}), \qquad \nabla_w^j \mathbf{u}_k \to \mathbf{w}_j \text{ in } L^p\left(M, T^{(0,j)}(TM)\otimes\mathbf{E}\right), \quad j = 1,\dots,m.$$

Applying Lemma 9.1.12 gives $\mathbf{w}_0 \in W^{m,p}(M,\mathbf{E})$ and

$$\nabla_w^j \mathbf{w}_0 = \mathbf{w}_j, \qquad j = 1,\dots,m.$$

Therefore

$$(\mathbf{w}_j)_{j=0}^m = J_m(\mathbf{w}_0) \in J_m(W^{m,p}(M,\mathbf{E})),$$

proving that $J_m(W^{m,p}(M,\mathbf{E}))$ is closed.
Finally, since $\prod_{j=0}^{m} L^p(M, T^{(0,j)}(TM) \otimes \mathbf{E})$ is a Banach space and $J_m(W^{m,p}(M,\mathbf{E}))$ is a closed subspace, $J_m(W^{m,p}(M,\mathbf{E}))$ is a Banach space. Since $J_m\colon W^{m,p}(M,\mathbf{E}) \longrightarrow J_m(W^{m,p}(M,\mathbf{E}))$ is an isometry onto its image, we conclude that $W^{m,p}(M,\mathbf{E})$ is a Banach space. □

Among the properties of Sobolev spaces are, in certain cases, uniform convexity, reflexivity, and separability. We record uniform convexity in the following definition:

Definition 9.1.15. (Uniform convexity) Let $(X, \|\cdot\|)$ be a normed space. We say that X is *uniformly convex* if

for every $\varepsilon > 0$ there exists $\delta > 0$ such that, for any $x, y \in X$ with

$$\|x\| = \|y\| = 1 \quad \text{and} \quad \|x - y\| \geq \varepsilon,$$

, we have

$$\left\| \frac{x+y}{2} \right\| \leq 1 - \delta.$$

To establish uniform convexity, we first recall an important theorem of functional analysis, the Milman–Pettis theorem:

Theorem 9.1.16. (Milman–Pettis) Every uniformly convex Banach space is reflexive.

The following inequalities are named after James A. Clarkson [39], who studied bounds of this kind for norms on L^p spaces. In the special case of a Hilbert space, its geometric structure considerably simplifies the argument, allowing these inequalities to be deduced directly from the parallelogram law.

Lemma 9.1.17. (Clarkson-type inequalities in Hilbert spaces) Let $(H, \langle \cdot, \cdot \rangle)$ be a Hilbert space and $\| \cdot \|$ its induced norm.

(a) If $2 \leq p < \infty$, then for any $u, v \in H$,

$$\left\| \frac{u+v}{2} \right\|^p + \left\| \frac{u-v}{2} \right\|^p \leq \frac{\|u\|^p + \|v\|^p}{2}.$$

(b) If $1 < p \leq 2$ and q is the conjugate exponent of p, then for any $u, v \in H$,

$$\left\| \frac{u+v}{2} \right\|^q + \left\| \frac{u-v}{2} \right\|^q \leq \left(\frac{\|u\|^p + \|v\|^p}{2} \right)^{\frac{q}{p}}.$$

The scalar inequality used below is [39, Theorem 2].

Proof. For any $u, v \in H$, the parallelogram law implies

$$\left\| \frac{u+v}{2} \right\|^2 + \left\| \frac{u-v}{2} \right\|^2 = \frac{\|u\|^2 + \|v\|^2}{2}.$$

Define

$$A = \left\| \frac{u+v}{2} \right\|^2, \qquad B = \left\| \frac{u-v}{2} \right\|^2,$$

so that

$$A + B = \frac{\|u\|^2 + \|v\|^2}{2}.$$

First prove (a). Since $p \geq 2$, we have $\frac{p}{2} \geq 1$. For $A, B \geq 0$, this gives

$$A^{\frac{p}{2}} + B^{\frac{p}{2}} \leq (A + B)^{\frac{p}{2}}.$$

On the other hand, convexity of the function $t \mapsto t^{\frac{p}{2}}$ on $[0,\infty)$ yields

$$(A+B)^{\frac{p}{2}} = \left(\frac{\|u\|^2+\|v\|^2}{2}\right)^{\frac{p}{2}} \leq \frac{\left(\|u\|^2\right)^{\frac{p}{2}}+\left(\|v\|^2\right)^{\frac{p}{2}}}{2} = \frac{\|u\|^p+\|v\|^p}{2}.$$

Substituting A and B gives the result.

Finally, prove (b). Let $x = \|u\|$ and $y = \|v\|$. By the parallelogram law, the sum of our constants is

$$A+B = \frac{x^2+y^2}{2}.$$

The triangle inequality gives the following upper and lower bounds for A:

$$\left|\frac{x-y}{2}\right| = \frac{|\|u\|-\|v\||}{2} \leq \left\|\frac{u+v}{2}\right\| \leq \frac{\|u\|+\|v\|}{2} = \frac{x+y}{2}.$$

Squaring shows that A belongs to the closed interval

$$I = \left[\left(\frac{x-y}{2}\right)^2, \left(\frac{x+y}{2}\right)^2\right].$$

To bound the quantity $A^{\frac{q}{2}}+B^{\frac{q}{2}}$, consider the real-variable function $f : I \longrightarrow \mathbb{R}$ defined by

$$f(t) = t^{\frac{q}{2}} + \left(\frac{x^2+y^2}{2} - t\right)^{\frac{q}{2}}.$$

Since $1 < p \leq 2$, the conjugate exponent satisfies $q \geq 2$, so $r = \frac{q}{2} \geq 1$. Computing the derivatives of f gives:

$$f'(t) = rt^{r-1} - r\left(\frac{x^2+y^2}{2} - t\right)^{r-1},$$
$$f''(t) = r(r-1)t^{r-2} + r(r-1)\left(\frac{x^2+y^2}{2} - t\right)^{r-2}.$$

Since $r \geq 1$, it follows that $r(r-1) \geq 0$. Moreover, on the domain under consideration, both t and $\left(\frac{x^2+y^2}{2} - t\right)$ are nonnegative, so $f''(t) \geq 0$ for every $t \in I$. Therefore f is convex.
The maximum of a convex function on a closed interval is always attained at at least one endpoint. Evaluating f at the endpoints of I gives the same value in both cases:

$$f\left(\left(\frac{x+y}{2}\right)^2\right) = f\left(\left(\frac{x-y}{2}\right)^2\right) = \left(\frac{x+y}{2}\right)^q + \left|\frac{x-y}{2}\right|^q.$$

Since the constant $A \in I$, evaluation at $t = A$ yields

$$A^{\frac{q}{2}}+B^{\frac{q}{2}} = f(A) \leq \left(\frac{x+y}{2}\right)^q + \left|\frac{x-y}{2}\right|^q.$$

This step geometrically reduces the vector problem to one involving nonnegative real scalars. Applying the

cited scalar inequality to the real numbers $x, y \geq 0$ and $1 < p \leq 2$ gives

$$\left(\frac{x+y}{2}\right)^q + \left|\frac{x-y}{2}\right|^q \leq \left(\frac{x^p+y^p}{2}\right)^{\frac{q}{p}}.$$

Combining the inequalities yields the desired result. □

Proposition 9.1.18. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle with bundle metric $\mathbf{h_E}$. If $1 < p < \infty$, then $L^p(M, \mathbf{E})$ is uniformly convex.

Proof. Let $\mathbf{u}, \mathbf{v} \in L^p(M, \mathbf{E})$ be such that

$$\|\mathbf{u}\|_{L^p(M,\mathbf{E})} = \|\mathbf{v}\|_{L^p(M,\mathbf{E})} = 1, \qquad \|\mathbf{u} - \mathbf{v}\|_{L^p(M,\mathbf{E})} \geq \varepsilon,$$

with $\varepsilon > 0$. For each $x \in M$, the fiber $(\mathbf{E}_x, \mathbf{h_E}(x))$ is a Hilbert space, so Lemma 9.1.17 applies pointwise, giving two cases:

Case $2 \leq p < \infty$. Applying Lemma 9.1.17 (a) to $\mathbf{u}(x), \mathbf{v}(x) \in \mathbf{E}_x$ and then integrating with respect to $\lambda_\mathbf{g}$ gives

$$\int_M \left|\frac{\mathbf{u}+\mathbf{v}}{2}\right|^p_{\mathbf{h_E}} d\lambda_\mathbf{g} + \int_M \left|\frac{\mathbf{u}-\mathbf{v}}{2}\right|^p_{\mathbf{h_E}} d\lambda_\mathbf{g} \leq \frac{1}{2}\int_M \left(|\mathbf{u}|^p_{\mathbf{h_E}} + |\mathbf{v}|^p_{\mathbf{h_E}}\right) d\lambda_\mathbf{g}.$$

By the definition of the norm on $L^p(M, \mathbf{E})$, this is equivalent to

$$\left\|\frac{\mathbf{u}+\mathbf{v}}{2}\right\|^p_{L^p(M,\mathbf{E})} + \left\|\frac{\mathbf{u}-\mathbf{v}}{2}\right\|^p_{L^p(M,\mathbf{E})} \leq \frac{\|\mathbf{u}\|^p_{L^p(M,\mathbf{E})} + \|\mathbf{v}\|^p_{L^p(M,\mathbf{E})}}{2} = 1.$$

Moreover,

$$\left\|\frac{\mathbf{u}-\mathbf{v}}{2}\right\|^p_{L^p(M,\mathbf{E})} = \frac{1}{2^p}\|\mathbf{u}-\mathbf{v}\|^p_{L^p(M,\mathbf{E})} \geq \left(\frac{\varepsilon}{2}\right)^p.$$

Substituting into the preceding inequality,

$$\left\|\frac{\mathbf{u}+\mathbf{v}}{2}\right\|^p_{L^p(M,\mathbf{E})} \leq 1 - \left(\frac{\varepsilon}{2}\right)^p.$$

Taking pth roots,

$$\left\|\frac{\mathbf{u}+\mathbf{v}}{2}\right\|_{L^p(M,\mathbf{E})} \leq \left(1 - \left(\frac{\varepsilon}{2}\right)^p\right)^{\frac{1}{p}}$$

Defining

$$\delta(\varepsilon) := 1 - \left(1 - \left(\frac{\varepsilon}{2}\right)^p\right)^{\frac{1}{p}} > 0,$$

gives the result.

Case $1 < p < 2$. Let q be the conjugate exponent of p. Applying Lemma 9.1.17 (b) to $\mathbf{u}(x), \mathbf{v}(x) \in \mathbf{E}_x$ gives the pointwise inequality

$$\left|\frac{\mathbf{u}+\mathbf{v}}{2}\right|^q_{\mathbf{h_E}} + \left|\frac{\mathbf{u}-\mathbf{v}}{2}\right|^q_{\mathbf{h_E}} \leq \left(\frac{|\mathbf{u}|^p_{\mathbf{h_E}} + |\mathbf{v}|^p_{\mathbf{h_E}}}{2}\right)^{\frac{q}{p}}.$$

Raising both sides to the power $\frac{p}{q}$ and integrating with respect to $\lambda_{\mathbf{g}}$ yields

$$\int_M \left(\left| \frac{\mathbf{u}+\mathbf{v}}{2} \right|_{\mathbf{h_E}}^q + \left| \frac{\mathbf{u}-\mathbf{v}}{2} \right|_{\mathbf{h_E}}^q \right)^{\frac{p}{q}} d\lambda_{\mathbf{g}} \leq \frac{1}{2} \int_M \left(|\mathbf{u}|_{\mathbf{h_E}}^p + |\mathbf{v}|_{\mathbf{h_E}}^p \right) d\lambda_{\mathbf{g}}.$$

Since $\|\mathbf{u}\|_{L^p(M,\mathbf{E})} = \|\mathbf{v}\|_{L^p(M,\mathbf{E})} = 1$, the right-hand side is exactly 1. On the other hand, since $p < 2$, the exponent satisfies $\frac{p}{q} = p - 1 < 1$. Applying the reverse Minkowski inequality of Proposition B.7.4 with $r = \frac{p}{q}$ bounds the left-hand side from below, giving:

$$\left(\int_M \left| \frac{\mathbf{u}+\mathbf{v}}{2} \right|_{\mathbf{h_E}}^p d\lambda_{\mathbf{g}} \right)^{\frac{q}{p}} + \left(\int_M \left| \frac{\mathbf{u}-\mathbf{v}}{2} \right|_{\mathbf{h_E}}^p d\lambda_{\mathbf{g}} \right)^{\frac{q}{p}} \leq \left(\int_M \left(\left| \frac{\mathbf{u}+\mathbf{v}}{2} \right|_{\mathbf{h_E}}^q + \left| \frac{\mathbf{u}-\mathbf{v}}{2} \right|_{\mathbf{h_E}}^q \right)^{\frac{p}{q}} d\lambda_{\mathbf{g}} \right)^{\frac{q}{p}}.$$

Since the integral on the right is bounded by 1 and $1^{\frac{q}{p}} = 1$, in terms of the norm on $L^p(M,\mathbf{E})$ this reads

$$\left\| \frac{\mathbf{u}+\mathbf{v}}{2} \right\|_{L^p(M,\mathbf{E})}^q + \left\| \frac{\mathbf{u}-\mathbf{v}}{2} \right\|_{L^p(M,\mathbf{E})}^q \leq 1.$$

As in the preceding case, we have

$$\left\| \frac{\mathbf{u}-\mathbf{v}}{2} \right\|_{L^p(M,\mathbf{E})}^q \geq \left(\frac{\varepsilon}{2} \right)^q,$$

which implies

$$\left\| \frac{\mathbf{u}+\mathbf{v}}{2} \right\|_{L^p(M,\mathbf{E})}^q \leq 1 - \left(\frac{\varepsilon}{2} \right)^q.$$

Taking qth roots, we conclude

$$\left\| \frac{\mathbf{u}+\mathbf{v}}{2} \right\|_{L^p(M,\mathbf{E})} \leq \left(1 - \left(\frac{\varepsilon}{2} \right)^q \right)^{\frac{1}{q}} = 1 - \delta(\varepsilon),$$

with the explicit choice

$$\delta(\varepsilon) := 1 - \left(1 - \left(\frac{\varepsilon}{2} \right)^q \right)^{\frac{1}{q}} > 0.$$

In both cases, we have found $\delta(\varepsilon) > 0$ depending only on ε and p. This proves that $L^p(M,\mathbf{E})$ is uniformly convex. □

We therefore have the following:

Corollary 9.1.19. (Uniform convexity and reflexivity of $W^{m,p}(M,\mathbf{E})$) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h_E}$ and a connection $\nabla^{\mathbf{E}}$. If $1 < p < \infty$, the Sobolev space $W^{m,p}(M,\mathbf{E})$ is uniformly convex. In particular, by Theorem 9.1.16, $W^{m,p}(M,\mathbf{E})$ is reflexive.

Stability of uniform convexity under ℓ^p products is [39, Theorem 1].

Proof. By Proposition 9.1.18, for each $j \in \{0,\dots,m\}$, $L^p(M, T^{(0,j)}(TM) \otimes \mathbf{E})$ is uniformly convex. Thus the product $\prod_{j=0}^{m} L^p(M, T^{(0,j)}(TM) \otimes \mathbf{E})$ equipped with the norm ℓ^p is uniformly convex. Uniform convexity passes to subspaces and is preserved by isometries, so Theorem 9.1.14 implies that $W^{m,p}(M,\mathbf{E})$ is uniformly con-

vex. □

Separability will be an important property, and the spaces L^p inherit it from a property of measure spaces with the same name:

Definition 9.1.20. (Separable measure space) Let $(X, \mathcal{A}, \mu)$ be a measure space. We say that $(X, \mathcal{A}, \mu)$ is a *separable measure space* if there exists a countable family of sets $\mathcal{C} \subseteq \mathcal{A}$ such that the σ-algebra $\mathcal{A}$ is contained in the completion of the σ-algebra generated by $\mathcal{C}$ (denoted by $\overline{\sigma(\mathcal{C})}^{\mu}$). That is:

$$\mathcal{A} \subseteq \overline{\sigma(\mathcal{C})}^{\mu}.$$

In the special case where $\mathcal{A}$ is already complete, this becomes the equality:

$$\mathcal{A} = \overline{\sigma(\mathcal{C})}^{\mu}.$$

For a proof of the following lemma, see [22].

Lemma 9.1.21. (Separability of $L^p(X, \mu)$) Let $(X, \mathcal{A}, \mu)$ be a σ-finite measure space and let $1 \leq p < \infty$. If the measure space $(X, \mathcal{A}, \mu)$ is separable, then $L^p(X, \mathcal{A}, \mu)$ is separable.

This tells us that $L^p(M)$ is separable for $1 \leq p < \infty$ because $(M, \mathcal{L}_M, \lambda_g)$ is a separable measure space:

Proposition 9.1.22. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, and let $\lambda_{\mathbf{g}}$ be the associated Riemann–Lebesgue measure. Then the measure space $(M, \mathcal{L}_M, \lambda_{\mathbf{g}})$ is separable and σ-finite.

Proof. Since M is a smooth manifold, it is a second-countable topological space. In particular, its topology has a countable base of open subsets $(U_k)_{k \in \mathbb{N}}$ on M.
Let $\mathcal{B}$ be the Borel σ-algebra of M. Then

$$\mathcal{B} = \sigma\big(\{U_k \mid k \in \mathbb{N}\}\big).$$

Moreover, by Lemma 2.15.11, $\mathcal{L}_M$ agrees with the completion of $\mathcal{B}$ with respect to $\lambda_{\mathbf{g}}$, that is, $\mathcal{L}_M = \overline{\mathcal{B}}^{\lambda_{\mathbf{g}}}$, and $\lambda_{\mathbf{g}}$ is σ-finite.
Therefore

$$\mathcal{L}_M = \overline{\sigma(\{U_k \mid k \in \mathbb{N}\})}^{\lambda_{\mathbf{g}}},$$

showing that $(M, \mathcal{L}_M, \lambda_{\mathbf{g}})$ is a separable measure space. □

We use this to prove separability of $L^p(M, \mathbf{E})$:

Theorem 9.1.23. Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle with bundle metric $\mathbf{h}_{\mathbf{E}}$. If $1 \leq p < \infty$, then $L^p(M, \mathbf{E})$ is separable.

Proof. Let $(U_k, \varphi_k)_{k \in \mathbb{N}}$ be a countable atlas of M. Refining it by bundle trivialization domains, we may assume that for every k there is a local $\mathbf{h}_{\mathbf{E}}$-orthonormal frame $(\mathbf{e}_{1,k}, \ldots, \mathbf{e}_{r,k})$ of $\mathbf{E}$ over U_k. Let $(\psi_k)_{k \in \mathbb{N}}$ be a smooth partition of unity subordinate to $(U_k)_{k \in \mathbb{N}}$.

For each $k \in \mathbb{N}$, since $L^p(U_k)$ is separable, fix a countable dense subset $\mathcal{D}_k \subseteq L^p(U_k)$. Define

$$\mathcal{D} := \left\{ \sum_{k=1}^{N} \psi_k \left(\sum_{j=1}^{r} f_{j,k}\, \widetilde{\mathbf{e}}_{j,k} \right) \;\middle|\; N \in \mathbb{N},\ \ f_{j,k} \in \mathcal{D}_k \right\},$$

where $\widetilde{\mathbf{e}}_{j,k}$ denotes the extension of $\mathbf{e}_{j,k}$ by zero outside U_k. Then $\mathcal{D}$ is countable and $\mathcal{D} \subseteq L^p(M, \mathbf{E})$.
Let us show that $\mathcal{D}$ is dense in $L^p(M, \mathbf{E})$. Let $\mathbf{s} \in L^p(M, \mathbf{E})$ and let $\varepsilon > 0$. For $N \in \mathbb{N}$, define

$$\mathbf{s}_N := \sum_{k=1}^{N} \psi_k \mathbf{s}.$$

Writing $w_N := \sum_{k>N} \psi_k$, we have $0 \le w_N \le 1$ and $w_N(x) \to 0$ for every $x \in M$ (since $\sum_{k=1}^{\infty} \psi_k(x) = 1$). Moreover,

$$|\mathbf{s} - \mathbf{s}_N|_{\mathbf{h_E}} = |w_N \mathbf{s}|_{\mathbf{h_E}} = w_N\, |\mathbf{s}|_{\mathbf{h_E}} \le |\mathbf{s}|_{\mathbf{h_E}}.$$

Therefore

$$\|\mathbf{s} - \mathbf{s}_N\|^p_{L^p(M,\mathbf{E})} = \int_M |\mathbf{s} - \mathbf{s}_N|^p_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} = \int_M w_N^p\, |\mathbf{s}|^p_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \longrightarrow 0,$$

by Theorem B.6.14, since $w_N^p |\mathbf{s}|^p_{\mathbf{h_E}} \to 0$ pointwise and

$$0 \le w_N^p |\mathbf{s}|^p_{\mathbf{h_E}} \le |\mathbf{s}|^p_{\mathbf{h_E}} \in L^1(M).$$

In particular, there exists $N \in \mathbb{N}$ such that

$$\|\mathbf{s} - \mathbf{s}_N\|_{L^p(M,\mathbf{E})} < \frac{\varepsilon}{2}.$$

Now fix $k \in \{1, \dots, N\}$. On U_k, write

$$\mathbf{s} \restriction_{U_k} = \sum_{j=1}^{r} a_{j,k}\, \mathbf{e}_{j,k}, \qquad a_{j,k} \text{ measurable on } U_k.$$

Since the frame is $\mathbf{h_E}$-orthonormal, for almost every $x \in U_k$ we have

$$|\mathbf{s}(x)|^2_{\mathbf{h_E}} = \sum_{j=1}^{r} |a_{j,k}(x)|^2,$$

and in particular $|a_{j,k}(x)| \le |\mathbf{s}(x)|_{\mathbf{h_E}}$. Hence

$$\|a_{j,k}\|^p_{L^p(U_k)} = \int_{U_k} |a_{j,k}|^p\, d\lambda_{\mathbf{g}} \le \int_{U_k} |\mathbf{s}|^p_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \le \int_M |\mathbf{s}|^p_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} = \|\mathbf{s}\|^p_{L^p(M,\mathbf{E})} < \infty,$$

, and therefore $a_{j,k} \in L^p(U_k)$ for every $j \in \{1, \dots, r\}$.
Since $\mathcal{D}_k$ is dense in $L^p(U_k)$, choose $f_{j,k} \in \mathcal{D}_k$ such that

$$\|a_{j,k} - f_{j,k}\|_{L^p(U_k)} < \frac{\varepsilon}{2Nr}, \qquad j \in \{1, \dots, r\}.$$

Define

$$u := \sum_{k=1}^{N} \psi_k \left(\sum_{j=1}^{r} f_{j,k} \widetilde{\mathbf{e}}_{j,k} \right) \in \mathcal{D}.$$

For each $k \in \{1, \dots, N\}$, using $\psi_k \le 1$ and orthonormality of the frame, for almost every $x \in U_k$ we have

$$\left| \psi_k(x) \sum_{j=1}^{r} (a_{j,k}(x) - f_{j,k}(x)) \mathbf{e}_{j,k}(x) \right|_{\mathbf{h_E}}^p = |\psi_k(x)|^p \left(\sum_{j=1}^{r} |a_{j,k}(x) - f_{j,k}(x)|^2 \right)^{\frac{p}{2}} \le \left(\sum_{j=1}^{r} |a_{j,k}(x) - f_{j,k}(x)| \right)^p.$$

Applying the inequality

$$\left(\sum_{j=1}^{r} b_j \right)^p \le r^{p-1} \sum_{j=1}^{r} b_j^p, \qquad b_j \ge 0,$$

gives

$$\left| \psi_k \sum_{j=1}^{r} (a_{j,k} - f_{j,k}) \mathbf{e}_{j,k} \right|_{\mathbf{h_E}}^p \le r^{p-1} \sum_{j=1}^{r} |a_{j,k} - f_{j,k}|^p \quad \text{in } U_k.$$

Integrating and using $\operatorname{supp}(\psi_k) \subset U_k$ yields

$$\left\| \psi_k \sum_{j=1}^{r} (a_{j,k} - f_{j,k}) \widetilde{\mathbf{e}}_{j,k} \right\|_{L^p(M,\mathbf{E})}^p \le r^{p-1} \sum_{j=1}^{r} \|a_{j,k} - f_{j,k}\|_{L^p(U_k)}^p.$$

In particular,

$$\left\| \psi_k \sum_{j=1}^{r} (a_{j,k} - f_{j,k}) \widetilde{\mathbf{e}}_{j,k} \right\|_{L^p(M,\mathbf{E})} \le r^{1-\frac{1}{p}} \left(\sum_{j=1}^{r} \|a_{j,k} - f_{j,k}\|_{L^p(U_k)}^p \right)^{\frac{1}{p}} < \frac{\varepsilon}{2N}.$$

Summing over $k \in \{1, \dots, N\}$,

$$\|\mathbf{s}_N - u\|_{L^p(M,\mathbf{E})} \le \sum_{k=1}^{N} \left\| \psi_k \sum_{j=1}^{r} (a_{j,k} - f_{j,k}) \widetilde{\mathbf{e}}_{j,k} \right\|_{L^p(M,\mathbf{E})} < \sum_{k=1}^{N} \frac{\varepsilon}{2N} = \frac{\varepsilon}{2}.$$

Finally,

$$\|\mathbf{s} - u\|_{L^p(M,\mathbf{E})} \le \|\mathbf{s} - \mathbf{s}_N\|_{L^p(M,\mathbf{E})} + \|\mathbf{s}_N - u\|_{L^p(M,\mathbf{E})} < \varepsilon.$$

Since $\mathbf{s}$ and ε were arbitrary, $\mathcal{D}$ is dense in $L^p(M,\mathbf{E})$. Consequently, $L^p(M,\mathbf{E})$ is separable. □

Corollary 9.1.24. (Separability of $W^{m,p}(M,\mathbf{E})$) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h_E}$ and a connection $\nabla^{\mathbf{E}}$. If $1 \le p < \infty$, the Sobolev space $W^{m,p}(M,\mathbf{E})$ is separable.

Proof. By Theorem 9.1.14, the operator

$$J_m \colon W^{m,p}(M,\mathbf{E}) \longrightarrow \prod_{j=0}^{m} L^p\left(M, T^{(0,j)}(TM) \otimes \mathbf{E}\right), \qquad J_m(u) = \left((\nabla^{\mathbf{E}})^j u\right)_{j=0}^m,$$

is an isometry onto its image, and $J_m\big(W^{m,p}(M,\mathbf{E})\big)$ is a closed subspace.
By Theorem 9.1.23, for each $j \in \{0,\dots,m\}$ the space $L^p\big(M, T^{(0,j)}(TM)\otimes\mathbf{E}\big)$ is separable. Consequently, the finite product $\prod_{j=0}^{m} L^p\big(M, T^{(0,j)}(TM)\otimes\mathbf{E}\big)$ is separable.
Since every subspace of a separable metric space is separable, $J_m\big(W^{m,p}(M,\mathbf{E})\big)$ is separable. Finally, since J_m is an isometry onto its image (and hence a homeomorphism onto its image), we conclude that $W^{m,p}(M,\mathbf{E})$ is separable. □

We now study the dual of $L^1(M,\mathbf{E})$. Besides extending classical L^1–L^∞ duality to sections, this identification gives a concrete description of the weak topology of $L^1(M,\mathbf{E})$ through the bundle inner product and integration.

Proposition 9.1.25. (Dual of $L^1(M,\mathbf{E})$) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{E}\to M$ be a smooth real vector bundle of finite rank equipped with a bundle metric $\mathbf{h_E}$. Then the map

$$J_{\mathbf{E}}\colon L^\infty(M,\mathbf{E}) \longrightarrow (L^1(M,\mathbf{E}))', \qquad J_{\mathbf{E}}(\mathbf{v})(\mathbf{u}) := \int_M \langle \mathbf{u},\mathbf{v}\rangle_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}},$$

is an isometric isomorphism. In particular, $(L^1(M,\mathbf{E}))' \cong L^\infty(M,\mathbf{E})$ and $\sigma(L^1(M,\mathbf{E}),L^\infty(M,\mathbf{E}))$ agrees with $\sigma(L^1(M,\mathbf{E}),(L^1(M,\mathbf{E}))')$.

Proof. Riemann–Lebesgue measure is σ-finite. For $\mathbf{v}\in L^\infty(M,\mathbf{E})$, Hölder's inequality (Proposition B.7.9) implies $|J_{\mathbf{E}}(\mathbf{v})(\mathbf{u})| \le \|\mathbf{v}\|_{L^\infty(M,\mathbf{E})}\|\mathbf{u}\|_{L^1(M,\mathbf{E})}$ for every $\mathbf{u}\in L^1(M,\mathbf{E})$, so $J_{\mathbf{E}}$ is well defined and $\|J_{\mathbf{E}}(\mathbf{v})\| \le \|\mathbf{v}\|_{L^\infty(M,\mathbf{E})}$. Let us show that $J_{\mathbf{E}}$ is surjective. Let $\Lambda\in(L^1(M,\mathbf{E}))'$. Take a countable open cover $(U_j)_{j\in\mathbb{N}}$ of M, with a local trivialization of $\mathbf{E}$ defined over each U_j, and fix a smooth local orthonormal frame $(\mathbf{e}_{j,1},\dots,\mathbf{e}_{j,r})$ on each of these open subsets. Define the disjoint Borel sets $A_1 := U_1$ and

$$A_j := U_j \setminus \bigcup_{i=1}^{j-1} U_i, \qquad j\ge 2.$$

Then $M = \bigcup_{j\in\mathbb{N}} A_j$. For $j\in\mathbb{N}$ and $a\in\{1,\dots,r\}$, define

$$\Lambda_{j,a}\colon L^1(A_j)\longrightarrow\mathbb{R}, \qquad \Lambda_{j,a}(f) := \Lambda(\widetilde{f\mathbf{e}_{j,a}}),$$

where the tilde denotes extension by zero outside A_j. Since Λ is continuous,

$$|\Lambda_{j,a}(f)| = |\Lambda(\widetilde{f\mathbf{e}_{j,a}})| \le \|\Lambda\|\,\|\widetilde{f\mathbf{e}_{j,a}}\|_{L^1(M,\mathbf{E})}.$$

Moreover, since the frame is orthonormal, $|\mathbf{e}_{j,a}|_{\mathbf{h_E}} = 1$ on A_j, so

$$\|\widetilde{f\mathbf{e}_{j,a}}\|_{L^1(M,\mathbf{E})} = \int_{A_j} |f\mathbf{e}_{j,a}|_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} = \int_{A_j} |f|\, d\lambda_{\mathbf{g}} = \|f\|_{L^1(A_j)}.$$

Consequently, $|\Lambda_{j,a}(f)| \le \|\Lambda\|\|f\|_{L^1(A_j)}$, and hence $\|\Lambda_{j,a}\| \le \|\Lambda\|$. By Theorem B.7.7, applied to $L^1(A_j)$, there

exists a unique $v_j^a \in L^\infty(A_j)$ such that

$$\Lambda_{j,a}(f) = \int_{A_j} f v_j^a \, d\lambda_{\mathbf{g}}, \qquad \|v_j^a\|_{L^\infty(A_j)} = \|\Lambda_{j,a}\| \le \|\Lambda\|.$$

Define a measurable section $\mathbf{v}$ by $\mathbf{v} \restriction_{A_j} := \sum_{a=1}^{r} v_j^a \mathbf{e}_{j,a}$. Since the frames are orthonormal, $|\mathbf{v}|_{\mathbf{h_E}}^2 = \sum_{a=1}^{r} |v_j^a|^2 \le r\|\Lambda\|^2$ almost everywhere on A_j, giving $|\mathbf{v}|_{\mathbf{h_E}} \le \sqrt{r}\|\Lambda\|$ almost everywhere and therefore $\mathbf{v} \in L^\infty(M, \mathbf{E})$.

For $\mathbf{u} \in L^1(M, \mathbf{E})$, write $u_j^a := \langle \mathbf{u}, \mathbf{e}_{j,a} \rangle_{\mathbf{h_E}}$ on A_j and define $\mathbf{u}_N := \sum_{j=1}^{N} \mathbf{1}_{A_j} \mathbf{u}$. Since

$$\|\mathbf{u} - \mathbf{u}_N\|_{L^1(M,\mathbf{E})} = \sum_{j>N} \int_{A_j} |\mathbf{u}|_{\mathbf{h_E}} \, d\lambda_{\mathbf{g}} \longrightarrow 0,$$

we have $\mathbf{u}_N \to \mathbf{u}$ in $L^1(M, \mathbf{E})$. Moreover, $\mathbf{u}_N = \sum_{j=1}^{N} \sum_{a=1}^{r} \widetilde{u_j^a e_{j,a}}$.

By linearity of Λ and the definition of $\Lambda_{j,a}$,

$$\Lambda(\mathbf{u}_N) = \sum_{j=1}^{N} \sum_{a=1}^{r} \Lambda\big(\widetilde{u_j^a e_{j,a}}\big) = \sum_{j=1}^{N} \sum_{a=1}^{r} \Lambda_{j,a}(u_j^a) = \sum_{j=1}^{N} \sum_{a=1}^{r} \int_{A_j} u_j^a v_j^a \, d\lambda_{\mathbf{g}}.$$

Since the frames are orthonormal, $\langle \mathbf{u}, \mathbf{v} \rangle_{\mathbf{h_E}} = \sum_{a=1}^{r} u_j^a v_j^a$ on each A_j, so

$$\sum_{j=1}^{N} \sum_{a=1}^{r} \int_{A_j} u_j^a v_j^a \, d\lambda_{\mathbf{g}} = \int_M \mathbf{1}_{\bigcup_{j=1}^{N} A_j} \langle \mathbf{u}, \mathbf{v} \rangle_{\mathbf{h_E}} \, d\lambda_{\mathbf{g}}.$$

Moreover,

$$\mathbf{1}_{\bigcup_{j=1}^{N} A_j} \langle \mathbf{u}, \mathbf{v} \rangle_{\mathbf{h_E}} \longrightarrow \langle \mathbf{u}, \mathbf{v} \rangle_{\mathbf{h_E}} \quad \text{almost everywhere,}$$

and

$$\left| \mathbf{1}_{\bigcup_{j=1}^{N} A_j} \langle \mathbf{u}, \mathbf{v} \rangle_{\mathbf{h_E}} \right| \le |\mathbf{u}|_{\mathbf{h_E}} |\mathbf{v}|_{\mathbf{h_E}} \in L^1(M),$$

since $\mathbf{u} \in L^1(M, \mathbf{E})$ and $\mathbf{v} \in L^\infty(M, \mathbf{E})$. By Theorem B.6.14 and continuity of Λ,

$$\Lambda(\mathbf{u}) = \lim_{N\to\infty} \Lambda(\mathbf{u}_N) = \lim_{N\to\infty} \sum_{j=1}^{N} \sum_{a=1}^{r} \int_{A_j} u_j^a v_j^a \, d\lambda_{\mathbf{g}} = \int_M \langle \mathbf{u}, \mathbf{v} \rangle_{\mathbf{h_E}} \, d\lambda_{\mathbf{g}}.$$

Consequently, $\Lambda = J_{\mathbf{E}}(\mathbf{v})$.

Finally, prove that $J_{\mathbf{E}}$ is isometric. We already know that $\|J_{\mathbf{E}}(\mathbf{v})\| \le \|\mathbf{v}\|_{L^\infty(M,\mathbf{E})}$. Suppose that $\mathbf{v} \neq 0$ and let $0 < \varepsilon < \|\mathbf{v}\|_{L^\infty(M,\mathbf{E})}$. By the definition of essential supremum, the set

$$A_\varepsilon := \left\{ x \in M \;\middle|\; |\mathbf{v}(x)|_{\mathbf{h_E}} > \|\mathbf{v}\|_{L^\infty(M,\mathbf{E})} - \varepsilon \right\}$$

has positive measure, since otherwise $|\mathbf{v}|_{\mathbf{h_E}} \le \|\mathbf{v}\|_{L^\infty(M,\mathbf{E})} - \varepsilon$ almost everywhere, contradicting the definition of $\|\mathbf{v}\|_{L^\infty(M,\mathbf{E})}$. Since $\lambda_{\mathbf{g}}$ is σ-finite, there exist measurable sets $(C_k)_{k\in\mathbb{N}}$ such that $M = \bigcup_{k\in\mathbb{N}} C_k$ and $\lambda_{\mathbf{g}}(C_k) < \infty$. Since $A_\varepsilon = \bigcup_{k\in\mathbb{N}} (A_\varepsilon \cap C_k)$ has positive measure, there exists $k \in \mathbb{N}$ such that $B_\varepsilon := A_\varepsilon \cap C_k$ satisfies $0 < \lambda_{\mathbf{g}}(B_\varepsilon) < \infty$.

Define

$$\mathbf{u}_\varepsilon(x) := \begin{cases} \dfrac{\mathbf{v}(x)}{\lambda_{\mathbf{g}}(B_\varepsilon)|\mathbf{v}(x)|_{\mathbf{h_E}}}, & x \in B_\varepsilon, \\ 0_x, & x \notin B_\varepsilon. \end{cases}$$

Since $B_\varepsilon \subseteq A_\varepsilon$ and $\varepsilon < \|\mathbf{v}\|_{L^\infty(M,\mathbf{E})}$, we have $|\mathbf{v}|_{\mathbf{h_E}} > 0$ on B_ε. Moreover,

$$\|\mathbf{u}_\varepsilon\|_{L^1(M,\mathbf{E})} = \frac{1}{\lambda_{\mathbf{g}}(B_\varepsilon)} \int_{B_\varepsilon} 1 \, d\lambda_{\mathbf{g}} = 1,$$

and

$$J_{\mathbf{E}}(\mathbf{v})(\mathbf{u}_\varepsilon) = \frac{1}{\lambda_{\mathbf{g}}(B_\varepsilon)} \int_{B_\varepsilon} |\mathbf{v}|_{\mathbf{h_E}} \, d\lambda_{\mathbf{g}} > \|\mathbf{v}\|_{L^\infty(M,\mathbf{E})} - \varepsilon.$$

By the definition of the operator norm,

$$\|J_{\mathbf{E}}(\mathbf{v})\| = \sup_{\substack{\mathbf{u}\in L^1(M,\mathbf{E}) \\ \|\mathbf{u}\|_{L^1(M,\mathbf{E})}\le 1}} |J_{\mathbf{E}}(\mathbf{v})(\mathbf{u})| \ge |J_{\mathbf{E}}(\mathbf{v})(\mathbf{u}_\varepsilon)| > \|\mathbf{v}\|_{L^\infty(M,\mathbf{E})} - \varepsilon.$$

Since this inequality holds for every $0 < \varepsilon < \|\mathbf{v}\|_{L^\infty(M,\mathbf{E})}$, letting $\varepsilon \to 0$ gives $\|J_{\mathbf{E}}(\mathbf{v})\| \ge \|\mathbf{v}\|_{L^\infty(M,\mathbf{E})}$. Consequently, $\|J_{\mathbf{E}}(\mathbf{v})\| = \|\mathbf{v}\|_{L^\infty(M,\mathbf{E})}$, and $J_{\mathbf{E}}$ is an isometric isomorphism. □

For a smooth *real* vector bundle $\mathbf{E} \to M$ of finite rank equipped with a bundle metric $\mathbf{h_E}$, consider on $L^1(M,\mathbf{E}) \times L^\infty(M,\mathbf{E})$ the duality

$$\mathfrak{b}_{\mathbf{E}}(u,\mathbf{v}) := \int_M \langle u, \mathbf{v}\rangle_{\mathbf{h_E}} \, d\lambda_{\mathbf{g}}.$$

By Proposition 9.1.25, the pairing $\mathfrak{b}_{\mathbf{E}}$ identifies $L^\infty(M,\mathbf{E})$ isometrically with $(L^1(M,\mathbf{E}))'$. Consequently,

$$\sigma(L^1(M,\mathbf{E}), L^\infty(M,\mathbf{E})) = \sigma(L^1(M,\mathbf{E}), (L^1(M,\mathbf{E}))'),$$

that is, $\sigma(L^1(M,\mathbf{E}), L^\infty(M,\mathbf{E}))$ agrees with the weak topology of $L^1(M,\mathbf{E})$. Thus a net $(u_\gamma)_\gamma$ converges to u in this topology if and only if

$$\int_M \langle u_\gamma, \mathbf{v}\rangle_{\mathbf{h_E}} \, d\lambda_{\mathbf{g}} \longrightarrow \int_M \langle u, \mathbf{v}\rangle_{\mathbf{h_E}} \, d\lambda_{\mathbf{g}}$$

for every $\mathbf{v} \in L^\infty(M,\mathbf{E})$.

If $\mathbf{E}$ is complex Hermitian, the complex-linear formulation replaces the second factor with $L^\infty(M,\overline{\mathbf{E}})$ and uses $\mathfrak{b}_{\mathbf{E}}(u,\overline{v}) = \int_M \mathbf{h_E}(u,v) \, d\lambda_{\mathbf{g}}$; this version, for every $1 \le p < \infty$, is proved in Corollary B.7.8 of Appendix B.

9.1.2 Compatibility with restrictions and local expressions for covariant derivatives on vector bundles

Another important property of Sobolev sections is that restriction to an open subset gives a Sobolev section on that open subset.

Proposition 9.1.26. Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a smooth connection $\nabla^{\mathbf{E}}$. If $U\subseteq M$ is open, $\mathbf{u}\in W^{m,p}(M,\mathbf{E})$, and $s\in\{0,\dots,m\}$, then $\mathbf{u}\restriction_U\in W^{m,p}(U,\mathbf{E}\restriction_U)$ and $\nabla^s_w(\mathbf{u}\restriction_U)=(\nabla^s_w\mathbf{u})\restriction_U$ almost everywhere on U.

Proof. Let $s\leq m$. We must prove that $\mathbf{u}\restriction_U$ has a weak covariant derivative of order s on $L^p(U,T^{(0,s)}(TU)\otimes\mathbf{E}\restriction_U)$. To this end, take $\sigma\in\Gamma_c(T^{(0,s)}(TU)\otimes\mathbf{E}\restriction_U)$. We may extend σ to $\widetilde{\sigma}\in\Gamma_c(T^{(0,s)}(TM)\otimes\mathbf{E})$ as in Lemma 9.1.6. On the other hand, since $\mathbf{u}\in W^{m,p}(M,\mathbf{E})$, there exists $\nabla^s_w\mathbf{u}$, the sth weak covariant derivative of $\mathbf{u}$. It satisfies

$$\int_M\langle\nabla^s_w\mathbf{u},\widetilde{\sigma}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}d\lambda_{\mathbf{g}}=\int_M\langle\mathbf{u},(\nabla^s)^*\widetilde{\sigma}\rangle_{\mathbf{h}_{\mathbf{E}}}d\lambda_{\mathbf{g}}.$$

Since $\sigma\equiv\widetilde{\sigma}$ on U, which is open, Remark 8.1.16 gives $(\nabla^s)^*\widetilde{\sigma}\equiv(\nabla^s)^*\sigma$ on U. Then

$$\int_U\langle(\nabla^s_w\mathbf{u})\restriction_U,\sigma\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}d\lambda_{\mathbf{g}}=\int_M\langle\nabla^s_w\mathbf{u},\widetilde{\sigma}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}d\lambda_{\mathbf{g}}=\int_M\langle\mathbf{u},(\nabla^s)^*\widetilde{\sigma}\rangle_{\mathbf{h}_{\mathbf{E}}}d\lambda_{\mathbf{g}}=\int_U\langle\mathbf{u}\restriction_U,(\nabla^s)^*\sigma\rangle_{\mathbf{h}_{\mathbf{E}}}d\lambda_{\mathbf{g}},$$

where the last equality holds because Proposition 8.1.15 gives $\operatorname{supp}((\nabla^s)^*\widetilde{\sigma})\subseteq\operatorname{supp}(\widetilde{\sigma})=\operatorname{supp}(\sigma)\subseteq U$ and $(\nabla^s)^*\widetilde{\sigma}\equiv(\nabla^s)^*\sigma$ on U. Thus $(\nabla^s_w\mathbf{u})\restriction_U$ satisfies the identity characterizing the sth weak covariant derivative of $\mathbf{u}\restriction_U$. By uniqueness of the weak covariant derivative, $\nabla^s_w(\mathbf{u}\restriction_U)=(\nabla^s_w\mathbf{u})\restriction_U$ almost everywhere on U. Since $s\leq m$ was arbitrary, $\mathbf{u}\restriction_U\in W^{m,p}(U,\mathbf{E}\restriction_U)$. □

Studying local properties of Sobolev spaces is important because it gives a way to work with them computationally. To achieve this, the reader should first become thoroughly familiar with coordinate expressions for higher-order covariant derivatives on smooth vector bundles. Such expressions are common in the literature in certain cases, but higher orders are less often treated because of their complexity. In this section, we calculate these local expressions in detail.

Lemma 9.1.27. Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary with a connection ∇ on TM, and let $\mathbf{E}$ be a smooth vector bundle with a connection $\nabla^{\mathbf{E}}$. Also denote by ∇ the induced connection on the tensor bundle $T^{(k,l)}(TM)\otimes\mathbf{E}$ characterized by Proposition 2.4.27. Let $U\subseteq M$ be an open subset on which $(\mathbf{E}_1,\dots,\mathbf{E}_n)$ is a local frame of TM over U, $(\varepsilon^1,\dots,\varepsilon^n)$ its associated dual coframe, and $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ a local frame of $\mathbf{E}$ over U. If $\mathbf{F}\in\Gamma(T^{(k,l)}(TM)\otimes\mathbf{E})$ is expressed locally as

$$\mathbf{F}=F^{i_1\dots i_k a}_{j_1\dots j_l}\mathbf{E}_{i_1}\otimes\cdots\otimes\mathbf{E}_{i_k}\otimes\varepsilon^{j_1}\otimes\cdots\otimes\varepsilon^{j_l}\otimes\mathbf{e}_a,$$

then the components of $\nabla\mathbf{F}$ in these frames are

$$(\nabla_{\mathbf{E}_c}\mathbf{F})^{i_1\dots i_k a}_{j_1\dots j_l}=\mathbf{E}_c\big(F^{i_1\dots i_k a}_{j_1\dots j_l}\big)+\sum_{t=1}^{k}\Gamma^{i_t}_{cs}F^{i_1\dots s\dots i_k a}_{j_1\dots j_l}-\sum_{t=1}^{l}\Gamma^{s}_{cj_t}F^{i_1\dots i_k a}_{j_1\dots s\dots j_l}+\sum_{b=1}^{r}(A_c)^a_b F^{i_1\dots i_k b}_{j_1\dots j_l},$$

where the connection coefficients are given by $\nabla_{\mathbf{E}_c}\mathbf{E}_j=\Gamma^s_{cj}\mathbf{E}_s$ and $\nabla^{\mathbf{E}}_{\mathbf{E}_c}\mathbf{e}_b=(A_c)^a_b\mathbf{e}_a$.

Proof. The covariant derivative of $\mathbf{F}$ in the direction $\mathbf{E}_c$ is

$$\nabla_{\mathbf{E}_c}\mathbf{F} = \nabla_{\mathbf{E}_c}\left(\sum_{a=1}^{r}\mathbf{F}^{(a)}\otimes\mathbf{e}_a\right),$$

where $\mathbf{F}^{(a)} \in \Gamma(T^{(k,l)}(TM))$ is the tensor field with components $(\mathbf{F}^{(a)})^{i_1\dots i_k}_{j_1\dots j_l} = F^{i_1\dots i_k a}_{j_1\dots j_l}$. By Proposition 2.4.27, applying the Leibniz rule gives

$$\nabla_{\mathbf{E}_c}\mathbf{F} = \sum_{a=1}^{r}\left((\nabla_{\mathbf{E}_c}\mathbf{F}^{(a)})\otimes\mathbf{e}_a + \mathbf{F}^{(a)}\otimes\nabla^{\mathbf{E}}_{\mathbf{E}_c}\mathbf{e}_a\right). \tag{9.2}$$

By Proposition 2.4.15, the coefficients of the first term in (9.2) are

$$(\nabla_{\mathbf{E}_c}\mathbf{F}^{(a)})^{i_1\dots i_k}_{j_1\dots j_l} = \mathbf{E}_c(F^{i_1\dots i_k a}_{j_1\dots j_l}) + \sum_{t=1}^{k}\Gamma^{i_t}_{cs}F^{i_1\dots s\dots i_k a}_{j_1\dots j_l} - \sum_{t=1}^{l}\Gamma^{s}_{cj_t}F^{i_1\dots i_k a}_{j_1\dots s\dots j_l}.$$

For the second term in (9.2), substitute $\nabla^{\mathbf{E}}_{\mathbf{E}_c}\mathbf{e}_b = (A_c)^a_b\mathbf{e}_a$. Changing the summation index for the local frame $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ to b in (9.2) yields

$$\sum_{b=1}^{r}\mathbf{F}^{(b)}\otimes\nabla^{\mathbf{E}}_{\mathbf{E}_c}\mathbf{e}_b = \sum_{b=1}^{r}\mathbf{F}^{(b)}\otimes\left(\sum_{a=1}^{r}(A_c)^a_b\mathbf{e}_a\right) = \sum_{a=1}^{r}\left(\sum_{b=1}^{r}(A_c)^a_b\mathbf{F}^{(b)}\right)\otimes\mathbf{e}_a.$$

The component of this term corresponding to $\mathbf{e}_a$ is $\displaystyle\sum_{b=1}^{r}(A_c)^a_b F^{i_1\dots i_k b}_{j_1\dots j_l}$, completing the proof. □

This gives the following local expression for higher-order derivatives:

Lemma 9.1.28. (Local expression for the sth covariant derivative) Let M be a smooth manifold with or without boundary equipped with a connection ∇ on TM, and let $\pi_{\mathbf{E}}\colon \mathbf{E}\longrightarrow M$ be a smooth vector bundle of rank r equipped with a connection $\nabla^{\mathbf{E}}$. Let $(U,x^1,\dots,x^n)$ be a smooth chart of M and $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ a local frame of $\mathbf{E}$ over U. Denote the connection coefficients by

$$\nabla_{\partial_i}\partial_j = \sum_{k=1}^{n}\Gamma^k_{ij}\partial_k, \qquad \nabla^{\mathbf{E}}_{\partial_i}\mathbf{e}_b = \sum_{a=1}^{r}(A_i)^a_b\mathbf{e}_a.$$

If $\mathbf{u}\in\Gamma(\mathbf{E})$ has coordinate expression $\mathbf{u} = \displaystyle\sum_{b=1}^{r}u^b\mathbf{e}_b$ on U, then for every integer $s\geq 1$, the components of the sth covariant derivative $\nabla^s\mathbf{u}\in\Gamma(T^{(0,s)}(TM)\otimes\mathbf{E})$ are given by

$$(\nabla^s\mathbf{u})^a_{i_1\dots i_s} = \partial_{i_1}\cdots\partial_{i_s}u^a + \sum_{b=1}^{r}\sum_{|\beta|\leq s-1}\left(B_\beta\right)^a_{b\,i_1\dots i_s}\partial^\beta u^b, \tag{9.3}$$

where the coefficients $\left(B_\beta\right)^a_{b\,i_1\dots i_s}$ are smooth functions on U depending only on the connection coefficients Γ^k_{ij}, $(A_i)^a_b$, and their partial derivatives through order $s-1$.

Proof. We prove the assertion by induction on s. For $s = 1$, the expression for the connection on $\mathbf{E}$ in the chosen frame gives

$$(\nabla \mathbf{u})^a_i = \partial_i u^a + \sum_{b=1}^{r} (A_i)^a{}_b u^b.$$

This is (9.3) with $\big(B_0^{(1)}\big)^a_{b,i} = (A_i)^a{}_b$.

Now suppose that, for some $s \geq 1$, there exist smooth coefficients $B_\beta^{(s)}$, with $|\beta| \leq s-1$, for which

$$(\nabla^s \mathbf{u})^a_{i_2 \dots i_{s+1}} = \partial_{i_2} \cdots \partial_{i_{s+1}} u^a + \sum_{b=1}^{r} \sum_{|\beta| \leq s-1} \big(B_\beta^{(s)}\big)^a_{b,i_2 \dots i_{s+1}} \partial^\beta u^b. \tag{9.4}$$

As part of the induction hypothesis, also suppose these coefficients depend only on Γ^k_{ij}, $(A_i)^a{}_b$, and their partial derivatives of order at most $s-1$.

Set $\mathbf{G} := \nabla^s \mathbf{u}$ and abbreviate $I = (i_2, \dots, i_{s+1})$. For $t \in \{2, \dots, s+1\}$, denote by $I_t(d)$ the list obtained from I by replacing i_t with d. The formula for the induced connection on $T^{(0,s)}(TM) \otimes \mathbf{E}$ gives

$$(\nabla \mathbf{G})^a_{i_1 I} = \partial_{i_1} G^a_I - \sum_{t=2}^{s+1} \sum_{d=1}^{n} \Gamma^d_{i_1 i_t} G^a_{I_t(d)} + \sum_{c=1}^{r} (A_{i_1})^a{}_c G^c_I. \tag{9.5}$$

Substitute (9.4) into each of the three terms of (9.5). In the first, the Leibniz rule gives

$$\partial_{i_1} G^a_I = \partial_{i_1} \partial_{i_2} \cdots \partial_{i_{s+1}} u^a + \sum_{b=1}^{r} \sum_{|\beta| \leq s-1} \partial_{i_1} \Big(\big(B_\beta^{(s)}\big)^a_{b,I} \Big) \partial^\beta u^b + \sum_{b=1}^{r} \sum_{|\beta| \leq s-1} \big(B_\beta^{(s)}\big)^a_{b,I} \partial^{\beta + e_{i_1}} u^b,$$

where e_{i_1} is the multi-index whose only nonzero component is the i_1th. The second term becomes

$$-\sum_{t=2}^{s+1} \sum_{d=1}^{n} \Gamma^d_{i_1 i_t} G^a_{I_t(d)} = -\sum_{t=2}^{s+1} \sum_{d=1}^{n} \Gamma^d_{i_1 i_t} \partial_{i_2} \cdots \partial_{i_{t-1}} \partial_d \partial_{i_{t+1}} \cdots \partial_{i_{s+1}} u^a - \sum_{t=2}^{s+1} \sum_{d=1}^{n} \sum_{b=1}^{r} \sum_{|\beta| \leq s-1} \Gamma^d_{i_1 i_t} \big(B_\beta^{(s)}\big)^a_{b,I_t(d)} \partial^\beta u^b.$$

Finally, the term corresponding to the connection on $\mathbf{E}$ is

$$\sum_{c=1}^{r} (A_{i_1})^a{}_c G^c_I = \sum_{c=1}^{r} (A_{i_1})^a{}_c \partial_{i_2} \cdots \partial_{i_{s+1}} u^c + \sum_{c=1}^{r} \sum_{b=1}^{r} \sum_{|\beta| \leq s-1} (A_{i_1})^a{}_c \big(B_\beta^{(s)}\big)^c_{b,I} \partial^\beta u^b.$$

These three equalities contain exactly one term with $s+1$ derivatives of a component of $\mathbf{u}$, namely

$$\partial_{i_1} \partial_{i_2} \cdots \partial_{i_{s+1}} u^a.$$

The terms in the third line of the first expansion contain derivatives of order $|\beta| + 1 \leq s$; the first summand of the second expansion and the first of the third contain derivatives of order s; and all remaining summands contain derivatives of order at most $s-1$.

For fixed $a, b, i_1, \dots, i_{s+1}$ and a multi-index γ with $|\gamma| \leq s$, define $\big(B_\gamma^{(s+1)}\big)^a_{b,i_1 \dots i_{s+1}}$ as the sum of the coefficients multiplying $\partial^\gamma u^b$ in the preceding three expansions. This is a finite sum of products of Γ^k_{ij}, $(A_i)^a{}_b$, $B_\beta^{(s)}$, and $\partial_{i_1} B_\beta^{(s)}$. By the induction hypothesis, $B_\beta^{(s)}$ depends on the connection coefficients and their derivatives

through order $s-1$, while $\partial_{i_1} B_\beta^{(s)}$ depends on them through order s. Consequently, $B_\gamma^{(s+1)}$ is smooth and depends only on Γ_{ij}^k, $(A_i)^a{}_b$, and their partial derivatives of order at most s. With this definition, we obtain

$$(\nabla^{s+1}\mathbf{u})^a_{i_1\dots i_{s+1}} = \partial_{i_1}\cdots\partial_{i_{s+1}}u^a + \sum_{b=1}^{r}\sum_{|\gamma|\le s}\big(B_\gamma^{(s+1)}\big)^a_{b,i_1\dots i_{s+1}}\partial^\gamma u^b,$$

which is the assertion for $s+1$ and completes the induction. □

9.1.3 The integration-by-parts formula for vector bundles and the formal adjoint

One of the most important examples of a formal adjoint is that of the sth covariant derivative. This adjoint can be computed globally and explicitly from an integration-by-parts formula. This is natural, since the concept of formal adjoint is motivated precisely by the integration-by-parts formulas that gave rise to weak derivatives in the Euclidean case.

In this section, we prove an original result found in [41] that made possible an intrinsic, unified treatment of Sobolev spaces. Its derivation was initially motivated by [33], which sought to establish the Meyers–Serrin theorem on manifolds in certain cases by giving explicit expressions for first- and second-order weak covariant derivatives. Subsequent analysis of these ideas culminated in the work mentioned first. The result is as follows:

Theorem 9.1.29. (Integration-by-parts formula for higher-order covariant derivatives on vector bundles) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary and Levi–Civita connection ∇. Let $\mathbf{E}\longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_\mathbf{E}$ and a compatible connection $\nabla^\mathbf{E}$. Also denote by ∇ the induced connection on the tensor bundle $T^{(k,l)}(TM)\otimes\mathbf{E}$ characterized by Proposition 2.4.27. If $s\ge 1$, $\mathbf{F}\in\Gamma_c\big(T^{(k,l)}(TM)\otimes\mathbf{E}\big)$, and $\mathbf{G}\in\Gamma_c\big(T^{(k,l+s)}(TM)\otimes\mathbf{E}\big)$, then

$$\int_M \langle\nabla^s\mathbf{F},\mathbf{G}\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\,d\lambda_\mathbf{g} = (-1)^s\int_M\big\langle\mathbf{F},(\mathrm{tr}_\mathbf{g}\circ\nabla)^s\mathbf{G}\big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\,d\lambda_\mathbf{g}$$

$$+\sum_{j=0}^{s-1}(-1)^{s-1-j}\int_{\partial M}\Big\langle\nabla^j\mathbf{F},\iota_{\boldsymbol{\nu}}\big((\mathrm{tr}_\mathbf{g}\circ\nabla)^{s-1-j}\mathbf{G}\big)\Big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\,d\lambda_{\widetilde{\mathbf{g}}},$$

where $\boldsymbol{\nu}$ is the outward unit normal to ∂M and $\iota_{\boldsymbol{\nu}}$ denotes contraction of $\boldsymbol{\nu}$ in the first covariant index. More precisely, if

$$\mathbf{H}\in\Gamma\big(T^{(k,m+1)}(TM)\otimes\mathbf{E}\big),$$

then $\iota_{\boldsymbol{\nu}}\mathbf{H}\in\Gamma\big((T^{(k,m)}(TM)\otimes\mathbf{E})\restriction_{\partial M}\big)$ and, in local coordinates on the boundary,

$$\big(\iota_{\boldsymbol{\nu}}\mathbf{H}\big)^{i_1\dots i_k a}_{j_1\dots j_m} := \nu^q\,H^{i_1\dots i_k a}_{qj_1\dots j_m},$$

where $\boldsymbol{\nu}=\nu^q\partial_q$ in those coordinates. If $\partial M=\varnothing$, the sum of integrals over ∂M is interpreted as zero, and no choice of normal is involved.

Here $\mathrm{tr}_\mathbf{g}$ denotes contraction, using $\mathbf{g}$, of the first two covariant indices of $\nabla\mathbf{H}$. More precisely, if $m\ge 1$ and $\mathbf{H}\in\Gamma\big(T^{(k,m)}(TM)\otimes\mathbf{E}\big)$, then $\nabla\mathbf{H}\in\Gamma\big(T^{(k,m+1)}(TM)\otimes\mathbf{E}\big)$ and, in local coordinates,

$$\big(\mathrm{tr}_\mathbf{g}(\nabla\mathbf{H})\big)^{i_1\dots i_k a}_{j_1\dots j_{m-1}} := g^{pq}\,(\nabla\mathbf{H})^{i_1\dots i_k a}_{pqj_1\dots j_{m-1}},$$

that is, the new derivative index is contracted with the first covariant index inherited from $\mathbf{H}$.

Before proving the integration-by-parts formula, we recover several classical identities as special cases of Theorem 9.1.29. These examples will clarify the meaning of each contraction and each boundary term.

Example 9.1.30. (Classical integration-by-parts formulas as special cases of Theorem 9.1.29) We show how several classical integration-by-parts formulas arise as special cases of Theorem 9.1.29. In every part we take $s = 1$ and $k = l = 0$, so that

$$\mathbf{F} \in \Gamma_c(\mathbf{E}), \qquad \mathbf{G} \in \Gamma_c(T^*M \otimes \mathbf{E}).$$

When $\mathbf{E}$ is trivial of rank 1, we identify $\Gamma_c(\mathbf{E})$ with $C_c^\infty(M)$ and $\Gamma_c(T^*M \otimes \mathbf{E})$ with $\Gamma_c(T^*M)$.
Recall that, if $(M, \mathbf{g})$ is a Riemannian manifold, the musical isomorphism $\flat\colon T_xM \longrightarrow T_x^*M$ defined by $X^\flat = \mathbf{g}(\mathbf{X}, \cdot)$ is a linear isomorphism whose inverse is $\sharp\colon T_x^*M \longrightarrow T_xM$. Moreover, these isomorphisms preserve the inner product in the sense that, for $\alpha, \beta \in T_x^*M$ and $\mathbf{X}, Y \in T_xM$, we have

$$\langle \alpha, \beta \rangle_{\mathbf{g}} = \mathbf{g}(\alpha^\sharp, \beta^\sharp), \qquad \mathbf{g}(\mathbf{X}, Y) = \langle X^\flat, Y^\flat \rangle_{\mathbf{g}}.$$

If $\mathbf{E}$ is a vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$, recall that the inner product induced on $T^*M \otimes \mathbf{E}$ by $\mathbf{g}$ and $\mathbf{h}_{\mathbf{E}}$ is denoted by $\langle \cdot, \cdot \rangle_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}}$.
For simple tensor fields it is defined by

$$\langle \alpha \otimes s, \beta \otimes t \rangle_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}} = \langle \alpha, \beta \rangle_{\mathbf{g}} \, \mathbf{h}_{\mathbf{E}}(s, t).$$

When $\mathbf{E} = M \times \mathbb{R}$ is trivial of rank 1 with the usual metric $\mathbf{h}_{\mathbf{E}}(a, b) = ab$, there is a canonical identification

$$T^*M \otimes \mathbf{E} \cong T^*M, \qquad \alpha \otimes a \longleftrightarrow a\,\alpha.$$

Under this identification we have

$$\langle \alpha \otimes a, \beta \otimes b \rangle_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}} = ab \, \langle \alpha, \beta \rangle_{\mathbf{g}} = \langle a\alpha, b\beta \rangle_{\mathbf{g}},$$

so the induced product $\langle \cdot, \cdot \rangle_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}}$ agrees with the usual Riemannian inner product on T^*M. Consequently, when $\mathbf{E}$ is trivial of rank 1, we omit the distinction between the two metrics.

a) Let $\Omega \subset \mathbb{R}^n$ be a bounded open subset with smooth boundary. We consider $M = \overline{\Omega}$ with the Euclidean metric

$$\overline{\mathbf{g}} = \sum_{i=1}^{n} \mathbf{d}x^i \otimes \mathbf{d}x^i, \qquad (\overline{g}_{ij}) = \delta_{ij}, \quad (\overline{g}^{ij}) = \delta^{ij}.$$

We take the trivial bundle $\mathbf{E} = M \times \mathbb{R}$ with the usual bundle metric $\mathbf{h}_{\mathbf{E}}(a, b) = ab$ and the flat connection induced by the Euclidean Levi–Civita connection.

We apply Theorem 9.1.29. The corresponding identity is

$$\int_M \langle \nabla \mathbf{F}, \mathbf{G} \rangle_{\overline{\mathbf{g}}, \mathbf{h}_{\mathbf{E}}} \, d\lambda_n = -\int_M \langle \mathbf{F}, (\mathrm{tr}_{\overline{\mathbf{g}}} \circ \nabla)\mathbf{G} \rangle_{\mathbf{h}_{\mathbf{E}}} \, d\lambda_n + \int_{\partial M} \langle \mathbf{F}, \iota_{\boldsymbol{\nu}} \mathbf{G} \rangle_{\mathbf{h}_{\mathbf{E}}} \, dS.$$

Since $\mathbf{E}$ is trivial of rank 1, this identity reduces to

$$\int_M \langle \nabla \mathbf{F}, \mathbf{G} \rangle_{\overline{\mathbf{g}}} \, d\lambda_n = -\int_M \mathbf{F} \, (\mathrm{tr}_{\overline{\mathbf{g}}} \circ \nabla) \mathbf{G} \, d\lambda_n + \int_{\partial M} \mathbf{F} \, \iota_{\boldsymbol{\nu}} \mathbf{G} \, dS.$$

We take $u, v \in C^\infty(M)$ and choose

$$\mathbf{F} = u, \qquad \mathbf{G} = \nabla v.$$

In general, for a smooth function v on a Riemannian manifold, the covariant derivative agrees with the differential:

$$\nabla v = dv = (\partial_i v) \, \mathbf{d}x^i.$$

Thus, in Cartesian coordinates,

$$(\nabla v)_i = \partial_i v.$$

Moreover,

$$\langle \nabla u, \nabla v \rangle_{\overline{\mathbf{g}}} = \overline{g}^{ij} (\partial_i u)(\partial_j v) = \sum_{i=1}^{n} (\partial_i u)(\partial_i v).$$

The general expression for the covariant derivative of a 1-form is

$$(\nabla H)_{ij} = \partial_i H_j - \Gamma_{ij}^k H_k.$$

Applying this to $H = \nabla v$ gives

$$(\nabla(\nabla v))_{ij} = \partial_i \partial_j v - \Gamma_{ij}^k \partial_k v.$$

Since the Euclidean Levi–Civita connection satisfies $\Gamma_{ij}^k = 0$, we obtain

$$(\mathrm{tr}_{\overline{\mathbf{g}}} \circ \nabla)(\nabla v) = \delta^{ij} \partial_i \partial_j v = \Delta v.$$

Moreover,

$$\iota_{\boldsymbol{\nu}} (\nabla v) = \partial_{\boldsymbol{\nu}} v.$$

Therefore,

$$\int_\Omega \nabla u \cdot \nabla v \, d\lambda_n = -\int_\Omega u \, \Delta v \, d\lambda_n + \int_{\partial\Omega} u \, \partial_{\boldsymbol{\nu}} v \, dS.$$

b) Under the preceding hypotheses, subtracting the identities obtained for (u, v) and (v, u) gives

$$\int_\Omega \left(u \, \Delta v - v \, \Delta u \right) d\lambda_n = \int_{\partial\Omega} \left(u \, \partial_{\boldsymbol{\nu}} v - v \, \partial_{\boldsymbol{\nu}} u \right) dS,$$

which is known as Green's second identity.

c) Now let $(M, \mathbf{g})$ be a Riemannian manifold with boundary. Again take $\mathbf{E} = M \times \mathbb{R}$. For $u, v \in C_c^\infty(M)$, take $\mathbf{F} = u$ and $\mathbf{G} = \nabla v$, with ∇ the Levi-Civita connection.

The abstract identity is

$$\int_M \langle \nabla u, \nabla v \rangle_{\mathbf{g}, \mathbf{h}_\mathbf{E}} \, d\lambda_{\mathbf{g}} = -\int_M \langle u, (\mathrm{tr}_{\mathbf{g}} \circ \nabla)(\nabla v) \rangle_{\mathbf{h}_\mathbf{E}} \, d\lambda_{\mathbf{g}} + \int_{\partial M} \langle u, \iota_{\boldsymbol{\nu}} (\nabla v) \rangle_{\mathbf{h}_\mathbf{E}} \, d\lambda_{\widetilde{\mathbf{g}}}.$$

Since $\mathbf{E}$ is trivial of rank 1, it reduces to

$$\int_M \langle \nabla u, \nabla v \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} = -\int_M u \, (\mathrm{tr}_{\mathbf{g}} \circ \nabla)(\nabla v) \, d\lambda_{\mathbf{g}} + \int_{\partial M} u \, \iota_{\boldsymbol{\nu}}(\nabla v) \, d\lambda_{\tilde{\mathbf{g}}}.$$

In local coordinates,

$$(\nabla v)_j = \partial_j v, \qquad (\nabla(\nabla v))_{ij} = \partial_i \partial_j v - \Gamma_{ij}^k \partial_k v.$$

Therefore,

$$(\mathrm{tr}_{\mathbf{g}} \circ \nabla)(\nabla v) = g^{ij} \left(\partial_i \partial_j v - \Gamma_{ij}^k \partial_k v \right).$$

Let us verify that this expression agrees with the coordinate expression for the Laplace–Beltrami Laplacian,

$$\Delta_{\mathbf{g}} v = \frac{1}{\sqrt{\det(\mathbf{g})}} \, \partial_i \left(\sqrt{\det(\mathbf{g})} \, g^{ij} \partial_j v \right).$$

By the definition of the metric trace,

$$(\mathrm{tr}_{\mathbf{g}} \circ \nabla)(\nabla v) = g^{ij} (\nabla(\nabla v))_{ij},$$

and since $(\nabla v)_j = \partial_j v$, we have

$$(\nabla(\nabla v))_{ij} = \partial_i \partial_j v - \Gamma_{ij}^k \partial_k v.$$

Therefore,

$$(\mathrm{tr}_{\mathbf{g}} \circ \nabla)(\nabla v) = g^{ij} \partial_i \partial_j v - g^{ij} \Gamma_{ij}^k \partial_k v. \tag{9.6}$$

On the other hand,

$$\Delta_{\mathbf{g}} v = \frac{1}{\sqrt{\det(\mathbf{g})}} \, \partial_i \big(\sqrt{\det(\mathbf{g})} \, g^{ij} \partial_j v \big).$$

Applying the Leibniz rule,

$$\Delta_{\mathbf{g}} v = \frac{1}{\sqrt{\det(\mathbf{g})}} \Big(\partial_i \big(\sqrt{\det(\mathbf{g})} \, g^{ij} \big) \, \partial_j v + \sqrt{\det(\mathbf{g})} \, g^{ij} \partial_i \partial_j v \Big)$$

$$= g^{ij} \partial_i \partial_j v + \frac{1}{\sqrt{\det(\mathbf{g})}} \, \partial_i \big(\sqrt{\det(\mathbf{g})} \, g^{ij} \big) \, \partial_j v.$$

We now expand the remaining term using the Leibniz rule once more:

$$\partial_i \left(\sqrt{\det(\mathbf{g})} \, g^{ij} \right) = \left(\partial_i \sqrt{\det(\mathbf{g})} \right) g^{ij} + \sqrt{\det(\mathbf{g})} \, \partial_i g^{ij}.$$

Dividing by $\sqrt{\det(\mathbf{g})}$ gives

$$\frac{1}{\sqrt{\det(\mathbf{g})}} \partial_i \left(\sqrt{\det(\mathbf{g})} \, g^{ij} \right) = g^{ij} \frac{\partial_i \sqrt{\det(\mathbf{g})}}{\sqrt{\det(\mathbf{g})}} + \partial_i g^{ij}.$$

By Remark 2.14.7,

$$\frac{\partial_i \sqrt{\det(\mathbf{g})}}{\sqrt{\det(\mathbf{g})}} = \Gamma_{ik}^k,$$

and, by compatibility of the connection with the metric (see 2.4.17),

$$\partial_i g^{ij} + \Gamma^k_{ik} g^{ij} = -g^{ik}\Gamma^j_{ik},$$

we conclude that

$$\frac{1}{\sqrt{\det(\mathbf{g})}}\partial_i\left(\sqrt{\det(\mathbf{g})}\, g^{ij}\right) = -g^{ik}\Gamma^j_{ik}.$$

Substitution into the expression for $\Delta_{\mathbf{g}} v$ yields

$$\Delta_{\mathbf{g}} v = g^{ij}\partial_i\partial_j v - g^{ik}\Gamma^j_{ik}\partial_j v.$$

Renaming the dummy index $j \mapsto k$ gives

$$\Delta_{\mathbf{g}} v = g^{ij}\partial_i\partial_j v - g^{ij}\Gamma^k_{ij}\partial_k v,$$

which agrees with (9.6). Therefore,

$$(\mathrm{tr}_{\mathbf{g}} \circ \nabla)(\nabla v) = \Delta_{\mathbf{g}} v.$$

Moreover,

$$\langle \nabla u, \nabla v\rangle_{\mathbf{g}} = g^{ij}(\partial_i u)(\partial_j v) = \mathbf{g}(\mathrm{grad}_{\mathbf{g}}\, u, \mathrm{grad}_{\mathbf{g}}\, v).$$

Finally,

$$\iota_{\boldsymbol{\nu}}(\nabla v) = \nu^j \partial_j v = \mathbf{g}(\mathrm{grad}_{\mathbf{g}}\, v, \boldsymbol{\nu}) = \partial_{\boldsymbol{\nu}} v.$$

Substituting into the theorem gives

$$\int_M \mathbf{g}(\mathrm{grad}_{\mathbf{g}}\, u, \mathrm{grad}_{\mathbf{g}}\, v)\, d\lambda_{\mathbf{g}} = -\int_M u\, \Delta_{\mathbf{g}} v\, d\lambda_{\mathbf{g}} + \int_{\partial M} u\, \partial_{\boldsymbol{\nu}} v\, d\lambda_{\tilde{\mathbf{g}}}.$$

d) Let $\mathbf{X} \in \Gamma_c(TM)$ and let $\boldsymbol{\alpha} = \mathbf{X}^\flat$. We apply Theorem 9.1.29 with $\mathbf{F} \equiv 1$ and $\mathbf{G} = \boldsymbol{\alpha}$. Since $\nabla(1) = 0$, we obtain

$$0 = -\int_M (\mathrm{tr}_{\mathbf{g}} \circ \nabla)\boldsymbol{\alpha}\, d\lambda_{\mathbf{g}} + \int_{\partial M} \iota_{\boldsymbol{\nu}}\boldsymbol{\alpha}\, d\lambda_{\tilde{\mathbf{g}}}.$$

In local coordinates we have $(\nabla\boldsymbol{\alpha})_{ij} = \partial_i\alpha_j - \Gamma^k_{ij}\alpha_k$, and hence

$$(\mathrm{tr}_{\mathbf{g}} \circ \nabla)\boldsymbol{\alpha} = g^{ij}(\partial_i\alpha_j - \Gamma^k_{ij}\alpha_k).$$

Writing $\alpha_j = g_{jk}X^k$ and applying the Leibniz rule,

$$\partial_i\alpha_j = \partial_i(g_{jk}X^k) = (\partial_i g_{jk})X^k + g_{jk}\partial_i X^k.$$

Substituting into the preceding expression gives

$$(\mathrm{tr}_{\mathbf{g}} \circ \nabla)\boldsymbol{\alpha} = g^{ij}(\partial_i g_{jk})X^k + g^{ij}g_{jk}\partial_i X^k - g^{ij}\Gamma^m_{ij}g_{mk}X^k.$$

Since $g^{ij}g_{jk} = \delta^i_k$, the second term is $\partial_i X^i$.

To simplify the remaining terms, we use Corollary 2.4.16, which in coordinates states that

$$\partial_i g_{jk} = \Gamma^s_{ij} g_{sk} + \Gamma^s_{ik} g_{js}.$$

Multiplying by g^{ij} gives

$$g^{ij}\partial_i g_{jk} = g^{ij}\Gamma^s_{ij} g_{sk} + g^{ij}\Gamma^s_{ik} g_{js}.$$

The second term satisfies $g^{ij}\Gamma^s_{ik} g_{js} = \Gamma^s_{ik}\delta^i_s = \Gamma^i_{ik}$, and therefore

$$g^{ij}(\partial_i g_{jk}) - g^{ij}\Gamma^s_{ij} g_{sk} = \Gamma^i_{ik}.$$

Substitution into the expression for $(\mathrm{tr}_{\mathbf{g}} \circ \nabla)\boldsymbol{\alpha}$ shows that

$$(\mathrm{tr}_{\mathbf{g}} \circ \nabla)\boldsymbol{\alpha} = \partial_i X^i + \Gamma^i_{ik} X^k = \mathrm{div}_{\mathbf{g}} \mathbf{X}.$$

On the other hand, $\iota_{\boldsymbol{\nu}}\boldsymbol{\alpha} = \boldsymbol{\alpha}(\boldsymbol{\nu}) = \mathbf{g}(\mathbf{X}, \boldsymbol{\nu})$. Substituting into the initial identity finally gives

$$\int_M \mathrm{div}_{\mathbf{g}} \mathbf{X}\, d\lambda_{\mathbf{g}} = \int_{\partial M} \mathbf{g}(\mathbf{X}, \boldsymbol{\nu})\, d\lambda_{\tilde{\mathbf{g}}}.$$

The preceding examples illustrate the structure that the general formula must preserve. We now turn to its proof.

Proof of Theorem 9.1.29. We proceed by induction on s. The general idea is to "transfer" derivatives from $\mathbf{F}$ to $\mathbf{G}$ by covariant integration by parts, keeping track of the boundary terms that arise at each step.

Case $s = 1$. Fix a point $p \in \mathrm{Int}(M)$ and choose normal coordinates centered at p, with associated coordinate frame $(\partial_1, \dots, \partial_n)$. In these coordinates,

$$g_{ij}(p) = \delta_{ij}, \qquad \Gamma^k_{ij}(p) = 0,$$

and, in particular, $\nabla_{\partial_i}\partial_j(p) = 0$ for all indices $i, j \in \{1, \dots, n\}$.
Now let $\mathbf{F} \in \Gamma_c\big(T^{(k,l)}(TM) \otimes \mathbf{E}\big)$ and $\mathbf{G} \in \Gamma_c\big(T^{(k,l+1)}(TM) \otimes \mathbf{E}\big)$. Define a map

$$\Phi \colon \mathfrak{X}(M) \longrightarrow C^\infty(M, \mathbb{K}), \qquad \Phi(\mathbf{Y}) := \big\langle \mathbf{F}, \iota_{\mathbf{Y}}\mathbf{G} \big\rangle_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}}.$$

The map $\mathbf{Y} \mapsto \iota_{\mathbf{Y}}\mathbf{G}$ is $C^\infty(M, \mathbb{R})$–linear in $\mathbf{Y}$, by the multilinearity of the tensor field $\mathbf{G}$ in its arguments. Consequently, Φ defines a smooth real 1–form if $\mathbf{E}$ is real and a smooth complex 1–form if $\mathbf{E}$ is complex. In the latter case, all the following arguments take place in the complexified bundles, and the divergence theorem is applied separately to the real and imaginary parts. Thus consider $\mathbf{X} := \Phi^\sharp$, which defines a smooth vector field, complexified in the complex case, characterized (according to Definition 2.1.10) by

$$\langle \mathbf{X}, \mathbf{Y} \rangle_{\mathbf{g}} = \Phi(\mathbf{Y}) = \big\langle \mathbf{F}, \iota_{\mathbf{Y}}\mathbf{G} \big\rangle_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}}, \qquad \forall\, \mathbf{Y} \in \mathfrak{X}(M).$$

In particular, for each $c \in \{1, \dots, n\}$,

$$\langle \mathbf{X}, \partial_c \rangle_{\mathbf{g}} = \big\langle \mathbf{F}, \iota_{\partial_c}\mathbf{G} \big\rangle_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}}. \tag{9.7}$$

At the point p, the divergence of $\mathbf{X}$ is expressed as

$$\operatorname{div}_{\mathbf{g}} \mathbf{X}(p) = \sum_{c=1}^{n} \left\langle \nabla_{\partial_c} \mathbf{X}, \partial_c \right\rangle_{\mathbf{g}}(p).$$

Compatibility of ∇ with $\mathbf{g}$ tells us that

$$\left\langle \nabla_{\partial_c} \mathbf{X}, \partial_c \right\rangle_{\mathbf{g}} = \partial_c \left(\langle \mathbf{X}, \partial_c \rangle_{\mathbf{g}} \right) - \left\langle \mathbf{X}, \nabla_{\partial_c} \partial_c \right\rangle_{\mathbf{g}}.$$

Evaluating at p and using $\nabla_{\partial_c} \partial_c(p) = 0$ (since $\Gamma_{cc}^{k}(p) = 0$), we find that

$$\operatorname{div}_{\mathbf{g}} \mathbf{X}(p) = \sum_{c=1}^{n} \partial_c \left(\langle \mathbf{X}, \partial_c \rangle_{\mathbf{g}} \right)(p). \tag{9.8}$$

Substituting (9.7) into (9.8) gives

$$\operatorname{div}_{\mathbf{g}} \mathbf{X}(p) = \sum_{c=1}^{n} \partial_c \left(\left\langle \mathbf{F}, \iota_{\partial_c} \mathbf{G} \right\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}} \right)(p). \tag{9.9}$$

The induced connection on $T^{(k,l)}(TM) \otimes \mathbf{E}$ (which we continue to denote by ∇) is compatible with the inner product $\langle \cdot, \cdot \rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}$. Consequently, for each c,

$$\partial_c \left(\left\langle \mathbf{F}, \iota_{\partial_c} \mathbf{G} \right\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}} \right) = \left\langle \nabla_{\partial_c} \mathbf{F}, \iota_{\partial_c} \mathbf{G} \right\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}} + \left\langle \mathbf{F}, \nabla_{\partial_c} \left(\iota_{\partial_c} \mathbf{G} \right) \right\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}. \tag{9.10}$$

Evaluating (9.10) at p and substituting into (9.9) gives

$$\operatorname{div}_{\mathbf{g}} \mathbf{X}(p) = \sum_{c=1}^{n} \left(\left\langle \nabla_{\partial_c} \mathbf{F}, \iota_{\partial_c} \mathbf{G} \right\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}(p) + \left\langle \mathbf{F}, \nabla_{\partial_c} \left(\iota_{\partial_c} \mathbf{G} \right) \right\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}(p) \right). \tag{9.11}$$

For the second term we use the identity (the Leibniz rule for contraction)

$$\nabla_{\partial_c} \left(\iota_{\partial_c} \mathbf{G} \right) = \iota_{\partial_c} \left(\nabla_{\partial_c} \mathbf{G} \right) + \iota_{\nabla_{\partial_c} \partial_c} \mathbf{G},$$

which follows from Proposition 2.4.23. Evaluating at p and using $\nabla_{\partial_c} \partial_c(p) = 0$ gives

$$\nabla_{\partial_c} \left(\iota_{\partial_c} \mathbf{G} \right)(p) = \iota_{\partial_c} \left(\nabla_{\partial_c} \mathbf{G} \right)(p).$$

Substituting this into (9.11) yields

$$\operatorname{div}_{\mathbf{g}} \mathbf{X}(p) = \sum_{c=1}^{n} \left(\left\langle \nabla_{\partial_c} \mathbf{F}, \iota_{\partial_c} \mathbf{G} \right\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}(p) + \left\langle \mathbf{F}, \iota_{\partial_c} (\nabla_{\partial_c} \mathbf{G}) \right\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}(p) \right). \tag{9.12}$$

In the chosen normal coordinates we have

$$\nabla \mathbf{F} = \sum_{c=1}^{n} \mathbf{d}x^c \otimes \nabla_{\partial_c} \mathbf{F}, \qquad \iota_{\partial_c} \mathbf{G} = \mathbf{G}(\partial_c, \cdot),$$

because the derivative index and the inserted index both occupy the first position. The definition of the tensor product metric then implies

$$\sum_{c=1}^{n} \big\langle \nabla_{\partial_c} \mathbf{F}, \iota_{\partial_c} \mathbf{G} \big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} = \langle \nabla \mathbf{F}, \mathbf{G} \rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \quad \text{en } p.$$

Likewise,

$$\operatorname{tr}_\mathbf{g}(\nabla \mathbf{G}) = \sum_{c=1}^{n} (\nabla_{\partial_c} \mathbf{G})(\partial_c, \cdot) = \sum_{c=1}^{n} \iota_{\partial_c} (\nabla_{\partial_c} \mathbf{G}) \quad \text{en } p,$$

and the second sum in (9.12) is $\langle \mathbf{F}, \operatorname{tr}_\mathbf{g}(\nabla \mathbf{G}) \rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}(p)$.

Combining the two identifications gives

$$\operatorname{div}_\mathbf{g} \mathbf{X}(p) = \big\langle \nabla \mathbf{F}, \mathbf{G} \big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}(p) + \big\langle \mathbf{F}, \operatorname{tr}_\mathbf{g}(\nabla \mathbf{G}) \big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}(p).$$

Since $p \in \operatorname{Int}(M)$ is arbitrary, the pointwise identity holds on $\operatorname{Int}(M)$. Both sides are smooth functions up to the boundary, and $\operatorname{Int}(M)$ is dense in M; by continuity, the identity also holds on ∂M. It therefore holds throughout M:

$$\operatorname{div}_\mathbf{g} \mathbf{X} = \langle \nabla \mathbf{F}, \mathbf{G} \rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} + \langle \mathbf{F}, \operatorname{tr}_\mathbf{g}(\nabla \mathbf{G}) \rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}.$$

Integrating over M and applying Theorem 2.14.21 (the divergence theorem) gives

$$\int_M \operatorname{div}_\mathbf{g} \mathbf{X} \, d\lambda_\mathbf{g} = \int_{\partial M} \langle \mathbf{X}, \boldsymbol{\nu} \rangle_\mathbf{g} \, d\lambda_{\tilde{\mathbf{g}}}.$$

The field $\mathbf{X}$ has compact support, since it vanishes wherever $\mathbf{F}$ or $\mathbf{G}$ vanishes; thus the divergence theorem also applies when M is noncompact. If $\partial M = \varnothing$, the right-hand side is zero by the convention in the statement. On the boundary, by the definition of $\mathbf{X}$ (and of Φ),

$$\langle \mathbf{X}, \boldsymbol{\nu} \rangle_\mathbf{g} = (\mathbf{X}^\flat)(\boldsymbol{\nu}) = \Phi(\boldsymbol{\nu}) = \big\langle \mathbf{F}, \iota_{\boldsymbol{\nu}} \mathbf{G} \big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}.$$

Combining this with the preceding pointwise identity gives

$$\int_M \big\langle \nabla \mathbf{F}, \mathbf{G} \big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} = -\int_M \big\langle \mathbf{F}, \operatorname{tr}_\mathbf{g}(\nabla \mathbf{G}) \big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} + \int_{\partial M} \big\langle \mathbf{F}, \iota_{\boldsymbol{\nu}} \mathbf{G} \big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_{\tilde{\mathbf{g}}}.$$

This proves the case $s = 1$.

We now verify the induction step. Suppose that the identity in the statement holds for some integer $s \geq 1$, that is, for every

$$\mathbf{F} \in \Gamma_c\big(T^{(k,l)}(TM) \otimes \mathbf{E}\big), \quad \mathbf{H} \in \Gamma_c\big(T^{(k,l+s)}(TM) \otimes \mathbf{E}\big),$$

we have

$$\int_M \langle \nabla^s \mathbf{F}, \mathbf{H} \rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} = (-1)^s \int_M \big\langle \mathbf{F}, (\operatorname{tr}_\mathbf{g} \circ \nabla)^s \mathbf{H} \big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g}$$
$$+ \sum_{j=0}^{s-1} (-1)^{s-1-j} \int_{\partial M} \Big\langle \nabla^j \mathbf{F}, \iota_{\boldsymbol{\nu}} \big((\operatorname{tr}_\mathbf{g} \circ \nabla)^{s-1-j} \mathbf{H} \big) \Big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_{\tilde{\mathbf{g}}}.$$

Our goal is to show that the same identity holds for $s+1$. Thus let

$$\mathbf{G} \in \Gamma_c\big(T^{(k,l+s+1)}(TM) \otimes \mathbf{E}\big).$$

We apply the case $s = 1$ to the pair of fields $\nabla^s \mathbf{F}$ and $\mathbf{G}$. This gives

$$\int_M \langle \nabla^{s+1}\mathbf{F}, \mathbf{G}\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g} = -\int_M \big\langle \nabla^s \mathbf{F}, \mathrm{tr}_\mathbf{g}(\nabla \mathbf{G})\big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g} + \int_{\partial M} \big\langle \nabla^s \mathbf{F},\, \iota_{\boldsymbol{\nu}} \mathbf{G}\big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_{\tilde{\mathbf{g}}}.$$

Now define

$$\mathbf{H} := \mathrm{tr}_\mathbf{g}(\nabla \mathbf{G}) \in \Gamma_c\big(T^{(k,l+s)}(TM) \otimes \mathbf{E}\big).$$

Applying the induction hypothesis to the pair $(\mathbf{F}, \mathbf{H})$ gives

$$\int_M \langle \nabla^s \mathbf{F}, \mathbf{H}\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g} = (-1)^s \int_M \big\langle \mathbf{F}, (\mathrm{tr}_\mathbf{g} \circ \nabla)^s \mathbf{H}\big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g}$$

$$+ \sum_{j=0}^{s-1} (-1)^{s-1-j} \int_{\partial M} \Big\langle \nabla^j \mathbf{F},\, \iota_{\boldsymbol{\nu}} \big((\mathrm{tr}_\mathbf{g} \circ \nabla)^{s-1-j} \mathbf{H}\big)\Big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_{\tilde{\mathbf{g}}}.$$

Since $\mathbf{H} = \mathrm{tr}_\mathbf{g}(\nabla \mathbf{G})$, we have

$$(\mathrm{tr}_\mathbf{g} \circ \nabla)^s \mathbf{H} = (\mathrm{tr}_\mathbf{g} \circ \nabla)^{s+1} \mathbf{G}, \qquad (\mathrm{tr}_\mathbf{g} \circ \nabla)^{s-1-j} \mathbf{H} = (\mathrm{tr}_\mathbf{g} \circ \nabla)^{s-j} \mathbf{G},$$

and therefore

$$\int_M \big\langle \nabla^s \mathbf{F}, \mathrm{tr}_\mathbf{g}(\nabla \mathbf{G})\big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g} = (-1)^s \int_M \big\langle \mathbf{F}, (\mathrm{tr}_\mathbf{g} \circ \nabla)^{s+1} \mathbf{G}\big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g}$$

$$+ \sum_{j=0}^{s-1} (-1)^{s-1-j} \int_{\partial M} \Big\langle \nabla^j \mathbf{F},\, \iota_{\boldsymbol{\nu}} \big((\mathrm{tr}_\mathbf{g} \circ \nabla)^{s-j} \mathbf{G}\big)\Big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_{\tilde{\mathbf{g}}}.$$

Substituting this identity into the expression for $\displaystyle\int_M \langle \nabla^{s+1}\mathbf{F}, \mathbf{G}\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g}$ gives

$$\int_M \langle \nabla^{s+1}\mathbf{F}, \mathbf{G}\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g} = (-1)^{s+1} \int_M \big\langle \mathbf{F}, (\mathrm{tr}_\mathbf{g} \circ \nabla)^{s+1} \mathbf{G}\big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g}$$

$$+ \sum_{j=0}^{s-1} (-1)^{s-j} \int_{\partial M} \Big\langle \nabla^j \mathbf{F},\, \iota_{\boldsymbol{\nu}} \big((\mathrm{tr}_\mathbf{g} \circ \nabla)^{s-j} \mathbf{G}\big)\Big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_{\tilde{\mathbf{g}}} + \int_{\partial M} \big\langle \nabla^s \mathbf{F},\, \iota_{\boldsymbol{\nu}} \mathbf{G}\big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_{\tilde{\mathbf{g}}}.$$

The last boundary term already has the desired form if we interpret $(\mathrm{tr}_\mathbf{g} \circ \nabla)^0$ as the identity:

$$\int_{\partial M} \big\langle \nabla^s \mathbf{F},\, \iota_{\boldsymbol{\nu}} \mathbf{G}\big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_{\tilde{\mathbf{g}}} = (-1)^{s-s} \int_{\partial M} \Big\langle \nabla^s \mathbf{F},\, \iota_{\boldsymbol{\nu}} \big((\mathrm{tr}_\mathbf{g} \circ \nabla)^{s-s} \mathbf{G}\big)\Big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_{\tilde{\mathbf{g}}}.$$

We can therefore incorporate this term into the preceding sum by taking $j = s$, obtaining

$$\int_M \langle \nabla^{s+1}\mathbf{F}, \mathbf{G}\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g} = (-1)^{s+1} \int_M \big\langle \mathbf{F}, (\mathrm{tr}_\mathbf{g} \circ \nabla)^{s+1} \mathbf{G}\big\rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g}$$

$$+\sum_{j=0}^{s}(-1)^{s-j}\int_{\partial M}\left\langle \nabla^{j}\mathbf{F},\, \iota_{\boldsymbol{\nu}}\big((\mathrm{tr}_{\mathbf{g}}\circ\nabla)^{s-j}\mathbf{G}\big)\right\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}} d\lambda_{\tilde{\mathbf{g}}},$$

which is precisely the formula in the statement for $s+1$. The result then follows by induction on s. □

As a corollary, we can extend the usual Green's formula to the Bochner Laplacian:

Corollary 9.1.31. (Green's formula for the Bochner Laplacian) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\pi_{\mathbf{E}}\colon \mathbf{E}\longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. Let $\boldsymbol{\nu}$ be the outward unit normal to ∂M.
Then, for any $\mathbf{u},\mathbf{v}\in\Gamma_c(\mathbf{E})$, we have

$$\int_M \langle\nabla^{\mathbf{E}}\mathbf{u},\nabla^{\mathbf{E}}\mathbf{v}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}} = \int_M \langle\mathbf{u},\Delta_B\mathbf{v}\rangle_{\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}} + \int_{\partial M}\left\langle \mathbf{u},\nabla^{\mathbf{E}}_{\boldsymbol{\nu}}\mathbf{v}\right\rangle_{\mathbf{h}_{\mathbf{E}}} d\lambda_{\tilde{\mathbf{g}}},$$

where, by definition,

$$\Delta_B := (\nabla^{\mathbf{E}})^{*}_{h}\nabla^{\mathbf{E}}.$$

When $\partial M\neq\varnothing$, we use the formal differential adjoint up to the boundary from Remark 8.2.4; no domain for L^2 with boundary conditions has yet been chosen.

Proof. We apply Theorem 9.1.29 with $s=1$ and $k=l=0$, taking

$$\mathbf{F}=\mathbf{u}\in\Gamma_c(\mathbf{E}),\qquad \mathbf{G}=\nabla^{\mathbf{E}}\mathbf{v}\in\Gamma_c(T^{*}M\otimes\mathbf{E}).$$

The identity in the theorem takes the form

$$\int_M \langle\nabla^{\mathbf{E}}\mathbf{u},\nabla^{\mathbf{E}}\mathbf{v}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}} = -\int_M \left\langle \mathbf{u},(\mathrm{tr}_{\mathbf{g}}\circ\nabla)(\nabla^{\mathbf{E}}\mathbf{v})\right\rangle_{\mathbf{h}_{\mathbf{E}}} d\lambda_{\mathbf{g}} + \int_{\partial M}\left\langle \mathbf{u},\,\iota_{\boldsymbol{\nu}}(\nabla^{\mathbf{E}}\mathbf{v})\right\rangle_{\mathbf{h}_{\mathbf{E}}} d\lambda_{\tilde{\mathbf{g}}}.$$

By the convention adopted in the definition of the Bochner Laplacian,

$$\Delta_B = -(\mathrm{tr}_{\mathbf{g}}\circ\nabla)\circ\nabla^{\mathbf{E}},$$

and the interior term can therefore be rewritten as

$$-\left\langle \mathbf{u},(\mathrm{tr}_{\mathbf{g}}\circ\nabla)(\nabla^{\mathbf{E}}\mathbf{v})\right\rangle_{\mathbf{h}_{\mathbf{E}}} = \langle\mathbf{u},\Delta_B\mathbf{v}\rangle_{\mathbf{h}_{\mathbf{E}}}.$$

It remains only to identify the boundary term. In local coordinates $(x^1,\dots,x^n)$ we write $\boldsymbol{\nu}=\nu^i\partial_i$. By the definition of interior multiplication $\iota_{\boldsymbol{\nu}}$ in the first covariant index, $\iota_{\boldsymbol{\nu}}(\nabla^{\mathbf{E}}\mathbf{v})=\nu^i(\nabla^{\mathbf{E}}\mathbf{v})_i$. Moreover, $(\nabla^{\mathbf{E}}\mathbf{v})_i=\nabla^{\mathbf{E}}_{\partial_i}\mathbf{v}$. Substitution gives $\iota_{\boldsymbol{\nu}}(\nabla^{\mathbf{E}}\mathbf{v})=\nu^i\nabla^{\mathbf{E}}_{\partial_i}\mathbf{v}$. Finally, using the $C^\infty(M)$-linearity of the connection in the vector field,

$$\nabla^{\mathbf{E}}_{\boldsymbol{\nu}}\mathbf{v}=\nabla^{\mathbf{E}}_{\nu^i\partial_i}\mathbf{v}=\nu^i\nabla^{\mathbf{E}}_{\partial_i}\mathbf{v},$$

we conclude that $\iota_{\boldsymbol{\nu}}(\nabla^{\mathbf{E}}\mathbf{v})=\nabla^{\mathbf{E}}_{\boldsymbol{\nu}}\mathbf{v}$. Substituting into the preceding formula gives the stated identity. □

The following result is another corollary of this integration-by-parts formula:

Corollary 9.1.32. (Local expression for the formal adjoint of ∇^s) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a vector bundle with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. For $s\geq 1$, the formal adjoint of

$$\nabla^s\colon \Gamma(\mathbf{E})\longrightarrow \Gamma\big(T^{(0,s)}(TM)\otimes\mathbf{E}\big)$$

is given by

$$(\nabla^s)^* = (-1)^s(\mathrm{tr}_{\mathbf{g}}\circ\nabla)^s.$$

Moreover, in a chart $(U,x^1,\dots,x^n)$, if $\mathbf{G}\in\Gamma\big(T^{(0,s)}(TM)\otimes\mathbf{E}\big)$ has components $G^a_{j_1\dots j_s}$, then

$$\big((\nabla^s)^*\mathbf{G}\big)^a = (-1)^s\left[\frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_{i_1}\cdots\partial_{i_s}\Big(\sqrt{\det(\mathbf{g})}\,g^{i_1j_1}\cdots g^{i_sj_s}\,G^a_{j_1\dots j_s}\Big)+\sum_{b=1}^{r}\sum_{|\beta|\leq s-1}\big(C_\beta\big)_b^{\,a\,j_1\dots j_s}\,\partial^\beta\big(G^b_{j_1\dots j_s}\big)\right], \tag{9.13}$$

where the coefficients $\big(C_\beta\big)_b^{\,a\,j_1\dots j_s}$ are smooth functions on U that depend only on g_{ij}, the connection coefficients Γ^k_{ij} and $(A_i)^a_b$, and their partial derivatives of orders up to $s-1$.

Proof. Since M has no boundary, the boundary terms in Theorem 9.1.29 vanish, and therefore

$$\int_M\langle\nabla^s\mathbf{F},\mathbf{G}\rangle_{\mathbf{g},\mathbf{h_E}}\,d\lambda_{\mathbf{g}} = (-1)^s\int_M\big\langle\mathbf{F},(\mathrm{tr}_{\mathbf{g}}\circ\nabla)^s\mathbf{G}\big\rangle_{\mathbf{g},\mathbf{h_E}}\,d\lambda_{\mathbf{g}},\qquad\forall\,\mathbf{F}\in\Gamma_c(\mathbf{E}),\ \forall\,\mathbf{G}\in\Gamma_c\big(T^{(0,s)}(TM)\otimes\mathbf{E}\big).$$

By Corollary 8.2.3 (existence and uniqueness of the formal adjoint),

$$(\nabla^s)^* = (-1)^s(\mathrm{tr}_{\mathbf{g}}\circ\nabla)^s.$$

It remains to verify the local formula (9.13). Fix a chart $(U,x^1,\dots,x^n)$ and a local frame $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ of $\mathbf{E}\restriction_U$. Let $m\geq 0$ and $\mathbf{H}\in\Gamma\big(T^{(0,m+1)}(TM)\otimes\mathbf{E}\big)$ with components $H^a_{qj_1\dots j_m}$. By definition,

$$\big((\mathrm{tr}_{\mathbf{g}}\circ\nabla)\mathbf{H}\big)^a_{j_1\dots j_m} = g^{pq}\,(\nabla_{\partial_p}\mathbf{H})^a_{qj_1\dots j_m}.$$

Applying Lemma 9.1.27 (with $k=0$, $l=m+1$) gives

$$\begin{aligned}\big((\mathrm{tr}_{\mathbf{g}}\circ\nabla)\mathbf{H}\big)^a_{j_1\dots j_m} &= g^{pq}\partial_p\big(H^a_{qj_1\dots j_m}\big)-\Gamma^\alpha_{pq}\,g^{pq}\,H^a_{\alpha j_1\dots j_m}\\ &\quad-\sum_{\ell=1}^{m}\Gamma^\alpha_{pj_\ell}\,g^{pq}\,H^a_{qj_1\dots j_{\ell-1}\alpha j_{\ell+1}\dots j_m}+\sum_{b=1}^{r}(A_p)^a_b\,g^{pq}H^b_{qj_1\dots j_m}.\end{aligned} \tag{9.14}$$

Using Remark 2.14.7, which tells us that $\Gamma^\alpha_{\alpha p}=\dfrac{1}{\sqrt{\det(\mathbf{g})}}\partial_p\Big(\sqrt{\det(\mathbf{g})}\Big)$ and the identity in Corollary 2.4.17, which can be written as $\partial_p(g^{pq})=-\Gamma^p_{p\alpha}g^{\alpha q}-\Gamma^q_{p\alpha}g^{p\alpha}$, we obtain the equality

$$g^{pq}\partial_p\big(Y_q\big)-\Gamma^\alpha_{pq}g^{pq}Y_\alpha=\frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_p\Big(\sqrt{\det(\mathbf{g})}\,g^{pq}Y_q\Big),\qquad\forall(Y_q)_{q=1}^n. \tag{9.15}$$

To verify it, we expand the right-hand side:

$$\frac{1}{\sqrt{\det(\mathbf{g})}}\partial_p\left(\sqrt{\det(\mathbf{g})}g^{pq}Y_q\right) = \frac{1}{\sqrt{\det(\mathbf{g})}}\left(\partial_p\left(\sqrt{\det(\mathbf{g})}\right)g^{pq}Y_q + \cancel{\sqrt{\det(\mathbf{g})}}\partial_p(g^{pq})Y_q + \cancel{\sqrt{\det(\mathbf{g})}}g^{pq}\partial_p(Y_q)\right)$$

$$= \Gamma^{\alpha}_{\alpha p}g^{pq}Y_q + \partial_p(g^{pq})Y_q + g^{pq}\partial_p(Y_q)$$

$$= \underbrace{\Gamma^{p}_{p\alpha}g^{\alpha q}Y_q}_{p\leftrightarrow\alpha} - \Gamma^{p}_{p\alpha}g^{\alpha q}Y_q - \Gamma^{q}_{p\alpha}g^{p\alpha}Y_q + g^{pq}\partial_p(Y_q)$$

$$= g^{pq}\partial_p(Y_q) - \underbrace{\Gamma^{q}_{p\alpha}g^{p\alpha}Y_q}_{\alpha\leftrightarrow q}$$

$$= g^{pq}\partial_p(Y_q) - \Gamma^{\alpha}_{pq}g^{pq}Y_\alpha.$$

Applying (9.15) with $Y_q = H^a_{qj_1\dots j_m}$, we can rewrite equation (9.14) as

$$((\mathrm{tr}_{\mathbf{g}}\circ\nabla)\mathbf{H})^a_{j_1\dots j_m} = \frac{1}{\sqrt{\det(\mathbf{g})}}\partial_p\left(\sqrt{\det(\mathbf{g})}g^{pq}H^a_{qj_1\dots j_m}\right) - \sum_{\ell=1}^{m}\Gamma^{\alpha}_{pj_\ell}g^{pq}H^a_{qj_1\dots j_{\ell-1}\alpha j_{\ell+1}\dots j_m} + \sum_{b=1}^{r}(A_p)^a_b g^{pq}H^b_{qj_1\dots j_m}. \tag{9.16}$$

We prove by induction on $s\geq 1$ that, for every $\mathbf{G}\in\Gamma\left(T^{(0,s)}(TM)\otimes\mathbf{E}\right)$ with components $G^a_{j_1\dots j_s}$, we have

$$\left((\mathrm{tr}_{\mathbf{g}}\circ\nabla)^s\mathbf{G}\right)^a = \frac{1}{\sqrt{\det(\mathbf{g})}}\partial_{i_1}\cdots\partial_{i_s}\left(\sqrt{\det(\mathbf{g})}g^{i_1j_1}\cdots g^{i_sj_s}G^a_{j_1\dots j_s}\right) + \sum_{b=1}^{r}\sum_{|\beta|\leq s-1}\left(C_\beta\right)^{aj_1\dots j_s}_b\partial^\beta\left(G^b_{j_1\dots j_s}\right). \tag{9.17}$$

For $s=1$, taking $m=0$ in (9.16) gives

$$((\mathrm{tr}_{\mathbf{g}}\circ\nabla)\mathbf{G})^a = \frac{1}{\sqrt{\det(\mathbf{g})}}\partial_p\left(\sqrt{\det(\mathbf{g})}g^{pq}G^a_q\right) + \sum_{b=1}^{r}(A_p)^a_b g^{pq}G^b_q,$$

which has the form (9.17) with $|\beta|=0$. Now suppose that (9.17) holds for some $s\geq 1$, and let us prove the case $s+1$. Let $\mathbf{G}\in\Gamma\left(T^{(0,s+1)}(TM)\otimes\mathbf{E}\right)$ and define

$$\mathbf{H} := (\mathrm{tr}_{\mathbf{g}}\circ\nabla)\mathbf{G}\in\Gamma\left(T^{(0,s)}(TM)\otimes\mathbf{E}\right).$$

By the induction hypothesis applied to $\mathbf{H}$, we have

$$\left((\mathrm{tr}_{\mathbf{g}}\circ\nabla)^s\mathbf{H}\right)^a = \frac{1}{\sqrt{\det(\mathbf{g})}}\partial_{i_1}\cdots\partial_{i_s}\left(\sqrt{\det(\mathbf{g})}g^{i_1j_1}\cdots g^{i_sj_s}H^a_{j_1\dots j_s}\right) + \sum_{b=1}^{r}\sum_{|\beta|\leq s-1}\left(C_\beta\right)^{aj_1\dots j_s}_b\partial^\beta\left(H^b_{j_1\dots j_s}\right). \tag{9.18}$$

Since, by definition,

$$(\mathrm{tr}_{\mathbf{g}}\circ\nabla)^s\mathbf{H} = (\mathrm{tr}_{\mathbf{g}}\circ\nabla)^{s+1}\mathbf{G},$$

it suffices to expand the components $H^a_{j_1\dots j_s}$ explicitly in terms of $\mathbf{G}$. Using (9.16) with $m = s$ gives

$$\begin{aligned} H^a_{j_1\dots j_s} = \frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_p\Big(\sqrt{\det(\mathbf{g})}\,g^{pq}G^a_{qj_1\dots j_s}\Big) - \sum_{\ell=1}^{s}\Gamma^{\alpha}_{pj_\ell}\,g^{pq}\,G^a_{qj_1\dots j_{\ell-1}\alpha j_{\ell+1}\dots j_s} \\ + \sum_{b=1}^{r}(A_p)^a_b\,g^{pq}G^b_{qj_1\dots j_s}. \end{aligned} \tag{9.19}$$

Substituting (9.19) into the leading term of (9.18) and separating the summands gives

$$\frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_{i_1}\cdots\partial_{i_s}\Big(\sqrt{\det(\mathbf{g})}\,g^{i_1j_1}\cdots g^{i_sj_s}\,H^a_{j_1\dots j_s}\Big) = \text{(I)} + \text{(II)} + \text{(III)}. \tag{9.20}$$

where

$$\text{(I)} := \frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_{i_1}\cdots\partial_{i_s}\Big(g^{i_1j_1}\cdots g^{i_sj_s}\partial_p\big(\sqrt{\det(\mathbf{g})}\,g^{pq}G^a_{qj_1\dots j_s}\big)\Big),$$

$$\text{(II)} := -\frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_{i_1}\cdots\partial_{i_s}\Big(\sqrt{\det(\mathbf{g})}\,g^{i_1j_1}\cdots g^{i_sj_s}\sum_{\ell=1}^{s}\Gamma^{\alpha}_{pj_\ell}\,g^{pq}\,G^a_{qj_1\dots j_{\ell-1}\alpha j_{\ell+1}\dots j_s}\Big),$$

$$\text{(III)} := \frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_{i_1}\cdots\partial_{i_s}\Big(\sqrt{\det(\mathbf{g})}\,g^{i_1j_1}\cdots g^{i_sj_s}\sum_{b=1}^{r}(A_p)^a_b\,g^{pq}G^b_{qj_1\dots j_s}\Big).$$

For the term (I), we write

$$\text{(I)} = \frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_{i_1}\cdots\partial_{i_s}\Big(\big(g^{i_1j_1}\cdots g^{i_sj_s}\big)\,\partial_p\big(\sqrt{\det(\mathbf{g})}\,g^{pq}G^a_{qj_1\dots j_s}\big)\Big).$$

We move the factor $g^{i_1j_1}\cdots g^{i_sj_s}$ inside ∂_p using the identity

$$\big(g^{i_1j_1}\cdots g^{i_sj_s}\big)\,\partial_p(f) = \partial_p\Big(\big(g^{i_1j_1}\cdots g^{i_sj_s}\big)f\Big) - \partial_p\big(g^{i_1j_1}\cdots g^{i_sj_s}\big)\,f, \qquad \forall\, f\in C^\infty(U).$$

Applying it to $f = \sqrt{\det(\mathbf{g})}\,g^{pq}G^a_{qj_1\dots j_s}$ gives

$$\begin{aligned} \text{(I)} = \frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_{i_1}\cdots\partial_{i_s}\partial_p\Big(\sqrt{\det(\mathbf{g})}\,g^{pq}g^{i_1j_1}\cdots g^{i_sj_s}\,G^a_{qj_1\dots j_s}\Big) \\ - \frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_{i_1}\cdots\partial_{i_s}\Big(\partial_p\big(g^{i_1j_1}\cdots g^{i_sj_s}\big)\,\sqrt{\det(\mathbf{g})}\,g^{pq}G^a_{qj_1\dots j_s}\Big). \end{aligned} \tag{9.21}$$

The first term in (9.21) is the leading term of order $s+1$. In the second term, the factor $\partial_p(g^{i_1j_1}\cdots g^{i_sj_s})$ already contains the derivative separated from the leading term. Only the s outer derivatives $\partial_{i_1}\cdots\partial_{i_s}$ remain to be distributed between the coefficients and $\mathbf{G}$ by the Leibniz rule; even when they all act on $\mathbf{G}$, the order of differentiation of its components is at most s. Consequently, there are smooth coefficients $\big(B_\beta\big)^{a\,j_1\dots j_sq}_c$ with $|\beta|\le s$ such that

$$\text{(I)} = \frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_{i_1}\cdots\partial_{i_s}\partial_p\Big(\sqrt{\det(\mathbf{g})}\,g^{pq}g^{i_1j_1}\cdots g^{i_sj_s}\,G^a_{qj_1\dots j_s}\Big) + \sum_{c=1}^{r}\sum_{|\beta|\le s}\big(B_\beta\big)^{a\,j_1\dots j_sq}_c\,\partial^\beta\big(G^c_{qj_1\dots j_s}\big). \tag{9.22}$$

Now consider (II). Here no additional derivative ∂_p acts on $\mathbf{G}$. Thus, expanding the operator $\partial_{i_1}\cdots\partial_{i_s}$ acting

on the product

$$\sqrt{\det(\mathbf{g})}\, g^{i_1 j_1}\cdots g^{i_s j_s}\,\Gamma^{\alpha}_{p j_\ell}\, g^{pq}\, G^{a}_{q j_1\ldots j_{\ell-1}\alpha j_{\ell+1}\ldots j_s},$$

by the Leibniz rule yields only terms in which at most s derivatives act on the components of $\mathbf{G}$. Consequently, there are smooth coefficients $\big(\widetilde{B}_\beta\big)_c^{a\,j_1\ldots j_s q}$ with $|\beta|\le s$ such that

$$\text{(II)} = \sum_{c=1}^{r}\sum_{|\beta|\le s}\big(\widetilde{B}_\beta\big)_c^{a\,j_1\ldots j_s q}\,\partial^\beta\big(G^{c}_{q j_1\ldots j_s}\big). \tag{9.23}$$

In (III) the dependence on $\mathbf{G}$ is linear and contains no additional derivatives of $\mathbf{G}$. By the Leibniz formula, each of the s outer derivatives can act on that factor at most once more; thus only derivatives $\partial^\beta\mathbf{G}$ with $|\beta|\le s$ arise. Therefore, there are smooth coefficients $\big(\widehat{B}_\beta\big)_c^{a\,j_1\ldots j_s q}$ with $|\beta|\le s$ such that

$$\text{(III)} = \sum_{c=1}^{r}\sum_{|\beta|\le s}\big(\widehat{B}_\beta\big)_c^{a\,j_1\ldots j_s q}\,\partial^\beta\big(G^{c}_{q j_1\ldots j_s}\big). \tag{9.24}$$

Substituting (9.22), (9.23), and (9.24) into (9.20) gives

$$\begin{aligned}\frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_{i_1}\cdots\partial_{i_s}\Big(\sqrt{\det(\mathbf{g})}\,g^{i_1 j_1}\cdots g^{i_s j_s}\,H^{a}_{j_1\ldots j_s}\Big) &= \frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_p\partial_{i_1}\cdots\partial_{i_s}\Big(\sqrt{\det(\mathbf{g})}\,g^{pq}g^{i_1 j_1}\cdots g^{i_s j_s}\,G^{a}_{q j_1\ldots j_s}\Big)\\ &\quad+\sum_{c=1}^{r}\sum_{|\beta|\le s}\big(D_\beta\big)_c^{a\,j_1\ldots j_s q}\,\partial^\beta\big(G^{c}_{q j_1\ldots j_s}\big),\end{aligned} \tag{9.25}$$

where

$$\big(D_\beta\big)_c^{a\,j_1\ldots j_s q} := \big(B_\beta\big)_c^{a\,j_1\ldots j_s q} + \big(\widetilde{B}_\beta\big)_c^{a\,j_1\ldots j_s q} + \big(\widehat{B}_\beta\big)_c^{a\,j_1\ldots j_s q},\qquad |\beta|\le s.$$

On the other hand, for the lower-order term in (9.18),

$$\sum_{b=1}^{r}\sum_{|\beta|\le s-1}\big(C_\beta\big)_b^{a\,j_1\ldots j_s}\,\partial^\beta\big(H^{b}_{j_1\ldots j_s}\big),$$

substituting (9.19) into $H^{b}_{j_1\ldots j_s}$ shows that each $\partial^\beta(H^{b}_{j_1\ldots j_s})$ is a linear combination (with smooth coefficients) of terms $\partial^\gamma(G^{c}_{q j_1\ldots j_s})$ with $|\gamma|\le|\beta|+1\le s$. Consequently, there are smooth coefficients $\big(\overline{D}_\beta\big)_c^{a\,j_1\ldots j_s q}$ with $|\beta|\le s$ such that

$$\sum_{b=1}^{r}\sum_{|\beta|\le s-1}\big(C_\beta\big)_b^{a\,j_1\ldots j_s}\,\partial^\beta\big(H^{b}_{j_1\ldots j_s}\big) = \sum_{c=1}^{r}\sum_{|\beta|\le s}\big(\overline{D}_\beta\big)_c^{a\,j_1\ldots j_s q}\,\partial^\beta\big(G^{c}_{q j_1\ldots j_s}\big). \tag{9.26}$$

Combining (9.18), (9.25), and (9.26), we conclude that there are smooth coefficients $\big(C_\beta\big)_c^{a\,j_1\ldots j_s q}$ with $|\beta|\le s$ such that

$$\big((\mathrm{tr}_{\mathbf{g}}\circ\nabla)^{s+1}\mathbf{G}\big)^{a} = \frac{1}{\sqrt{\det(\mathbf{g})}}\,\partial_{i_1}\cdots\partial_{i_s}\partial_p\Big(\sqrt{\det(\mathbf{g})}\,g^{pq}g^{i_1 j_1}\cdots g^{i_s j_s}\,G^{a}_{q j_1\ldots j_s}\Big) + \sum_{c=1}^{r}\sum_{|\beta|\le s}\big(C_\beta\big)_c^{a\,j_1\ldots j_s q}\,\partial^\beta\big(G^{c}_{q j_1\ldots j_s}\big).$$

Finally, we rename $p=i_1$ and $q=j_1$, simultaneously replacing the previous indices (i_ℓ, j_ℓ) by $(i_{\ell+1}, j_{\ell+1})$ for $\ell\in\{1,\ldots,s\}$. The partial derivatives commute, so their outer order can be rearranged, while the indices of $\mathbf{G}$ remain in their original order. This gives exactly the form of (9.17) for $s+1$, completing the induction.

□

Let us consider some examples illustrating the preceding result.

Example 9.1.33. Let $\Omega \subseteq \mathbb{R}^n$ be open, and regard $M := \Omega$ as a smooth manifold without boundary, equipped with the Euclidean metric $\overline{\mathbf{g}}$. In the trivial line bundle

$$\mathbf{E} := M \times \mathbb{R} \longrightarrow M$$

, let $\mathbf{e}(p) := (p, 1)$ be the constant unit section. Every section has a unique expression $\mathbf{u} = u\mathbf{e}$, with $u \in C^\infty(\Omega)$; the trivial metric and connection satisfy

$$\mathbf{h}_{\mathbf{E}}(u\mathbf{e}, v\mathbf{e}) = uv, \qquad \nabla^{\mathbf{E}}_{\partial_i}(u\mathbf{e}) = (\partial_i u)\mathbf{e}.$$

For each $s \geq 0$, the bundle isomorphism

$$I_s \colon T^{(0,s)}(TM) \otimes \mathbf{E} \longrightarrow T^{(0,s)}(TM), \qquad I_s\big(\xi \otimes \lambda \mathbf{e}(p)\big) := \lambda \xi,$$

identifies $\nabla^s \mathbf{u}$ with the Euclidean derivative $D^s u$. In particular,

$$\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} = \left(\sum_{s=0}^{m} \|D^s u\|^p_{L^p(\Omega)} \right)^{1/p}$$

if $1 \leq p < \infty$, with the usual modification using maxima when $p = \infty$. The same identification in the weak derivative identity shows that

$$\mathbf{u} \in W^{m,p}(M, \mathbf{E}) \quad \Longleftrightarrow \quad u \in W^{m,p}(\Omega).$$

Thus the bundle definition recovers precisely the scalar Sobolev space for the trivial rank-one bundle.

The formal adjoint allows us to define certain nonlinear operators important in the study of PDEs, such as the p–Laplacian, in the setting of vector bundles.

Definition 9.1.34. (The scalar and vector bundle p-Laplacian) Let $(M, \mathbf{g})$ be a Riemannian manifold without boundary, and let $p > 1$.

(a) If $u \in C^2(M)$, the *scalar p-Laplacian* of u is defined by

$$\Delta_p u := \operatorname{div}\big(|\nabla u|^{p-2}_{\mathbf{g}} \nabla u\big).$$

Equivalently, using the formal adjoint of the covariant derivative,

$$\Delta_p u = -\nabla^*\big(|\nabla u|^{p-2}_{\mathbf{g}} \nabla u\big).$$

When $p = 2$, this recovers the Laplace–Beltrami Laplacian $\Delta_2 u = \Delta_{\mathbf{g}} u$.

(b) Now let $\mathbf{E} \to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible

connection $\nabla^{\mathbf{E}}$. If $\mathbf{u} \in \Gamma^2(\mathbf{E})$, the *p-Laplacian associated with* $\nabla^{\mathbf{E}}$ is defined by

$$\Delta_p^{\mathbf{E}}\mathbf{u} := -\left(\nabla^{\mathbf{E}}\right)^* \left(|\nabla^{\mathbf{E}}\mathbf{u}|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}^{p-2}\nabla^{\mathbf{E}}\mathbf{u}\right).$$

In both definitions we adopt $|\xi|^{p-2}\xi = 0$ when $\xi = 0$. If $1 < p < 2$, even for data of class C^2, this flux may fail to be of class C^1 at its zeros. In that case, the divergence and adjoint in the preceding formulas are interpreted weakly: for a test section $\boldsymbol{\varphi}$ supported in the interior, the value of $\Delta_p^{\mathbf{E}}\mathbf{u}$ is determined by

$$\langle \Delta_p^{\mathbf{E}}\mathbf{u}, \boldsymbol{\varphi}\rangle = -\int_M \left\langle |\nabla^{\mathbf{E}}\mathbf{u}|^{p-2}\nabla^{\mathbf{E}}\mathbf{u}, \nabla^{\mathbf{E}}\boldsymbol{\varphi}\right\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}} d\lambda_{\mathbf{g}}.$$

The scalar case is obtained using the trivial bundle. The flux is continuous and hence locally integrable, so this identity is always defined. When the flux is of class C^1, it recovers the classical expression, and the following boundary formula applies. For $p \geq 2$, data of class C^2 ensure this regularity of the flux.

Our integration-by-parts formula also yields further integration-by-parts formulas, such as the following:

Proposition 9.1.35. (Integration-by-parts formula for the p-Laplacian) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, and let $p > 1$.
In the scalar case, let $u \in C^2(M)$ be such that $|\nabla u|_{\mathbf{g}}^{p-2}\nabla u$ is of class C^1. Then, for every $\varphi \in C_c^\infty(M)$,

$$\int_M |\nabla u|_{\mathbf{g}}^{p-2}\langle \nabla u, \nabla\varphi\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}} = -\int_M \varphi\, \Delta_p u\, d\lambda_{\mathbf{g}} + \int_{\partial M} \varphi\, |\nabla u|_{\mathbf{g}}^{p-2}\partial_\nu u\, d\lambda_{\tilde{\mathbf{g}}}.$$

More generally, let $\pi_{\mathbf{E}}\colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. If $\mathbf{u} \in \Gamma^2(\mathbf{E})$ is such that $|\nabla^{\mathbf{E}}\mathbf{u}|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}^{p-2}\nabla^{\mathbf{E}}\mathbf{u}$ is of class C^1, then, for every $\boldsymbol{\varphi} \in \Gamma_c(\mathbf{E})$,

$$\int_M |\nabla^{\mathbf{E}}\mathbf{u}|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}^{p-2}\langle \nabla^{\mathbf{E}}\mathbf{u}, \nabla^{\mathbf{E}}\boldsymbol{\varphi}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}} = -\int_M \langle \Delta_p^{\mathbf{E}}\mathbf{u}, \boldsymbol{\varphi}\rangle_{\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}} + \int_{\partial M} \left\langle \iota_\nu\left(|\nabla^{\mathbf{E}}\mathbf{u}|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}^{p-2}\nabla^{\mathbf{E}}\mathbf{u}\right), \boldsymbol{\varphi}\right\rangle_{\mathbf{h}_{\mathbf{E}}} d\lambda_{\tilde{\mathbf{g}}}.$$

In particular, if $\boldsymbol{\varphi}$ has compact support contained in $\mathrm{Int}(M)$, the boundary term vanishes.

Proof. We first prove the bundle identity. Define $\mathbf{A}_{\mathbf{u}} := |\nabla^{\mathbf{E}}\mathbf{u}|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}^{p-2}\nabla^{\mathbf{E}}\mathbf{u}$, so that $\mathbf{A}_{\mathbf{u}} \in \Gamma^1(T^*M \otimes \mathbf{E})$ by the regularity hypothesis. The calculation in the case $s = 1$ of Green's formula uses only continuous first derivatives, so it remains valid with this regularity. We also multiply $\mathbf{A}_{\mathbf{u}}$ by a compactly supported smooth function equal to one on a neighborhood of $\operatorname{supp}\boldsymbol{\varphi}$; this leaves every integral unchanged and satisfies the support condition. We apply Theorem 9.1.29 with $s = 1$, $k = l = 0$, $\mathbf{F} = \boldsymbol{\varphi}$, and $\mathbf{G} = \mathbf{A}_{\mathbf{u}}$. Then

$$\int_M \langle \nabla^{\mathbf{E}}\boldsymbol{\varphi}, \mathbf{A}_{\mathbf{u}}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}} = -\int_M \left\langle \boldsymbol{\varphi}, (\mathrm{tr}_{\mathbf{g}} \circ \nabla)\mathbf{A}_{\mathbf{u}}\right\rangle_{\mathbf{h}_{\mathbf{E}}} d\lambda_{\mathbf{g}} + \int_{\partial M} \langle \boldsymbol{\varphi}, \iota_\nu \mathbf{A}_{\mathbf{u}}\rangle_{\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\tilde{\mathbf{g}}}.$$

Since $(\nabla^{\mathbf{E}})^*\mathbf{A}_{\mathbf{u}} = -(\mathrm{tr}_{\mathbf{g}} \circ \nabla)\mathbf{A}_{\mathbf{u}}$ and, by definition, $\Delta_p^{\mathbf{E}}\mathbf{u} = -(\nabla^{\mathbf{E}})^*\mathbf{A}_{\mathbf{u}}$, we conjugate the preceding identity in the complex case, or use symmetry in the real case. The interior term then becomes $-\langle \Delta_p^{\mathbf{E}}\mathbf{u}, \boldsymbol{\varphi}\rangle_{\mathbf{h}_{\mathbf{E}}}$. Moreover, with the bar acting trivially in the real case, $\overline{\langle \nabla^{\mathbf{E}}\boldsymbol{\varphi}, \mathbf{A}_{\mathbf{u}}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}} = |\nabla^{\mathbf{E}}\mathbf{u}|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}^{p-2}\langle \nabla^{\mathbf{E}}\mathbf{u}, \nabla^{\mathbf{E}}\boldsymbol{\varphi}\rangle_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}$. Substitution of these two identities gives the bundle formula.
The scalar case follows by taking $\mathbf{E} = M \times \mathbb{R}$ with its trivial metric and connection and identifying a section

with its component function u. In this case $\mathbf{A}_u = |\nabla u|_{\mathbf{g}}^{p-2}\nabla u$ and

$$\iota_{\boldsymbol{\nu}}\mathbf{A}_u = \langle \mathbf{A}_u, \boldsymbol{\nu}\rangle_{\mathbf{g}} = |\nabla u|_{\mathbf{g}}^{p-2}\langle \nabla u, \boldsymbol{\nu}\rangle_{\mathbf{g}} = |\nabla u|_{\mathbf{g}}^{p-2}\partial_{\boldsymbol{\nu}} u.$$

Thus the preceding identity becomes exactly the scalar formula. □

The integration-by-parts formula also allows us to compare the usual covariant norm on H^m with a norm defined by powers of the Laplacian. This equivalence is a recurring tool in geometric analysis, since it translates control of derivatives into spectral control. The next section establishes the result with the hypotheses and constants needed in the vector bundle setting.

9.1.4 Equivalence of norms: an application of the integration-by-parts formula in vector bundles

In the Euclidean case, the integration-by-parts formula is fundamental to Sobolev space theory and nonlinear analysis. In this section we use it to prove, on a closed manifold M, the equivalence of the usual norm on $H^m(M) := W^{m,2}(M)$ and a norm defined by powers of the Laplacian. We begin with the corresponding identity on Euclidean domains:

Theorem 9.1.36. (An equivalent norm on $H_0^m(\Omega)$ in terms of the Laplacian) Let $\Omega \subset \mathbb{R}^n$ be an open set, and let $m \in \mathbb{N}$. For every function $u \in H_0^m(\Omega)$, the standard Sobolev norm of order m, defined using the partial derivative operator,

$$\|u\|_{H^m(\Omega)}^2 := \sum_{j=0}^{m} \int_\Omega |\nabla^j u|^2 \, d\lambda_n,$$

is exactly equal to the norm structured in powers of the Laplacian operator $\Delta = \sum_{i=1}^{n} \partial_i^2$, given by

$$\|u\|_{\Delta}^2 := \sum_{\substack{j=0 \\ j \text{ even}}}^{m} \int_\Omega |\Delta^{\frac{j}{2}} u|^2 \, d\lambda_n + \sum_{\substack{j=1 \\ j \text{ odd}}}^{m} \int_\Omega \left|\nabla \Delta^{\frac{j-1}{2}} u\right|^2 d\lambda_n.$$

Moreover, equality holds term by term for each order of differentiation $j \in \{0, \dots, m\}$.

Proof. First let $u \in H_0^m(\Omega)$. By the definition of this space, there is a sequence $(u_\nu)_{\nu\in\mathbb{N}} \subseteq C_c^\infty(\Omega)$ such that $u_\nu \to u$ in $H^m(\Omega)$. In particular, for every multi-index α with $|\alpha| \le m$,

$$D^\alpha u_\nu \longrightarrow D^\alpha u \qquad \text{in } L^2(\Omega).$$

If $j = 2k \le m$, the operator Δ^k is a finite linear combination, with constant coefficients, of partial derivatives of order j. If $j = 2k+1 \le m$, each component of $\nabla\Delta^k$ is likewise a finite linear combination of partial derivatives of order j. Therefore,

$$\Delta^k u_\nu \longrightarrow \Delta^k u \quad \text{and} \quad \nabla\Delta^k u_\nu \longrightarrow \nabla\Delta^k u$$

in L^2 whenever the corresponding order does not exceed m. Thus, once the term-by-term equalities have

been proved for u_ν, we can pass to the limit in each of them. It therefore suffices to establish them for a function $u \in C_c^\infty(\Omega)$. For such a function, all integrations by parts have no boundary terms. Moreover, partial derivatives commute, and all norms are taken with respect to the Euclidean metric, by contraction of indices.

We proceed by induction on j and prove, for every $u \in C_c^\infty(\Omega)$, the equality corresponding to order j.

For $j = 0$ and $j = 1$ the assertion follows immediately from the definition.

Now consider the fundamental case $j = 2$. Observe that

$$\int_\Omega |\nabla^2 u|^2 \, d\lambda_n = \int_\Omega \sum_{p,q=1}^{n} (\partial_p \partial_q u)^2 \, d\lambda_n.$$

We first integrate by parts with respect to the variable x^q and then with respect to x^p. Since u has compact support in Ω and partial derivatives commute, we obtain

$$\int_\Omega (\partial_p \partial_q u)^2 \, d\lambda_n = -\int_\Omega (\partial_p u)\, \partial_p \partial_q^2 u \, d\lambda_n = \int_\Omega (\partial_p^2 u)(\partial_q^2 u) \, d\lambda_n.$$

Summing over p, q gives

$$\int_\Omega |\nabla^2 u|^2 \, d\lambda_n = \int_\Omega \left(\sum_{p=1}^{n} \partial_p^2 u \right) \left(\sum_{q=1}^{n} \partial_q^2 u \right) d\lambda_n = \int_\Omega |\Delta u|^2 \, d\lambda_n.$$

Now suppose that the assertion holds for all orders less than $j \geq 3$. For each list $(i_1, \dots, i_{j-2})$, the function $\partial_{i_1} \cdots \partial_{i_{j-2}} u$ belongs to $C_c^\infty(\Omega)$. Applying the identity already proved for two derivatives to each of these functions, and summing over all indices, gives, in tensor notation,

$$\int_\Omega |\nabla^j u|^2 \, d\lambda_n = \int_\Omega |\Delta(\nabla^{j-2} u)|^2 \, d\lambda_n.$$

Since the Laplacian commutes with partial derivatives in $\mathbb{R}^n$, we have

$$\Delta(\nabla^{j-2} u) = \nabla^{j-2}(\Delta u),$$

and therefore

$$\int_\Omega |\nabla^j u|^2 \, d\lambda_n = \int_\Omega |\nabla^{j-2}(\Delta u)|^2 \, d\lambda_n.$$

The function $v := \Delta u$ also belongs to $C_c^\infty(\Omega)$. We can therefore apply the induction hypothesis to it at order $j - 2$.

If j is even, then $j - 2$ is even, and we obtain

$$\int_\Omega |\nabla^{j-2}(\Delta u)|^2 = \int_\Omega |\Delta^{\frac{j-2}{2}}(\Delta u)|^2 = \int_\Omega |\Delta^{\frac{j}{2}} u|^2.$$

If j is odd, then $j - 2$ is odd, and we obtain

$$\int_\Omega |\nabla^{j-2}(\Delta u)|^2 = \int_\Omega \left|\nabla \Delta^{\frac{j-3}{2}}(\Delta u)\right|^2 = \int_\Omega \left|\nabla \Delta^{\frac{j-1}{2}} u\right|^2.$$

In both cases this recovers exactly the corresponding term in the structured norm. This proves the term-by-term identities for functions in $C_c^\infty(\Omega)$. Applying them to the sequence (u_ν) chosen at the beginning and using the convergence in L^2 established there, we pass to the limit on both sides of each identity. This gives the same equalities for every $u \in H_0^m(\Omega)$; summing them for $0 \le j \le m$ yields equality of the two norms. □

To extend this result to Riemannian manifolds, we first introduce notation that simplifies the manipulation of tensor contractions, together with an auxiliary analytic result.

Notation 9.1.37. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, and let

$$\pi_{\mathbf{E}} \colon \mathbf{E} \longrightarrow M, \qquad \pi_{\mathbf{F}} \colon \mathbf{F} \longrightarrow M$$

be smooth vector bundles of finite rank, equipped with smooth bundle metrics $\mathbf{h}_{\mathbf{E}}$ and $\mathbf{h}_{\mathbf{F}}$.
Let $\mathbf{G}_1, \dots, \mathbf{G}_r, \mathbf{H}$ be vector bundles obtained from $\mathbf{E}$, $\mathbf{F}$, their duals, and the tangent and cotangent bundles of M by finitely many tensor products. Let also

$$\mathbf{u}_1 \in \Gamma(\mathbf{G}_1), \dots, \mathbf{u}_r \in \Gamma(\mathbf{G}_r).$$

We say that a section $\mathbf{T} \in \Gamma(\mathbf{H})$ has the form

$$\mathbf{u}_1 * \cdots * \mathbf{u}_r$$

if there is a smooth bundle homomorphism

$$\Phi \colon \mathbf{G}_1 \otimes \cdots \otimes \mathbf{G}_r \longrightarrow \mathbf{H}$$

obtained by composition and finite linear combination of the following natural operations:

(a) tensor products;

(b) permutations of tensor factors;

(c) contractions between a bundle and its dual;

(d) the bundle isomorphisms induced by the bundle metrics $\mathbf{h}_{\mathbf{E}}$, $\mathbf{h}_{\mathbf{F}}$ and the Riemannian metric $\mathbf{g}$, together with their inverses.

and such that

$$\mathbf{T} = \Phi(\mathbf{u}_1 \otimes \cdots \otimes \mathbf{u}_r).$$

In particular, if $\mathbf{u} \in \Gamma(\mathbf{G})$ and $\mathbf{v} \in \Gamma(\mathbf{K})$, the expression

$$\mathbf{u} * \mathbf{v}$$

denotes any section obtained from $\mathbf{u} \otimes \mathbf{v}$ by a finite combination of the preceding operations. Different occurrences of the symbol $*$ may correspond to different bundle homomorphisms.

Let us consider an example illustrating how this notation works.

Example 9.1.38. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary. Consider

$$\mathbf{R} \in \Gamma(T^{(0,4)}(TM)), \qquad \boldsymbol{\omega} \in \Gamma(T^{(0,1)}(TM)).$$

There is a canonical bundle isomorphism

$$T^{(0,4)}(TM) \otimes T^{(0,1)}(TM) \cong T^{(0,5)}(TM).$$

Define a bundle homomorphism

$$\Phi \colon T^{(0,5)}(TM) \longrightarrow T^{(0,1)}(TM)$$

by metric contractions with $\mathbf{g}^{-1} \in \Gamma(T^{(2,0)}(TM))$. More explicitly, in local coordinates, if

$$\mathbf{A} \in \Gamma(T^{(0,5)}(TM)),$$

and A_{abcde} are its components, then the components of $\Phi(\mathbf{A})$ are

$$\Phi(\mathbf{A})_b = g^{ae} g^{cd} A_{abcde}.$$

This homomorphism is obtained from tensor products, permutations, and contractions, so it is among those allowed in Notation 9.1.37.
Evaluating at $\mathbf{A} = \mathbf{R} \otimes \boldsymbol{\omega}$ gives

$$\Phi(\mathbf{R} \otimes \boldsymbol{\omega})_i = g^{jk} g^{lm} R_{jilm} \omega_k.$$

Consequently,

$$\mathbf{T} = \Phi(\mathbf{R} \otimes \boldsymbol{\omega})$$

is a term of the type $\mathbf{R} * \boldsymbol{\omega}$.

Lemma 9.1.39. Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, and let

$$\mathbf{E}_1, \dots, \mathbf{E}_r, \mathbf{H} \longrightarrow M$$

be smooth vector bundles of finite rank, equipped with smooth bundle metrics.
Let

$$\Phi \colon \mathbf{E}_1 \otimes \cdots \otimes \mathbf{E}_r \longrightarrow \mathbf{H}$$

be a smooth bundle homomorphism obtained by composition and finite linear combination of tensor products, permutations of factors, contractions, and the isomorphisms induced by the bundle metrics and the Riemannian metric $\mathbf{g}$, together with their inverses.
Then, for every compact set $K \subseteq M$, there is a constant $C_K > 0$ such that, for every $x \in K$ and all

$$v_i \in (\mathbf{E}_i)_x, \qquad i = 1, \dots, r,$$

, we have

$$\left|\Phi_x(v_1 \otimes \cdots \otimes v_r)\right|_{\mathbf{h}_\mathbf{H}} \leq C_K |v_1|_{\mathbf{h}_{\mathbf{E}_1}} \cdots |v_r|_{\mathbf{h}_{\mathbf{E}_r}}.$$

In particular, if $\mathbf{u}_i \in \Gamma(\mathbf{E}_i)$ for $i = 1,\dots,r$, then

$$|\Phi(\mathbf{u}_1 \otimes \cdots \otimes \mathbf{u}_r)(x)|_{\mathbf{h}_\mathbf{H}} \leq C_K\, |\mathbf{u}_1(x)|_{\mathbf{h}_{\mathbf{E}_1}} \cdots |\mathbf{u}_r(x)|_{\mathbf{h}_{\mathbf{E}_r}}, \qquad \forall x \in K.$$

Consequently, if $T = \mathbf{u}_1 * \cdots * \mathbf{u}_r$, then

$$|T(x)|_{\mathbf{h}_\mathbf{H}} \leq C_K\, |\mathbf{u}_1(x)|_{\mathbf{h}_{\mathbf{E}_1}} \cdots |\mathbf{u}_r(x)|_{\mathbf{h}_{\mathbf{E}_r}}, \qquad \forall x \in K.$$

Proof. Fix $x \in M$. Consider the map

$$\widetilde{\Phi}_x \colon (\mathbf{E}_1)_x \times \cdots \times (\mathbf{E}_r)_x \longrightarrow \mathbf{H}_x, \qquad \widetilde{\Phi}_x(v_1,\dots,v_r) := \Phi_x(v_1 \otimes \cdots \otimes v_r).$$

Let

$$\theta_x : (\mathbf{E}_1)_x \times \cdots \times (\mathbf{E}_r)_x \longrightarrow (\mathbf{E}_1)_x \otimes \cdots \otimes (\mathbf{E}_r)_x, \qquad \theta_x(v_1,\dots,v_r) = v_1 \otimes \cdots \otimes v_r.$$

The map θ_x is multilinear. On the other hand, since Φ is a bundle homomorphism,

$$\Phi_x \colon (\mathbf{E}_1)_x \otimes \cdots \otimes (\mathbf{E}_r)_x \longrightarrow \mathbf{H}_x$$

is linear. Consequently,

$$\widetilde{\Phi}_x = \Phi_x \circ \theta_x$$

is multilinear.

Denote by $|\cdot|_{\mathbf{h}_{\mathbf{E}_i,x}}$ the norm on $(\mathbf{E}_i)_x$ induced by the bundle metric $\mathbf{h}_{\mathbf{E}_i}$, and by $|\cdot|_{\mathbf{h}_{\mathbf{H},x}}$ the norm on $\mathbf{H}_x$ induced by the bundle metric of $\mathbf{H}$. Since the spaces involved are finite-dimensional, every multilinear map between them is continuous. Thus there is a constant $C(x) > 0$ such that

$$|\Phi_x(v_1 \otimes \cdots \otimes v_r)|_{\mathbf{h}_{\mathbf{H},x}} \leq C(x)\, |v_1|_{\mathbf{h}_{\mathbf{E}_1,x}} \cdots |v_r|_{\mathbf{h}_{\mathbf{E}_r,x}}$$

for any $v_i \in (\mathbf{E}_i)_x$, with $i \in \{1,\dots,r\}$.

It remains to show that this constant can be chosen uniformly on compact sets. Let $p \in K$. Choose open sets $U_p, V_p \subseteq M$ such that

$$p \in U_p, \qquad \overline{U_p} \subseteq V_p, \qquad \overline{U_p} \text{ is compact},$$

and such that all the bundles

$$\mathbf{E}_1,\dots,\mathbf{E}_r,\mathbf{H}$$

admit smooth local frames over V_p. Fix local frames on V_p,

$$e_1^{(i)},\dots,e_{m_i}^{(i)} \quad \text{for } \mathbf{E}_i, \qquad \varepsilon_1,\dots,\varepsilon_\ell \quad \text{for } \mathbf{H}.$$

In these frames there are smooth functions

$$\Phi^b_{a_1\cdots a_r} \colon V_p \longrightarrow \mathbb{R}$$

such that

$$\Phi_x\big(e_{a_1}^{(1)}(x)\otimes\cdots\otimes e_{a_r}^{(r)}(x)\big)=\sum_{b=1}^{\ell}\Phi^{b}_{a_1\cdots a_r}(x)\,\varepsilon_b(x).$$

Since the frames and these functions are defined on a neighborhood of $\overline{U_p}$, their continuity and the compactness of $\overline{U_p}$ give $A_p>0$ such that

$$|\Phi^{b}_{a_1\cdots a_r}(x)|\le A_p\qquad\forall x\in\overline{U_p}.$$

Now let $x\in\overline{U_p}$ and, for each $i\in\{1,\dots,r\}$, write

$$v_i=\sum_{a_i=1}^{m_i}v_i^{a_i}\,e_{a_i}^{(i)}(x).$$

Then

$$\Phi_x(v_1\otimes\cdots\otimes v_r)=\sum_{\substack{1\le b\le\ell\\1\le a_i\le m_i}}\Phi^{b}_{a_1\cdots a_r}(x)\,v_1^{a_1}\cdots v_r^{a_r}\,\varepsilon_b(x).$$

By the triangle inequality,

$$|\Phi_x(v_1\otimes\cdots\otimes v_r)|_{\mathbf{h}_{\mathbf{H},x}}\le\sum_{\substack{1\le b\le\ell\\1\le a_i\le m_i}}|\Phi^{b}_{a_1\cdots a_r}(x)||v_1^{a_1}|\cdots|v_r^{a_r}||\varepsilon_b(x)|_{\mathbf{h}_{\mathbf{H},x}}.$$

Using the bound $|\Phi^{b}_{a_1\cdots a_r}(x)|\le A_p$ gives

$$|\Phi_x(v_1\otimes\cdots\otimes v_r)|_{\mathbf{h}_{\mathbf{H},x}}\le A_p\sum_{\substack{1\le b\le\ell\\1\le a_i\le m_i}}|v_1^{a_1}|\cdots|v_r^{a_r}||\varepsilon_b(x)|_{\mathbf{h}_{\mathbf{H},x}}.$$

Since $\overline{U_p}$ is compact and the sections ε_b are smooth, there is $B_p>0$ such that

$$|\varepsilon_b(x)|_{\mathbf{h}_{\mathbf{H},x}}\le B_p\qquad\forall x\in\overline{U_p},\ \forall b.$$

Therefore,

$$|\Phi_x(v_1\otimes\cdots\otimes v_r)|_{\mathbf{h}_{\mathbf{H},x}}\le A_pB_p\sum_{\substack{1\le b\le\ell\\1\le a_i\le m_i}}|v_1^{a_1}|\cdots|v_r^{a_r}|.$$

Now,

$$\sum_{\substack{1\le b\le\ell\\1\le a_i\le m_i}}|v_1^{a_1}|\cdots|v_r^{a_r}|=\sum_{b=1}^{\ell}\sum_{a_1=1}^{m_1}\cdots\sum_{a_r=1}^{m_r}|v_1^{a_1}|\cdots|v_r^{a_r}|.$$

Since the inner expression is independent of b, we obtain

$$\sum_{\substack{1\le b\le\ell\\1\le a_i\le m_i}}|v_1^{a_1}|\cdots|v_r^{a_r}|=\ell\sum_{a_1=1}^{m_1}\cdots\sum_{a_r=1}^{m_r}|v_1^{a_1}|\cdots|v_r^{a_r}|.$$

Moreover, by distributivity,

$$\sum_{a_1=1}^{m_1}\cdots\sum_{a_r=1}^{m_r}|v_1^{a_1}|\cdots|v_r^{a_r}| = \left(\sum_{a_1=1}^{m_1}|v_1^{a_1}|\right)\cdots\left(\sum_{a_r=1}^{m_r}|v_r^{a_r}|\right).$$

Consequently,

$$|\Phi_x(v_1\otimes\cdots\otimes v_r)|_{\mathbf{h}_{\mathbf{H},x}} \le A_p B_p\,\ell\prod_{i=1}^{r}\left(\sum_{a_i=1}^{m_i}|v_i^{a_i}|\right).$$

For each $i\in\{1,\dots,r\}$, the local frame $\mathbf{e}_1^{(i)},\dots,\mathbf{e}_{m_i}^{(i)}$ induces on each fiber $(\mathbf{E}_i)_x$, with $x\in\overline{U_p}$, the norm

$$\|v_i\|_{(i),x} := \sum_{a_i=1}^{m_i}|v_i^{a_i}|.$$

The matrix of $\mathbf{h}_{\mathbf{E}_i}$ in this frame and its inverse depend smoothly on x. Their coefficients are bounded on $\overline{U_p}$, and their positive minors are bounded away from zero. The compactness of $\overline{U_p}$ and of the unit sphere in each component space gives constants $0<d_{p,i}\le D_{p,i}<+\infty$, independent of x, such that

$$d_{p,i}|v_i|_{\mathbf{h}_{\mathbf{E}_i},x} \le \|v_i\|_{(i),x} \le D_{p,i}|v_i|_{\mathbf{h}_{\mathbf{E}_i},x} \qquad \forall x\in\overline{U_p},\ \forall v_i\in(\mathbf{E}_i)_x.$$

Substituting these estimates into the preceding inequality gives

$$|\Phi_x(v_1\otimes\cdots\otimes v_r)|_{\mathbf{h}_{\mathbf{H},x}} \le A_pB_p\,\ell\,D_{p,1}\cdots D_{p,r}\,|v_1|_{\mathbf{h}_{\mathbf{E}_1,x}}\cdots|v_r|_{\mathbf{h}_{\mathbf{E}_r,x}}$$

for every $x\in\overline{U_p}$. Defining

$$C_p := A_pB_p\,\ell\,D_{p,1}\cdots D_{p,r},$$

yields

$$|\Phi_x(v_1\otimes\cdots\otimes v_r)|_{\mathbf{h}_{\mathbf{H},x}} \le C_p\,|v_1|_{\mathbf{h}_{\mathbf{E}_1,x}}\cdots|v_r|_{\mathbf{h}_{\mathbf{E}_r,x}} \qquad \forall x\in\overline{U_p}.$$

The open sets U_p, with $p\in K$, cover K. By compactness there is a finite subcover

$$U_{p_1},\dots,U_{p_N}.$$

Defining

$$C_K := \max\{C_{p_1},\dots,C_{p_N}\},$$

gives

$$|\Phi_x(v_1\otimes\cdots\otimes v_r)|_{\mathbf{h}_{\mathbf{H},x}} \le C_K\,|v_1|_{\mathbf{h}_{\mathbf{E}_1,x}}\cdots|v_r|_{\mathbf{h}_{\mathbf{E}_r,x}} \qquad \forall x\in K.$$

The assertion for sections follows by taking $v_i=\mathbf{u}_i(x)$. □

Proposition 9.1.40. (Leibniz rule for the operator $*$) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary. Let $\mathbf{E}_1,\dots,\mathbf{E}_r,\mathbf{F}\longrightarrow M$ be smooth vector bundles with bundle metrics (Hermitian in the complex case) and connections compatible with them. We use the Levi–Civita connection on the tangent and

cotangent factors, and the induced connections on all products, duals, and homomorphism bundles. Let

$$\mathbf{\Phi}\colon \mathbf{E}_1 \otimes \cdots \otimes \mathbf{E}_r \longrightarrow \mathbf{F}$$

be a smooth bundle homomorphism obtained using tensor products, permutations, contractions, and the isomorphisms induced by the bundle metrics and the Riemannian metric.
If $\mathbf{u}_i \in \Gamma(\mathbf{E}_i)$ for $i = 1, \dots, r$, define

$$\mathbf{T} = \mathbf{\Phi}(\mathbf{u}_1 \otimes \cdots \otimes \mathbf{u}_r) = \mathbf{u}_1 * \cdots * \mathbf{u}_r.$$

Then, for every $\mathbf{X} \in \mathfrak{X}(M)$,

$$\nabla_{\mathbf{X}}\mathbf{T} = \sum_{i=1}^{r} \mathbf{u}_1 * \cdots * (\nabla_{\mathbf{X}}\mathbf{u}_i) * \cdots * \mathbf{u}_r.$$

Proof. By definition, $\mathbf{T} = \mathbf{\Phi}(\mathbf{u}_1 \otimes \cdots \otimes \mathbf{u}_r)$. We regard $\mathbf{\Phi}$ as a section of $\operatorname{Hom}(\mathbf{E}_1 \otimes \cdots \otimes \mathbf{E}_r, \mathbf{F})$, with the connection induced by those on $\mathbf{E}_1, \dots, \mathbf{E}_r$ and $\mathbf{F}$.
By the definition of this connection, for every $\mathbf{S} \in \Gamma(\mathbf{E}_1 \otimes \cdots \otimes \mathbf{E}_r)$ we have

$$(\nabla_{\mathbf{X}}\mathbf{\Phi})(\mathbf{S}) = \nabla_{\mathbf{X}}(\mathbf{\Phi}(\mathbf{S})) - \mathbf{\Phi}(\nabla_{\mathbf{X}}\mathbf{S}).$$

Applying this to $\mathbf{S} = \mathbf{u}_1 \otimes \cdots \otimes \mathbf{u}_r$ gives

$$\nabla_{\mathbf{X}}\mathbf{T} = (\nabla_{\mathbf{X}}\mathbf{\Phi})(\mathbf{u}_1 \otimes \cdots \otimes \mathbf{u}_r) + \mathbf{\Phi}\big(\nabla_{\mathbf{X}}(\mathbf{u}_1 \otimes \cdots \otimes \mathbf{u}_r)\big).$$

By construction, $\mathbf{\Phi}$ is a combination of tensor products, permutations, contractions, and isomorphisms induced by the metrics. Compatibility of the connections ensures that the musical identifications are parallel; contractions, permutations, and tensor products are also parallel for the induced connections. Each operation therefore commutes with the connection in the sense of Definition 2.4.33. It follows that $\mathbf{\Phi}$ is parallel, that is, $\nabla_{\mathbf{X}}\mathbf{\Phi} = 0$.
Consequently,

$$\nabla_{\mathbf{X}}\mathbf{T} = \mathbf{\Phi}\big(\nabla_{\mathbf{X}}(\mathbf{u}_1 \otimes \cdots \otimes \mathbf{u}_r)\big).$$

Applying the Leibniz rule for the tensor product,

$$\nabla_{\mathbf{X}}(\mathbf{u}_1 \otimes \cdots \otimes \mathbf{u}_r) = \sum_{i=1}^{r} \mathbf{u}_1 \otimes \cdots \otimes (\nabla_{\mathbf{X}}\mathbf{u}_i) \otimes \cdots \otimes \mathbf{u}_r,$$

and substituting gives

$$\nabla_{\mathbf{X}}\mathbf{T} = \sum_{i=1}^{r} \mathbf{\Phi}\big(\mathbf{u}_1 \otimes \cdots \otimes (\nabla_{\mathbf{X}}\mathbf{u}_i) \otimes \cdots \otimes \mathbf{u}_r\big).$$

This is equivalent to

$$\nabla_{\mathbf{X}}\mathbf{T} = \sum_{i=1}^{r} \mathbf{u}_1 * \cdots * (\nabla_{\mathbf{X}}\mathbf{u}_i) * \cdots * \mathbf{u}_r,$$

as required. □

To study equivalence of norms, we need to control the commutator of covariant derivatives with the Laplacian. Recall the curvature $\mathbf{R}^{\mathbf{E}}$ of the connection, introduced in Definition 8.2.21. The product connection on tensor bundles combines $\mathbf{R}^{\mathbf{E}}$ with the Riemannian curvature; both therefore appear in the following commutator.

Lemma 9.1.41. (Commutator of the Bochner Laplacian with covariant derivatives) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. For $\ell\in\mathbb{N}_0$, set

$$\mathbf{E}_\ell := T^{(0,\ell)}(TM)\otimes\mathbf{E},$$

with the induced product metric and connection, and denote the covariant derivative by $\nabla_\ell\colon\Gamma(\mathbf{E}_\ell)\to\Gamma(\mathbf{E}_{\ell+1})$. For $m\in\mathbb{N}$ we write

$$\nabla^m := \nabla_{\ell+m-1}\circ\cdots\circ\nabla_\ell,$$

so that each new derivative index occupies the first covariant factor. Let

$$\Delta_{B,\ell} := (\nabla_\ell)^*_h\nabla_\ell = -\operatorname{tr}_{\mathbf{g}}(\nabla_\ell^2)$$

be the Bochner Laplacian on $\mathbf{E}_\ell$. Then, for every $\mathbf{u}\in\Gamma(\mathbf{E}_\ell)$,

$$\Delta_{B,\ell+m}(\nabla^m\mathbf{u})-\nabla^m(\Delta_{B,\ell}\mathbf{u}) = \sum_{k=0}^{m}\nabla^k\operatorname{Rm}*\nabla^{m-k}\mathbf{u}. \tag{9.27}$$

Here Rm represents either $\mathbf{R}^M$ or $\mathbf{R}^{\mathbf{E}}$, depending on the summand, with their induced connections, and $*$ denotes a finite sum of tensor products, permutations, and universal contractions. The coefficients and the number of terms depend only on m, ℓ, $\dim M$, and the rank of $\mathbf{E}$.

Proof. We first prove the identity for a single derivative. Let $\mathbf{F}\to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{F}}$ and a compatible connection $\nabla^{\mathbf{F}}$, curvature $\mathbf{R}^{\mathbf{F}}$, and Bochner Laplacian

$$\Delta_B^{\mathbf{F}} := (\nabla^{\mathbf{F}})^*\nabla^{\mathbf{F}} = -\operatorname{tr}_{\mathbf{g}}\big((\nabla^{\mathbf{F}})^2\big).$$

We claim that, for each $\mathbf{v}\in\Gamma(\mathbf{F})$, each $x\in M$, each $\mathbf{X}\in T_xM$, and any orthonormal basis $(\mathbf{e}_1,\dots,\mathbf{e}_n)$ of T_xM, we have

$$\big(\nabla^{\mathbf{F}}\Delta_B^{\mathbf{F}}\mathbf{v}-\Delta_B^{T^*M\otimes\mathbf{F}}(\nabla^{\mathbf{F}}\mathbf{v})\big)(\mathbf{X}) = \nabla^{\mathbf{F}}_{\operatorname{Ric}^\sharp\mathbf{X}}\mathbf{v}+2\sum_{i=1}^{n}\mathbf{R}^{\mathbf{F}}(\mathbf{e}_i,\mathbf{X})\nabla^{\mathbf{F}}_{\mathbf{e}_i}\mathbf{v}+\sum_{i=1}^{n}(\nabla_{\mathbf{e}_i}\mathbf{R}^{\mathbf{F}})(\mathbf{e}_i,\mathbf{X})\mathbf{v}. \tag{9.28}$$

All terms on the right-hand side are evaluated at x. The sums are tensor contractions and thus do not depend on the chosen orthonormal basis.

First suppose that $x\in\operatorname{Int}M$. Both sides of (9.28) belong to $T^*_xM\otimes\mathbf{F}_x$; we therefore fix an arbitrary vector $\mathbf{X}\in T_xM$ and compare their values at $\mathbf{X}$. Extend $\mathbf{X},\mathbf{e}_1,\dots,\mathbf{e}_n$ to local fields, denoted in the same way, such that

$$\nabla^M_{\mathbf{Y}}\mathbf{X}(x)=0,\qquad \nabla^M_{\mathbf{Y}}\mathbf{e}_i(x)=0$$

for every $\mathbf{Y}\in T_xM$ and every i. These extensions are obtained by taking constant components in normal coordinates centered at x.

Set $\mathbf{A}:=\nabla^{\mathbf{F}}\mathbf{v}\in\Gamma(T^*M\otimes\mathbf{F})$. According to the convention in Proposition 2.4.29, the first two arguments

of $\nabla^3\mathbf{v} = \nabla^2\mathbf{A}$ are the added derivative indices, and the third is the original argument of $\mathbf{A}$. Since the Levi–Civita connection commutes with metric contractions by Proposition 2.4.37, at the point x we have

$$\begin{aligned}(\nabla^{\mathbf{F}}\Delta_B^{\mathbf{F}}\mathbf{v})(\mathbf{X}) &= -\sum_{i=1}^{n}(\nabla^3\mathbf{v})(\mathbf{X},\mathbf{e}_i,\mathbf{e}_i),\\ \big(\Delta_B^{T^*M\otimes\mathbf{F}}\mathbf{A}\big)(\mathbf{X}) &= -\sum_{i=1}^{n}(\nabla^3\mathbf{v})(\mathbf{e}_i,\mathbf{e}_i,\mathbf{X}).\end{aligned} \tag{9.29}$$

The first equality follows by differentiating the tensor $-\operatorname{tr}_{\mathbf{g}}\nabla^2\mathbf{v}$, rather than a formula valid only at x. Subtracting the two equalities in (9.29) gives

$$\big(\nabla^{\mathbf{F}}\Delta_B^{\mathbf{F}}\mathbf{v} - \Delta_B^{T^*M\otimes\mathbf{F}}\mathbf{A}\big)(\mathbf{X}) = \sum_{i=1}^{n}\big[(\nabla^3\mathbf{v})(\mathbf{e}_i,\mathbf{e}_i,\mathbf{X}) - (\nabla^3\mathbf{v})(\mathbf{X},\mathbf{e}_i,\mathbf{e}_i)\big]. \tag{9.30}$$

We interchange the indices in two steps. The Ricci identity in Proposition 8.2.23, first applied to $\mathbf{v}$ and then covariantly differentiated in the direction $\mathbf{e}_i$, gives

$$(\nabla^3\mathbf{v})(\mathbf{e}_i,\mathbf{e}_i,\mathbf{X}) - (\nabla^3\mathbf{v})(\mathbf{e}_i,\mathbf{X},\mathbf{e}_i) = (\nabla_{\mathbf{e}_i}\mathbf{R}^{\mathbf{F}})(\mathbf{e}_i,\mathbf{X})\mathbf{v} + \mathbf{R}^{\mathbf{F}}(\mathbf{e}_i,\mathbf{X})\nabla^{\mathbf{F}}_{\mathbf{e}_i}\mathbf{v}. \tag{9.31}$$

Indeed, the terms in which the derivative acts on $\mathbf{e}_i$ or $\mathbf{X}$ vanish at x by the choice of extensions.
We now apply the same Ricci identity to the section $\mathbf{A} = \nabla^{\mathbf{F}}\mathbf{v}$ of the bundle $T^*M\otimes\mathbf{F}$. By the product curvature formula (8.15),

$$(\nabla^3\mathbf{v})(\mathbf{e}_i,\mathbf{X},\mathbf{e}_i) - (\nabla^3\mathbf{v})(\mathbf{X},\mathbf{e}_i,\mathbf{e}_i) = \mathbf{R}^{\mathbf{F}}(\mathbf{e}_i,\mathbf{X})\nabla^{\mathbf{F}}_{\mathbf{e}_i}\mathbf{v} - \nabla^{\mathbf{F}}_{\mathbf{R}^M(\mathbf{e}_i,\mathbf{X})\mathbf{e}_i}\mathbf{v}. \tag{9.32}$$

Adding (9.31) and (9.32), then summing over i and using (9.30), gives

$$\big(\nabla^{\mathbf{F}}\Delta_B^{\mathbf{F}}\mathbf{v} - \Delta_B^{T^*M\otimes\mathbf{F}}(\nabla^{\mathbf{F}}\mathbf{v})\big)(\mathbf{X}) = \sum_{i=1}^{n}(\nabla_{\mathbf{e}_i}\mathbf{R}^{\mathbf{F}})(\mathbf{e}_i,\mathbf{X})\mathbf{v} + 2\sum_{i=1}^{n}\mathbf{R}^{\mathbf{F}}(\mathbf{e}_i,\mathbf{X})\nabla^{\mathbf{F}}_{\mathbf{e}_i}\mathbf{v} - \nabla^{\mathbf{F}}_{\sum_{i=1}^{n}\mathbf{R}^M(\mathbf{e}_i,\mathbf{X})\mathbf{e}_i}\mathbf{v}.$$

Proposition 2.10.9 states that $-\sum_{i=1}^{n}\mathbf{R}^M(\mathbf{e}_i,\mathbf{X})\mathbf{e}_i = \operatorname{Ric}^\sharp\mathbf{X}$, and we therefore obtain (9.28). Since x and $\mathbf{X}$ were arbitrary, the identity holds on $\operatorname{Int}M$. If M has boundary, both sides are smooth sections up to ∂M and $\operatorname{Int}M$ is dense in M; by continuity, the identity also holds on the boundary.
As a check on the sign, if $\mathbf{F} = M\times\mathbb{R}$ has the trivial connection, the preceding formula reduces to

$$d\Delta_B f - \Delta_B^{T^*M}(df) = df\circ\operatorname{Ric}^\sharp.$$

We now apply the identity to $\mathbf{F} = \mathbf{E}_\ell = T^{(0,\ell)}(TM)\otimes\mathbf{E}$. By (8.13), the curvature of $\mathbf{E}_\ell$ is the sum of the action of $\mathbf{R}^{\mathbf{E}}$ on the factor $\mathbf{E}$ and the actions of $\mathbf{R}^M$ on the covariant factors. Moving (9.28) to the other side and absorbing the signs and universal contractions into the symbol $*$ gives

$$\Delta_{B,\ell+1}(\nabla\mathbf{u}) - \nabla(\Delta_{B,\ell}\mathbf{u}) = \operatorname{Rm}*\nabla\mathbf{u} + \nabla\operatorname{Rm}*\mathbf{u}. \tag{9.33}$$

This is the case $m = 1$.

Suppose that (9.27) holds for some $m \geq 1$. Then

$$\Delta_{B,\ell+m+1}(\nabla^{m+1}\mathbf{u}) - \nabla^{m+1}(\Delta_{B,\ell}\mathbf{u}) = \big(\Delta_{B,\ell+m+1}\nabla - \nabla\Delta_{B,\ell+m}\big)(\nabla^m\mathbf{u}) + \nabla\big(\Delta_{B,\ell+m}(\nabla^m\mathbf{u}) - \nabla^m(\Delta_{B,\ell}\mathbf{u})\big).$$

By (9.33), the first term is a universal sum of terms of the types $\mathrm{Rm}*\nabla^{m+1}\mathbf{u}$ and $\nabla\mathrm{Rm}*\nabla^m\mathbf{u}$. For the second we use the induction hypothesis and the Leibniz rule in Proposition 9.1.40:

$$\nabla\big(\Delta_{B,\ell+m}(\nabla^m\mathbf{u}) - \nabla^m(\Delta_{B,\ell}\mathbf{u})\big) = \sum_{k=0}^{m}\Big(\nabla^{k+1}\mathrm{Rm}*\nabla^{m-k}\mathbf{u} + \nabla^k\mathrm{Rm}*\nabla^{m+1-k}\mathbf{u}\Big).$$

All the resulting terms have the form $\nabla^q\mathrm{Rm}*\nabla^{m+1-q}\mathbf{u}$ with $0 \leq q \leq m+1$. Regrouping, for each q, the universal contractions that occur, we conclude that

$$\Delta_{B,\ell+m+1}(\nabla^{m+1}\mathbf{u}) - \nabla^{m+1}(\Delta_{B,\ell}\mathbf{u}) = \sum_{q=0}^{m+1}\nabla^q\mathrm{Rm}*\nabla^{m+1-q}\mathbf{u}.$$

This completes the induction. □

Theorem 9.1.42. (Equivalence of norms on $H^m(M,\mathbf{E})$ in terms of the Bochner Laplacian) Let $(M,\mathbf{g})$ be a closed Riemannian manifold, and let $\mathbf{E} \to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$. Let $m \in \mathbb{N}$. For $\mathbf{u} \in \Gamma(\mathbf{E})$ define

$$\|\mathbf{u}\|^2_{H^m(M,\mathbf{E})} := \sum_{j=0}^{m}\int_M |\nabla^j\mathbf{u}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}},$$

and

$$\|\mathbf{u}\|^2_{\Delta_B} := \sum_{\substack{j=0\\ j\text{ even}}}^{m}\int_M |\Delta_B^{\frac{j}{2}}\mathbf{u}|^2_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} + \sum_{\substack{j=1\\ j\text{ odd}}}^{m}\int_M \big|\nabla\Delta_B^{\frac{j-1}{2}}\mathbf{u}\big|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

Denote by $H^m(M,\mathbf{E})$ the completion of $\Gamma(\mathbf{E})$ with respect to the first norm. Then there are constants $c, C > 0$ such that

$$c\|\mathbf{u}\|^2_{H^m(M,\mathbf{E})} \leq \|\mathbf{u}\|^2_{\Delta_B} \leq C\|\mathbf{u}\|^2_{H^m(M,\mathbf{E})}, \qquad \forall\mathbf{u} \in \Gamma(\mathbf{E}).$$

Consequently, the second norm determines the same completion. For an element of $H^m(M,\mathbf{E})$, each term containing a power of Δ_B is understood as the limit in L^2 of the corresponding term of a smooth Cauchy sequence.

Proof. Since M is closed, it is compact and $\partial M = \varnothing$. We prove the inequalities on $\Gamma(\mathbf{E})$; the assertion about completions will then follow by continuity.
Throughout what follows, all integrations by parts have no boundary terms.

We first prove that

$$\|\mathbf{u}\|^2_{\Delta_B} \leq C\|\mathbf{u}\|^2_{H^m(M,\mathbf{E})}.$$

By definition,

$$\Delta_B = \nabla^*\nabla = -\mathrm{tr}_{\mathbf{g}}(\nabla^2).$$

Since the connection is compatible with the metric, covariant differentiation commutes with contraction. Define the contractions

$$C_k^{\mathrm{even}}(T) := g^{i_1 i_2} \cdots g^{i_{2k-1} i_{2k}} T_{i_1 \cdots i_{2k}},$$
$$\big(C_k^{\mathrm{odd}}(S)\big)_a := g^{i_1 i_2} \cdots g^{i_{2k-1} i_{2k}} S_{a i_1 \cdots i_{2k}}.$$

The first contracts the pairs $(1,2),(3,4),\ldots$; the second leaves the first index free and contracts $(2,3),(4,5),\ldots$. Induction on k gives

$$\Delta_B^k \mathbf{u} = (-1)^k C_k^{\mathrm{even}}(\nabla^{2k}\mathbf{u}).$$

Set $\Phi_k := (-1)^k C_k^{\mathrm{even}}$. Since Φ_k is obtained using contractions and linear combinations, Lemma 9.1.39 implies that there is a constant $C_k > 0$ such that

$$|\Delta_B^k \mathbf{u}|_{\mathbf{h_E}} \le C_k |\nabla^{2k}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}.$$

Squaring and integrating gives

$$\int_M |\Delta_B^k \mathbf{u}|^2_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \le C_k^2 \int_M |\nabla^{2k}\mathbf{u}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

Since $\nabla \mathbf{g} = 0$, differentiating each factor $\mathbf{g}^{-1}$ used in the contraction gives zero; by the Leibniz rule,

$$\nabla \Delta_B^k \mathbf{u} = (-1)^k \nabla\big(C_k^{\mathrm{even}}(\nabla^{2k}\mathbf{u})\big) = (-1)^k C_k^{\mathrm{odd}}(\nabla^{2k+1}\mathbf{u}).$$

We therefore define

$$\Psi_k \colon T^{(0,2k+1)}(TM) \otimes \mathbf{E} \longrightarrow T^*M \otimes \mathbf{E}, \qquad \Psi_k(S) := (-1)^k C_k^{\mathrm{odd}}(S).$$

Thus

$$\nabla \Delta_B^k \mathbf{u} = \Psi_k(\nabla^{2k+1}\mathbf{u}),$$

and, again by Lemma 9.1.39, there is $C_k' > 0$ such that

$$|\nabla \Delta_B^k \mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \le C_k' |\nabla^{2k+1}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}.$$

Squaring and integrating gives

$$\int_M |\nabla \Delta_B^k \mathbf{u}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \le (C_k')^2 \int_M |\nabla^{2k+1}\mathbf{u}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

Consequently, each even summand of $\|\mathbf{u}\|^2_{\Delta_B}$ is bounded by the corresponding even-order summand of $\|\mathbf{u}\|^2_{H^m(M,\mathbf{E})}$, and each odd summand of $\|\mathbf{u}\|^2_{\Delta_B}$ is bounded by the corresponding odd-order summand of $\|\mathbf{u}\|^2_{H^m(M,\mathbf{E})}$. Adding all the terms, we conclude that there is a constant $C > 0$ such that

$$\|\mathbf{u}\|^2_{\Delta_B} \le C \|\mathbf{u}\|^2_{H^m(M,\mathbf{E})}.$$

We now prove that

$$\|\mathbf{u}\|^2_{H^m(M,\mathbf{E})} \le C\|\mathbf{u}\|^2_{\Delta_B}.$$

We formulate the inductive estimate for all smooth sections. For $0 \le j \le m$ and $\mathbf{v} \in \Gamma(\mathbf{E})$, introduce the truncated quantity

$$\mathcal{N}_j(\mathbf{v})^2 := \sum_{\substack{0\le r\le j\\ r \text{ even}}} \|\Delta_B^{\frac{r}{2}}\mathbf{v}\|^2_{L^2(M,\mathbf{E})} + \sum_{\substack{1\le r\le j\\ r \text{ odd}}} \|\nabla^{\mathbf{E}}\Delta_B^{\frac{r-1}{2}}\mathbf{v}\|^2_{L^2(M,T^*M\otimes\mathbf{E})}. \tag{9.34}$$

Thus $\mathcal{N}_m(\mathbf{u}) = \|\mathbf{u}\|_{\Delta_B}$. We prove the following quantified assertion by induction: for each $j \in \{0,\dots,m\}$ there is $C_j > 0$ such that, for every smooth section $\mathbf{v} \in \Gamma(\mathbf{E})$,

$$\int_M |\nabla^j\mathbf{v}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \le C_j\mathcal{N}_j(\mathbf{v})^2.$$

Since the estimate is formulated for every smooth section, at the step of order $j-2$ we may take $\mathbf{v} = \Delta_B\mathbf{u}$.
For $j = 0$ and every $\mathbf{v} \in \Gamma(\mathbf{E})$ we have

$$\int_M |\mathbf{v}|^2_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} = \mathcal{N}_0(\mathbf{v})^2,$$

since the truncated sum contains only the term of order zero.
For $j = 1$ and every $\mathbf{v} \in \Gamma(\mathbf{E})$ we have

$$\int_M |\nabla\mathbf{v}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \le \mathcal{N}_1(\mathbf{v})^2,$$

since this is the odd term of order one.
Now consider the case $j = 2$. Applying Corollary 9.1.31 to the bundle $T^*M \otimes \mathbf{E}$ gives

$$\int_M |\nabla^2\mathbf{u}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} = \int_M \langle\nabla\mathbf{u}, \Delta_{B,1}(\nabla\mathbf{u})\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

By Lemma 9.1.41 with $m = 1$,

$$\Delta_{B,1}(\nabla\mathbf{u}) = \nabla(\Delta_{B,0}\mathbf{u}) + \mathrm{Rm}*\nabla\mathbf{u} + \nabla\mathrm{Rm}*\mathbf{u}.$$

Substituting,

$$\int_M |\nabla^2\mathbf{u}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} = \int_M \langle\nabla\mathbf{u}, \nabla(\Delta_B\mathbf{u})\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} + \int_M \langle\nabla\mathbf{u}, \mathrm{Rm}*\nabla\mathbf{u}\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} + \int_M \langle\nabla\mathbf{u}, \nabla\mathrm{Rm}*\mathbf{u}\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

Applying Corollary 9.1.31 once more, now to the bundle $\mathbf{E}$, gives

$$\int_M \langle\nabla\mathbf{u}, \nabla(\Delta_B\mathbf{u})\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} = \int_M |\Delta_B\mathbf{u}|^2_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

Moreover, since M is compact, the curvature tensor is uniformly bounded and, by Lemma 9.1.39, there is a constant $C > 0$ such that

$$|\mathrm{Rm}*\nabla\mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \le C|\nabla\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}.$$

Consequently,

$$\left|\int_M \langle\nabla\mathbf{u}, \mathrm{Rm}*\nabla\mathbf{u}\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}\right| \le C\int_M |\nabla\mathbf{u}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

Likewise, the compactness of M gives a uniform bound on $\nabla \operatorname{Rm}$, so that

$$|\nabla \operatorname{Rm} * \mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \le C|\mathbf{u}|_{\mathbf{h}_\mathbf{E}}.$$

By the Cauchy–Schwarz inequality,

$$\left| \int_M \langle \nabla \mathbf{u}, \nabla \operatorname{Rm} * \mathbf{u} \rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \right| \le C \|\nabla \mathbf{u}\|_{L^2(M,T^*M\otimes\mathbf{E})} \|\mathbf{u}\|_{L^2(M,\mathbf{E})}.$$

The two factors correspond to lower-order terms appearing in $\|\mathbf{u}\|_{\Delta_B}$. The elementary inequality $2ab \le a^2 + b^2$, applied with $a = \|\nabla \mathbf{u}\|_{L^2(M,T^*M\otimes\mathbf{E})}$ and $b = \|\mathbf{u}\|_{L^2(M,\mathbf{E})}$, gives

$$\left| \int_M \langle \nabla \mathbf{u}, \nabla \operatorname{Rm} * \mathbf{u} \rangle_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \right| \le C \|\nabla \mathbf{u}\|^2_{L^2(M,T^*M\otimes\mathbf{E})} + C \|\mathbf{u}\|^2_{L^2(M,\mathbf{E})}.$$

Consequently,

$$\int_M |\nabla^2 \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \le \int_M |\Delta_B \mathbf{u}|^2_{\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} + C \int_M |\nabla \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} + C \int_M |\mathbf{u}|^2_{\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g}.$$

The three terms on the right-hand side appear, respectively, in $\mathcal{N}_2(\mathbf{u})^2$. Therefore,

$$\int_M |\nabla^2 \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \le C_2 \mathcal{N}_2(\mathbf{u})^2.$$

Now let $j \ge 3$ and suppose that, for every integer $l < j$ and every $\mathbf{v} \in \Gamma(\mathbf{E})$, we have already proved that

$$\int_M |\nabla^l \mathbf{v}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \le C_l \mathcal{N}_l(\mathbf{v})^2.$$

We want to prove the same estimate for j.

Write $\nabla^j \mathbf{u} = \nabla^2(\nabla^{j-2}\mathbf{u})$. The argument for the case $j = 2$ depends only on compatibility of the connection and the uniform bounds on the curvature and its first derivative. It therefore applies to the bundle $T^{(0,j-2)}(TM) \otimes \mathbf{E}$ and the section $\nabla^{j-2}\mathbf{u}$. The curvature of this product bundle and its first derivative are sums of contractions of $\mathbf{R}^M$, $\mathbf{R}^\mathbf{E}$, and their derivatives; all are bounded because M is compact. This yields

$$\begin{aligned} \int_M |\nabla^j \mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \le \int_M |\Delta_{B,j-2}(\nabla^{j-2}\mathbf{u})|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} + C \int_M |\nabla^{j-1}\mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \\ + C \int_M |\nabla^{j-2}\mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g}. \end{aligned}$$

By the induction hypothesis, the last two terms are bounded by $C\mathcal{N}_j(\mathbf{u})^2$, since $\mathcal{N}_l(\mathbf{u}) \le \mathcal{N}_j(\mathbf{u})$ for $l < j$. Thus it suffices to estimate the first.

Applying Lemma 9.1.41 with $m = j - 2$ gives

$$\Delta_{B,j-2}(\nabla^{j-2}\mathbf{u}) = \nabla^{j-2}(\Delta_B \mathbf{u}) + \sum_{k=0}^{j-2} \nabla^k \operatorname{Rm} * \nabla^{j-2-k}\mathbf{u}.$$

Squaring, using the inequality

$$|A_0 + \cdots + A_N|^2 \le C \sum_{r=0}^{N} |A_r|^2,$$

, and integrating, we obtain

$$\int_M |\Delta_{B,j-2}(\nabla^{j-2}\mathbf{u})|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \le C \int_M |\nabla^{j-2}(\Delta_B \mathbf{u})|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} + C \sum_{k=0}^{j-2} \int_M |\nabla^k \operatorname{Rm} * \nabla^{j-2-k}\mathbf{u}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

Since M is compact, all covariant derivatives of Rm are uniformly bounded. By Lemma 9.1.39, for each k there is a constant $C_k > 0$ such that

$$|\nabla^k \operatorname{Rm} * \nabla^{j-2-k}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}} \le C_k |\nabla^{j-2-k}\mathbf{u}|_{\mathbf{g},\mathbf{h_E}}.$$

Therefore,

$$\int_M |\Delta_{B,j-2}(\nabla^{j-2}\mathbf{u})|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \le C \int_M |\nabla^{j-2}(\Delta_B \mathbf{u})|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} + C \sum_{l=0}^{j-2} \int_M |\nabla^l \mathbf{u}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

By the induction hypothesis, the lower-order sum is controlled by $\mathcal{N}_j(\mathbf{u})^2$. Consequently,

$$\int_M |\nabla^j \mathbf{u}|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \le C \int_M |\nabla^{j-2}(\Delta_B \mathbf{u})|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} + C\mathcal{N}_j(\mathbf{u})^2.$$

We now apply the inductive assertion, which holds for every smooth section, to $\mathbf{v} = \Delta_B \mathbf{u}$ at order $j-2$. Since $j-2 < j$, we obtain

$$\int_M |\nabla^{j-2}(\Delta_B \mathbf{u})|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \le C \left(\sum_{\substack{\ell=0 \\ \ell \text{ even}}}^{j-2} \int_M \left|\Delta_B^{\frac{\ell}{2}}(\Delta_B \mathbf{u})\right|^2_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} + \sum_{\substack{\ell=1 \\ \ell \text{ odd}}}^{j-2} \int_M \left|\nabla \Delta_B^{\frac{\ell-1}{2}}(\Delta_B \mathbf{u})\right|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \right).$$

We now rewrite each of these sums.
For the even sum,

$$\Delta_B^{\frac{\ell}{2}}(\Delta_B \mathbf{u}) = \Delta_B^{\frac{\ell}{2}+1}\mathbf{u}.$$

If ℓ ranges over the even integers between 0 and $j-2$, then $r = \ell + 2$ ranges over the even integers between 2 and j. Therefore,

$$\sum_{\substack{\ell=0 \\ \ell \text{ even}}}^{j-2} \int_M \left|\Delta_B^{\frac{\ell}{2}}(\Delta_B \mathbf{u})\right|^2_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} = \sum_{\substack{r=2 \\ r \text{ even}}}^{j} \int_M \left|\Delta_B^{\frac{r}{2}}\mathbf{u}\right|^2_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

For the odd sum,

$$\nabla \Delta_B^{\frac{\ell-1}{2}}(\Delta_B \mathbf{u}) = \nabla \Delta_B^{\frac{\ell+1}{2}}\mathbf{u}.$$

If ℓ ranges over the odd integers between 1 and $j-2$, then $s = \ell + 2$ ranges over the odd integers between 3 and j. Thus

$$\sum_{\substack{\ell=1 \\ \ell \text{ odd}}}^{j-2} \int_M \left|\nabla \Delta_B^{\frac{\ell-1}{2}}(\Delta_B \mathbf{u})\right|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} = \sum_{\substack{s=3 \\ s \text{ odd}}}^{j} \int_M \left|\nabla \Delta_B^{\frac{s-1}{2}}\mathbf{u}\right|^2_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

Substituting these identities into the preceding estimate gives

$$\int_M |\nabla^{j-2}(\Delta_B \mathbf{u})|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g} \le C\left(\sum_{\substack{r=2\\ r\ \text{even}}}^{j}\int_M \left|\Delta_B^{\frac{r}{2}}\mathbf{u}\right|^2_{\mathbf{h}_\mathbf{E}} d\lambda_\mathbf{g} + \sum_{\substack{s=3\\ s\ \text{odd}}}^{j}\int_M \left|\nabla\Delta_B^{\frac{s-1}{2}}\mathbf{u}\right|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}} d\lambda_\mathbf{g}\right).$$

Each of these terms appears in the definition of $\mathcal{N}_j(\mathbf{u})^2$. Equivalently, $\mathcal{N}_{j-2}(\Delta_B\mathbf{u}) \le \mathcal{N}_j(\mathbf{u})$: the even powers and odd terms shift by exactly two orders. Consequently,

$$\int_M |\nabla^{j-2}(\Delta_B \mathbf{u})|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g} \le C\mathcal{N}_j(\mathbf{u})^2.$$

Returning to the previous estimate for $\displaystyle\int_M |\nabla^j\mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g}$, we conclude that

$$\int_M |\nabla^j\mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g} \le C_j\mathcal{N}_j(\mathbf{u})^2.$$

This completes the induction step. Finally, $\mathcal{N}_j(\mathbf{u}) \le \mathcal{N}_m(\mathbf{u}) = \|\mathbf{u}\|_{\Delta_B}$ for $j \le m$. Summing over $j \in \{0,\dots,m\}$ gives

$$\|\mathbf{u}\|^2_{H^m(M,\mathbf{E})} = \sum_{j=0}^{m}\int_M |\nabla^j\mathbf{u}|^2_{\mathbf{g},\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g} \le C\|\mathbf{u}\|^2_{\Delta_B}.$$

Together with the inequality proved at the beginning,

$$\|\mathbf{u}\|^2_{\Delta_B} \le C\|\mathbf{u}\|^2_{H^m(M,\mathbf{E})},$$

this gives the two stated inequalities with positive constants. If $(\mathbf{u}_\nu)$ is Cauchy in the norm of H^m, the forward inequality shows that each sequence $\Delta_B^k\mathbf{u}_\nu$ and $\nabla\Delta_B^k\mathbf{u}_\nu$ appearing in the structured norm is Cauchy in the corresponding space L^2. We define these terms in the completion by their limits. The reverse inequality proves that this procedure adds no new elements and is independent of the representative sequence. This justifies the final assertion in the statement. □

9.1.5 Local characterization of Sobolev spaces in vector bundles

In this subsection we show how to characterize Sobolev sections through their component functions. To this end, we first prove an analogue of Lemma 7.1.8 for arbitrary vector bundles:

Lemma 9.1.43. Let M be a smooth manifold with or without boundary, let $K \subseteq M$ be compact, and let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle of finite rank. Let $\mathbf{h}$ and $\widetilde{\mathbf{h}}$ be two smooth bundle metrics on $\mathbf{E}$. Then there are constants $c, C > 0$ such that, for every $p \in K$ and every $v \in \mathbf{E}_p$,

$$c\,\mathbf{h}_p(v,v) \le \widetilde{\mathbf{h}}_p(v,v) \le C\,\mathbf{h}_p(v,v).$$

Equivalently, $\sqrt{c}\,|v|_\mathbf{h} \le |v|_{\widetilde{\mathbf{h}}} \le \sqrt{C}\,|v|_\mathbf{h}$ in the same fibers. In particular, if M is compact, we may take $K = M$.

Proof. If $K = \varnothing$ or the bundle has rank zero, it suffices to take $c = C = 1$. Suppose that $K \neq \varnothing$ and the rank is $r \geq 1$. Let $p \in M$. Consider

$$S_p := \{v \in \mathbf{E}_p \mid \mathbf{h}_p(v, v) = 1\}.$$

This set is closed and bounded in a finite-dimensional normed vector space, and is therefore compact. Moreover, the function $f_p : S_p \longrightarrow \mathbb{R}$, given by $f_p(v) = \widetilde{\mathbf{h}}_p(v, v)$, is continuous and hence attains its maximum. Thus the function $f : M \longrightarrow \mathbb{R}$ defined by

$$f(p) := \max_{v \in S_p} f_p(v)$$

is well defined. We prove its continuity by identifying the spheres in nearby fibers with a fixed sphere. On a neighborhood U of any point $p_* \in M$, the Gram–Schmidt process applied to a smooth frame gives a frame $\mathbf{e}_1, \ldots, \mathbf{e}_r$ orthonormal for $\mathbf{h}$. If the bundle is real, set $\mathbb{K} = \mathbb{R}$; if it is complex with Hermitian metrics, set $\mathbb{K} = \mathbb{C}$. Define

$$S := \left\{ w \in \mathbb{K}^r \;\middle|\; \sum_{a=1}^{r} |w^a|^2 = 1 \right\}, \qquad F(q, w) := \widetilde{\mathbf{h}}_q \left(\sum_{a=1}^{r} w^a \mathbf{e}_a(q), \sum_{a=1}^{r} w^a \mathbf{e}_a(q) \right).$$

For $q \in U$, the map $w \mapsto \sum_{a=1}^{r} w^a \mathbf{e}_a(q)$ identifies S with S_q. Hence $f(q) = \max_{w \in S} F(q, w)$. Let $H_{ab}(q) = \widetilde{\mathbf{h}}_q(\mathbf{e}_a(q), \mathbf{e}_b(q))$ be the continuous coefficients of the second metric in that frame. The Cauchy–Schwarz inequality gives $\sum_{a=1}^{r} |w^a| \leq \sqrt{r}$ for $w \in S$. Consequently,

$$\begin{aligned} \sup_{w \in S} |F(q, w) - F(p_*, w)| &\leq \max_{1 \leq a, b \leq r} |H_{ab}(q) - H_{ab}(p_*)| \sup_{w \in S} \left(\sum_{a=1}^{r} |w^a| \right)^2 \\ &\leq r \max_{1 \leq a, b \leq r} |H_{ab}(q) - H_{ab}(p_*)| \longrightarrow 0 \qquad (q \to p_*). \end{aligned}$$

If two functions on S differ by at most ε at every point, their maxima differ by at most ε: first use $F(q, w) \leq F(p_*, w) + \varepsilon$, and then the inequality with the two points interchanged. Thus

$$|f(q) - f(p_*)| \leq \sup_{w \in S} |F(q, w) - F(p_*, w)|,$$

which proves continuity of f on p_*. Since the point was arbitrary, f is continuous on M. The compactness of K gives $p_0 \in K$ such that $f(p) \leq f(p_0) =: C$ for every $p \in K$.
Moreover,

$$C = f(p_0) = \max_{v \in S_{p_0}} \widetilde{\mathbf{h}}_{p_0}(v, v) > 0,$$

since $v \neq 0$ for every $v \in S_{p_0}$. Thus, for every $p \in K$ and every $v \in S_p$, we have

$$\widetilde{\mathbf{h}}_p(v, v) \leq C.$$

Define $m(p) := \min_{v \in S_p} \widetilde{\mathbf{h}}_p(v, v)$. In the preceding frame, $m(q) = \min_{w \in S} F(q, w)$. The same inequalities between

$F(q,w)$ and $F(p_*,w)$, now taking minima, give

$$|m(q)-m(p_*)| \le \sup_{w\in S} |F(q,w)-F(p_*,w)| \longrightarrow 0.$$

Thus m is also continuous. Each $m(p)$ is positive because the minimum is attained at a nonzero vector and $\widetilde{\mathbf{h}}_p$ is positive definite. The compactness of K implies that m attains a minimum there, which remains positive: $c := \min_{p\in K} m(p) > 0$. Therefore, for every $p \in K$ and every $v \in S_p$, we have

$$c \le \widetilde{\mathbf{h}}_p(v,v).$$

Now let $p \in K$ and $v \in \mathbf{E}_p \setminus \{0\}$. Then $\dfrac{v}{|v|_{\mathbf{h}_p}} \in S_p$, so that

$$c \le \widetilde{\mathbf{h}}_p\left(\frac{v}{|v|_{\mathbf{h}_p}}, \frac{v}{|v|_{\mathbf{h}_p}}\right) \le C.$$

This implies that

$$c\,|v|^2_{\mathbf{h}_p} \le \widetilde{\mathbf{h}}_p(v,v) \le C\,|v|^2_{\mathbf{h}_p},$$

that is,

$$c\,\mathbf{h}_p(v,v) \le \widetilde{\mathbf{h}}_p(v,v) \le C\,\mathbf{h}_p(v,v).$$

The case $v = 0$ is immediate, since all the preceding quantities equal 0. □

With this in mind, we are ready to prove the following lemma, which allows us to work locally with these globally and intrinsically defined Sobolev spaces. Unlike the abstract definition of $W^{m,p}$, this lemma assumes that the connection is compatible with the bundle metric, because the proof uses the explicit form of the formal adjoint obtained from the integration-by-parts formula.

Lemma 9.1.44. Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary. Let $m \in \mathbb{N}_0$ and $1 \le p < \infty$, let (U,φ) be a regular coordinate ball in M, and let $\pi_{\mathbf{E}}\colon \mathbf{E} \longrightarrow M$ be a smooth real vector bundle of rank r equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. Let $\mathbf{F} \in L^1_{\mathrm{loc}}(M,\mathbf{E})$ and let $\{\mathbf{e}_1,\dots,\mathbf{e}_r\}$ be a local frame of $\mathbf{E}$ defined on a neighborhood of $\overline{U}$. Suppose that $\mathbf{F} = \sum_{a=1}^{r} F^a \mathbf{e}_a$ on U. Then

$$\mathbf{F}\restriction_U \in W^{m,p}(U,\mathbf{E}\restriction_U) \quad \text{if and only if} \quad F^a \circ \varphi^{-1} \in W^{m,p}(\varphi(U))$$

for every $1 \le a \le r$.
Moreover, there are constants $C_m, c_m > 0$ (independent of $\mathbf{F}$) such that

$$c_m \sum_{a=1}^{r} \left\|F^a \circ \varphi^{-1}\right\|_{W^{m,p}(\varphi(U))} \le \|\mathbf{F}\|_{W^{m,p}(U,\mathbf{E}\restriction_U)} \le C_m \sum_{a=1}^{r} \left\|F^a \circ \varphi^{-1}\right\|_{W^{m,p}(\varphi(U))}$$

for every $\mathbf{F} \in W^{m,p}(U,\mathbf{E}\restriction_U)$.

Proof. The case $m = 0$ follows directly from uniform equivalence of the fiber norms over the compact set $\overline{U}$ and equivalence of the volume elements. Thus suppose that $m \geq 1$. Fix $s \geq 1$ and denote by $I_s = (i_1, \ldots, i_s)$, $J_s = (j_1, \ldots, j_s)$, etc., the ordered tuples or blocks of indices in $\{1, \ldots, n\}$. We adopt the Einstein summation convention for these blocks. Define

$$\partial_{I_s} := \partial_{i_1} \cdots \partial_{i_s}, \quad g^{I_s J_s} := \prod_{l=1}^{s} g^{i_l j_l}, \quad g_{J_s T_s} := \prod_{l=1}^{s} g_{j_l t_l}.$$

Also, let $\beta_{I_s} \in \mathbb{N}_0^n$ be the multi-index associated with the block I_s such that $\partial^{\beta_{I_s}} \equiv \partial_{I_s}$.
Since $\nabla^{\mathbf{E}}$ is compatible with $\mathbf{h}_{\mathbf{E}}$, we may use the expression for the adjoint obtained in Corollary 9.1.32. Set $h_{ab} := \mathbf{h}_{\mathbf{E}}(\mathbf{e}_a, \mathbf{e}_b)$ and $(h^{ab}) := (h_{ab})^{-1}$. Written in the chosen frame, with the leading term separated from the lower-order terms, that formula gives

$$\left((\nabla^s)^* \boldsymbol{\Psi}\right)^a = (-1)^s \frac{h^{ab}}{\sqrt{\det(\mathbf{g})}} \partial_{I_s} \left(\sqrt{\det(\mathbf{g})} h_{bc} g^{I_s J_s} \Psi^c_{J_s} \right) + \sum_{|\beta| \leq s-1} (Q_\beta)_c^{a J_s} \partial^\beta \Psi^c_{J_s},$$

with smooth coefficients Q_β; the fiber indices b, c range over $\{1, \ldots, r\}$. The metric factors arise when both inner products are written in components before integrating by parts. Expanding by the Leibniz rule and using $h^{ab} h_{bc} = \delta^a_c$, the term of order s is $(-1)^s g^{I_s J_s} \partial_{I_s} \Psi^a_{J_s}$. All the remaining terms have order at most $s-1$. Moving $\sqrt{\det(\mathbf{g})}$ inside the leading derivative changes only terms of this lower order. Thus the local expression used below has the indicated leading term and smooth lower-order coefficients D_β; metric compatibility is precisely the hypothesis that allows us to identify the formal adjoint with the formula in Corollary 9.1.32.

($\Rightarrow$) First suppose that $\mathbf{F} \restriction_U \in W^{m,p}(U, \mathbf{E} \restriction_U)$. Then, for each $s \leq m$, the sth weak covariant derivative of $\mathbf{F} \restriction_U$ exists; denote it by $\mathbf{G} \in L^p\left(U, T^{(0,s)}(TU) \otimes \mathbf{E} \restriction_U\right)$. By definition, for every $\boldsymbol{\Psi} \in \Gamma_c\left(T^{(0,s)}(TU) \otimes \mathbf{E} \restriction_U\right)$ we have

$$\int_U \langle \mathbf{F}, (\nabla^s)^* \boldsymbol{\Psi} \rangle_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}} \, d\lambda_{\mathbf{g}} = \int_U \langle \mathbf{G}, \boldsymbol{\Psi} \rangle_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}} \, d\lambda_{\mathbf{g}}.$$

In local coordinates, writing $\mathbf{F} = F^a \mathbf{e}_a$ and $\boldsymbol{\Psi} = \Psi^c_{J_s} \mathbf{d}x^{J_s} \otimes \mathbf{e}_c$, this identity reads

$$\int_U h_{bc} F^b \left((\nabla^s)^* \boldsymbol{\Psi}\right)^c d\lambda_{\mathbf{g}} = \int_U g^{I_s J_s} h_{bc} G^b_{I_s} \Psi^c_{J_s} \, d\lambda_{\mathbf{g}}.$$

Now fix a target block $T_s = (t_1, \ldots, t_s)$ and a fiber index a. Given $\psi \in C_c^\infty(\varphi(U))$, define the test tensor field $\boldsymbol{\Psi}$ by its components:

$$\Psi^c_{J_s} = \frac{1}{\sqrt{\det(\mathbf{g})}} h^{ca} g_{J_s T_s} (\psi \circ \varphi). \tag{9.35}$$

The coordinate open set U, regarded as a manifold, has no boundary, and the test sections have compact support in it. Thus Theorem 8.2.3, in the local form described at the beginning of this proof, applies on U, and the formal adjoint acts on $\boldsymbol{\Psi}$ as

$$\left((\nabla^s)^* \boldsymbol{\Psi}\right)^c = (-1)^s \left[\frac{1}{\sqrt{\det(\mathbf{g})}} \partial_{I_s} \left(\sqrt{\det(\mathbf{g})} g^{I_s J_s} \Psi^c_{J_s} \right) + \sum_{|\beta| \leq s-1} \left(D_\beta\right)_d^{c J_s} \partial^\beta \Psi^d_{J_s} \right].$$

Substituting (9.35) into this expression and using $\frac{\sqrt{\det(\mathbf{g})}}{\sqrt{\det(\mathbf{g})}} = 1$, $g^{I_s J_s} g_{J_s T_s} = \delta^{I_s}_{T_s}$, we obtain

$$\big((\nabla^s)^*\boldsymbol{\Psi}\big)^c = (-1)^s \left[\frac{1}{\sqrt{\det(\mathbf{g})}} \partial_{T_s}\big(h^{ca}(\psi\circ\varphi)\big) + \sum_{|\beta|\le s-1} \big(D_\beta\big)^{cJ_s}_{d} \partial^\beta \left(\frac{h^{da} g_{J_s T_s}}{\sqrt{\det(\mathbf{g})}} (\psi\circ\varphi) \right) \right].$$

Let $I_1 := \int_U \langle \mathbf{F}, (\nabla^s)^*\boldsymbol{\Psi}\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}$ and $I_2 := \int_U \langle \mathbf{G}, \boldsymbol{\Psi}\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}}$. Substituting (9.35) into I_2 and noting that $g^{I_s J_s} g_{J_s T_s} = \delta^{I_s}_{T_s}$ gives

$$I_2 = \int_U \frac{1}{\sqrt{\det(\mathbf{g})}} \delta^{I_s}_{T_s} \delta^a_b G^b_{I_s} (\psi\circ\varphi)\, d\lambda_{\mathbf{g}} = \int_{\varphi(U)} (G^a_{T_s}\circ\varphi^{-1})\psi\, d\lambda_n. \tag{9.36}$$

For I_1, we use the Leibniz formula in ∂_{T_s}:

$$\partial_{T_s}\big(h^{ca}(\psi\circ\varphi)\big) = h^{ca}\partial_{T_s}(\psi\circ\varphi) + \sum_{\alpha<\beta_{T_s}} \binom{\beta_{T_s}}{\alpha} \partial^\alpha(\psi\circ\varphi)\partial^{\beta_{T_s}-\alpha}(h^{ca}).$$

Substituting back into the integral I_1 gives

$$I_1 = (-1)^s \int_U \frac{1}{\sqrt{\det(\mathbf{g})}} F^a \partial_{T_s}(\psi\circ\varphi)\, d\lambda_{\mathbf{g}}$$

$$+(-1)^s \sum_{\alpha<\beta_{T_s}} \int_U \frac{1}{\sqrt{\det(\mathbf{g})}} h_{bc} F^b \binom{\beta_{T_s}}{\alpha} \partial^\alpha(\psi\circ\varphi)\partial^{\beta_{T_s}-\alpha}(h^{ca})\, d\lambda_{\mathbf{g}}$$

$$+ \sum_{|\beta|\le s-1} (-1)^s \int_U h_{bc} F^b \big(D_\beta\big)^{cJ_s}_{d} \partial^\beta \left(\frac{h^{da} g_{J_s T_s}}{\sqrt{\det(\mathbf{g})}} (\psi\circ\varphi) \right) d\lambda_{\mathbf{g}}.$$

We now proceed by induction on s. For $s = 1$, we have $T_1 = (t_1)$, $J_1 = (j_1)$, so the expression reduces to

$$I_1 = -\int_{\varphi(U)} (F^a\circ\varphi^{-1})\partial_{t_1}\psi\, d\lambda_n - \int_{\varphi(U)} ((h_{bc}F^b)\circ\varphi^{-1})\partial_{t_1}\left(h^{ca}\circ\varphi^{-1}\right)\psi\, d\lambda_n$$

$$- \int_{\varphi(U)} \left(\left(h_{bc}F^b (D_0)^{cj_1}_{d} h^{da} g_{j_1 t_1} \right)\circ\varphi^{-1} \right)\psi\, d\lambda_n.$$

Define

$$H^a_{t_1} := h_{bc}F^b\partial_{t_1}(h^{ca}) + h_{bc}F^b (D_0)^{cj_1}_{d} h^{da} g_{j_1 t_1}.$$

Since $\mathbf{F}\restriction_U \in W^{m,p}(U, \mathbf{E}\restriction_U)$ implies $F^b\circ\varphi^{-1} \in L^p(\varphi(U))$, and the metric coefficients are smooth on the compact set $\overline{\varphi(U)}$, it follows that $H^a_{t_1}\circ\varphi^{-1} \in L^p(\varphi(U))$. Since $I_1 = I_2$, we obtain

$$-\int_{\varphi(U)} (F^a\circ\varphi^{-1})\partial_{t_1}\psi\, d\lambda_n = \int_{\varphi(U)} \big((G^a_{t_1}\circ\varphi^{-1}) + (H^a_{t_1}\circ\varphi^{-1})\big)\psi\, d\lambda_n,$$

which shows that $F^a\circ\varphi^{-1} \in W^{1,p}(\varphi(U))$.

Now suppose that the assertion holds through order $s-1$ for $s \le m$. The induction hypothesis ensures that the components of $\mathbf{F}$ on U have weak derivatives of order $\le s-1$, so we may integrate by parts in the weak sense in the lower-order terms.

First, consider the terms arising from the Leibniz expansion in I_1:

$$(-1)^s \sum_{\alpha<\beta_{T_s}} \int_U \frac{h_{bc}F^b}{\sqrt{\det(\mathbf{g})}} \binom{\beta_{T_s}}{\alpha} \partial^\alpha(\psi\circ\varphi)\partial^{\beta_{T_s}-\alpha}(h^{ca})\, d\lambda_{\mathbf{g}}$$

$$= (-1)^s \sum_{\alpha<\beta_{T_s}} \int_{\varphi(U)} \left[\left(h_{bc}F^b \binom{\beta_{T_s}}{\alpha} \partial^{\beta_{T_s}-\alpha}(h^{ca}) \right) \circ \varphi^{-1} \right] \partial^\alpha \psi \, d\lambda_n.$$

Since $|\alpha| < |\beta_{I_s}| = s$, we have $|\alpha| \le s-1$. Integrating by parts (in the weak sense) $|\alpha|$ times transfers the derivatives from ψ to the coefficient (which involves F^b), so the preceding term equals

$$\sum_{\alpha<\beta_{T_s}} (-1)^{s+|\alpha|} \int_{\varphi(U)} \partial^\alpha \left[\left(h_{bc}F^b \binom{\beta_{T_s}}{\alpha} \partial^{\beta_{T_s}-\alpha}(h^{ca}) \right) \circ \varphi^{-1} \right] \psi \, d\lambda_n.$$

Second, consider the terms in I_1 involving the connection coefficients (D_β). Using the same change of variables and recalling that $|\beta| \le s-1$, we obtain

$$\sum_{|\beta|\le s-1} (-1)^s \int_U h_{bc}F^b (D_\beta)_d^{cJ_s} \partial^\beta \left(\frac{h^{da}g_{J_sT_s}}{\sqrt{\det(\mathbf{g})}}(\psi\circ\varphi) \right) d\lambda_{\mathbf{g}}$$

$$= (-1)^s \sum_{|\beta|\le s-1} \int_{\varphi(U)} \left[\left(h_{bc}F^b (D_\beta)_d^{cJ_s} \sqrt{\det(\mathbf{g})} \right) \circ \varphi^{-1} \right] \partial^\beta \left(\left(\frac{h^{da}g_{J_sT_s}}{\sqrt{\det(\mathbf{g})}} \circ \varphi^{-1} \right) \psi \right) d\lambda_n.$$

Integrating by parts $|\beta|$ times gives

$$= (-1)^s \sum_{|\beta|\le s-1} (-1)^{|\beta|} \int_{\varphi(U)} \partial^\beta \left[\left(h_{bc}F^b (D_\beta)_d^{cJ_s} \sqrt{\det(\mathbf{g})} \right) \circ \varphi^{-1} \right] \left(\frac{h^{da}g_{J_sT_s}}{\sqrt{\det(\mathbf{g})}} \circ \varphi^{-1} \right) \psi \, d\lambda_n.$$

Now define $\widetilde{G}^a_{T_s}$ on $\varphi(U)$ by grouping $G^a_{T_s}\circ\varphi^{-1}$ (which comes from the integral I_2) and moving to the right-hand side the terms computed above from I_1 (introducing an extra factor -1, which changes to $(-1)^{s+1}$):

$$\widetilde{G}^a_{T_s} := G^a_{T_s}\circ\varphi^{-1} + \sum_{\alpha<\beta_{T_s}} (-1)^{s+1+|\alpha|} \partial^\alpha \left[\left(h_{bc}F^b \binom{\beta_{T_s}}{\alpha} \partial^{\beta_{T_s}-\alpha}(h^{ca}) \right) \circ \varphi^{-1} \right]$$

$$+ \sum_{|\beta|\le s-1} (-1)^{s+1+|\beta|} \partial^\beta \left[\left(h_{bc}F^b (D_\beta)_d^{cJ_s} \sqrt{\det(\mathbf{g})} \right) \circ \varphi^{-1} \right] \left(\frac{h^{da}g_{J_sT_s}}{\sqrt{\det(\mathbf{g})}} \circ \varphi^{-1} \right).$$

The induction hypothesis states that $F^b\circ\varphi^{-1} \in W^{s-1,p}(\varphi(U))$ for every $b \in \{1,\dots,r\}$. Since $\widetilde{G}^a_{T_s}$ consists of smooth bounded functions (defined on $\overline{\varphi(U)}$) and weak derivatives of $F^b\circ\varphi^{-1}$ of order at most $s-1$, we conclude that $\widetilde{G}^a_{T_s} \in L^p(\varphi(U))$. Using the equality $I_1 = I_2$ and the definition of $\widetilde{G}$ gives

$$(-1)^s \int_{\varphi(U)} (F^a\circ\varphi^{-1}) \partial_{T_s}\psi \, d\lambda_n = \int_{\varphi(U)} \widetilde{G}^a_{T_s} \psi \, d\lambda_n.$$

This shows that $F^a\circ\varphi^{-1}$ has a weak derivative $\partial_{T_s}(F^a\circ\varphi^{-1}) = \widetilde{G}^a_{T_s} \in L^p(\varphi(U))$. Therefore, $F^a\circ\varphi^{-1} \in W^{s,p}(\varphi(U))$.

Since $s \le m$ was arbitrary, we conclude that $F^a \circ \varphi^{-1} \in W^{m,p}(\varphi(U))$ for every $a \in \{1,\dots,r\}$.

($\Leftarrow$) Now suppose that $F^a \circ \varphi^{-1} \in W^{m,p}(\varphi(U))$ for every $a \in \{1,\dots,r\}$. Fix $s \le m$ and take $\boldsymbol{\Psi} \in \Gamma_c\big(T^{(0,s)}(TU) \otimes \mathbf{E}\restriction_U\big)$. We have

$$\int_U \langle \mathbf{F}, (\nabla^s)^* \boldsymbol{\Psi} \rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} = \int_U h_{ab} F^a \big((\nabla^s)^* \boldsymbol{\Psi}\big)^b\, d\lambda_{\mathbf{g}}.$$

By the local expression for the formal adjoint justified at the beginning of this proof, the adjoint has the coordinate form

$$\big((\nabla^s)^* \boldsymbol{\Psi}\big)^b = (-1)^s \left[\frac{1}{\sqrt{\det(\mathbf{g})}} \partial_{I_s} \left(\sqrt{\det(\mathbf{g})}\, g^{I_s J_s} \Psi^b_{J_s} \right) + \sum_{|\beta| \le s-1} \big(D_\beta\big)_c^{b J_s}\, \partial^\beta \Psi^c_{J_s} \right].$$

The integral can then be written as a sum of two terms, I_1 and I_2. Expanding in coordinates gives

$$\int_U \langle \mathbf{F}, (\nabla^s)^* \boldsymbol{\Psi} \rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} = \underbrace{(-1)^s \int_U h_{ab} F^a \frac{1}{\sqrt{\det(\mathbf{g})}} \partial_{I_s} \left(\sqrt{\det(\mathbf{g})}\, g^{I_s J_s} \Psi^b_{J_s} \right) d\lambda_{\mathbf{g}}}_{I_1}$$

$$\underbrace{+ (-1)^s \sum_{|\beta| \le s-1} \int_U h_{ab} F^a \big(D_\beta\big)_c^{b J_s}\, \partial^\beta \Psi^c_{J_s}\, d\lambda_{\mathbf{g}}}_{I_2}.$$

Changing the domain of integration to $\varphi(U)$ and writing the compositions explicitly gives

$$I_1 = (-1)^s \int_{\varphi(U)} \left[(h_{ab} F^a) \circ \varphi^{-1} \right] \partial_{I_s} \left(\left(\sqrt{\det(\mathbf{g})}\, g^{I_s J_s} \Psi^b_{J_s} \right) \circ \varphi^{-1} \right) d\lambda_n,$$

$$I_2 = (-1)^s \sum_{|\beta| \le s-1} \int_{\varphi(U)} \left[\left(h_{ab} F^a (D_\beta)_c^{b J_s} \sqrt{\det(\mathbf{g})} \right) \circ \varphi^{-1} \right] \partial^\beta (\Psi^c_{J_s} \circ \varphi^{-1})\, d\lambda_n.$$

We now integrate by parts in the weak sense in I_1 (which is valid because $F^a \circ \varphi^{-1} \in W^{m,p}(\varphi(U))$ and $s \le m$):

$$I_1 = \int_{\varphi(U)} \partial_{I_s} \left[\left(h_{ab} \circ \varphi^{-1} \right) (F^a \circ \varphi^{-1}) \right] \left(\sqrt{\det(\mathbf{g})}\, g^{I_s J_s} \Psi^b_{J_s} \circ \varphi^{-1} \right) d\lambda_n.$$

Applying the Leibniz rule to the bracketed term gives

$$I_1 = \int_{\varphi(U)} \left[\left(h_{ab} g^{I_s J_s} \sqrt{\det(\mathbf{g})} \circ \varphi^{-1} \right) \partial_{I_s} (F^a \circ \varphi^{-1}) \right] (\Psi^b_{J_s} \circ \varphi^{-1})\, d\lambda_n$$

$$+ \int_{\varphi(U)} \left[\sum_{\substack{I_s \\ \alpha < \beta_{I_s}}} \binom{\beta_{I_s}}{\alpha} \partial^{\beta_{I_s} - \alpha} \left(h_{ab} \circ \varphi^{-1} \right) \partial^\alpha (F^a \circ \varphi^{-1}) \left(\left(g^{I_s J_s} \sqrt{\det(\mathbf{g})} \Psi^b_{J_s} \right) \circ \varphi^{-1} \right) \right] d\lambda_n.$$

Define the coefficient functions $(B_\gamma)_{abI_s}$ on $\varphi(U)$ for each $|\gamma| \le s-1$ by

$$(B_\gamma)_{ab}^{J_s} := \sum_{\substack{I_s \\ \gamma < \beta_{I_s}}} \binom{\beta_{I_s}}{\gamma} \partial^{\beta_{I_s}-\gamma}\left(h_{ab}\circ\varphi^{-1}\right)\left(\left(g^{I_sJ_s}\sqrt{\det(\mathbf{g})}\right)\circ\varphi^{-1}\right).$$

Substituting this definition into I_1 gives

$$I_1 = \int_{\varphi(U)}\left[\left(h_{ab}g^{I_sJ_s}\sqrt{\det(\mathbf{g})}\circ\varphi^{-1}\right)\partial_{I_s}(F^a\circ\varphi^{-1}) + \sum_{|\gamma|\le s-1}(B_\gamma)_{ab}^{J_s}\partial^\gamma(F^a\circ\varphi^{-1})\right](\Psi_{J_s}^b\circ\varphi^{-1})\,d\lambda_n.$$

For I_2, integrating by parts $|\beta|$ times gives

$$I_2 = \sum_{|\beta|\le s-1}(-1)^{s+|\beta|}\int_{\varphi(U)}\partial^\beta\left[\left(\left(h_{ab}(D_\beta)_c^{bJ_s}\sqrt{\det(\mathbf{g})}\right)\circ\varphi^{-1}\right)(F^a\circ\varphi^{-1})\right](\Psi_{J_s}^c\circ\varphi^{-1})\,d\lambda_n.$$

Applying the Leibniz rule once more to expand the derivative ∂^β of the product gives

$$I_2 = \int_{\varphi(U)}\sum_{|\beta|\le s-1}(-1)^{s+|\beta|}\sum_{\gamma\le\beta}\binom{\beta}{\gamma}\partial^{\beta-\gamma}\left(\left(h_{ab}(D_\beta)_c^{bJ_s}\sqrt{\det(\mathbf{g})}\right)\circ\varphi^{-1}\right)\partial^\gamma(F^a\circ\varphi^{-1})(\Psi_{J_s}^c\circ\varphi^{-1})\,d\lambda_n.$$

Define the coefficient functions $(C_\gamma)_{ac}^{J_s}$ on $\varphi(U)$ for each $|\gamma| \le s-1$ by

$$(C_\gamma)_{ac}^{J_s} := \sum_{\substack{|\beta|\le s-1 \\ \gamma\le\beta}}(-1)^{s+|\beta|}\binom{\beta}{\gamma}\partial^{\beta-\gamma}\left(\left(h_{ab}(D_\beta)_c^{bJ_s}\sqrt{\det(\mathbf{g})}\right)\circ\varphi^{-1}\right).$$

Substituting this definition into I_2 gives

$$I_2 = \int_{\varphi(U)}\sum_{|\gamma|\le s-1}(C_\gamma)_{ac}^{J_s}\partial^\gamma(F^a\circ\varphi^{-1})(\Psi_{J_s}^c\circ\varphi^{-1})\,d\lambda_n.$$

We now combine both results. To unify the notation, in I_1 we rename the fiber index $b \to c$ (and use h_{ac}). In this way,

$$\int_U \langle \mathbf{F}, (\nabla^s)^*\mathbf{\Psi}\rangle\,d\lambda_{\mathbf{g}} =$$

$$\int_{\varphi(U)}\left[\left(h_{ac}g^{I_sJ_s}\sqrt{\det(\mathbf{g})}\circ\varphi^{-1}\right)\partial_{I_s}(F^a\circ\varphi^{-1}) + \sum_{|\gamma|\le s-1}\left((B_\gamma)_{ac}^{J_s}+(C_\gamma)_{ac}^{J_s}\right)\partial^\gamma(F^a\circ\varphi^{-1})\right](\Psi_{J_s}^c\circ\varphi^{-1})\,d\lambda_n.$$

Now define the correction coefficients $(\widehat{D}_\gamma)$ on U by taking the *pullback* of B and C and inverting the metric weights:

$$\left(\widehat{D}_\gamma\right)_{bI_s}^a := \frac{g_{I_s\tilde{J}_s}h^{a\tilde{c}}}{\sqrt{\det(\mathbf{g})}}\left[\left((B_\gamma)_{b\tilde{c}}^{\tilde{J}_s}\circ\varphi\right)+\left((C_\gamma)_{b\tilde{c}}^{\tilde{J}_s}\circ\varphi\right)\right].$$

Then define $\mathbf{G} \in L^p(U, T^{(0,s)}(TU) \otimes \mathbf{E} \restriction_U)$ in coordinates by

$$G^a_{I_s} = \partial_{I_s} F^a + \sum_{|\gamma| \le s-1} (\widehat{D}_\gamma)^a_{b\, I_s} \partial^\gamma F^b. \tag{9.37}$$

Let us show that $\mathbf{G}$ is the desired weak covariant derivative of order s:

$$\int_U \langle \mathbf{G}, \mathbf{\Psi} \rangle_{\mathbf{g}, \mathbf{h_E}} \, d\lambda_{\mathbf{g}} = \int_U h_{ac} g^{I_s J_s} G^a_{I_s} \Psi^c_{J_s} \, d\lambda_{\mathbf{g}}$$

$$= \int_U h_{ac} g^{I_s J_s} \left(\partial_{I_s} F^a + \sum_{|\gamma| \le s-1} (\widehat{D}_\gamma)^a_{b\, I_s} \partial^\gamma F^b \right) \Psi^c_{J_s} \, d\lambda_{\mathbf{g}}.$$

The first term agrees with the principal part. For the lower-order terms, we substitute the definition of $\widehat{D}_\gamma$:

$$\int_U \sum_{|\gamma| \le s-1} h_{ac} g^{I_s J_s} \left(\frac{g_{I_s \tilde{J}_s} h^{a\tilde{c}}}{\sqrt{\det(\mathbf{g})}} \left[\left((B_\gamma)^{\tilde{J}_s}_{b\tilde{c}} \circ \varphi \right) + \left((C_\gamma)^{\tilde{J}_s}_{b\tilde{c}} \circ \varphi \right) \right] \right) \partial^\gamma F^b \Psi^c_{J_s} \, d\lambda_{\mathbf{g}}$$

$$= \int_U \sum_{|\gamma| \le s-1} \frac{1}{\sqrt{\det(\mathbf{g})}} (h_{ac} h^{a\tilde{c}}) (g^{I_s J_s} g_{I_s \tilde{J}_s}) \left[\left((B_\gamma)^{\tilde{J}_s}_{b\tilde{c}} \circ \varphi \right) + \left((C_\gamma)^{\tilde{J}_s}_{b\tilde{c}} \circ \varphi \right) \right] \partial^\gamma F^b \Psi^c_{J_s} \, d\lambda_{\mathbf{g}}.$$

Using the identities $h_{ac} h^{a\tilde{c}} = \delta^{\tilde{c}}_c$ and $g^{I_s J_s} g_{I_s \tilde{J}_s} = \delta^{J_s}_{\tilde{J}_s}$ gives

$$= \int_U \sum_{|\gamma| \le s-1} \frac{1}{\sqrt{\det(\mathbf{g})}} \left[\left((B_\gamma)^{J_s}_{bc} \circ \varphi \right) + \left((C_\gamma)^{J_s}_{bc} \circ \varphi \right) \right] \partial^\gamma F^b \Psi^c_{J_s} \, d\lambda_{\mathbf{g}}.$$

$$= \int_{\varphi(U)} \sum_{|\gamma| \le s-1} \left[(B_\gamma)^{J_s}_{bc} + (C_\gamma)^{J_s}_{bc} \right] \partial^\gamma (F^b \circ \varphi^{-1}) (\Psi^c_{J_s} \circ \varphi^{-1}) \, d\lambda_n.$$

This expression agrees exactly with the expansion of $\int_U \langle \mathbf{F}, (\nabla^s)^* \mathbf{\Psi} \rangle \, d\lambda_{\mathbf{g}}$. Therefore, $\mathbf{G}$ is the sth weak covariant derivative of $\mathbf{F}$ on U. Moreover, $\mathbf{G} \in L^p(U, T^{(0,s)}(TU) \otimes \mathbf{E} \restriction_U)$, since each coordinate component is a linear combination of weak derivatives of the components of $\mathbf{F}$ (through order s) multiplied by smooth bounded functions (bounded on U because U is a regular coordinate ball). Since $s \le m$ was arbitrary, we conclude that $\mathbf{F} \restriction_U \in W^{m,p}\left(U, \mathbf{E} \restriction_U\right)$.

Finally, we prove both norm inequalities quantitatively. Set $n := \dim M$, $\Omega := \varphi(U)$, and $f^a := F^a \circ \varphi^{-1}$ for $a \in \{1, \dots, r\}$. Recall that

$$\|\mathbf{F}\|_{W^{m,p}(U, \mathbf{E} \restriction_U)} = \left(\sum_{s=0}^{m} \int_U |\nabla^s_w \mathbf{F}|^p_{\mathbf{g}, \mathbf{h_E}} \, d\lambda_{\mathbf{g}} \right)^{1/p}.$$

At order zero we understand $\nabla^0_w \mathbf{F} = \mathbf{F}$.

Define the bundle metric $\overline{\mathbf{h}}_{\mathbf{E}}$ by making the frame $\mathbf{e}_1, \dots, \mathbf{e}_r$ orthonormal. Explicitly, if $v = \sum_{a=1}^{r} v^a \mathbf{e}_a(x)$ and

$w = \sum_{a=1}^{r} w^a \mathbf{e}_a(x)$, set

$$\overline{\mathbf{h}}_{\mathbf{E},x}(v,w) = \sum_{a=1}^{r} v^a w^a.$$

Also let $\delta := \varphi^*\overline{\mathbf{g}}$, where $\overline{\mathbf{g}}$ is the Euclidean metric on Ω. The chart and frame are defined on a neighborhood of $\overline{U}$, so these auxiliary metrics are as well. For each $q \in \{0,\dots,m\}$ define

$$\|\mathbf{F}\|_{\mathrm{aux},q,p} := \left(\sum_{s=0}^{q} \int_U |\nabla_w^s \mathbf{F}|^p_{\delta,\overline{\mathbf{h}}_{\mathbf{E}}}\, d\lambda_\delta \right)^{1/p}.$$

The covariant derivatives in this expression remain the original ones: only the fiber norm of each tensor and the measure have changed.

For each $s \in \{0,\dots,m\}$ we apply Lemma 9.1.43 to the two induced metrics on $T^{(0,s)}(TM)\otimes\mathbf{E}$ over the compact set $\overline{U}$. There are numbers $a_s, b_s > 0$ such that, for every $x \in \overline{U}$ and every $\mathbf{T} \in T^{(0,s)}_x(TM)\otimes\mathbf{E}_x$,

$$a_s|\mathbf{T}|_{\delta,\overline{\mathbf{h}}_{\mathbf{E}}} \le |\mathbf{T}|_{\mathbf{g},\mathbf{h}_{\mathbf{E}}} \le b_s|\mathbf{T}|_{\delta,\overline{\mathbf{h}}_{\mathbf{E}}}.$$

Taking $a_* := \min_{0\le s\le m} a_s > 0$ and $b_* := \max_{0\le s\le m} b_s < \infty$ gives constants valid simultaneously for all orders under consideration. On the other hand, in the coordinates of φ,

$$d\lambda_{\mathbf{g}} = \rho\, d\lambda_\delta, \qquad \rho := \sqrt{\det(\mathbf{g})}.$$

The function ρ is smooth and strictly positive on a neighborhood of $\overline{U}$. By compactness there are $\rho_-, \rho_+ > 0$ such that $\rho_- \le \rho(x) \le \rho_+$ for every $x \in \overline{U}$. Thus, for each $q \in \{0,\dots,m\}$,

$$\begin{aligned} a_*^p \rho_- \sum_{s=0}^{q} \int_U |\nabla_w^s \mathbf{F}|^p_{\delta,\overline{\mathbf{h}}_{\mathbf{E}}}\, d\lambda_\delta &\le \sum_{s=0}^{q} \int_U |\nabla_w^s \mathbf{F}|^p_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}} \\ &\le b_*^p \rho_+ \sum_{s=0}^{q} \int_U |\nabla_w^s \mathbf{F}|^p_{\delta,\overline{\mathbf{h}}_{\mathbf{E}}}\, d\lambda_\delta. \end{aligned}$$

With $c := a_*\rho_-^{1/p}$ and $C := b_*\rho_+^{1/p}$, taking pth roots and specializing to $q = m$ gives

$$c\|\mathbf{F}\|_{\mathrm{aux},m,p} \le \|\mathbf{F}\|_{W^{m,p}(U,\mathbf{E}\restriction_U)} \le C\|\mathbf{F}\|_{\mathrm{aux},m,p}. \tag{9.38}$$

The same comparison holds at each order $q \le m$ with these constants.

We now pass from covariant derivatives to partial derivatives. For $s \in \{1,\dots,m\}$ write $\mathcal{I}_s := \{1,\dots,n\}^s$; its elements are ordered blocks $I_s = (i_1,\dots,i_s)$. For $s = 0$ set $\mathcal{I}_0 := \{\varnothing\}$ and $\partial_\varnothing f^a := f^a$. Formula (9.37) reads

$$\big((\nabla_w^s \mathbf{F})^a_{I_s}\big) \circ \varphi^{-1} = \partial_{I_s} f^a + \sum_{b=1}^{r} \sum_{\substack{\gamma\in\mathbb{N}_0^n \\ |\gamma|\le s-1}} A^{abI_s}_{s,\gamma}\, \partial^\gamma f^b, \tag{9.39}$$

where

$$A^{abI_s}_{s,\gamma} := \big((\widehat{D}_\gamma)^a_{bI_s}\big) \circ \varphi^{-1}.$$

Each coefficient extends smoothly to a neighborhood of $\overline{\Omega}$ and, in particular, belongs to $L^\infty(\Omega)$. If $m \geq 1$, define

$$K := \max_{\substack{1\leq s\leq m,\ 1\leq a,b\leq r \\ I_s\in\mathcal{I}_s,\ \gamma\in\mathbb{N}_0^n,\ |\gamma|\leq s-1}} \|A_{s,\gamma}^{abI_s}\|_{L^\infty(\Omega)} < \infty.$$

The maximum contains finitely many coefficients. If $m = 0$, set $K := 0$, since there are no lower-order terms. Denote by

$$G_{s,I_s}^a := \big((\nabla_w^s \mathbf{F})_{I_s}^a\big) \circ \varphi^{-1}, \qquad Q_s := \left(\sum_{a=1}^r \sum_{I_s\in\mathcal{I}_s} |G_{s,I_s}^a|^2\right)^{1/2}.$$

In particular, $G_{0,\varnothing}^a = f^a$. The coordinate frame tensors, together with the frame $\mathbf{e}_a$, are orthonormal for the auxiliary metrics. Moreover, $\varphi_*\lambda_\delta = \lambda_n$. These two observations give the exact equalities

$$\begin{aligned}\|\mathbf{F}\|_{\mathrm{aux},m,p} &= \left(\sum_{s=0}^m \int_\Omega Q_s(x)^p \, d\lambda_n(x)\right)^{1/p} \\ &= \left[\sum_{s=0}^m \int_\Omega \left(\sum_{a=1}^r \sum_{I_s\in\mathcal{I}_s} \left|\partial_{I_s} f^a + \sum_{b=1}^r \sum_{\substack{\gamma\in\mathbb{N}_0^n \\ |\gamma|\leq s-1}} A_{s,\gamma}^{abI_s} \partial^\gamma f^b\right|^2\right)^{p/2} d\lambda_n\right]^{1/p}.\end{aligned}$$

In the summand $s = 0$, the inner sum of lower-order terms is zero, and the expression inside the bars is simply f^a.

For the upper bound, fix $s \in \{1,\dots,m\}$. The inequality $|A+B|^2 \leq 2|A|^2 + 2|B|^2$ and the bound K on the coefficients imply, almost everywhere on Ω,

$$\begin{aligned}Q_s^2 &\leq 2\sum_{a=1}^r \sum_{I_s\in\mathcal{I}_s} |\partial_{I_s} f^a|^2 \\ &\quad + 2rn^s K^2 \left(\sum_{b=1}^r \sum_{\substack{\gamma\in\mathbb{N}_0^n \\ |\gamma|\leq s-1}} |\partial^\gamma f^b|\right)^2 \\ &= 2\sum_{a=1}^r \sum_{\substack{\alpha\in\mathbb{N}_0^n \\ |\alpha|=s}} \frac{s!}{\alpha!} |\partial^\alpha f^a|^2 + 2rn^s K^2 \left(\sum_{b=1}^r \sum_{\substack{\gamma\in\mathbb{N}_0^n \\ |\gamma|\leq s-1}} |\partial^\gamma f^b|\right)^2.\end{aligned}$$

The factor rn^s counts the pairs (a, I_s). The factor $s!/\alpha!$ counts the ordered blocks producing the same derivative ∂^α; distributional partial derivatives commute, so this grouping is valid for weak derivatives as well. Since $s!/\alpha! \leq s!$ and the Euclidean norm of a finite family is at most the sum of the absolute values of its components, it follows that

$$Q_s \leq \sqrt{2}\big(\sqrt{s!} + \sqrt{rn^s}\,K\big) \sum_{b=1}^r \sum_{\substack{\beta\in\mathbb{N}_0^n \\ |\beta|\leq m}} |\partial^\beta f^b|.$$

At order zero the same bound holds with the factor 1. Set

$$B_0 := 1, \qquad B_s := \sqrt{2}\big(\sqrt{s!} + \sqrt{r n^s}\, K\big)\ (1 \le s \le m), \qquad B := \max_{0 \le s \le m} B_s.$$

There are $N_m := \binom{n+m}{m}$ multi-indices of order at most m. Applying the finite-sum inequality

$$\left(\sum_{j=1}^{N} t_j\right)^p \le N^{p-1} \sum_{j=1}^{N} t_j^p \qquad (t_j \ge 0,\ N \in \mathbb{N}),$$

with $N = rN_m$, and then using the definition of the Euclidean Sobolev norm, gives

$$\begin{aligned} \|\mathbf{F}\|_{\mathrm{aux},m,p}^p &\le (m+1) B^p (rN_m)^{p-1} \sum_{a=1}^{r} \sum_{\substack{\beta \in \mathbb{N}_0^n \\ |\beta| \le m}} \int_\Omega |\partial^\beta f^a|^p \, d\lambda_n \\ &= (m+1) B^p (rN_m)^{p-1} \sum_{a=1}^{r} \|f^a\|_{W^{m,p}(\Omega)}^p. \end{aligned}$$

Thus, with $C_{\mathrm{aux},m} := (m+1)^{1/p} B (rN_m)^{1-1/p}$, taking roots and using $(\sum_{a=1}^{r} t_a^p)^{1/p} \le \sum_{a=1}^{r} t_a$ yields

$$\|\mathbf{F}\|_{\mathrm{aux},m,p} \le C_{\mathrm{aux},m} \sum_{a=1}^{r} \|f^a\|_{W^{m,p}(\Omega)}. \tag{9.40}$$

For the lower bound, we proceed by induction on the order. For $q \in \{0, \dots, m\}$, write

$$S_q := \sum_{a=1}^{r} \|f^a\|_{W^{q,p}(\Omega)}, \qquad U_q := \|\mathbf{F}\|_{\mathrm{aux},q,p}.$$

The inductive assertion is that there are $K_q > 0$, independent of $\mathbf{F}$, such that

$$S_q \le K_q U_q. \tag{9.41}$$

For $q = 0$, the pointwise inequality $|f^a| \le Q_0$ gives $\|f^a\|_{L^p(\Omega)} \le U_0$ for each $a \in \{1, \dots, r\}$. Summing gives $S_0 \le r U_0$, so we may take $K_0 := r$.

Suppose the result has been proved for $q = s - 1$, with $1 \le s \le m$. For each $\alpha \in \mathbb{N}_0^n$ with $|\alpha| = s$, choose a block $I(\alpha) \in \mathcal{I}_s$ containing the index j exactly α_j times for each $j \in \{1, \dots, n\}$. Solving in (9.39) gives

$$\partial^\alpha f^a = G^a_{s,I(\alpha)} - \sum_{b=1}^{r} \sum_{\substack{\gamma \in \mathbb{N}_0^n \\ |\gamma| \le s-1}} A_{s,\gamma}^{abI(\alpha)} \partial^\gamma f^b.$$

Since $|G^{a}_{s,I(\alpha)}| \le Q_s$, the triangle inequality in $L^p(\Omega)$ and the estimate for bounded multipliers give

$$\|\partial^{\alpha} f^{a}\|_{L^p(\Omega)} \le U_s + K \sum_{b=1}^{r} \sum_{\substack{\gamma \in \mathbb{N}_0^n \\ |\gamma| \le s-1}} \|\partial^{\gamma} f^{b}\|_{L^p(\Omega)}.$$

For each component b, Hölder's inequality for the finite sum of its $N_{s-1} = \binom{n+s-1}{s-1}$ derivatives gives

$$\begin{aligned} \sum_{\substack{\gamma \in \mathbb{N}_0^n \\ |\gamma| \le s-1}} \|\partial^{\gamma} f^{b}\|_{L^p(\Omega)} &\le N_{s-1}^{1-1/p} \left(\sum_{\substack{\gamma \in \mathbb{N}_0^n \\ |\gamma| \le s-1}} \|\partial^{\gamma} f^{b}\|_{L^p(\Omega)}^{p} \right)^{1/p} \\ &= N_{s-1}^{1-1/p} \|f^{b}\|_{W^{s-1,p}(\Omega)}. \end{aligned}$$

For $p = 1$ this inequality is an equality. There are $d_s := \binom{n+s-1}{s}$ multi-indices of order exactly s. Thus, summing the preceding bound over the r components and these d_s multi-indices gives

$$\sum_{a=1}^{r} \sum_{\substack{\alpha \in \mathbb{N}_0^n \\ |\alpha| = s}} \|\partial^{\alpha} f^{a}\|_{L^p(\Omega)} \le r d_s U_s + r d_s K N_{s-1}^{1-1/p} S_{s-1}.$$

The definition of the Sobolev norm also implies

$$\begin{aligned} S_s &\le S_{s-1} + \sum_{a=1}^{r} \sum_{\substack{\alpha \in \mathbb{N}_0^n \\ |\alpha| = s}} \|\partial^{\alpha} f^{a}\|_{L^p(\Omega)} \\ &\le r d_s U_s + \bigl(1 + r d_s K N_{s-1}^{1-1/p}\bigr) S_{s-1}. \end{aligned}$$

By the induction hypothesis, $S_{s-1} \le K_{s-1} U_{s-1} \le K_{s-1} U_s$; the second inequality follows because the auxiliary norm of order s contains all the terms of the norm of order $s-1$. Consequently, (9.41) holds for $q = s$ with

$$K_s := r d_s + \bigl(1 + r d_s K N_{s-1}^{1-1/p}\bigr) K_{s-1}.$$

The induction reaches $s = m$ and proves

$$K_m^{-1} \sum_{a=1}^{r} \|f^{a}\|_{W^{m,p}(\Omega)} \le \|\mathbf{F}\|_{\mathrm{aux},m,p}. \tag{9.42}$$

Finally, combine (9.40), (9.42), and (9.38). Taking $c_m := c/K_m$ and $C_m := C C_{\mathrm{aux},m}$ gives

$$\begin{aligned} c_m \sum_{a=1}^{r} \|F^{a} \circ \varphi^{-1}\|_{W^{m,p}(\varphi(U))} &\le \|\mathbf{F}\|_{W^{m,p}(U, \mathbf{E}\restriction_U)}, \\ \|\mathbf{F}\|_{W^{m,p}(U, \mathbf{E}\restriction_U)} &\le C_m \sum_{a=1}^{r} \|F^{a} \circ \varphi^{-1}\|_{W^{m,p}(\varphi(U))}. \end{aligned}$$

The constants depend on m, p, n, r, the fixed chart and frame, the comparison bounds for the metrics and

volume on $\overline{U}$, and the $L^\infty(\Omega)$ norms of the coefficients appearing through order m. None depends on $\mathbf{F}$. The argument includes $m = 0$ under the indicated conventions and does not use approximation by smooth sections.

□

Before formulating the result for sections, we recall the Euclidean version to be used in local trivializations.

Definition 9.1.45. Let $\Omega \subseteq \mathbb{R}^n$ be open, let $m \in \mathbb{N}_0$, and let $1 \le p < \infty$. Define $C^{m,p}(\Omega) := \{u \in C^\infty(\Omega) \mid \|u\|_{W^{m,p}(\Omega)} < \infty\}$ and denote its completion with respect to the norm $\|\cdot\|_{W^{m,p}(\Omega)}$ by $H^{m,p}(\Omega)$.

Theorem 9.1.46. (Meyers–Serrin) Let $\Omega \subseteq \mathbb{R}^n$ be open, $m \in \mathbb{N}_0$, and $1 \le p < \infty$. Then $H^{m,p}(\Omega) = W^{m,p}(\Omega)$.

A proof can be found in [102, 1].

9.1.6 The Meyers–Serrin approximation theorem in vector bundles

The bundle version of Meyers–Serrin compares the definition using weak covariant derivatives with the completion of smooth sections. To formulate it, we first introduce the space $H^{m,p}(M,\mathbf{E})$, analogous to the construction in Definition 7.1.3.

Definition 9.1.47. Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h_E}$ and a connection $\nabla^{\mathbf{E}}$, and let $m \in \mathbb{N}_0$ and $1 \le p < \infty$. Define

$$C^{m,p}(M,\mathbf{E}) := \{\mathbf{u} \in \Gamma(\mathbf{E}) \mid \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} < \infty\},$$

where $\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} := \left(\sum_{s=0}^{m} \int_M |\nabla^s \mathbf{u}|^p_{\mathbf{g},\mathbf{h_E}} \, d\lambda_{\mathbf{g}}\right)^{\frac{1}{p}}$.

Define

$$H^{m,p}(M,\mathbf{E}) := \overline{C^{m,p}(M,\mathbf{E})}^{\|\cdot\|_{W^{m,p}(M,\mathbf{E})}},$$

which is the completion of $C^{m,p}(M,\mathbf{E})$ with respect to the Sobolev norm $\|\cdot\|_{W^{m,p}(M,\mathbf{E})}$.

As in the Euclidean case of Theorem 9.1.46, both constructions agree. The equality $H = W$ thus extends from functions to sections of a vector bundle.

Theorem 9.1.48. (Meyers–Serrin for vector bundles) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, let $\pi_{\mathbf{E}} \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h_E}$ and a compatible connection $\nabla^{\mathbf{E}}$, and let $m \in \mathbb{N}_0$ and $1 \le p < \infty$. Then

$$H^{m,p}(M,\mathbf{E}) = W^{m,p}(M,\mathbf{E}).$$

Proof. By Proposition 1.2.11, there is a countable locally finite open cover of M by regular coordinate balls $(U_\alpha, \varphi_\alpha)_{\alpha\in\mathbb{N}}$. Refining it if necessary, we may require that $\overline{U_\alpha}$ lie in the domain of a local frame of $\mathbf{E}$. Let $(\psi_\alpha)_{\alpha\in\mathbb{N}}$ be a smooth partition of unity subordinate to this cover.

Now consider a section $\mathbf{F} \in W^{m,p}(M,\mathbf{E})$. We can write

$$\mathbf{F} = \sum_{\alpha=1}^{\infty} \psi_\alpha \mathbf{F},$$

where the sum is locally finite. For each α, the product $\psi_\alpha \mathbf{F} \restriction_{U_\alpha}$ belongs to $W^{m,p}(U_\alpha, \mathbf{E} \restriction_{U_\alpha})$, since ψ_α is smooth and has compact support contained in U_α.
Fix α and work in the chart $(U_\alpha, \varphi_\alpha)$, together with one of these local frames $(\mathbf{e}_1,\dots,\mathbf{e}_r)$, defined on a neighborhood of $\overline{U_\alpha}$. Applying Lemma 9.1.44 to $(\psi_\alpha \mathbf{F}) \restriction_{U_\alpha}$ gives, for every fiber index $a \in \{1,\dots,r\}$,

$$\big(\psi_\alpha \mathbf{F}\big)^a \circ \varphi_\alpha^{-1} \in W^{m,p}(\varphi_\alpha(U_\alpha)).$$

Moreover, there are constants $C_{m,\alpha} > 0$ such that, for every section $\mathbf{H} \in W^{m,p}(U_\alpha, \mathbf{E} \restriction_{U_\alpha})$,

$$\|\mathbf{H}\|_{W^{m,p}(U_\alpha, \mathbf{E}\restriction_{U_\alpha})} \le C_{m,\alpha} \sum_{a=1}^{r} \Big\| H^a \circ \varphi_\alpha^{-1} \Big\|_{W^{m,p}(\varphi_\alpha(U_\alpha))}.$$

Write $\Omega_\alpha := \varphi_\alpha(U_\alpha) \subset \mathbb{R}^n$. The support of each component $\big(\psi_\alpha \mathbf{F}\big)^a \circ \varphi_\alpha^{-1}$ is a compact subset of Ω_α. The classical Meyers–Serrin theorem on domains in $\mathbb{R}^n$, Theorem 9.1.46, provides smooth approximants in $W^{m,p}(\Omega_\alpha)$. To obtain compactly supported approximants, choose $\chi_\alpha \in C_c^\infty(\Omega_\alpha)$ equal to one on a neighborhood of the preceding support and multiply by χ_α. The Leibniz rule shows directly that multiplication by χ_α is continuous on $W^{m,p}(\Omega_\alpha)$. Thus, for each $\alpha \in \mathbb{N}$ and each component $a \in \{1,\dots,r\}$, there is a sequence

$$(\widetilde{G}_{\alpha,k})^a \in C_c^\infty(\Omega_\alpha), \qquad k \in \mathbb{N},$$

such that

$$\sum_{a=1}^{r} \Big\| (\widetilde{G}_{\alpha,k})^a - \big(\psi_\alpha \mathbf{F}\big)^a \circ \varphi_\alpha^{-1} \Big\|_{W^{m,p}(\Omega_\alpha)} \xrightarrow[k\to\infty]{} 0.$$

From these smooth functions we define a smooth section $\mathbf{G}_{\alpha,k} \in \Gamma(\mathbf{E} \restriction_{U_\alpha})$ by

$$\mathbf{G}_{\alpha,k} = \sum_{a=1}^{r} \Big[(\widetilde{G}_{\alpha,k})^a \circ \varphi_\alpha \Big]\, \mathbf{e}_a.$$

The estimate in Lemma 9.1.44 then gives

$$\|\mathbf{G}_{\alpha,k} - (\psi_\alpha \mathbf{F}) \restriction_{U_\alpha} \|_{W^{m,p}(U_\alpha, \mathbf{E}\restriction_{U_\alpha})} \xrightarrow[k\to\infty]{} 0.$$

Extending each $\mathbf{G}_{\alpha,k}$ by zero outside U_α, we may regard it as a global compactly supported section, that is, $\mathbf{G}_{\alpha,k} \in \Gamma_c(\mathbf{E})$, and moreover

$$\|\mathbf{G}_{\alpha,k} - (\psi_\alpha \mathbf{F}) \restriction_{U_\alpha} \|_{W^{m,p}(U_\alpha, \mathbf{E}\restriction_{U_\alpha})} = \left(\sum_{s=0}^{m} \int_{U_\alpha} |\nabla_w^s (\mathbf{G}_{\alpha,k} - (\psi_\alpha \mathbf{F}) \restriction_{U_\alpha})|^p_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \right)^{\frac{1}{p}}.$$

Since $\operatorname{supp}(\mathbf{G}_{\alpha,k} - \psi_\alpha \mathbf{F}) \subseteq U_\alpha$ and ∇^s_w is a local operator (Proposition 9.1.8), the preceding expression equals

$$\left(\sum_{s=0}^{m} \int_M |\nabla^s_w (\mathbf{G}_{\alpha,k} - \psi_\alpha \mathbf{F})|^p_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \right)^{\frac{1}{p}}.$$

Consequently,

$$\|\mathbf{G}_{\alpha,k} - \psi_\alpha \mathbf{F}\|_{W^{m,p}(M,\mathbf{E})} \xrightarrow[k\to\infty]{} 0.$$

Now fix $\alpha \in \mathbb{N}$ and an integer $q \in \mathbb{N}$. By the preceding convergence, there is $k_{\alpha,q} \in \mathbb{N}$ such that

$$\|\psi_\alpha \mathbf{F} - \mathbf{G}_{\alpha,k_{\alpha,q}}\|_{W^{m,p}(U_\alpha, \mathbf{E}\restriction_{U_\alpha})} < \frac{1}{2^{\alpha+q}}.$$

Since $\operatorname{supp}(\mathbf{G}_{\alpha,k}) \subseteq U_\alpha$ for $\alpha, k \in \mathbb{N}$ and the family $(U_\alpha)_{\alpha\in\mathbb{N}}$ is locally finite, the sum

$$\mathbf{G}_q := \sum_{\alpha=1}^{\infty} \mathbf{G}_{\alpha,k_{\alpha,q}}$$

is locally finite and therefore defines a global smooth section $\mathbf{G}_q \in \Gamma(\mathbf{E})$.
Let us now show that $\mathbf{G}_q$ approximates $\mathbf{F}$ in the Sobolev norm. Using the triangle inequality gives

$$\|\mathbf{F} - \mathbf{G}_q\|_{W^{m,p}(M,\mathbf{E})} \leq \sum_{\alpha=1}^{\infty} \|\psi_\alpha \mathbf{F} - \mathbf{G}_{\alpha,k_{\alpha,q}}\|_{W^{m,p}(M,\mathbf{E})} \leq \sum_{\alpha=1}^{\infty} \frac{1}{2^{\alpha+q}} = \frac{1}{2^q}.$$

In particular,

$$\|\mathbf{G}_q\|_{W^{m,p}(M,\mathbf{E})} \leq \|\mathbf{F}\|_{W^{m,p}(M,\mathbf{E})} + \|\mathbf{F} - \mathbf{G}_q\|_{W^{m,p}(M,\mathbf{E})} \leq \|\mathbf{F}\|_{W^{m,p}(M,\mathbf{E})} + 2^{-q} < \infty,$$

so that $\mathbf{G}_q \in W^{m,p}(M,\mathbf{E}) \cap \Gamma(\mathbf{E})$ for every $q \in \mathbb{N}$.
Since $2^{-q} \to 0$ as $q \to \infty$, we conclude that $\mathbf{G}_q \to \mathbf{F}$ in $W^{m,p}(M,\mathbf{E})$. That is, every section in $W^{m,p}(M,\mathbf{E})$ can be approximated in the Sobolev norm by smooth sections, showing that

$$H^{m,p}(M,\mathbf{E}) = W^{m,p}(M,\mathbf{E}).$$

□

Theorem 9.1.49. (Chain rule for Lipschitz functions) Let $(M,\mathbf{g})$ be a Riemannian manifold without boundary, let $1 \leq p < \infty$, and let $u \in W^{1,p}_{\text{loc}}(M)$ be a real-valued function. If $\Phi\colon \mathbb{R} \longrightarrow \mathbb{R}$ is L-Lipschitz, then $\Phi \circ u \in W^{1,p}_{\text{loc}}(M)$ and

$$|d(\Phi \circ u)|_\mathbf{g} \leq L |du|_\mathbf{g}$$

almost everywhere. On the set of points x for which Φ is differentiable at $u(x)$, we have

$$d(\Phi \circ u)_x = \Phi'(u(x))\, du_x$$

almost everywhere. Moreover, $du = 0$ almost everywhere on each level set $\{u = c\}$.

If $u \in W^{1,p}(M)$ and $\Phi \circ u \in L^p(M)$, then $\Phi \circ u \in W^{1,p}(M)$. This integrability condition holds, in particular, when $\Phi(0) = 0$ or when $\lambda_{\mathbf{g}}(M) < \infty$.
For $u, v \in W^{1,p}_{\mathrm{loc}}(M)$ we obtain the formulas

$$d(u-c)_+ = \mathbf{1}_{\{u>c\}}\, du, \qquad du_- = -\mathbf{1}_{\{u<0\}}\, du,$$

and

$$d(u-v)_+ = \mathbf{1}_{\{u>v\}}(du - dv)$$

almost everywhere, where $t_+ := \max\{t, 0\}$ and $u_- := (-u)_+$.

Proof. We begin with a function $\Psi \in C^1(\mathbb{R})$ whose derivative is bounded. Let $U \Subset M$ be a regular coordinate ball. Since $u \in W^{1,p}_{\mathrm{loc}}(M)$, the restriction $u|_U$ belongs to $W^{1,p}(U)$. Apply the Meyers–Serrin theorem for vector bundles, Theorem 9.1.48, to the trivial real bundle over U. This gives a sequence $(u_j) \subseteq C^\infty(U) \cap W^{1,p}(U)$ such that $u_j \to u$ in $W^{1,p}(U)$. After passing to a subsequence, we may also assume that $u_j \to u$ almost everywhere on U. Since Ψ is Lipschitz, $\Psi(u_j) \to \Psi(u)$ in $L^p(U)$. For the differentials we have

$$d(\Psi \circ u_j) = \Psi'(u_j)\, du_j.$$

The inequality

$$\begin{aligned}\|\Psi'(u_j)du_j - \Psi'(u)du\|_{L^p(U,T^*U)} \le{}& \|\Psi'\|_{L^\infty(\mathbb{R})}\|du_j - du\|_{L^p(U,T^*U)} \\ &+ \|(\Psi'(u_j) - \Psi'(u))du\|_{L^p(U,T^*U)}\end{aligned}$$

shows that the left-hand side tends to zero. Indeed, the first term converges to zero by approximation in $W^{1,p}(U)$, and the second by the dominated convergence theorem B.6.14, since $\Psi'(u_j) \to \Psi'(u)$ almost everywhere and $|\Psi'(u_j) - \Psi'(u)|^p |du|^p_{\mathbf{g}} \le 2^p \|\Psi'\|^p_{L^\infty(\mathbb{R})} |du|^p_{\mathbf{g}}$. Closedness of the weak differential, Lemma 9.1.12, then implies that

$$d(\Psi \circ u) = \Psi'(u)\, du$$

on U. Since the regular coordinate balls with compact closure cover M, the identity holds locally throughout the manifold.
Before treating an arbitrary Lipschitz function, we prove the assertion about level sets. Fix $c \in \mathbb{R}$ and choose $\eta \in C^\infty_c(\mathbb{R})$ such that $0 \le \eta \le 1$, $\eta = 1$ on $[-1, 1]$, and $\eta = 0$ outside $[-2, 2]$. For $\varepsilon > 0$ define

$$\Psi_\varepsilon(t) := \int_c^t \eta\left(\frac{s-c}{\varepsilon}\right) ds.$$

We have $|\Psi_\varepsilon| \le 2\varepsilon$ and $\Psi_\varepsilon'(t) = \eta\left(\frac{t-c}{\varepsilon}\right)$. By what we have already proved,

$$d(\Psi_\varepsilon \circ u) = \eta\left(\frac{u-c}{\varepsilon}\right) du.$$

Fix a regular coordinate ball $U \Subset M$. Since $|\Psi_\varepsilon \circ u| \le 2\varepsilon$, we have $\Psi_\varepsilon \circ u \to 0$ in $L^p(U)$. On the other hand,

$$\eta\left(\frac{u-c}{\varepsilon}\right) du \longrightarrow \mathbf{1}_{\{u=c\}}\, du$$

in $L^p(U, T^*U)$ by the dominated convergence theorem B.6.14. Indeed, the scalar factor converges pointwise to $\mathbf{1}_{\{u=c\}}$ and its absolute value is bounded by one. Apply Lemma 9.1.12 to any sequence $\varepsilon_j \to 0^+$. The functions converge to zero and their differentials converge to $\mathbf{1}_{\{u=c\}} du$, so the latter must be the weak differential of the zero function. Consequently, $\mathbf{1}_{\{u=c\}} du = 0$ almost everywhere on U. Since these balls cover M, the assertion holds throughout the manifold.

Now let Φ be an L-Lipschitz function. Take the one-dimensional mollifier from Theorem B.9.1 and set $\Phi_j := \Phi * \rho_{\frac{1}{j}}$. Then $\Phi_j \in C^\infty(\mathbb{R})$,

$$\|\Phi_j - \Phi\|_{L^\infty(\mathbb{R})} \longrightarrow 0, \qquad |\Phi_j'| \le L.$$

In particular, $\Phi_j(u) \to \Phi(u)$ in $L^p(Q)$ for every $Q \Subset M$. By the first part of the proof,

$$d(\Phi_j \circ u) = \Phi_j'(u)\, du.$$

Again fix a regular coordinate ball $U \Subset M$ and write $a_j := \Phi_j'(u)$. The sequence (a_j) lies in the closed ball of radius L in $L^\infty(U)$. Since $L^1(U)$ is separable by Lemma 9.1.21, Corollary B.11.30 allows us to pass to a subsequence, without changing notation, such that $a_j \rightharpoonup^* a$ in $L^\infty(U)$ for some function a with $|a| \le L$ almost everywhere. Let $\omega \in \Gamma_c(T^*U)$. Since $\langle du, \omega\rangle_{\mathbf{g}} \in L^1(U)$, weak-$*$ convergence gives

$$\int_U a_j \langle du, \omega\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}} \longrightarrow \int_U a \langle du, \omega\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}}.$$

For each j, the defining identity for the weak differential reads

$$\int_U a_j \langle du, \omega\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}} = \int_U \Phi_j(u) d^*\omega\, d\lambda_{\mathbf{g}}.$$

The right-hand side converges to $\displaystyle\int_U \Phi(u) d^*\omega\, d\lambda_{\mathbf{g}}$, since $\Phi_j(u) \to \Phi(u)$ in $L^p(U)$ and $d^*\omega$ is smooth with compact support. Therefore,

$$d(\Phi \circ u) = a\, du$$

on U. In particular, $|d(\Phi \circ u)|_{\mathbf{g}} \le L |du|_{\mathbf{g}}$ almost everywhere. On intersections of two balls, the differentials thus obtained agree by uniqueness of the weak derivative. They therefore define the weak differential of $\Phi \circ u$ throughout M.

It remains to identify the coefficient a at values where Φ is differentiable. If Φ is differentiable at t, then $\Phi_j'(t) \to \Phi'(t)$. To see this directly, write

$$\Phi_j'(t) = j \int_{\mathbb{R}} \Phi\left(t - \frac{s}{j}\right) \rho'(s)\, ds.$$

Write $\Phi(t+h) = \Phi(t) + h\Phi'(t) + r(h)$. For each $\varepsilon > 0$ there is $\delta > 0$ such that $|r(h)| \le \varepsilon |h|$ if $|h| < \delta$. Moreover,

$$\Phi\left(t - \frac{s}{j}\right) = \Phi(t) - \frac{s}{j}\Phi'(t) + r\left(-\frac{s}{j}\right).$$

The remainder, multiplied by j, converges uniformly to zero for $s \in \operatorname{supp}\rho$. Indeed, if this support is

contained in $[-R,R]$ and $j > \frac{R}{\delta}$, then

$$\sup_{s\in[-R,R]} j\left|r\left(-\frac{s}{j}\right)\right| \le R\varepsilon.$$

Since $\int_{\mathbb{R}} \rho'(s)\,ds = 0$ and $\int_{\mathbb{R}} s\rho'(s)\,ds = -1$, the preceding formula converges to $\Phi'(t)$. Let $D \subseteq U$ be the measurable set of points x for which Φ is differentiable at $u(x)$. Then $a_j(x) \to \Phi'(u(x))$ on D. For each $\omega \in \Gamma_c(T^*U)$, the function $\mathbf{1}_D\langle du, \omega\rangle_{\mathbf{g}}$ belongs to $L^1(U)$. Weak-$*$ convergence and, on the other hand, the dominated convergence theorem B.6.14 on D give

$$\int_D a\langle du, \omega\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}} = \int_D \Phi'(u)\langle du, \omega\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}}.$$

Since ω is arbitrary, the localization principle implies that

$$a\,du = \Phi'(u)\,du$$

almost everywhere there. This proves the stated chain rule formula.

If $u \in W^{1,p}(M)$ and $\Phi(u) \in L^p(M)$, the bound on the differential shows that $d(\Phi(u)) \in L^p(M, T^*M)$, so that $\Phi(u) \in W^{1,p}(M)$. If $\Phi(0) = 0$, then $|\Phi(u)| \le L|u|$. If M has finite volume, use $|\Phi(u)| \le |\Phi(0)| + L|u|$. In both cases this gives the required integrability.

Finally, the function $t \mapsto (t-c)_+$ is differentiable outside c, with derivative equal to $\mathbf{1}_{(c,\infty)}$. The formula already proved holds outside $\{u = c\}$, and on this set $du = 0$. Therefore, $d(u-c)_+ = \mathbf{1}_{\{u>c\}}du$. The identity for u_- follows by applying this formula to $-u$, and the last identity follows by applying it to $u - v$. □

9.2 Sobolev embeddings and the Rellich–Kondrashov theorem for vector bundles

Sobolev embeddings are a basic tool for studying partial differential equations on bundles. On a compact manifold, a finite cover by regular coordinate balls reduces the problem to Euclidean embeddings for the components, after which the sections can be reconstructed using a partition of unity. Lemma 9.1.44 ensures that this procedure preserves Sobolev regularity exactly.

Theorem 9.2.1. (Sobolev embedding for vector bundles) Let $(M, \mathbf{g})$ be a closed Riemannian manifold of dimension n, and let $\mathbf{E} \longrightarrow M$ be a smooth real or complex vector bundle of finite rank, equipped with a bundle metric $\mathbf{h_E}$ (Hermitian in the complex case) and a compatible connection $\nabla^{\mathbf{E}}$. Let $j \ge 0$ and $m \ge 1$ be integers and $1 \le p, q < \infty$ such that

$$j + m - \frac{n}{p} \ge j - \frac{n}{q}.$$

Then the inclusion

$$W^{j+m,p}(M, \mathbf{E}) \hookrightarrow W^{j,q}(M, \mathbf{E})$$

is continuous.

Proof. Fix the orders and exponents in the statement. Choose a finite cover $(U_\alpha,\varphi_\alpha)_{\alpha=1}^N$ by regular coordinate balls and, on each U_α, a frame $(\mathbf{e}_{1,\alpha},\dots,\mathbf{e}_{r,\alpha})$ defined on a neighborhood of $\overline{U_\alpha}$. Take a partition of unity $(\psi_\alpha)_{\alpha=1}^N$ subordinate to this cover. Since M is compact, we may and do assume that

$$K_\alpha := \operatorname{supp}(\psi_\alpha) \Subset U_\alpha \qquad \text{for every } \alpha \in \{1,\dots,N\}.$$

Set $\Omega_\alpha := \varphi_\alpha(U_\alpha)$.
Compatibility of $\nabla^{\mathbf{E}}$ with $\mathbf{h}_{\mathbf{E}}$ allows us to apply Lemma 9.1.44 and its local comparison estimates. For complex components, we apply the Euclidean estimates to their real and imaginary parts. Theorem 3.3.16, with total orders $j+m$ and j, gives, for each α, a constant $C_\alpha > 0$ such that

$$\|v\|_{W^{j,q}(\Omega_\alpha)} \le C_\alpha \|v\|_{W^{j+m,p}(\Omega_\alpha)} \qquad \text{for every } v \in W_0^{j+m,p}(\Omega_\alpha). \tag{9.43}$$

The formulation with $W_0^{j+m,p}$ suffices: all functions appearing below have compact support in Ω_α.
Let $\mathbf{F} \in W^{j+m,p}(M,\mathbf{E})$ and write

$$\mathbf{F} = \sum_{a=1}^{r} F_\alpha^a \mathbf{e}_{a,\alpha} \qquad \text{in } U_\alpha.$$

The localized section $\psi_\alpha \mathbf{F}$ has support contained in K_α. By Lemma 9.1.44, the functions

$$v_\alpha^a := (\psi_\alpha F_\alpha^a) \circ \varphi_\alpha^{-1}$$

belong to $W^{j+m,p}(\Omega_\alpha)$. Moreover,

$$\operatorname{supp}(v_\alpha^a) \subseteq \varphi_\alpha(K_\alpha) \Subset \Omega_\alpha,$$

so that $v_\alpha^a \in W_0^{j+m,p}(\Omega_\alpha)$. Estimate (9.43) and the local comparison of norms give

$$\|(\psi_\alpha \mathbf{F}) \restriction_{U_\alpha}\|_{W^{j,q}(U_\alpha,\mathbf{E})} \le C'_\alpha \|(\psi_\alpha \mathbf{F}) \restriction_{U_\alpha}\|_{W^{j+m,p}(U_\alpha,\mathbf{E})} \tag{9.44}$$

for a constant $C'_\alpha > 0$ independent of $\mathbf{F}$.
Let us make the global reconstruction of each localized section precise. For $s \in \{0,\dots,j\}$, let

$$G_{\alpha,s} := \nabla_w^s\big((\psi_\alpha \mathbf{F}) \restriction_{U_\alpha}\big).$$

Locality of the weak covariant derivative implies the inclusion

$$\operatorname{supp}_{U_\alpha}(G_{\alpha,s}) \subseteq \operatorname{supp}_{U_\alpha}\big((\psi_\alpha \mathbf{F}) \restriction_{U_\alpha}\big) \subseteq K_\alpha;$$

equality of supports is neither needed nor valid in general. Denote by $\widetilde{G}_{\alpha,s}$ the extension of $G_{\alpha,s}$ by zero to M. Since $K_\alpha \Subset U_\alpha$, this extension belongs to $L^q(M, T^{(0,s)}(TM)\otimes\mathbf{E})$.
Let us show that $\widetilde{G}_{\alpha,s}$ is the sth weak covariant derivative of $\psi_\alpha \mathbf{F}$. Choose $\eta_\alpha \in C_c^\infty(U_\alpha)$ equal to one on a neighborhood of K_α. For $\mathbf{\Phi} \in \Gamma_c^\infty(T^{(0,s)}(TM)\otimes\mathbf{E})$, the section $\eta_\alpha \mathbf{\Phi} \restriction_{U_\alpha}$ is a test function on U_α. The

definition of $G_{\alpha,s}$ and locality of $(\nabla^s)^*$ give

$$\begin{aligned}\int_M \langle \widetilde{G}_{\alpha,s}, \mathbf{\Phi}\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} &= \int_{U_\alpha} \langle G_{\alpha,s}, \eta_\alpha \mathbf{\Phi}\rangle_{\mathbf{g},\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \\ &= \int_{U_\alpha} \left\langle \psi_\alpha \mathbf{F}, (\nabla^s)^*(\eta_\alpha \mathbf{\Phi})\right\rangle_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}} \\ &= \int_M \langle \psi_\alpha \mathbf{F}, (\nabla^s)^* \mathbf{\Phi}\rangle_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.\end{aligned}$$

In the last equality we used $\eta_\alpha = 1$ on a neighborhood of the support of $\psi_\alpha \mathbf{F}$. Therefore, $\psi_\alpha \mathbf{F} \in W^{j,q}(M,\mathbf{E})$ and its global norm agrees with the norm obtained by integrating over U_α.

Finally, we need a bound for localization in the source space. For smooth sections, the iterated Leibniz rule gives, for $0 \le s \le j+m$,

$$|\nabla^s(\psi_\alpha \mathbf{F})|_{\mathbf{g},\mathbf{h_E}} \le A_s \sum_{t=0}^{s} |\nabla^{s-t}\psi_\alpha|_{\mathbf{g}} |\nabla^t \mathbf{F}|_{\mathbf{g},\mathbf{h_E}}.$$

The derivatives of ψ_α are bounded because M is compact. Summing the L^p norms gives a constant $A_\alpha > 0$ such that

$$\|\psi_\alpha \mathbf{F}\|_{W^{j+m,p}(M,\mathbf{E})} \le A_\alpha \|\mathbf{F}\|_{W^{j+m,p}(M,\mathbf{E})}$$

for every smooth section $\mathbf{F}$. The Meyers–Serrin theorem and passage to the limit in distributions extend the inequality to every $\mathbf{F} \in W^{j+m,p}(M,\mathbf{E})$. Since the cover is finite, there is $A > 0$ such that

$$\|\psi_\alpha \mathbf{F}\|_{W^{j+m,p}(M,\mathbf{E})} \le A \|\mathbf{F}\|_{W^{j+m,p}(M,\mathbf{E})} \tag{9.45}$$

for every $\alpha \in \{1,\dots,N\}$.

Using $\mathbf{F} = \sum_{\alpha=1}^{N} \psi_\alpha \mathbf{F}$, the triangle inequality, (9.44), and (9.45) gives

$$\begin{aligned}\|\mathbf{F}\|_{W^{j,q}(M,\mathbf{E})} &\le \sum_{\alpha=1}^{N} \|\psi_\alpha \mathbf{F}\|_{W^{j,q}(M,\mathbf{E})} \\ &\le \sum_{\alpha=1}^{N} C'_\alpha \|\psi_\alpha \mathbf{F}\|_{W^{j+m,p}(M,\mathbf{E})} \\ &\le C \|\mathbf{F}\|_{W^{j+m,p}(M,\mathbf{E})}.\end{aligned}$$

This proves continuity of the embedding. □

Theorem 9.2.2. (Rellich–Kondrashov in vector bundles) Let $(M,\mathbf{g})$ be a compact Riemannian manifold without boundary of dimension n, and let $\mathbf{E} \to M$ be a smooth real or complex vector bundle of finite rank, equipped with a bundle metric $\mathbf{h_E}$ (Hermitian in the complex case) and a compatible connection $\nabla^{\mathbf{E}}$. Let $j \in \mathbb{N}_0$, let $m \ge 1$ be an integer, and let $1 \le p, q < \infty$ satisfy

$$j + m - \frac{n}{p} > j - \frac{n}{q}.$$

Then the inclusion

$$W^{j+m,p}(M,\mathbf{E}) \hookrightarrow W^{j,q}(M,\mathbf{E})$$

is compact.

Proof. Let $(\mathbf{F}_\nu)_{\nu\in\mathbb{N}}$ be a bounded sequence in $W^{j+m,p}(M,\mathbf{E})$. Compatibility of $\nabla^{\mathbf{E}}$ with $\mathbf{h}_{\mathbf{E}}$ allows us to apply the local comparison of norms in Lemma 9.1.44. In the complex case, consider the underlying real bundle with metric $\operatorname{Re}\mathbf{h}_{\mathbf{E}}$ and the induced real connection; its pointwise norm agrees with the Hermitian norm, and its components are the real and imaginary parts of the complex components. Retain the cover, frames, and functions ψ_α from the preceding proof. By (9.45), for each α the sequence $(\psi_\alpha \mathbf{F}_\nu)_\nu$ is bounded in $W^{j+m,p}(M,\mathbf{E})$. Lemma 9.1.44 then shows that, for each pair (α,a), the sequence

$$v^a_{\alpha,\nu} := \big(\psi_\alpha(\mathbf{F}_\nu)^a_\alpha\big)\circ\varphi_\alpha^{-1}$$

is bounded in $W^{j+m,p}(\Omega_\alpha)$. Moreover,

$$\operatorname{supp}(v^a_{\alpha,\nu}) \subseteq \varphi_\alpha(K_\alpha) \Subset \Omega_\alpha$$

for every ν. In particular, $v^a_{\alpha,\nu} \in W^{j+m,p}_0(\Omega_\alpha)$.
For each pair (α,a), Theorem 3.4.2 gives a subsequence converging in $W^{j,q}(\Omega_\alpha)$. Since there are only Nr pairs, a finite diagonal extraction produces a subsequence, which we do not relabel, such that $(v^a_{\alpha,\nu})_\nu$ is Cauchy in $W^{j,q}(\Omega_\alpha)$ for every α and every a.
The local comparison of norms and reconstruction by extension by zero used in the proof of the preceding theorem give, for $\nu,\mu\in\mathbb{N}$,

$$\begin{aligned}\|\mathbf{F}_\nu-\mathbf{F}_\mu\|_{W^{j,q}(M,\mathbf{E})} &\le \sum_{\alpha=1}^{N}\|\psi_\alpha(\mathbf{F}_\nu-\mathbf{F}_\mu)\|_{W^{j,q}(M,\mathbf{E})}\\ &\le C\sum_{\alpha=1}^{N}\sum_{a=1}^{r}\|v^a_{\alpha,\nu}-v^a_{\alpha,\mu}\|_{W^{j,q}(\Omega_\alpha)}.\end{aligned}$$

The right-hand side tends to zero as $\nu,\mu\to\infty$. The subsequence is therefore Cauchy in the Banach space $W^{j,q}(M,\mathbf{E})$ and converges in it. This proves compactness. □

Corollary 9.2.3. (Embeddings and the critical exponent) Under the geometric hypotheses of the preceding theorems, let $j\ge 0$ and $m\ge 1$ be integers, and let $1\le p<n/m$. Then

$$W^{j+m,p}(M,\mathbf{E}) \hookrightarrow W^{j,q}(M,\mathbf{E})$$

continuously for $1\le q\le p^*_m := \dfrac{np}{n-mp}$, and compactly for $1\le q<p^*_m$.

Proof. Since $mp<n$, the condition $j+m-\dfrac{n}{p}\ge j-\dfrac{n}{q}$ is equivalent to $q\le p^*_m$, and the strict inequality is equivalent to $q<p^*_m$. Apply Theorems 9.2.1 and 9.2.2, respectively. □

9.2.1 Embeddings into spaces of Hölder sections

Solutions of many variational problems are initially obtained as elements of a Sobolev space. The localization principle for vector bundles in Lemma 9.1.6 allows us to convert the variational identity into a local equation in the weak sense. This step alone, however, does not yield classical regularity. The next question is when the weak solution admits a differentiable representative and with what continuity its derivatives vary. As in the Euclidean case, the embedding does not replace estimates specific to the equation: once those estimates give a bound in $W^{m,p}(M,\mathbf{E})$, spaces of Hölder sections translate this Sobolev regularity into quantitative classical regularity.

Before defining these spaces, we must specify how to compare vectors belonging to different fibers. We use the notation for parallel transport fixed in Definition 2.7.13. Throughout this subsection the manifolds have no boundary. Initially we assume that M is connected, because the Riemannian distance $d_{\mathbf{g}}$ was defined under this hypothesis. If M is disconnected, the definitions and results apply componentwise. In particular, connectedness imposes no restriction for compact manifolds, which have finitely many connected components.

Definition 9.2.4. (Fiberwise separation by parallel transport) Let $(M,\mathbf{g})$ be a connected Riemannian manifold without boundary such that $\operatorname{inj}(M)>0$. Let $\mathbf{F}\longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{F}}$ and a compatible connection $\nabla^{\mathbf{F}}$. Fix

$$\rho_M := \min\{1, \operatorname{inj}(M)\}.$$

If $x,y\in M$ satisfy $0<d_{\mathbf{g}}(x,y)<\rho_M$, denote by $\gamma_{xy}\colon[0,1]\longrightarrow M$ the unique minimizing geodesic parametrized with constant speed satisfying

$$\gamma_{xy}(0)=x, \qquad \gamma_{xy}(1)=y.$$

For $\xi\in\mathbf{F}_x$ and $\eta\in\mathbf{F}_y$, define

$$|\xi-\eta|_{\mathbf{h}_{\mathbf{F}};x,y} := \left|\xi - P^{\mathbf{F}}_{\gamma_{xy},1\to 0}(\eta)\right|_{\mathbf{h}_{\mathbf{F}}(x)}. \tag{9.46}$$

Since $\nabla^{\mathbf{F}}$ is compatible with $\mathbf{h}_{\mathbf{F}}$, parallel transport is an isometry. Proposition 2.7.14 then gives the equivalent expression

$$|\xi-\eta|_{\mathbf{h}_{\mathbf{F}};x,y} = \left|P^{\mathbf{F}}_{\gamma_{xy},0\to 1}(\xi)-\eta\right|_{\mathbf{h}_{\mathbf{F}}(y)}.$$

When $x=y$, set

$$|\xi-\eta|_{\mathbf{h}_{\mathbf{F}};x,x} := |\xi-\eta|_{\mathbf{h}_{\mathbf{F}}(x)}.$$

If $\mathbf{T}\in\Gamma^0(\mathbf{F})$ and $S\subseteq M$ satisfies $\operatorname{diam}_{\mathbf{g}}(S)<\rho_M$, define the fiberwise oscillation of $\mathbf{T}$ on S by

$$\operatorname{osc}_{\mathbf{F}}(\mathbf{T};S) := \sup_{x,y\in S} |\mathbf{T}(x)-\mathbf{T}(y)|_{\mathbf{h}_{\mathbf{F}};x,y}.$$

For $0<\alpha<1$, define

$$[\mathbf{T}]_{\alpha,\mathbf{F}} := \sup_{\substack{x,y\in M\\ 0<d_{\mathbf{g}}(x,y)<\rho_M}} \frac{|\mathbf{T}(x)-\mathbf{T}(y)|_{\mathbf{h}_{\mathbf{F}};x,y}}{d_{\mathbf{g}}(x,y)^{\alpha}}. \tag{9.47}$$

If $U\subseteq M$, write $[\mathbf{T}]_{\alpha,\mathbf{F};U}$ when the supremum is taken only over pairs $x,y\in U$.

Remark 9.2.5. (Choice of radius) The bound by 1 in the definition of ρ_M merely normalizes the scale. If $0 < \rho_1 \le \rho_2 \le \mathrm{inj}(M)$ and $[\mathbf{T}]_{\alpha,\mathbf{F};\rho_j}$ denotes the seminorm obtained using radius ρ_j, then

$$[\mathbf{T}]_{\alpha,\mathbf{F};\rho_1} \le [\mathbf{T}]_{\alpha,\mathbf{F};\rho_2}$$

and

$$[\mathbf{T}]_{\alpha,\mathbf{F};\rho_2} \le [\mathbf{T}]_{\alpha,\mathbf{F};\rho_1} + 2\rho_1^{-\alpha}\|\mathbf{T}\|_{L^\infty(M,\mathbf{F})}.$$

The second inequality follows by separating pairs at distance less than ρ_1 from those whose distance belongs to $[\rho_1,\rho_2)$. Thus, after adding the uniform norm, any two positive radii less than or equal to $\mathrm{inj}(M)$ produce equivalent norms.
One may also use the formulation in terms of balls

$$[\mathbf{T}]^{\mathrm{bol}}_{\alpha,\mathbf{F}} := \sup_{\substack{x\in M\\ 0<r<\frac{\rho_M}{2}}} \frac{\mathrm{osc}_{\mathbf{F}}(\mathbf{T}; B_{\mathbf{g}}(x,r))}{r^\alpha}.$$

If $x,y \in B_{\mathbf{g}}(z,r)$, then $d_{\mathbf{g}}(x,y) < 2r$, and therefore

$$[\mathbf{T}]^{\mathrm{bol}}_{\alpha,\mathbf{F}} \le 2^\alpha [\mathbf{T}]_{\alpha,\mathbf{F}}.$$

Conversely, if $d_{\mathbf{g}}(x,y) < \frac{\rho_M}{2}$, take $d_{\mathbf{g}}(x,y) < r < \frac{\rho_M}{2}$ and use $y \in B_{\mathbf{g}}(x,r)$. Letting $r \to d_{\mathbf{g}}(x,y)^+$ gives

$$\frac{|\mathbf{T}(x)-\mathbf{T}(y)|_{\mathbf{h}_{\mathbf{F}};x,y}}{d_{\mathbf{g}}(x,y)^\alpha} \le [\mathbf{T}]^{\mathrm{bol}}_{\alpha,\mathbf{F}}.$$

For $\frac{\rho_M}{2} \le d_{\mathbf{g}}(x,y) < \rho_M$, we have

$$\frac{|\mathbf{T}(x)-\mathbf{T}(y)|_{\mathbf{h}_{\mathbf{F}};x,y}}{d_{\mathbf{g}}(x,y)^\alpha} \le 2^{\alpha+1}\rho_M^{-\alpha}\|\mathbf{T}\|_{L^\infty(M,\mathbf{F})}.$$

Thus the quantities

$$\|\mathbf{T}\|_{L^\infty(M,\mathbf{F})} + [\mathbf{T}]_{\alpha,\mathbf{F}} \qquad \text{and} \qquad \|\mathbf{T}\|_{L^\infty(M,\mathbf{F})} + [\mathbf{T}]^{\mathrm{bol}}_{\alpha,\mathbf{F}}$$

are equivalent. The factor $\frac{1}{2}$ ensures that any two points of $B_{\mathbf{g}}(x,r)$ lie at distance less than ρ_M. Likewise, uniqueness of the minimizing geodesic requires $d_{\mathbf{g}}(x,y) < \mathrm{inj}(M)$; the non-strict inequality is insufficient.

Definition 9.2.6. (Hölder sections and Hölder sections up to the closure) Let $(M,\mathbf{g})$ be a connected Riemannian manifold without boundary with $\mathrm{inj}(M) > 0$, and let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. For $j \in \mathbb{N}_0$ set

$$\mathbf{E}_j := T^{(0,j)}(TM) \otimes \mathbf{E},$$

with the convention $\mathbf{E}_0 = \mathbf{E}$. On $\mathbf{E}_j$ consider the bundle metric induced by $\mathbf{g}$ and $\mathbf{h}_{\mathbf{E}}$, and the product connection induced by the Levi–Civita connection and $\nabla^{\mathbf{E}}$.

Let $k \in \mathbb{N}_0$ and $0 < \alpha < 1$. For $\mathbf{u} \in \Gamma^k(\mathbf{E})$ define

$$\|\nabla^j \mathbf{u}\|_{L^\infty(M,\mathbf{E}_j)} := \sup_{x\in M} |\nabla^j \mathbf{u}(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}}, \qquad 0 \le j \le k,$$

and

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} := \sum_{j=0}^{k} \|\nabla^j \mathbf{u}\|_{L^\infty(M,\mathbf{E}_j)} + [\nabla^k \mathbf{u}]_{\alpha,\mathbf{E}_k}. \tag{9.48}$$

The space of Hölder sections of order (k,α) is

$$\Gamma^{k,\alpha}(\mathbf{E}) := \left\{ \mathbf{u} \in \Gamma^k(\mathbf{E}) \,\middle|\, \|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} < \infty \right\}.$$

Now let $U \Subset M$ be open. For $\mathbf{u} \in \Gamma^k(\mathbf{E}\restriction_U)$ set

$$\mathcal{E}^{k,\alpha}_{\overline{U}}(\mathbf{u}) := \left\{ \widetilde{\mathbf{u}} \in \Gamma^{k,\alpha}(\mathbf{E}) \,\middle|\, \widetilde{\mathbf{u}}\restriction_U = \mathbf{u} \right\}.$$

Define

$$\Gamma^{k,\alpha}(\overline{U},\mathbf{E}) := \left\{ \mathbf{u} \in \Gamma^k(\mathbf{E}\restriction_U) \,\middle|\, \mathcal{E}^{k,\alpha}_{\overline{U}}(\mathbf{u}) \neq \varnothing \right\}$$

and equip this space with the extension norm

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\overline{U},\mathbf{E})} := \inf_{\widetilde{\mathbf{u}} \in \mathcal{E}^{k,\alpha}_{\overline{U}}(\mathbf{u})} \|\widetilde{\mathbf{u}}\|_{\Gamma^{k,\alpha}(\mathbf{E})}. \tag{9.49}$$

The second argument records the ambient bundle. We are not regarding $\overline{U}$ as a smooth manifold. Since U is dense in $\overline{U}$, an extension uniquely determines the values of $\mathbf{u}$ and its covariant derivatives through order k on the closure.

If M has finitely many connected components $M_1,\dots,M_N$, apply the definition on each component and write

$$\Gamma^{k,\alpha}(\mathbf{E}) := \left\{ \mathbf{u} \in \Gamma^k(\mathbf{E}) \,\middle|\, \mathbf{u}\restriction_{M_\nu} \in \Gamma^{k,\alpha}(\mathbf{E}\restriction_{M_\nu}) \text{ for every } \nu \in \{1,\dots,N\} \right\},$$

with the norm

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} := \max_{1\le\nu\le N} \|\mathbf{u}\restriction_{M_\nu}\|_{\Gamma^{k,\alpha}(\mathbf{E}\restriction_{M_\nu})}.$$

If

$$\|\mathbf{u}\|_{\Sigma} := \sum_{\nu=1}^{N} \|\mathbf{u}\restriction_{M_\nu}\|_{\Gamma^{k,\alpha}(\mathbf{E}\restriction_{M_\nu})},$$

then

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le \|\mathbf{u}\|_{\Sigma} \le N \|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})}.$$

This is the convention used for disconnected compact manifolds.

Remark 9.2.7. (Local extensions of sections) The global extension condition in the preceding definition is equivalent to the existence of an extension to an open neighborhood of $\overline{U}$. More precisely, it suffices that there be open sets

$$\overline{U} \subseteq V_0 \Subset V_1 \Subset V$$

and a section $\widehat{\mathbf{u}} \in \Gamma^k(\mathbf{E}\restriction_V)$ extending $\mathbf{u}$ and satisfying

$$\sum_{j=0}^{k} \|\nabla^j \widehat{\mathbf{u}}\|_{L^\infty(V_1,\mathbf{E}_j)} + [\nabla^k \widehat{\mathbf{u}}]_{\alpha,\mathbf{E}_k;V_1} < \infty.$$

Indeed, choose a cutoff function $\chi \in C_c^\infty(V_1)$ equal to one on a neighborhood of $\overline{V_0}$. The extension of $\chi\widehat{\mathbf{u}}$ by zero outside V_1, denoted by $\widetilde{\chi\widehat{\mathbf{u}}}$, belongs to $\Gamma^{k,\alpha}(\mathbf{E})$ and extends $\mathbf{u}$. The presence of V_1 ensures that all terms in the Leibniz rule are controlled on a compact subset of the extension domain. This is the analogue for sections of the convention used in $C^{k,\alpha}(\overline{\Omega})$.
The term $\|\nabla^k \mathbf{u}\|_{L^\infty(M,T^{(0,k)}(TM)\otimes\mathbf{E})}$ cannot be omitted from (9.48). The Hölder seminorm does not control the size of $\nabla^k \mathbf{u}$ and vanishes, for example, on parallel tensors.

The local comparison between the geometric norm and the scalar components uses two facts: uniform equivalence of the metric with the Euclidean metric on a regular coordinate ball, and control of parallel transport along short geodesics.

Lemma 9.2.8. (Local comparison of the Hölder seminorm) Let $(M,\mathbf{g})$ be a connected Riemannian manifold without boundary with $\operatorname{inj}(M) > 0$. Let (U,φ) be a regular coordinate ball in M. Let $\mathbf{F} \longrightarrow M$ be a smooth vector bundle of rank N, equipped with a bundle metric $\mathbf{h}_\mathbf{F}$ and a compatible connection $\nabla^\mathbf{F}$, and let $(\mathbf{f}_1,\dots,\mathbf{f}_N)$ be a local frame of $\mathbf{F}$ defined on a neighborhood of $\overline{U}$. If

$$\mathbf{T} = \sum_{A=1}^{N} T^A \mathbf{f}_A \qquad \text{on } U,$$

then

$$\mathbf{T} \in \Gamma^{0,\alpha}(\overline{U},\mathbf{F}) \quad \Longleftrightarrow \quad T^A \circ \varphi^{-1} \in C^{0,\alpha}(\overline{\varphi(U)})$$

for every $A \in \{1,\dots,N\}$. Moreover, there are constants $c_\alpha, C_\alpha > 0$, independent of $\mathbf{T}$, such that

$$\begin{aligned} c_\alpha \sum_{A=1}^{N} \|T^A \circ \varphi^{-1}\|_{C^{0,\alpha}(\overline{\varphi(U)})} &\le \|\mathbf{T}\|_{\Gamma^{0,\alpha}(\overline{U},\mathbf{F})} \\ &\le C_\alpha \sum_{A=1}^{N} \|T^A \circ \varphi^{-1}\|_{C^{0,\alpha}(\overline{\varphi(U)})}. \end{aligned} \tag{9.50}$$

Proof. Let U' be a larger regular coordinate ball, so that $\overline{U} \subseteq U'$ and the chart and frame are defined on U'. Choose an open set V with

$$\overline{U} \subseteq V \Subset U'.$$

Since $\overline{V}$ is compact, there is $0 < \delta < \rho_M$ such that every minimizing geodesic of length less than δ with endpoints in $\overline{V}$ remains in U'. Decreasing δ if necessary, the Euclidean segment joining $\varphi(x)$ to $\varphi(y)$ remains in $\varphi(U')$ whenever $x,y \in \overline{V}$ and $d_\mathbf{g}(x,y) < \delta$.

For $x, y \in \overline{V}$ with $d_{\mathbf{g}}(x,y) < \delta$, define the matrix $G(x,y)$ by

$$P^{\mathbf{F}}_{\gamma_{xy},1\to 0}\big(\mathbf{f}_B(y)\big) = \sum_{A=1}^{N} G^A_{\ B}(x,y)\mathbf{f}_A(x). \tag{9.51}$$

Let $R(t)$ be the matrix of the transport $P^{\mathbf{F}}_{\gamma_{xy},t\to 0}$ in the frame. By Proposition 2.7.18, $R(0) = I$ and R satisfies a linear system whose coefficients have norm bounded by $C|\dot\gamma_{xy}(t)|_{\mathbf{g}} = C d_{\mathbf{g}}(x,y)$. Grönwall's lemma 1.8.19 gives

$$\|R(t)\|_{\mathrm{op}(\mathbb{K}^N)} \le e^{C d_{\mathbf{g}}(x,y)t}$$

and, integrating the equation,

$$\|G(x,y) - I\|_{\mathrm{op}(\mathbb{K}^N)} = \|R(1) - R(0)\|_{\mathrm{op}(\mathbb{K}^N)} \le C d_{\mathbf{g}}(x,y). \tag{9.52}$$

Here and below the constant may increase, but is independent of x and y.
Uniform equivalence of $\mathbf{g}$ and the Euclidean metric in the chart gives constants $c_0, C_0 > 0$ such that

$$c_0|\varphi(x) - \varphi(y)| \le d_{\mathbf{g}}(x,y) \le C_0|\varphi(x) - \varphi(y)| \tag{9.53}$$

for the preceding pairs. The first inequality follows by estimating the length of the minimizing geodesic in coordinates. For the second, estimate the length of the curve whose coordinate expression is the segment joining $\varphi(x)$ to $\varphi(y)$.
For $z \in U'$, let

$$\mathcal{F}_z \colon \mathbb{K}^N \longrightarrow \mathbf{F}_z, \qquad \mathcal{F}_z(c^1,\dots,c^N) := \sum_{A=1}^{N} c^A \mathbf{f}_A(z).$$

If $\mathbf{S} = \sum_{A=1}^{N} S^A \mathbf{f}_A$ and $s(z) := (S^1(z),\dots,S^N(z))$, then (9.51) implies

$$\mathbf{S}(x) - P^{\mathbf{F}}_{\gamma_{xy},1\to 0}(\mathbf{S}(y)) = \mathcal{F}_x\big(s(x) - G(x,y)s(y)\big).$$

Therefore,

$$s(x) - G(x,y)s(y) = s(x) - s(y) + (I - G(x,y))s(y).$$

Uniform equivalence of the Euclidean norm of the components and $\mathbf{h}_{\mathbf{F}}$, together with (9.52) and (9.53), gives

$$\begin{aligned} &\|\mathbf{S}\|_{L^\infty(\overline{U},\mathbf{F})} + [\mathbf{S}]_{\alpha,\mathbf{F};\overline{U}} \\ &\qquad \le C \sum_{A=1}^{N} \Big(\|S^A \circ \varphi^{-1}\|_{C^0(\overline{\varphi(U)})} + [S^A \circ \varphi^{-1}]_{C^{0,\alpha}(\overline{\varphi(U)})} \Big). \end{aligned} \tag{9.54}$$

For the reverse inequality, solve for

$$s(x) - s(y) = \big(s(x) - G(x,y)s(y)\big) + (G(x,y) - I)s(y)$$

and repeat the same estimates. Pairs with $d_{\mathbf{g}}(x,y) \ge \delta$ are controlled by the uniform norms. This proves equivalence of the intrinsic norms on $\overline{U}$.

We turn to the extension norms. Let $\widetilde{\mathbf{T}} \in \mathcal{E}^{0,\alpha}_{\overline{U}}(\mathbf{T})$. Choose a cutoff function $\chi \in C^\infty_c(U')$ equal to one on a neighborhood of $\overline{U}$. The components of $\chi\widetilde{\mathbf{T}}$ in the frame, transported by φ and extended by zero outside $\varphi(U')$, are global extensions of $T^A \circ \varphi^{-1}$. Estimate (9.54), applied on a compact set containing $\operatorname{supp}\chi$, and the product rule give

$$\sum_{A=1}^{N} \|T^A \circ \varphi^{-1}\|_{C^{0,\alpha}(\overline{\varphi(U)})} \le C\|\widetilde{\mathbf{T}}\|_{\Gamma^{0,\alpha}(\mathbf{F})}.$$

Taking the infimum over $\widetilde{\mathbf{T}}$ yields the first inequality in (9.50).
Conversely, choose extensions $\widetilde{t^A} \in C^{0,\alpha}(\mathbb{R}^n)$ of $T^A \circ \varphi^{-1}$. On U' define

$$\widehat{\mathbf{T}} := \chi \sum_{A=1}^{N} (\widetilde{t^A} \circ \varphi)\mathbf{f}_A$$

and denote its extension by zero outside U' by $\widetilde{\widehat{\mathbf{T}}}$. This section belongs to $\Gamma^{0,\alpha}(\mathbf{F})$, extends $\mathbf{T}$, and satisfies

$$\|\widetilde{\widehat{\mathbf{T}}}\|_{\Gamma^{0,\alpha}(\mathbf{F})} \le C \sum_{A=1}^{N} \|\widetilde{t^A}\|_{C^{0,\alpha}(\mathbb{R}^n)}.$$

Taking the infimum first over the scalar extensions and then in the definition of the norm of $\mathbf{T}$ gives the second inequality. The two constructions also prove equivalence of membership. □

Lemma 9.2.9. (Multiplication by smooth functions in spaces of Hölder sections) Let $(M,\mathbf{g})$ be a connected Riemannian manifold without boundary with $\operatorname{inj}(M) > 0$, and let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric and a compatible connection. Let $k \in \mathbb{N}_0$, $0 < \alpha < 1$, and $\chi \in C^\infty_c(M)$. Then there is a constant $C_{\chi,k,\alpha} > 0$ such that

$$\|\chi\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le C_{\chi,k,\alpha}\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})}$$

for every $\mathbf{u} \in \Gamma^{k,\alpha}(\mathbf{E})$.

Proof. We first record two elementary estimates. Let $\mathbf{F} \to M$ be a bundle with a compatible connection, and let $\mathbf{S} \in \Gamma^1(\mathbf{F})$. For $x, y \in M$ with $0 < d_{\mathbf{g}}(x,y) < \rho_M$, Lemma 2.7.21, applied to $\gamma_{xy}\colon [0,1] \longrightarrow M$, gives

$$P^{\mathbf{F}}_{\gamma_{xy},1\to 0}(\mathbf{S}(y)) - \mathbf{S}(x) = \int_0^1 P^{\mathbf{F}}_{\gamma_{xy},t\to 0}\big(\nabla^{\mathbf{F}}_{\dot\gamma_{xy}(t)}\mathbf{S}\big)\,dt.$$

Since $|\dot\gamma_{xy}(t)|_{\mathbf{g}} = d_{\mathbf{g}}(x,y)$ and parallel transport is an isometry,

$$|\mathbf{S}(x) - \mathbf{S}(y)|_{\mathbf{h}_{\mathbf{F}};x,y} \le d_{\mathbf{g}}(x,y)\big\||\nabla^{\mathbf{F}}\mathbf{S}|_{\mathbf{g},\mathbf{h}_{\mathbf{F}}}\big\|_{L^\infty(M)}. \tag{9.55}$$

In particular, if $\rho_M \le 1$, a section with bounded derivative is Hölder continuous with any exponent $0 < \alpha < 1$ for the pairs appearing in (9.47).
Now let $\mathbf{F}_1, \mathbf{F}_2 \to M$ be vector bundles with bundle metrics (Hermitian in the complex case) and compatible connections, $\mathbf{A} \in \Gamma^0(\mathbf{F}_1)$ and $\mathbf{B} \in \Gamma^0(\mathbf{F}_2)$. The product connection satisfies the Leibniz rule, so uniqueness of

parallel transport implies

$$P^{\mathbf{F}_1\otimes\mathbf{F}_2}_{\gamma_{xy},1\to0} = P^{\mathbf{F}_1}_{\gamma_{xy},1\to0}\otimes P^{\mathbf{F}_2}_{\gamma_{xy},1\to0}.$$

Adding and subtracting $P^{\mathbf{F}_1}_{\gamma_{xy},1\to0}(\mathbf{A}(y))\otimes\mathbf{B}(x)$ gives

$$[\mathbf{A}\otimes\mathbf{B}]_{\alpha,\mathbf{F}_1\otimes\mathbf{F}_2} \le \|\mathbf{B}\|_{L^\infty(M,\mathbf{F}_2)}[\mathbf{A}]_{\alpha,\mathbf{F}_1} + \|\mathbf{A}\|_{L^\infty(M,\mathbf{F}_1)}[\mathbf{B}]_{\alpha,\mathbf{F}_2}. \tag{9.56}$$

The same estimate holds after any tensor contraction of uniformly bounded norm.

The iterated Leibniz rule distributes the j derivatives between χ and $\mathbf{u}$. More precisely, for each $j\in\{0,\dots,k\}$ there are integers $N_{j,\ell}$, universal coefficients $C_{j,\ell,\nu}$, and permutations $\tau_{j,\ell,\nu}$ of the j covariant indices such that

$$\nabla^j(\chi\mathbf{u}) = \sum_{\ell=0}^{j}\sum_{\nu=1}^{N_{j,\ell}} C_{j,\ell,\nu}\,\tau_{j,\ell,\nu}\big(\nabla^{j-\ell}\chi\otimes\nabla^\ell\mathbf{u}\big).$$

Here a sum with $N_{j,\ell}=0$ is understood to be empty. Since χ has compact support, its covariant derivatives of every order, and the derivatives of those sections, are uniformly bounded. The preceding formula therefore controls the uniform norms of $\nabla^j(\chi\mathbf{u})$.

For the seminorm of $\nabla^k(\chi\mathbf{u})$, if $\ell<k$, the section $\nabla^\ell\mathbf{u}$ has bounded derivative $\nabla^{\ell+1}\mathbf{u}$. By (9.55), both $\nabla^\ell\mathbf{u}$ and $\nabla^{k-\ell}\chi$ are Hölder continuous with exponent α. Estimate (9.56) controls the corresponding term. For $\ell=k$, apply the scalar version of the same estimate to the product $\chi\nabla^k\mathbf{u}$; the Hölder seminorm of $\nabla^k\mathbf{u}$ is part of (9.48). Summing the terms gives the stated inequality. □

We can now obtain the classical analogue of Lemma 9.1.44. The proof is based on the triangular coordinate expression for covariant derivatives.

Lemma 9.2.10. (Local characterization of Hölder sections) Let $(M,\mathbf{g})$ be a connected Riemannian manifold without boundary with $\operatorname{inj}(M)>0$. Let (U,φ) be a regular coordinate ball in M, and let $\mathbf{E}\longrightarrow M$ be a smooth vector bundle of rank r, equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla^{\mathbf{E}}$. Let $(\mathbf{e}_1,\dots,\mathbf{e}_r)$ be a local frame of $\mathbf{E}$ defined on a neighborhood of $\overline{U}$, and write

$$\mathbf{u} = \sum_{a=1}^{r} u^a\mathbf{e}_a \qquad \text{on } U.$$

Let $k\in\mathbb{N}_0$ and $0<\alpha<1$. Then

$$\mathbf{u}\in\Gamma^{k,\alpha}(\overline{U},\mathbf{E}) \iff u^a\circ\varphi^{-1}\in C^{k,\alpha}(\overline{\varphi(U)}) \quad \text{for every } a\in\{1,\dots,r\}.$$

Moreover, there are constants $c_{k,\alpha}, C_{k,\alpha}>0$, independent of $\mathbf{u}$, such that

$$\begin{aligned} c_{k,\alpha}\sum_{a=1}^{r}\|u^a\circ\varphi^{-1}\|_{C^{k,\alpha}(\overline{\varphi(U)})} &\le \|\mathbf{u}\|_{\Gamma^{k,\alpha}(\overline{U},\mathbf{E})} \\ &\le C_{k,\alpha}\sum_{a=1}^{r}\|u^a\circ\varphi^{-1}\|_{C^{k,\alpha}(\overline{\varphi(U)})}. \end{aligned} \tag{9.57}$$

Proof. The case $k = 0$ is Lemma 9.2.8. Suppose that $k \geq 1$. Let U' be a larger regular coordinate ball, so that $\overline{U} \subseteq U'$ and the chart and frame are defined on U'. In the chosen chart and frame, Lemma 9.1.28 gives, for each $s \in \{1, \dots, k\}$,

$$(\nabla^s \mathbf{u})^a_{i_1 \dots i_s} = \partial_{i_1} \cdots \partial_{i_s} u^a + \sum_{b=1}^{r} \sum_{|\beta| \leq s-1} (B_{s,\beta})^a_{b\, i_1 \dots i_s} \partial^\beta u^b. \tag{9.58}$$

The coefficients $B_{s,\beta}$ are smooth on U'. Their derivatives of the orders appearing below are therefore uniformly bounded on each compact subset of U'.

We first prove the left inequality in (9.57). Let $\widetilde{\mathbf{u}} \in \mathcal{E}^{k,\alpha}_{\overline{U}}(\mathbf{u})$. Choose a cutoff function $\chi \in C^\infty_c(U')$ equal to one on a neighborhood of $\overline{U}$ and set $\mathbf{v} := \chi \widetilde{\mathbf{u}}$. If $\mathbf{v} = \sum_{a=1}^{r} v^a \mathbf{e}_a$ on U', denote by $\widetilde{v}^a$ the extension of $v^a \circ \varphi^{-1}$ by zero outside $\varphi(U')$. Each $\widetilde{v}^a$ belongs to $C^k(\mathbb{R}^n)$ and extends $u^a \circ \varphi^{-1}$.

Solving for the principal part in (9.58) gives

$$\partial_{i_1} \cdots \partial_{i_s} v^a = (\nabla^s \mathbf{v})^a_{i_1 \dots i_s} - \sum_{b=1}^{r} \sum_{|\beta| \leq s-1} (B_{s,\beta})^a_{b\, i_1 \dots i_s} \partial^\beta v^b. \tag{9.59}$$

Uniform equivalence of the fiber norms and induction on s give

$$\sum_{a=1}^{r} \sum_{|\beta| \leq k} \|D^\beta \widetilde{v}^a\|_{L^\infty(\mathbb{R}^n)} \leq C \sum_{s=0}^{k} \|\nabla^s \mathbf{v}\|_{L^\infty(M, \mathbf{E}_s)}. \tag{9.60}$$

Let us prove this estimate by induction. For $0 \leq s \leq k$, set

$$S_s := \sum_{a=1}^{r} \sum_{|\beta| \leq s} \|D^\beta \widetilde{v}^a\|_{L^\infty(\mathbb{R}^n)}, \qquad T_s := \sum_{q=0}^{s} \|\nabla^q \mathbf{v}\|_{L^\infty(M, \mathbf{E}_q)}.$$

Since $\mathbf{v}$ has compact support in the domain of the frame, extension by zero does not change the suprema of its components. Uniform equivalence of the norm of a section and the norms of its components gives $S_0 \leq C_0 T_0$.

Suppose that $S_{s-1} \leq C_{s-1} T_{s-1}$ for some $1 \leq s \leq k$. Taking absolute values in (9.59), using the uniform bounds on the coefficients $B_{s,\beta}$ on the compact set containing the support of $\mathbf{v}$, and summing over a and all blocks $(i_1, \dots, i_s)$ gives

$$\sum_{a=1}^{r} \sum_{|\gamma| = s} \|D^\gamma \widetilde{v}^a\|_{L^\infty(\mathbb{R}^n)} \leq C'_s \left(\|\nabla^s \mathbf{v}\|_{L^\infty(M, \mathbf{E}_s)} + S_{s-1} \right).$$

Here passing from ordered blocks of indices to multi-indices changes only the constant, since both families are finite. Consequently,

$$\begin{aligned} S_s &\leq S_{s-1} + C'_s \left(\|\nabla^s \mathbf{v}\|_{L^\infty(M, \mathbf{E}_s)} + S_{s-1} \right) \\ &\leq \left((1 + C'_s) C_{s-1} + C'_s \right) T_s. \end{aligned}$$

This proves the induction step. Taking the maximum of the constants appearing for $0 \leq s \leq k$ yields (9.60). It remains to control the Hölder seminorms of the derivatives of order k. The components of $\nabla^k \mathbf{v}$ are Hölder continuous in coordinates by Lemma 9.2.8, applied to the bundle $\mathbf{E}_k = T^{(0,k)}(TM) \otimes \mathbf{E}$ over an intermediate ball containing the support of χ. If $|\beta| \leq k - 1$, estimate (9.60) controls the first derivatives of $D^\beta \widetilde{v}^b$. By the

mean value theorem, these functions are Lipschitz and, since their supports lie in a fixed compact set, they are Hölder continuous with exponent α on $\mathbb{R}^n$. The inequality

$$[f\mathbf{g}]_{C^{0,\alpha}(K)} \le \|f\|_{C^0(K)}[\mathbf{g}]_{C^{0,\alpha}(K)} + \|\mathbf{g}\|_{C^0(K)}[f]_{C^{0,\alpha}(K)}$$

applied to the lower-order terms in (9.59) gives

$$\sum_{a=1}^{r} [\widetilde{v}^a]_{C^{k,\alpha}(\mathbb{R}^n)} \le C\|\mathbf{v}\|_{\Gamma^{k,\alpha}(\mathbf{E})}.$$

Together with (9.60), this implies

$$\sum_{a=1}^{r} \|u^a \circ \varphi^{-1}\|_{C^{k,\alpha}(\overline{\varphi(U)})} \le C\|\widetilde{\mathbf{u}}\|_{\Gamma^{k,\alpha}(\mathbf{E})},$$

where we use Lemma 9.2.9 to control $\mathbf{v} = \chi\widetilde{\mathbf{u}}$. Taking the infimum over all extensions $\widetilde{\mathbf{u}}$ proves the first inequality in (9.57).

We prove the reverse inequality. For each $a \in \{1,\dots,r\}$ choose an extension $w^a \in C^{k,\alpha}(\mathbb{R}^n)$ of $u^a \circ \varphi^{-1}$. Let $\eta \in C_c^\infty(\varphi(U'))$ be a cutoff function equal to one on a neighborhood of $\overline{\varphi(U)}$. On U' define

$$\mathbf{w} := \sum_{a=1}^{r} \big((\eta w^a) \circ \varphi\big)\mathbf{e}_a$$

and denote its extension by zero outside U' by $\widetilde{\mathbf{w}}$. The presence of η ensures that $\widetilde{\mathbf{w}}$ is a global section of class C^k and that $\widetilde{\mathbf{w}}\restriction_U = \mathbf{u}$.

The direct formula (9.58), the Leibniz rule, and Lemma 9.2.8, again applied to the bundle $\mathbf{E}_k$, give

$$\|\widetilde{\mathbf{w}}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le C \sum_{a=1}^{r} \|w^a\|_{C^{k,\alpha}(\mathbb{R}^n)}.$$

The terms of order k are controlled by the seminorms of the w^a. The lower-order terms have an additional bounded derivative and are controlled by the mean value theorem, exactly as in the first part. Taking the infimum first over the scalar extensions w^a and then in the definition of the norm of $\mathbf{u}$ gives the second inequality in (9.57). The two constructions also prove equivalence of membership. □

The following localized version of the norm will allow us to combine estimates obtained in different charts.

Proposition 9.2.11. (Equivalence of the localized Hölder norm) Let $(M,\mathbf{g})$ be a compact connected Riemannian manifold without boundary. Let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric and a compatible connection. Consider regular coordinate balls $(U_i,\varphi_i)_{i=1}^N$ covering M and smooth cutoff functions $(\psi_i)_{i=1}^N$ such that

$$0 \le \psi_i \le 1, \qquad \operatorname{supp}(\psi_i) \Subset U_i, \qquad \sum_{i=1}^{N} \psi_i = 1.$$

For each i, let $(\mathbf{e}_{i,1},\dots,\mathbf{e}_{i,r})$ be a local frame of $\mathbf{E}$ defined on a neighborhood of $\overline{U_i}$, and write

$$\psi_i\mathbf{u} = \sum_{a=1}^{r} u_i^a \mathbf{e}_{i,a} \qquad \text{on } U_i.$$

If $k \in \mathbb{N}_0$ and $0 < \alpha < 1$, there are constants $c, C > 0$ such that

$$c\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le \sum_{i=1}^{N}\sum_{a=1}^{r} \|u_i^a \circ \varphi_i^{-1}\|_{C^{k,\alpha}(\overline{\varphi_i(U_i)})} \le C\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \tag{9.61}$$

for every $\mathbf{u} \in \Gamma^{k,\alpha}(\mathbf{E})$.

Proof. Lemma 9.2.9 gives a constant $C_0 > 0$, independent of i, such that

$$\|\psi_i\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le C_0\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})}.$$

Uniformity follows because only a finite family of cutoff functions is involved. Lemma 9.2.10, applied to $\psi_i\mathbf{u}\restriction_{U_i}$, gives the second inequality in (9.61).

We prove the first. Set $K_i := \varphi_i(\operatorname{supp}\psi_i) \Subset \varphi_i(U_i)$ and choose $\eta_i \in C_c^\infty(\varphi_i(U_i))$ such that $\eta_i = 1$ on a neighborhood of K_i. For each a take an extension $v_i^a \in C^{k,\alpha}(\mathbb{R}^n)$ of $u_i^a \circ \varphi_i^{-1}$. The function $\eta_i v_i^a$, extended by zero outside $\varphi_i(U_i)$, remains an extension of that component. On U_i reconstruct the section

$$\sum_{a=1}^{r} \big((\eta_i v_i^a) \circ \varphi_i\big)\mathbf{e}_{i,a}$$

and denote its extension by zero outside U_i by $\widetilde{\mathbf{u}}_i$. By construction, $\widetilde{\mathbf{u}}_i = \psi_i\mathbf{u}$. The local comparison and product rule give

$$\|\psi_i\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le C_i \sum_{a=1}^{r} \|v_i^a\|_{C^{k,\alpha}(\mathbb{R}^n)}.$$

Taking the infimum over the extensions v_i^a, summing over i, and using $\mathbf{u} = \sum_{i=1}^{N} \psi_i\mathbf{u}$ gives

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le C \sum_{i=1}^{N}\sum_{a=1}^{r} \|u_i^a \circ \varphi_i^{-1}\|_{C^{k,\alpha}(\overline{\varphi_i(U_i)})}.$$

This completes the proof. □

Corollary 9.2.12. (Completeness of spaces of Hölder sections) Let $(M, \mathbf{g})$ be a compact connected Riemannian manifold without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle with a bundle metric and a compatible connection. Let $k \in \mathbb{N}_0$ and $0 < \alpha < 1$. Then $\Gamma^{k,\alpha}(\mathbf{E})$ is a Banach space.

Proof. Let $(\mathbf{u}_j)_{j\in\mathbb{N}}$ be a Cauchy sequence in $\Gamma^{k,\alpha}(\mathbf{E})$. For each $i \in \{1,\dots,N\}$ write

$$\psi_i \mathbf{u}_j = \sum_{a=1}^{r} u_{i,j}^a \mathbf{e}_{i,a} \qquad \text{on } U_i.$$

For each pair (i,a), the components of $\psi_i\mathbf{u}_j$ form a Cauchy sequence in $C^{k,\alpha}(\overline{\varphi_i(U_i)})$ by (9.61). Proposition 3.5.4 gives a limit f_i^a in that space. Since the extension norm controls the uniform norm on the closure, f_i^a vanishes outside the fixed compact set $K_i = \varphi_i(\operatorname{supp}\psi_i)$, as do all the components of the sequence. Choose global extensions of the f_i^a, multiply them by the functions η_i from the preceding proof, and reconstruct global sections $\mathbf{v}_i$ supported in U_i. The estimate obtained in that proof gives

$$\|\psi_i\mathbf{u}_j - \mathbf{v}_i\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le C_i \sum_{a=1}^{r} \|(u_{i,j}^a \circ \varphi_i^{-1}) - f_i^a\|_{C^{k,\alpha}(\overline{\varphi_i(U_i)})},$$

and the right-hand side converges to zero. Define

$$\mathbf{u} := \sum_{i=1}^{N} \mathbf{v}_i.$$

Since $\mathbf{u}_j = \sum_{i=1}^{N} \psi_i\mathbf{u}_j$ and the sum is finite,

$$\|\mathbf{u}_j - \mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le \sum_{i=1}^{N} \|\psi_i\mathbf{u}_j - \mathbf{v}_i\|_{\Gamma^{k,\alpha}(\mathbf{E})} \longrightarrow 0.$$

Therefore, $\mathbf{u} \in \Gamma^{k,\alpha}(\mathbf{E})$ and the space is complete. □

We can now transfer the Euclidean embeddings to bundle sections.

Theorem 9.2.13. (Sobolev–Morrey embedding for vector bundles) Let $(M,\mathbf{g})$ be a compact Riemannian manifold without boundary of dimension n, and let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_\mathbf{E}$ and a compatible connection $\nabla^\mathbf{E}$. Let $m \in \mathbb{N}$, $1 \le p < \infty$, $k \in \mathbb{N}_0$, and $0 < \alpha < 1$. Suppose that

$$k + \alpha \le m - \frac{n}{p}. \tag{9.62}$$

Then each element of $W^{m,p}(M,\mathbf{E})$ admits a unique representative in $\Gamma^{k,\alpha}(\mathbf{E})$, and the map assigning this representative defines a continuous linear embedding

$$W^{m,p}(M,\mathbf{E}) \hookrightarrow \Gamma^{k,\alpha}(\mathbf{E}).$$

In particular, there is a constant $C > 0$ such that

$$\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le C\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \tag{9.63}$$

for every $\mathbf{u} \in W^{m,p}(M,\mathbf{E})$.

Proof. We may work on each connected component of M, and therefore assume that M is connected. Choose regular coordinate balls, cutoff functions, and local frames as in Proposition 9.2.11. For $\mathbf{u} \in W^{m,p}(M,\mathbf{E})$ write

$$\psi_i \mathbf{u} = \sum_{a=1}^{r} u_i^a \mathbf{e}_{i,a} \qquad \text{on } U_i.$$

The Leibniz estimate used in the proof of Theorem 9.2.1, in particular estimate (9.45) with $j = 0$, gives a constant $C_0 > 0$ such that

$$\|\psi_i \mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \le C_0 \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \tag{9.64}$$

for every $i \in \{1,\dots,N\}$.
Lemma 9.1.44 shows that $u_i^a \circ \varphi_i^{-1} \in W^{m,p}(\varphi_i(U_i))$ and that

$$\sum_{a=1}^{r} \|u_i^a \circ \varphi_i^{-1}\|_{W^{m,p}(\varphi_i(U_i))} \le C_i \|\psi_i \mathbf{u}\|_{W^{m,p}(U_i,\mathbf{E}\restriction_{U_i})}. \tag{9.65}$$

Since $\operatorname{supp}(\psi_i) \Subset U_i$, each component has compact support contained in $\varphi_i(U_i)$ and therefore belongs to $W_0^{m,p}(\varphi_i(U_i))$. Theorem 3.5.7 and (9.62) give

$$\|u_i^a \circ \varphi_i^{-1}\|_{C^{k,\alpha}(\overline{\varphi_i(U_i)})} \le C_i' \|u_i^a \circ \varphi_i^{-1}\|_{W^{m,p}(\varphi_i(U_i))}.$$

Take the Euclidean representatives of the components, reconstruct the section $\psi_i \mathbf{u}$ on U_i, and extend it by zero outside U_i. The sum of these sections represents $\mathbf{u}$, since it agrees almost everywhere with $\sum_{i=1}^{N} \psi_i \mathbf{u} = \mathbf{u}$. Proposition 9.2.11, the preceding estimates, and finiteness of the cover give

$$\begin{aligned}
\|\mathbf{u}\|_{\Gamma^{k,\alpha}(\mathbf{E})} &\le C \sum_{i=1}^{N} \sum_{a=1}^{r} \|u_i^a \circ \varphi_i^{-1}\|_{C^{k,\alpha}(\overline{\varphi_i(U_i)})} \\
&\le C \sum_{i=1}^{N} \sum_{a=1}^{r} \|u_i^a \circ \varphi_i^{-1}\|_{W^{m,p}(\varphi_i(U_i))} \\
&\le C \sum_{i=1}^{N} \|\psi_i \mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \le C' \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.
\end{aligned}$$

This proves (9.63).
Uniqueness of the representative follows as in the Euclidean case. If a continuous section vanishes almost everywhere but is nonzero at some point, its norm is positive on an open neighborhood of that point, which has positive Riemann–Lebesgue measure. Thus the section must vanish throughout M. □

Theorem 9.2.14. (Rellich–Kondrashov into Hölder sections) Let $(M,\mathbf{g})$ be a compact Riemannian manifold without boundary of dimension n, and let $\mathbf{E} \to M$ be a smooth vector bundle with a bundle metric and a compatible connection. Let $m \in \mathbb{N}$, $1 \le p < \infty$, $k \in \mathbb{N}_0$, and $0 < \alpha < 1$. If

$$k + \alpha < m - \frac{n}{p}, \tag{9.66}$$

then the embedding

$$W^{m,p}(M,\mathbf{E}) \hookrightarrow \Gamma^{k,\alpha}(\mathbf{E})$$

is compact.

Proof. Let $(\mathbf{u}_j)_{j\in\mathbb{N}}$ be a bounded sequence in $W^{m,p}(M,\mathbf{E})$. Use the cover, cutoff functions, and frames from the preceding proof. For each $i \in \{1,\dots,N\}$ write

$$\psi_i \mathbf{u}_j = \sum_{a=1}^{r} u_{i,j}^a \mathbf{e}_{i,a} \qquad \text{on } U_i.$$

Estimates (9.64) and (9.65) show that, for each pair (i,a), the sequence

$$\left(u_{i,j}^a \circ \varphi_i^{-1}\right)_{j\in\mathbb{N}}$$

is bounded in $W_0^{m,p}(\varphi_i(U_i))$. By Theorem 3.5.10, each of these sequences has a subsequence converging in $C^{k,\alpha}(\overline{\varphi_i(U_i)})$.

Only the Nr pairs of indices are involved. Extracting successive subsequences and relabeling the last one, we may assume that

$$u_{i,j}^a \circ \varphi_i^{-1} \quad \text{converges in} \quad C^{k,\alpha}(\overline{\varphi_i(U_i)})$$

for every $i \in \{1,\dots,N\}$ and every $a \in \{1,\dots,r\}$. In particular, the localized components form Cauchy sequences in those spaces. The first inequality in (9.61), applied to $\mathbf{u}_j - \mathbf{u}_\ell$, gives

$$\|\mathbf{u}_j - \mathbf{u}_\ell\|_{\Gamma^{k,\alpha}(\mathbf{E})} \le C \sum_{i=1}^{N} \sum_{a=1}^{r} \|(u_{i,j}^a - u_{i,\ell}^a) \circ \varphi_i^{-1}\|_{C^{k,\alpha}(\overline{\varphi_i(U_i)})}.$$

The right-hand side converges to zero as $j,\ell \to \infty$. Thus the subsequence is Cauchy in $\Gamma^{k,\alpha}(\mathbf{E})$ and converges in that space by Corollary 9.2.12. This proves compactness of the embedding. □

Corollary 9.2.15. (Regularity exponents for sections) Let $(M,\mathbf{g})$ be a compact Riemannian manifold without boundary of dimension n, and let $\mathbf{E} \to M$ be a smooth vector bundle with a bundle metric and a compatible connection. Let $m \in \mathbb{N}$ and $1 \le p < \infty$. Let

$$\sigma := m - \frac{n}{p} > 0.$$

Then the following assertions hold.

(a) If $\sigma = \ell + \theta$, with $\ell \in \mathbb{N}_0$ and $0 < \theta < 1$, then

$$W^{m,p}(M,\mathbf{E}) \hookrightarrow \Gamma^{\ell,\theta}(\mathbf{E})$$

continuously, and the embedding into $\Gamma^{\ell,\beta}(\mathbf{E})$ is compact for every $0 < \beta < \theta$.

(b) If $\sigma = s \in \mathbb{N}$, then for every $0 < \alpha < 1$ the embedding

$$W^{m,p}(M,\mathbf{E}) \hookrightarrow \Gamma^{s-1,\alpha}(\mathbf{E})$$

is compact and, in particular, continuous.

Proof. If $\sigma = \ell + \theta$ with $0 < \theta < 1$, Theorem 9.2.13 applied to $k = \ell$ and $\alpha = \theta$ gives the continuous embedding, since

$$\ell + \theta = m - \frac{n}{p}.$$

If $0 < \beta < \theta$, then

$$\ell + \beta < m - \frac{n}{p},$$

and Theorem 9.2.14 gives compactness of the embedding into $\Gamma^{\ell,\beta}(\mathbf{E})$.
If $\sigma = s \in \mathbb{N}$ and $0 < \alpha < 1$, we have

$$(s-1) + \alpha < s = m - \frac{n}{p}.$$

The same Rellich–Kondrashov theorem, with $k = s - 1$, gives the compact embedding into $\Gamma^{s-1,\alpha}(\mathbf{E})$. Every compact linear operator between normed spaces is continuous, which also proves the final assertion. □

9.2.2 Independence of Sobolev spaces in the compact case

As in the setting of Riemannian manifolds, Sobolev spaces on vector bundles over a compact Riemannian manifold are independent of the choice of metric and connection. To prove this, we establish some useful preliminary results. In particular, we formulate an analogue of Lemma 7.1.10 in the vector bundle setting.

Lemma 9.2.16. Let M be a smooth manifold with or without boundary, let $\mathbf{g}$ and $\widetilde{\mathbf{g}}$ be two Riemannian metrics on M, let ∇^{TM} and $\widetilde{\nabla}^{TM}$ be two connections on TM, let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle of finite rank, let $\mathbf{h}$ and $\widetilde{\mathbf{h}}$ be two smooth bundle metrics on $\mathbf{E}$, and let $\nabla^{\mathbf{E}}$ and $\widetilde{\nabla}^{\mathbf{E}}$ be two connections on $\mathbf{E}$.
Let $K \subseteq M$ be compact and $m \geq 0$. Then there are constants $c_m, C_m > 0$ such that

$$c_m \sum_{j=0}^{m} |\nabla^j \mathbf{u}(x)|^2_{\mathbf{g},\mathbf{h}} \leq \sum_{j=0}^{m} |\widetilde{\nabla}^j \mathbf{u}(x)|^2_{\widetilde{\mathbf{g}},\widetilde{\mathbf{h}}} \leq C_m \sum_{j=0}^{m} |\nabla^j \mathbf{u}(x)|^2_{\mathbf{g},\mathbf{h}}, \qquad \forall x \in K,$$

for every section $\mathbf{u} \in \Gamma^m(\mathbf{E})$.

Proof. If $K = \varnothing$, the assertion is immediate. Suppose that $K \neq \varnothing$. The connections ∇^{TM} and $\nabla^{\mathbf{E}}$ induce connections on $T^{(0,j)}(TM) \otimes \mathbf{E}$, also denoted by ∇. By Definition 1.7.10, we may consider

$$\mathscr{T}_m(\mathbf{E}) := \bigoplus_{j=0}^{m} T^{(0,j)}(TM) \otimes \mathbf{E}.$$

For $\mathbf{u} \in \Gamma(\mathbf{E})$ write

$$J^m_\nabla \mathbf{u} := (\mathbf{u}, \nabla\mathbf{u}, \ldots, \nabla^m \mathbf{u})$$

and, for each $p \in M$, define

$$\mathscr{D}_{\nabla,p}(\mathbf{E}) := \{J^m_\nabla \mathbf{u}(p) \mid \mathbf{u} \in \Gamma(\mathbf{E})\} \subseteq \mathscr{T}_m(\mathbf{E})_p.$$

Each $\mathscr{D}_{\nabla,p}(\mathbf{E})$ is a vector subspace by linearity of covariant derivatives.
Let (U, φ) be a smooth chart, let $(\mathbf{e}_1, \ldots, \mathbf{e}_r)$ be a smooth local frame of $\mathbf{E}$ on U, let $p \in U$, and set $x := \varphi(p)$

and $N := \binom{n+m}{m}$. If $\mathbf{u} = \sum_{a=1}^{r} u^a \mathbf{e}_a$, define the linear map

$$F^{\varphi,\mathbf{e}}_{\nabla,p} \colon \mathscr{D}_{\nabla,p}(\mathbf{E}) \longrightarrow \mathbb{K}^{rN}, \qquad F^{\varphi,\mathbf{e}}_{\nabla,p}(J^m_\nabla \mathbf{u}(p)) := \big(D^\alpha(u^a \circ \varphi^{-1})(x)\big)_{1\le a\le r,\ |\alpha|\le m},$$

using the multi-index notation from Definition 1.1.10. Lemma 9.1.28, in particular formula (9.3), gives

$$(\nabla^j \mathbf{u})^a_{i_1\dots i_j} = \partial_{i_1}\cdots\partial_{i_j}(u^a \circ \varphi^{-1}) + \sum_{b=1}^{r}\sum_{|\alpha|<j} A^{ab,\alpha}_{i_1\dots i_j} D^\alpha(u^b \circ \varphi^{-1}), \tag{9.67}$$

with smooth coefficients on U. Induction on j in (9.67) shows that the covariant jet determines all partial derivatives of the components through order m. Consequently, $F^{\varphi,\mathbf{e}}_{\nabla,p}$ is well defined and injective.
Let $a = (a^b_\alpha)_{1\le b\le r,\ |\alpha|\le m} \in \mathbb{K}^{rN}$. Proposition 1.3.6 gives a function $\chi \in C^\infty_c(U)$ equal to one on a neighborhood of p. The section

$$\mathbf{v}(q) := \chi(q) \sum_{b=1}^{r} \left(\sum_{|\alpha|\le m} \frac{a^b_\alpha}{\alpha!} (\varphi(q) - x)^\alpha \right) \mathbf{e}_b(q), \qquad q \in U,$$

extended by zero outside U belongs to $\Gamma(\mathbf{E})$ and satisfies $D^\alpha(v^b \circ \varphi^{-1})(x) = a^b_\alpha$. Thus $F^{\varphi,\mathbf{e}}_{\nabla,p}$ is surjective and hence an isomorphism.
Let $(e_1,\dots,e_{rN})$ be the standard basis of $\mathbb{K}^{rN}$. Expressing the covariant jets in terms of the prescribed partial jets using (9.67) shows that the components of the local sections

$$\boldsymbol{\sigma}_\nu(q) := (F^{\varphi,\mathbf{e}}_{\nabla,q})^{-1}(e_\nu), \qquad q \in U, \quad \nu \in \{1,\dots,rN\},$$

are smooth. Their values form a basis of $\mathscr{D}_{\nabla,q}(\mathbf{E})$ for every $q \in U$. By Lemma 1.7.52,

$$\mathscr{D}_\nabla(\mathbf{E}) := \bigcup_{p\in M} \mathscr{D}_{\nabla,p}(\mathbf{E})$$

is a smooth vector subbundle of $\mathscr{T}_m(\mathbf{E})$ of rank rN. The connections $\widetilde{\nabla}^{TM}$ and $\widetilde{\nabla}^{\mathbf{E}}$ similarly produce the subbundle $\mathscr{D}_{\widetilde{\nabla}}(\mathbf{E})$ and the isomorphisms $F^{\varphi,\mathbf{e}}_{\widetilde{\nabla},p}$.
The compact set K is covered by finitely many compact regular coordinate balls and, if M has boundary, compact regular coordinate half-balls

$$\overline{B}_1,\dots,\overline{B}_\ell,$$

each contained in the domain of a chart φ_i and a local frame $\mathbf{e}_i = (\mathbf{e}_{1,i},\dots,\mathbf{e}_{r,i})$ of $\mathbf{E}$. For $p \in \overline{B}_i$ and $v \in \mathbb{K}^{rN}$ set

$$Q_i(p,v) := \sum_{j=0}^{m} \left| \big((F^{\varphi_i,\mathbf{e}_i}_{\nabla,p})^{-1}(v)\big)_j \right|^2_{\mathbf{g},\mathbf{h}},$$

$$\widetilde{Q}_i(p,v) := \sum_{j=0}^{m} \left| \big((F^{\varphi_i,\mathbf{e}_i}_{\widetilde{\nabla},p})^{-1}(v)\big)_j \right|^2_{\widetilde{\mathbf{g}},\widetilde{\mathbf{h}}}.$$

The functions Q_i and $\widetilde{Q}_i$ are continuous and, for each p, are positive definite quadratic forms in v. If

$$\mathbb{S}^{rN}_{\mathbb{K}} := \{v \in \mathbb{K}^{rN} \mid \|v\|_2 = 1\},$$

then

$$R_i(p,v) := \frac{\widetilde{Q}_i(p,v)}{Q_i(p,v)}$$

is continuous and strictly positive on the compact set $\overline{B}_i \times \mathbb{S}^{rN}_{\mathbb{K}}$. Define

$$c_{i,m} := \min_{(p,v)\in\overline{B}_i\times\mathbb{S}^{rN}_{\mathbb{K}}} R_i(p,v) > 0, \qquad C_{i,m} := \max_{(p,v)\in\overline{B}_i\times\mathbb{S}^{rN}_{\mathbb{K}}} R_i(p,v) < \infty.$$

Homogeneity of Q_i and $\widetilde{Q}_i$ implies that

$$c_{i,m} Q_i(p,v) \le \widetilde{Q}_i(p,v) \le C_{i,m} Q_i(p,v) \tag{9.68}$$

for every $p \in \overline{B}_i$ and every $v \in \mathbb{K}^{rN}$.
Let $\mathbf{u} \in \Gamma^m(\mathbf{E})$ and let $p \in \overline{B}_i$. The preceding polynomial construction gives a smooth section whose partial derivative jet at p agrees with that of $\mathbf{u}$. Formula (9.3) then shows that the covariant jets of the two sections agree at p for either pair of connections. Thus

$$\begin{aligned} F^{\varphi_i,\mathbf{e}_i}_{\nabla,p}(J^m_\nabla \mathbf{u}(p)) &= \big(D^\alpha(u^a_i \circ \varphi_i^{-1})(\varphi_i(p))\big)_{1\le a\le r,\ |\alpha|\le m} \\ &= F^{\varphi_i,\mathbf{e}_i}_{\widetilde{\nabla},p}(J^m_{\widetilde{\nabla}} \mathbf{u}(p)). \end{aligned}$$

Applying (9.68) to this vector gives

$$c_{i,m} \sum_{j=0}^{m} |\nabla^j \mathbf{u}(p)|^2_{\mathbf{g},\mathbf{h}} \le \sum_{j=0}^{m} |\widetilde{\nabla}^j \mathbf{u}(p)|^2_{\widetilde{\mathbf{g}},\widetilde{\mathbf{h}}} \le C_{i,m} \sum_{j=0}^{m} |\nabla^j \mathbf{u}(p)|^2_{\mathbf{g},\mathbf{h}}.$$

Taking

$$c_m := \min_{1\le i\le \ell} c_{i,m} > 0, \qquad C_m := \max_{1\le i\le \ell} C_{i,m} < \infty,$$

yields the inequality throughout K. □

9.3 Interpolation: the Gagliardo–Nirenberg inequality

In this section we study the *Gagliardo–Nirenberg interpolation* inequality on manifolds (and in vector bundles). The inequality states the following:

Theorem 9.3.1. (Gagliardo–Nirenberg inequality for vector bundles) Let $(M,\mathbf{g})$ be a compact Riemannian manifold without boundary of dimension n, and let $\mathbf{E} \longrightarrow M$ be a smooth vector bundle of finite rank, equipped with a bundle metric $\mathbf{h}_\mathbf{E}$ and a compatible connection $\nabla^\mathbf{E}$. Let $m \ge 1$, $0 \le j \le m$, and $1 \le p < \infty$. Then there is a constant $C > 0$, depending only on $M, \mathbf{g}, \mathbf{E}, \mathbf{h}_\mathbf{E}, \nabla^\mathbf{E}, m, j$ and p, such that

$$\|\nabla^j \mathbf{F}\|_{L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})} \le C \|\mathbf{F}\|^{1-\frac{j}{m}}_{L^p(M,\mathbf{E})} \Big(\|\mathbf{F}\|_{L^p(M,\mathbf{E})} + \|\nabla^m \mathbf{F}\|_{L^p(M,T^{(0,m)}(TM)\otimes\mathbf{E})}\Big)^{\frac{j}{m}},$$

for every $\mathbf{F} \in W^{m,p}(M,\mathbf{E})$. Here we interpret $\nabla^0 \mathbf{F} = \mathbf{F}$, so that $T^{(0,0)}(TM)\otimes\mathbf{E} = \mathbf{E}$.

Proof. The cases $j = 0$ and $j = m$ are immediate. If $j = 0$, the inequality reduces to $\|\mathbf{F}\|_{L^p(M,\mathbf{E})} \le C\|\mathbf{F}\|_{L^p(M,\mathbf{E})}$; if $j = m$, it reduces to

$$\|\nabla^m \mathbf{F}\|_{L^p(M,T^{(0,m)}(TM)\otimes\mathbf{E})} \le C\left(\|\mathbf{F}\|_{L^p(M,\mathbf{E})} + \|\nabla^m \mathbf{F}\|_{L^p(M,T^{(0,m)}(TM)\otimes\mathbf{E})}\right).$$

Thus suppose that $0 < j < m$.

We first prove the inequality for smooth sections. Let $\mathbf{F} \in \Gamma(\mathbf{E})$. Since M is compact, we may take a finite cover $(U_\alpha, \varphi_\alpha)_{\alpha=1}^N$ of M by regular coordinate balls such that $\overline{U_\alpha}$ lies in the domain of a smooth local frame $(\mathbf{e}_{1,\alpha}, \dots, \mathbf{e}_{r,\alpha})$ of $\mathbf{E}$. Also take a partition of unity $(\psi_\alpha)_{\alpha=1}^N$ subordinate to this cover, with $\operatorname{supp}(\psi_\alpha) \subseteq U_\alpha$ for every α.

For each $\alpha \in \{1, \dots, N\}$ write

$$(\psi_\alpha \mathbf{F}) \restriction_{U_\alpha} = \sum_{a=1}^{r} F_\alpha^a \mathbf{e}_{a,\alpha},$$

and denote $\Omega_\alpha := \varphi_\alpha(U_\alpha)$. Since $\operatorname{supp}(\psi_\alpha) \subseteq U_\alpha$, we have $\operatorname{supp}(F_\alpha^a \circ \varphi_\alpha^{-1}) \Subset \Omega_\alpha$ for every $a \in \{1, \dots, r\}$. Define the extension of $F_\alpha^a \circ \varphi_\alpha^{-1}$ by zero to $\mathbb{R}^n$ by

$$\widetilde{F_\alpha^a \circ \varphi_\alpha^{-1}}(y) := \begin{cases} F_\alpha^a \circ \varphi_\alpha^{-1}(y), & y \in \Omega_\alpha, \\ 0, & y \in \mathbb{R}^n \setminus \Omega_\alpha. \end{cases}$$

Since $F_\alpha^a \circ \varphi_\alpha^{-1}$ is smooth and has compact support contained in Ω_α, its extension by zero belongs to $C_c^\infty(\mathbb{R}^n)$. Moreover, for every multi-index β, we have

$$D^\beta \widetilde{F_\alpha^a \circ \varphi_\alpha^{-1}} = \widetilde{D^\beta (F_\alpha^a \circ \varphi_\alpha^{-1})}.$$

Consequently, for each integer $s \ge 0$,

$$\sum_{|\beta|=s} \|D^\beta \widetilde{F_\alpha^a \circ \varphi_\alpha^{-1}}\|_{L^p(\mathbb{R}^n)} = \sum_{|\beta|=s} \|D^\beta (F_\alpha^a \circ \varphi_\alpha^{-1})\|_{L^p(\Omega_\alpha)}.$$

Applying the Euclidean Gagliardo–Nirenberg inequality on $\mathbb{R}^n$ in its classical form

$$\sum_{|\beta|=j} \|D^\beta v\|_{L^p(\mathbb{R}^n)} \le A \|v\|_{L^p(\mathbb{R}^n)}^{1-\frac{j}{m}} \left(\sum_{|\gamma|=m} \|D^\gamma v\|_{L^p(\mathbb{R}^n)} \right)^{\frac{j}{m}}, \qquad v \in C_c^\infty(\mathbb{R}^n),$$

gives, for $v = \widetilde{F_\alpha^a \circ \varphi_\alpha^{-1}}$,

$$\sum_{|\beta|=j} \|D^\beta (F_\alpha^a \circ \varphi_\alpha^{-1})\|_{L^p(\Omega_\alpha)} \le A \|F_\alpha^a \circ \varphi_\alpha^{-1}\|_{L^p(\Omega_\alpha)}^{1-\frac{j}{m}} \left(\sum_{|\gamma|=m} \|D^\gamma (F_\alpha^a \circ \varphi_\alpha^{-1})\|_{L^p(\Omega_\alpha)} \right)^{\frac{j}{m}}.$$

Summing over a and using Hölder's inequality from Proposition B.7.9 for the finite counting measure, with

exponents $\frac{m}{m-j}$ and $\frac{m}{j}$, gives

$$\sum_{a=1}^{r}\sum_{|\beta|=j}\|D^{\beta}(F_{\alpha}^{a}\circ\varphi_{\alpha}^{-1})\|_{L^{p}(\Omega_{\alpha})}\leq A\left(\sum_{a=1}^{r}\|F_{\alpha}^{a}\circ\varphi_{\alpha}^{-1}\|_{L^{p}(\Omega_{\alpha})}\right)^{1-\frac{j}{m}}\left(\sum_{a=1}^{r}\sum_{|\gamma|=m}\|D^{\gamma}(F_{\alpha}^{a}\circ\varphi_{\alpha}^{-1})\|_{L^{p}(\Omega_{\alpha})}\right)^{\frac{j}{m}}.$$

We now relate the Euclidean partial derivatives of the components to the covariant derivatives of $\psi_{\alpha}\mathbf{F}$. By Lemma 9.1.28, for each $s\in\{1,\dots,m\}$, the components of $\nabla^{s}(\psi_{\alpha}\mathbf{F})$ in the chart $(U_{\alpha},\varphi_{\alpha})$ and frame $(\mathbf{e}_{1,\alpha},\dots,\mathbf{e}_{r,\alpha})$ are given by

$$(\nabla^{s}(\psi_{\alpha}\mathbf{F}))^{a}_{i_{1}\dots i_{s}}=\partial_{i_{1}}\cdots\partial_{i_{s}}F_{\alpha}^{a}+\sum_{b=1}^{r}\sum_{|\beta|\leq s-1}(B_{\alpha,\beta})^{a}_{b\,i_{1}\dots i_{s}}\partial^{\beta}F_{\alpha}^{b},$$

where the coefficients $(B_{\alpha,\beta})^{a}_{b\,i_{1}\dots i_{s}}$ are smooth on U_{α}. Since $\operatorname{supp}(\psi_{\alpha}\mathbf{F})\subseteq U_{\alpha}$, all calculations take place on a compact subset of U_{α}, and therefore those coefficients, as well as the coefficients converting Riemannian measure to Euclidean measure in coordinates, are uniformly bounded. This triangular formula shows that there are constants $P_{\alpha,s},Q_{\alpha,s}>0$, independent of $\mathbf{F}$, such that

$$\|\nabla^{s}(\psi_{\alpha}\mathbf{F})\|_{L^{p}(M,T^{(0,s)}(TM)\otimes\mathbf{E})}\leq P_{\alpha,s}\sum_{a=1}^{r}\sum_{|\beta|\leq s}\|D^{\beta}(F_{\alpha}^{a}\circ\varphi_{\alpha}^{-1})\|_{L^{p}(\Omega_{\alpha})},$$

and

$$\sum_{a=1}^{r}\sum_{|\beta|\leq s}\|D^{\beta}(F_{\alpha}^{a}\circ\varphi_{\alpha}^{-1})\|_{L^{p}(\Omega_{\alpha})}\leq Q_{\alpha,s}\sum_{\ell=0}^{s}\|\nabla^{\ell}(\psi_{\alpha}\mathbf{F})\|_{L^{p}(M,T^{(0,\ell)}(TM)\otimes\mathbf{E})}.$$

In particular, using these estimates with $s=j$, also using the preceding Euclidean inequality for the orders $1,\dots,j$, and noting that order 0 corresponds to the L^{p} norm, we obtain a constant $R_{\alpha}>0$, independent of $\mathbf{F}$, such that

$$\|\nabla^{j}(\psi_{\alpha}\mathbf{F})\|_{L^{p}(M,T^{(0,j)}(TM)\otimes\mathbf{E})}\leq R_{\alpha}\|\psi_{\alpha}\mathbf{F}\|^{1-\frac{j}{m}}_{L^{p}(M,\mathbf{E})}\left(\sum_{\ell=0}^{m}\|\nabla^{\ell}(\psi_{\alpha}\mathbf{F})\|_{L^{p}(M,T^{(0,\ell)}(TM)\otimes\mathbf{E})}\right)^{\frac{j}{m}}.$$

Since the cover is finite, taking $R:=\max\{R_{\alpha}\mid 1\leq\alpha\leq N\}$ gives the same estimate with R in place of R_{α}.

We now sum over α. Since $\mathbf{F}=\sum_{\alpha=1}^{N}\psi_{\alpha}\mathbf{F}$, the triangle inequality gives

$$\|\nabla^{j}\mathbf{F}\|_{L^{p}(M,T^{(0,j)}(TM)\otimes\mathbf{E})}\leq\sum_{\alpha=1}^{N}\|\nabla^{j}(\psi_{\alpha}\mathbf{F})\|_{L^{p}(M,T^{(0,j)}(TM)\otimes\mathbf{E})}.$$

By the preceding estimate and Hölder's inequality from Proposition B.7.9 for the finite counting measure,

$$\|\nabla^{j}\mathbf{F}\|_{L^{p}(M,T^{(0,j)}(TM)\otimes\mathbf{E})}\leq R\left(\sum_{\alpha=1}^{N}\|\psi_{\alpha}\mathbf{F}\|_{L^{p}(M,\mathbf{E})}\right)^{1-\frac{j}{m}}\left(\sum_{\alpha=1}^{N}\sum_{\ell=0}^{m}\|\nabla^{\ell}(\psi_{\alpha}\mathbf{F})\|_{L^{p}(M,T^{(0,\ell)}(TM)\otimes\mathbf{E})}\right)^{\frac{j}{m}}.$$

It remains to control the terms involving $\psi_{\alpha}\mathbf{F}$ by $\mathbf{F}$. For the zeroth-order term, since each ψ_{α} is smooth and

the family is finite, there is $D_0 > 0$, independent of $\mathbf{F}$, such that

$$\sum_{\alpha=1}^{N} \|\psi_\alpha \mathbf{F}\|_{L^p(M,\mathbf{E})} \leq D_0 \|\mathbf{F}\|_{L^p(M,\mathbf{E})}.$$

On the other hand, for each $s \leq m$, the Leibniz rule for the induced connection on $T^{(0,s)}(TM) \otimes \mathbf{E}$ gives

$$|\nabla^s(\psi_\alpha \mathbf{F})|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \leq \sum_{t=0}^{s} \binom{s}{t} |\nabla^{s-t}\psi_\alpha|_{\mathbf{g}} |\nabla^t \mathbf{F}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}.$$

Since M is compact and the family $\{\psi_\alpha\}_{\alpha=1}^N$ is finite, the quantities $\| |\nabla^{s-t}\psi_\alpha|_{\mathbf{g}} \|_{L^\infty(M)}$, with $0 \leq t \leq s \leq m$ and $1 \leq \alpha \leq N$, are uniformly bounded. Consequently, there is $D_m > 0$, independent of $\mathbf{F}$, such that

$$\sum_{\alpha=1}^{N} \sum_{\ell=0}^{m} \|\nabla^\ell(\psi_\alpha \mathbf{F})\|_{L^p(M,T^{(0,\ell)}(TM)\otimes\mathbf{E})} \leq D_m \sum_{\ell=0}^{m} \|\nabla^\ell \mathbf{F}\|_{L^p(M,T^{(0,\ell)}(TM)\otimes\mathbf{E})}.$$

Substituting these estimates gives

$$\|\nabla^j \mathbf{F}\|_{L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})} \leq C_1 \|\mathbf{F}\|_{L^p(M,\mathbf{E})}^{1-\frac{j}{m}} \left(\sum_{\ell=0}^{m} \|\nabla^\ell \mathbf{F}\|_{L^p(M,T^{(0,\ell)}(TM)\otimes\mathbf{E})} \right)^{\frac{j}{m}}.$$

Finally, we use equivalence of the Sobolev norm with the norm given by the zeroth-order term and the covariant derivative of highest order; that is, there is $C_2 > 0$ such that

$$\sum_{\ell=0}^{m} \|\nabla^\ell \mathbf{F}\|_{L^p(M,T^{(0,\ell)}(TM)\otimes\mathbf{E})} \leq C_2 \left(\|\mathbf{F}\|_{L^p(M,\mathbf{E})} + \|\nabla^m \mathbf{F}\|_{L^p(M,T^{(0,m)}(TM)\otimes\mathbf{E})} \right).$$

This equivalence follows, for example, by applying Ehrling's lemma to the compact inclusions $W^{m,p}(M,\mathbf{E}) \hookrightarrow W^{\ell,p}(M,\mathbf{E}) \hookrightarrow L^p(M,\mathbf{E})$, for $0 < \ell < m$, and absorbing the intermediate terms. Therefore,

$$\|\nabla^j \mathbf{F}\|_{L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})} \leq C \|\mathbf{F}\|_{L^p(M,\mathbf{E})}^{1-\frac{j}{m}} \left(\|\mathbf{F}\|_{L^p(M,\mathbf{E})} + \|\nabla^m \mathbf{F}\|_{L^p(M,T^{(0,m)}(TM)\otimes\mathbf{E})} \right)^{\frac{j}{m}}$$

for every $\mathbf{F} \in \Gamma(\mathbf{E})$.

Now let $\mathbf{F} \in W^{m,p}(M,\mathbf{E})$. By Theorem 9.1.48, there is a sequence $(\mathbf{F}_k)_{k\in\mathbb{N}} \subseteq \Gamma(\mathbf{E}) \cap W^{m,p}(M,\mathbf{E})$ such that $\mathbf{F}_k \to \mathbf{F}$ in $W^{m,p}(M,\mathbf{E})$. In particular, $\mathbf{F}_k \to \mathbf{F}$ in $L^p(M,\mathbf{E})$, $\nabla^j \mathbf{F}_k \to \nabla_w^j \mathbf{F}$ in $L^p(M, T^{(0,j)}(TM)\otimes\mathbf{E})$, and $\nabla^m \mathbf{F}_k \to \nabla_w^m \mathbf{F}$ in $L^p(M, T^{(0,m)}(TM)\otimes\mathbf{E})$. Applying the inequality already proved to $\mathbf{F}_k$ gives

$$\|\nabla^j \mathbf{F}_k\|_{L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})} \leq C \|\mathbf{F}_k\|_{L^p(M,\mathbf{E})}^{1-\frac{j}{m}} \left(\|\mathbf{F}_k\|_{L^p(M,\mathbf{E})} + \|\nabla^m \mathbf{F}_k\|_{L^p(M,T^{(0,m)}(TM)\otimes\mathbf{E})} \right)^{\frac{j}{m}}.$$

Letting $k \to \infty$, we conclude that

$$\|\nabla^j \mathbf{F}\|_{L^p(M,T^{(0,j)}(TM)\otimes\mathbf{E})} \leq C \|\mathbf{F}\|_{L^p(M,\mathbf{E})}^{1-\frac{j}{m}} \left(\|\mathbf{F}\|_{L^p(M,\mathbf{E})} + \|\nabla_w^m \mathbf{F}\|_{L^p(M,T^{(0,m)}(TM)\otimes\mathbf{E})} \right)^{\frac{j}{m}}.$$

This completes the proof. □

9.4 Sobolev spaces on manifolds with boundary

In many applications, boundary conditions arise naturally when formulating a PDE. Sobolev spaces allow us to pass from a differential problem to its weak formulation; however, when the manifold has boundary, integration-by-parts formulas produce additional terms on ∂M. The identity with test sections supported in the interior determines the formal differential adjoint, as explained in Remark 8.2.4. Boundary conditions enter when choosing a domain for the realization of the operator in L^2 and determining the domain of its Hilbert space adjoint.

For this purpose, introduce the notation

$$\Gamma_{c,\mathrm{Int}(M)}(\mathbf{E}) := \{\mathbf{u} \in \Gamma(\mathbf{E}) | \mathrm{supp}(\mathbf{u}) \Subset \mathrm{Int}(M)\}.$$

That is, $\Gamma_{c,\mathrm{Int}(M)}(\mathbf{E})$ denotes the space of smooth sections whose compact support lies in the interior of M.

Under this convention, integration-by-parts formulas produce no boundary terms when the test sections belong to $\Gamma_{c,\mathrm{Int}(M)}$. For example, in Theorem 9.1.29, if we take $\mathbf{F} \in \Gamma(T^{(k,l)}(TM) \otimes \mathbf{E})$ and $\mathbf{G} \in \Gamma_{c,\mathrm{Int}(M)}(T^{(k,l+s)}(TM) \otimes \mathbf{E})$, the boundary term vanishes and the formula reduces to

$$\int_M \langle \nabla^s \mathbf{F}, \mathbf{G} \rangle_{\mathbf{g},\mathbf{h_E}} \, d\lambda_{\mathbf{g}} = (-1)^s \int_M \left\langle \mathbf{F}, (\mathrm{tr}_{\mathbf{g}} \circ \nabla)^s \mathbf{G} \right\rangle_{\mathbf{g},\mathbf{h_E}} d\lambda_{\mathbf{g}} + \sum_{j=0}^{s-1} (-1)^{s-1-j} \int_{\partial M} \left\langle \nabla^j \mathbf{F}, \iota_{\nu}\left((\mathrm{tr}_{\mathbf{g}} \circ \nabla)^{s-1-j} \mathbf{G}\right) \right\rangle_{\mathbf{g},\mathbf{h_E}} d\lambda_{\tilde{\mathbf{g}}}.$$

0

Thus, when defining weak derivatives on a manifold with boundary, we work with test sections belonging to $\Gamma_{c,\mathrm{Int}(M)}$. In this way, boundary conditions are not implicitly incorporated into the weak definition; they will be introduced later through the trace operator.

We next give the definitions needed to work with these Sobolev spaces.

Definition 9.4.1. (Interior formal adjoint) Let $(M, \mathbf{g})$ be a Riemannian manifold with nonempty boundary, and let $\mathbf{E}, \mathbf{F} \to M$ be smooth vector bundles equipped with bundle metrics $\mathbf{h_E}$ and $\mathbf{h_F}$, respectively. Let $P \in \mathbf{PDO}(\mathbf{E}, \mathbf{F})$. We say that $Q \in \mathbf{PDO}(\mathbf{F}, \mathbf{E})$ is an *interior formal adjoint* of P if, for every $\mathbf{u} \in \Gamma_{c,\mathrm{Int}(M)}(\mathbf{E})$ and every $\mathbf{v} \in \Gamma_{c,\mathrm{Int}(M)}(\mathbf{F})$, we have

$$\int_M \langle P\mathbf{u}, \mathbf{v} \rangle_{\mathbf{h_F}} \, d\lambda_{\mathbf{g}} = \int_M \langle \mathbf{u}, Q\mathbf{v} \rangle_{\mathbf{h_E}} \, d\lambda_{\mathbf{g}}.$$

In this case we write $Q = P_h^*$; the symbol P' is reserved for the complex–bilinear formal transpose.

The adjective "interior" recalls that the preceding identity is tested only against sections whose supports do not meet the boundary. Thus the operator P_h^* describes the formal Hermitian adjoint determined by the differential part of P, without yet choosing boundary conditions.

Theorem 9.4.2. (Existence and uniqueness of the interior formal adjoint) Let $(M, \mathbf{g})$ be a Riemannian manifold with nonempty boundary, and let $\mathbf{E}, \mathbf{F} \to M$ be smooth vector bundles with bundle metrics $\mathbf{h_E}, \mathbf{h_F}$. If $P \in \mathbf{PDO}^{(m)}(\mathbf{E}, \mathbf{F})$, then P admits a unique interior formal adjoint

$$P_h^* \in \mathbf{PDO}^{(m)}(\mathbf{F}, \mathbf{E}).$$

Moreover, let (U, φ) be a chart, and let $\mathbf{e}_1, \ldots, \mathbf{e}_r$ and $\mathbf{f}_1, \ldots, \mathbf{f}_s$ be local orthonormal frames of $\mathbf{E}$ and $\mathbf{F}$, re-

spectively, defined on U. Set

$$D^{\alpha}_{\varphi} a := \left[D^{\alpha}(a \circ \varphi^{-1}) \right] \circ \varphi, \qquad a \in C^{\infty}(U, \mathbb{K}).$$

If

$$P\left(\sum_{i=1}^{r} u^{i} \mathbf{e}_{i} \right) = \sum_{j=1}^{s} \left(\sum_{i=1}^{r} \sum_{|\alpha| \le m} a^{j}_{\alpha i} D^{\alpha}_{\varphi} u^{i} \right) \mathbf{f}_{j},$$

then

$$P^{*}_{h}\left(\sum_{j=1}^{s} v^{j} \mathbf{f}_{j} \right) = \frac{1}{\sqrt{\det(\mathbf{g})}} \sum_{i=1}^{r} \left[\sum_{j=1}^{s} \sum_{|\alpha| \le m} (-1)^{|\alpha|} D^{\alpha}_{\varphi}\left(\sqrt{\det(\mathbf{g})}\, \overline{a^{j}_{\alpha i}}\, v^{j} \right) \right] \mathbf{e}_{i},$$

where $g_{ab} = \mathbf{g}(\partial_a, \partial_b)$. In the real case the bar leaves $a^{j}_{\alpha i}$ unchanged.

Proof. Apply Theorem 8.2.3 to the manifold without boundary $\operatorname{Int}(M)$ and the operator restricted to its interior. The local expression proved there depends smoothly on the coefficients of P, the bundle metrics, and the coordinate weight $\sqrt{\det(\mathbf{g})}$ of the Riemannian measure; since all these data are smooth up to ∂M, its coefficients extend smoothly to each boundary chart and define the operator displayed above throughout M. For test sections supported in $\operatorname{Int}(M)$, the integral identity is precisely that of the cited theorem and produces no boundary terms.

If Q_1, Q_2 satisfy the interior identity, the uniqueness lemma of Chapter 8 applied on $\operatorname{Int}(M)$ gives $Q_1 = Q_2$ there. Their local coefficients are smooth up to the boundary and agree on the dense open interior; by continuity they also agree on the boundary. Therefore, $Q_1 = Q_2$ on M. □

Definition 9.4.3. (Weak covariant derivative on manifolds with boundary) Let $(M, \mathbf{g})$ be a Riemannian manifold with nonempty boundary and $\mathbf{E} \to M$ a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a smooth connection $\nabla^{\mathbf{E}}$. In constructing ∇^{s}, we use the product connection induced by Levi–Civita and $\nabla^{\mathbf{E}}$. Let $s \ge 0$ and let $\mathbf{u} \in L^{1}_{\mathrm{loc}}(M, \mathbf{E})$. We say that a section $\mathbf{v} \in L^{1}_{\mathrm{loc}}(M, T^{(0,s)}(TM) \otimes \mathbf{E})$ is the sth weak covariant derivative of $\mathbf{u}$ if, for every $\sigma \in \Gamma_{c,\operatorname{Int}(M)}(T^{(0,s)}(TM) \otimes \mathbf{E})$, we have

$$\int_{M} \langle \mathbf{v}, \sigma \rangle_{\mathbf{g}, \mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}} = \int_{M} \langle \mathbf{u}, (\nabla^{s})^{*}_{h} \sigma \rangle_{\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}}.$$

In this case we write $\mathbf{v} = \nabla^{s}_{w} \mathbf{u}$. For $s = 0$ we adopt the convention $\nabla^{0}_{w} \mathbf{u} = \mathbf{u}$.

In the preceding definition, $(\nabla^{s})^{*}_{h}$ denotes the interior formal Hermitian adjoint of ∇^{s}, not its bilinear transpose. This choice allows us to define weak derivatives without implicitly introducing boundary conditions.

Definition 9.4.4. (Global and local Sobolev spaces on manifolds with boundary) Let $(M, \mathbf{g})$ be a Riemannian manifold with nonempty boundary, and let $\pi \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a smooth connection $\nabla^{\mathbf{E}}$. Let $m \in \mathbb{N}_0$ and $1 \le p \le \infty$.

(a) *Global Sobolev spaces.* Define $W^{m,p}(M, \mathbf{E})$ to be the set of sections $\mathbf{u} \in L^{1}_{\mathrm{loc}}(M, \mathbf{E})$ such that, for every $s \in \{0, \dots, m\}$, the weak covariant derivative $\nabla^{s}_{w} \mathbf{u}$ exists and belongs to $L^{p}(M, T^{(0,s)}(TM) \otimes \mathbf{E})$. Equip

this space with the norm

$$\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} := \begin{cases} \left(\displaystyle\sum_{s=0}^{m} \int_M |\nabla_w^s \mathbf{u}|^p_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \right)^{\frac{1}{p}}, & 1 \le p < \infty, \\ \displaystyle\max_{0\le s\le m} \operatorname*{ess\,sup}_{x\in M} |\nabla_w^s \mathbf{u}(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}}, & p = \infty. \end{cases}$$

With this norm, $W^{m,p}(M,\mathbf{E})$ is a Banach space.

(b) *Local Sobolev spaces.* Define $W^{m,p}_{\mathrm{loc}}(M,\mathbf{E})$ to be the set of sections $\mathbf{u} \in L^1_{\mathrm{loc}}(M,\mathbf{E})$ such that, for every $s \in \{0,\dots,m\}$, the weak covariant derivative $\nabla_w^s \mathbf{u}$ exists and belongs to $L^p_{\mathrm{loc}}(M, T^{(0,s)}(TM) \otimes \mathbf{E})$.

If $K \subseteq M$ is compact, define the local seminorm

$$\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E};K)} := \begin{cases} \left(\displaystyle\sum_{s=0}^{m} \int_K |\nabla_w^s \mathbf{u}|^p_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \right)^{\frac{1}{p}}, & 1 \le p < \infty, \\ \displaystyle\max_{0\le s\le m} \operatorname*{ess\,sup}_{x\in K} |\nabla_w^s \mathbf{u}(x)|_{\mathbf{g},\mathbf{h}_\mathbf{E}}, & p = \infty. \end{cases}$$

We consider $W^{m,p}_{\mathrm{loc}}(M,\mathbf{E})$ with the family of seminorms $\{\|\cdot\|_{W^{m,p}(M,\mathbf{E};K)}\}_{K\subseteq M \text{ compact}}$.

Restriction to the interior identifies these spaces $W^{m,p}(M,\mathbf{E})$ isometrically with the spaces defined weakly on $\mathrm{Int}(M)$ using the restricted metric and connection. Indeed, the test sections are exactly those with compact support in the interior, and ∂M has zero n-dimensional Riemannian measure, so the global norms agree. The values of a measurable section on ∂M do not affect its equivalence class. In particular, Lemma 9.1.12 and completeness of Sobolev spaces also apply here for every $1 \le p \le \infty$, without a reflexivity hypothesis.

We give a local characterization of Sobolev spaces in the boundary case, analogous to Lemma 9.1.44, that will allow us to work with them. For this characterization we impose metric compatibility, since the proof uses the explicit formal adjoint formula obtained by integration by parts.

Lemma 9.4.5. Let $m \in \mathbb{N}_0$ and $1 \le p < \infty$, let (U,φ) be a regular coordinate half-ball in a Riemannian manifold M with nonempty boundary, and let $\pi_\mathbf{E} \colon \mathbf{E} \longrightarrow M$ be a smooth vector bundle of rank r, equipped with a bundle metric $\mathbf{h}_\mathbf{E}$ and a compatible connection $\nabla^\mathbf{E}$. Write

$$B_U^+ := \varphi(U \cap \mathrm{Int}(M)) = \varphi(U) \cap \{x_n > 0\}.$$

Let $\mathbf{F} \in L^1_{\mathrm{loc}}(M,\mathbf{E})$ and let $\{\mathbf{e}_1,\dots,\mathbf{e}_r\}$ be a local frame of $\mathbf{E}$ defined on a neighborhood of $\overline{U}$. Suppose that $\mathbf{F} = \displaystyle\sum_{a=1}^{r} F^a \mathbf{e}_a$ on U. Then

$$\mathbf{F}\restriction_U \in W^{m,p}(U,\mathbf{E}\restriction_U) \quad \text{if and only if} \quad F^a \circ \varphi^{-1} \in W^{m,p}(B_U^+)$$

for every $1 \le a \le r$.

Moreover, there are constants $C_m, c_m > 0$, independent of $\mathbf{F}$, such that

$$c_m \sum_{a=1}^{r} \left\| F^a \circ \varphi^{-1} \right\|_{W^{m,p}(B_U^+)} \leq \|\mathbf{F}\|_{W^{m,p}(U,\mathbf{E}\restriction_U)} \leq C_m \sum_{a=1}^{r} \left\| F^a \circ \varphi^{-1} \right\|_{W^{m,p}(B_U^+)}$$

for every $\mathbf{F} \in W^{m,p}(U, \mathbf{E}\restriction_U)$.

Proof. We repeat the argument of Lemma 9.1.44. First we verify that the coordinate test functions have compact support in the corresponding Euclidean open set; this verification allows all the integrations by parts used in that proof to be carried out without boundary terms.
Let (U, φ) be a regular coordinate half-ball, and recall that $B_U^+ = \varphi(U \cap \mathrm{Int}(M))$. Fix $s \geq 0$ and take a test section

$$\boldsymbol{\Psi} \in \Gamma_{c,\mathrm{Int}(M)}\big(T^{(0,s)}(TU) \otimes \mathbf{E}\restriction_U\big).$$

By definition, $\mathrm{supp}(\boldsymbol{\Psi})$ is compact and contained in $U \cap \mathrm{Int}(M)$.
Write locally

$$\boldsymbol{\Psi} = \sum_{\substack{1 \leq c \leq r \\ J_s \in \{1,\dots,n\}^s}} \Psi^c_{J_s}\, \mathbf{d}x^{J_s} \otimes \mathbf{e}_c,$$

where $(\mathbf{e}_1, \dots, \mathbf{e}_r)$ is the local frame of $\mathbf{E}$ over U and J_s ranges over blocks of indices of length s. For each $x \in U$, the family $\{\mathbf{d}x^{J_s} \otimes \mathbf{e}_c\}_{c,J_s}$ is a basis of the vector space $T^{(0,s)}_x M \otimes \mathbf{E}_x$. By pointwise linear independence, we have

$$\boldsymbol{\Psi}(x) = 0 \quad \text{if and only if} \quad \Psi^c_{J_s}(x) = 0 \text{ for every } c, J_s.$$

Thus the set where $\boldsymbol{\Psi}$ is nonzero agrees with the finite union of the sets where some component $\Psi^c_{J_s}$ is nonzero. Taking closures in U gives

$$\mathrm{supp}(\boldsymbol{\Psi}) = \bigcup_{c,J_s} \mathrm{supp}(\Psi^c_{J_s}).$$

In particular, for every pair of indices (c, J_s),

$$\mathrm{supp}(\Psi^c_{J_s}) \subseteq \mathrm{supp}(\boldsymbol{\Psi}) \Subset U \cap \mathrm{Int}(M).$$

Now compose with the chart. Since $\varphi\colon U \longrightarrow \varphi(U)$ is a homeomorphism, for each component we have

$$\mathrm{supp}(\Psi^c_{J_s} \circ \varphi^{-1}) = \varphi\big(\mathrm{supp}(\Psi^c_{J_s})\big).$$

Moreover,

$$\varphi\big(\mathrm{supp}(\Psi^c_{J_s})\big) \subseteq \varphi(\mathrm{supp}(\boldsymbol{\Psi})) \Subset \varphi(U \cap \mathrm{Int}(M)) = B_U^+.$$

Thus

$$\Psi^c_{J_s} \circ \varphi^{-1} \in C_c^\infty(B_U^+)$$

for every c, J_s.
Consequently, after passing to coordinates, the test functions that arise have compact support contained in the open set $B_U^+ \subseteq \mathbb{R}^n$. For this reason, all integrations by parts involved in the weak definition take place inside a Euclidean open set, without boundary terms. The local identities are therefore the same as for a regular coordinate ball, with the coordinate domain replaced by B_U^+.

The coordinate identities in the proof of Lemma 9.1.44 depend only on these integrations by parts and the bounded smoothness, on $\overline{U}$, of the coefficients of the metric, connection, and frame. Thus, with $\varphi(U)$ replaced by B_U^+, the induction constructed there gives

$$\mathbf{F}\restriction_U \in W^{m,p}(U,\mathbf{E}\restriction_U) \quad \text{if and only if} \quad F^a\circ\varphi^{-1}\in W^{m,p}(B_U^+)$$

for every $1\le a\le r$. Equivalence of norms is proved exactly as in the cited lemma. □

Theorem 9.4.6. (Meyers–Serrin on open sets with uniformly Lipschitz boundary) Let $\Omega\subseteq\mathbb{R}^n$ be an open set with uniformly Lipschitz continuous boundary in the sense of Definition 3.6.1. Let $m\in\mathbb{N}$ and $1\le p<\infty$. Then the restrictions to Ω of functions in $C_c^\infty(\mathbb{R}^n)$ form a dense subspace of $W^{m,p}(\Omega)$.

Proof. Let $u\in W^{m,p}(\Omega)$. By Theorem 3.6.2, there is $v:=\mathcal{E}u\in W^{m,p}(\mathbb{R}^n)$ such that $v\restriction_\Omega = u$ almost everywhere. We prove explicitly that $C_c^\infty(\mathbb{R}^n)$ is dense in $W^{m,p}(\mathbb{R}^n)$.
Choose $\chi\in C_c^\infty(\mathbb{R}^n)$ with $0\le\chi\le1$, $\chi=1$ on $B_{\mathrm{euc}}(0,1)$, and $\operatorname{supp}\chi\subset B_{\mathrm{euc}}(0,2)$, and set $\chi_R(x):=\chi(x/R)$ and $v_R:=\chi_R v$. For $|\alpha|\le m$, the weak Leibniz rule gives

$$D^\alpha v_R=\sum_{\beta\le\alpha}\binom{\alpha}{\beta}D^\beta\chi_R\,D^{\alpha-\beta}v.$$

The term with $\beta=0$ converges to $D^\alpha v$ in L^p by dominated convergence. If $\beta\neq0$, then

$$\|D^\beta\chi_R\,D^{\alpha-\beta}v\|_{L^p(\mathbb{R}^n)}\le R^{-|\beta|}\|D^\beta\chi\|_{L^\infty(\mathbb{R}^n)}\|D^{\alpha-\beta}v\|_{L^p(\mathbb{R}^n)}\longrightarrow0.$$

Since the sum has finitely many terms, $v_R\to v$ in $W^{m,p}(\mathbb{R}^n)$.
Now fix R. If ρ_ε is the mollifier from Theorem B.9.1, then $v_{R,\varepsilon}:=\rho_\varepsilon*v_R$ belongs to $C_c^\infty(\mathbb{R}^n)$ and

$$D^\alpha v_{R,\varepsilon}=\rho_\varepsilon*D^\alpha v_R,\qquad |\alpha|\le m.$$

Continuity of translations in L^p and Minkowski's integral inequality imply $\rho_\varepsilon*D^\alpha v_R\to D^\alpha v_R$ in L^p for each $|\alpha|\le m$. Therefore, $v_{R,\varepsilon}\to v_R$ in $W^{m,p}(\mathbb{R}^n)$. A diagonal choice gives $(\varphi_j)\subset C_c^\infty(\mathbb{R}^n)$ with $\varphi_j\to v$ in $W^{m,p}(\mathbb{R}^n)$. Since restriction to Ω does not increase any derivative norm,

$$\|\varphi_j\restriction_\Omega-u\|_{W^{m,p}(\Omega)}\le\|\varphi_j-v\|_{W^{m,p}(\mathbb{R}^n)}\longrightarrow0.$$

□

To discuss boundary conditions, we need to define an operator known as the *trace operator*. This operator is first constructed on smooth sections and then extended by density. For this reason, before introducing it, we must verify that the Meyers–Serrin theorem remains valid on manifolds with boundary.

The Euclidean Meyers–Serrin theorem for open sets with uniformly Lipschitz boundary, Theorem 9.4.6, allows approximation in boundary charts by restrictions of smooth functions defined on $\mathbb{R}^n$.

Definition 9.4.7. Let $(M,\mathbf{g})$ be a Riemannian manifold with nonempty boundary and $\mathbf{E}\longrightarrow M$ a smooth vector bundle equipped with a bundle metric $\mathbf{h}_\mathbf{E}$ and a smooth connection $\nabla^\mathbf{E}$. Let $m\in\mathbb{N}_0$ and let $1\le p<\infty$.

Define

$$C^{m,p}(M,\mathbf{E}) := \left\{ \mathbf{u} \in \Gamma(\mathbf{E}) \middle| \|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} < \infty \right\},$$

where, for a smooth section $\mathbf{u}$, the Sobolev norm is given by

$$\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} := \left(\sum_{s=0}^{m} \int_M |\nabla^s \mathbf{u}|^p_{\mathbf{g},\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \right)^{\frac{1}{p}}.$$

Define

$$H^{m,p}(M,\mathbf{E}) := \overline{C^{m,p}(M,\mathbf{E})}^{\|\cdot\|_{W^{m,p}(M,\mathbf{E})}}.$$

That is, $H^{m,p}(M,\mathbf{E})$ is the completion of the smooth sections with finite Sobolev norm.

As in the case without boundary, this definition agrees with the weak definition of Sobolev spaces. The technical difference is that, when working locally near ∂M, we use regular coordinate half-balls and pass to the Euclidean open set $\varphi(U \cap \mathrm{Int}(M))$.

Theorem 9.4.8. (Meyers–Serrin for vector bundles on manifolds with boundary) Let $(M,\mathbf{g})$ be a Riemannian manifold with nonempty boundary, and let $\pi_\mathbf{E} : \mathbf{E} \longrightarrow M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_\mathbf{E}$ and a compatible connection $\nabla^\mathbf{E}$. If $m \in \mathbb{N}$ and $1 \leq p < \infty$, then $H^{m,p}(M,\mathbf{E}) = W^{m,p}(M,\mathbf{E})$.

Proof. Since $C^{m,p}(M,\mathbf{E}) \subseteq W^{m,p}(M,\mathbf{E})$ and $W^{m,p}(M,\mathbf{E})$ is complete, we directly have $H^{m,p}(M,\mathbf{E}) \subseteq W^{m,p}(M,\mathbf{E})$. We prove the reverse inclusion.

By the analogue of Proposition 1.2.11 for manifolds with boundary, there is a countable locally finite open cover of M consisting of regular coordinate balls contained in $\mathrm{Int}(M)$ and regular coordinate half-balls near ∂M. Denote this cover by $(U_\alpha, \varphi_\alpha)_{\alpha\in\mathbb{N}}$. Refining if necessary, we may assume that $\overline{U_\alpha}$ lies in the domain of a local frame $(\mathbf{e}_{1,\alpha},\dots,\mathbf{e}_{r,\alpha})$ of $\mathbf{E}$. Take a smooth partition of unity $(\psi_\alpha)_{\alpha\in\mathbb{N}}$ subordinate to this cover, with $\mathrm{supp}(\psi_\alpha) \Subset U_\alpha$ for every α.

Let $\mathbf{F} \in W^{m,p}(M,\mathbf{E})$. Since the partition of unity is locally finite, we have $\mathbf{F} = \sum_{\alpha=1}^{\infty} \psi_\alpha \mathbf{F}$. Fix $\alpha \in \mathbb{N}$. Write locally $\mathbf{F} = \sum_{a=1}^{r} F^a_\alpha \mathbf{e}_{a,\alpha}$ on U_α.

If U_α is a regular coordinate ball, set $\Omega_\alpha := \varphi_\alpha(U_\alpha)$. If U_α is a regular coordinate half-ball, set $\Omega_\alpha := \varphi_\alpha(U_\alpha \cap \mathrm{Int}(M))$. In the first case, Ω_α is an open ball in $\mathbb{R}^n$. In the second, Ω_α is the interior of a half-ball and, in particular, is an open subset of $\mathbb{R}^n$ with continuous boundary.

By Lemma 9.1.44 if U_α is a regular coordinate ball, and by Lemma 9.4.5 if U_α is a regular coordinate half-ball, we have $F^a_\alpha \circ \varphi_\alpha^{-1} \in W^{m,p}(\Omega_\alpha)$ for every $a \in \{1,\dots,r\}$.

We now show that $(\psi_\alpha \mathbf{F}) \restriction_{U_\alpha} \in W^{m,p}(U_\alpha, \mathbf{E} \restriction_{U_\alpha})$. Its components are $(\psi_\alpha \mathbf{F})^a_\alpha = \psi_\alpha F^a_\alpha$, and composition with the chart gives

$$(\psi_\alpha \mathbf{F})^a_\alpha \circ \varphi_\alpha^{-1} = (\psi_\alpha \circ \varphi_\alpha^{-1})(F^a_\alpha \circ \varphi_\alpha^{-1}).$$

Since $\psi_\alpha \circ \varphi_\alpha^{-1}$ is smooth and its derivatives through order m are bounded on Ω_α, the Leibniz formula implies that $(\psi_\alpha \mathbf{F})^a_\alpha \circ \varphi_\alpha^{-1} \in W^{m,p}(\Omega_\alpha)$. For every multi-index β with $|\beta| \leq m$,

$$\partial^\beta \Big((\psi_\alpha \circ \varphi_\alpha^{-1})(F^a_\alpha \circ \varphi_\alpha^{-1}) \Big) = \sum_{\gamma \leq \beta} \binom{\beta}{\gamma} \partial^\gamma (\psi_\alpha \circ \varphi_\alpha^{-1}) \partial^{\beta-\gamma} (F^a_\alpha \circ \varphi_\alpha^{-1}),$$

and each term on the right-hand side belongs to $L^p(\Omega_\alpha)$. Applying the appropriate local lemma once more, we conclude that $(\psi_\alpha \mathbf{F})\restriction_{U_\alpha} \in W^{m,p}(U_\alpha, \mathbf{E}\restriction_{U_\alpha})$.

Moreover, by local equivalence of norms, there is a constant $C_{m,\alpha} > 0$ such that, for every section $\mathbf{H} \in W^{m,p}(U_\alpha, \mathbf{E}\restriction_{U_\alpha})$,

$$\|\mathbf{H}\|_{W^{m,p}(U_\alpha, \mathbf{E}\restriction_{U_\alpha})} \leq C_{m,\alpha} \sum_{a=1}^{r} \|H_\alpha^a \circ \varphi_\alpha^{-1}\|_{W^{m,p}(\Omega_\alpha)}.$$

We now approximate the components of $(\psi_\alpha \mathbf{F})\restriction_{U_\alpha}$. Here we distinguish the two types of charts.

If U_α is a regular coordinate ball, then $\Omega_\alpha = \varphi_\alpha(U_\alpha)$ is an open ball and $\operatorname{supp}((\psi_\alpha \mathbf{F})_\alpha^a \circ \varphi_\alpha^{-1}) \Subset \Omega_\alpha$, since $\operatorname{supp}(\psi_\alpha) \Subset U_\alpha$. By the Euclidean Meyers–Serrin theorem on Euclidean open sets, we may take functions $(\widetilde{G}_{\alpha,k})^a \in C_c^\infty(\Omega_\alpha)$ such that

$$\sum_{a=1}^{r} \left\| (\widetilde{G}_{\alpha,k})^a - (\psi_\alpha \mathbf{F})_\alpha^a \circ \varphi_\alpha^{-1} \right\|_{W^{m,p}(\Omega_\alpha)} \xrightarrow[k\to\infty]{} 0.$$

If U_α is a regular coordinate half-ball, use Theorem 9.4.6. Since Ω_α has uniformly Lipschitz boundary, for each component there is a sequence $(\widetilde{G}_{\alpha,k})^a \in C_c^\infty(\mathbb{R}^n)$ such that

$$\sum_{a=1}^{r} \left\| (\widetilde{G}_{\alpha,k})^a \restriction_{\Omega_\alpha} - (\psi_\alpha \mathbf{F})_\alpha^a \circ \varphi_\alpha^{-1} \right\|_{W^{m,p}(\Omega_\alpha)} \xrightarrow[k\to\infty]{} 0.$$

In this case we do not require the approximating functions to have compact support contained in Ω_α; we use only that they are restrictions to Ω_α of smooth functions defined on $\mathbb{R}^n$.

To return to the manifold and extend by zero outside U_α, choose $\chi_\alpha \in C_c^\infty(U_\alpha)$ such that $\chi_\alpha \equiv 1$ on a neighborhood of $\operatorname{supp}(\psi_\alpha)$. In this boundary case, replace $(\widetilde{G}_{\alpha,k})^a \restriction_{\Omega_\alpha}$ by $(\chi_\alpha \circ \varphi_\alpha^{-1})(\widetilde{G}_{\alpha,k})^a \restriction_{\Omega_\alpha}$.

This modification preserves convergence. To see this, write $\eta_\alpha := \chi_\alpha \circ \varphi_\alpha^{-1}$ and $f_\alpha^a := (\psi_\alpha \mathbf{F})_\alpha^a \circ \varphi_\alpha^{-1}$. Since $\chi_\alpha \equiv 1$ on a neighborhood of $\operatorname{supp}(\psi_\alpha)$, we have $\eta_\alpha f_\alpha^a = f_\alpha^a$. Therefore,

$$\eta_\alpha (\widetilde{G}_{\alpha,k})^a \restriction_{\Omega_\alpha} - f_\alpha^a = \eta_\alpha \left((\widetilde{G}_{\alpha,k})^a \restriction_{\Omega_\alpha} - f_\alpha^a \right).$$

Denote $h_{\alpha,k}^a := (\widetilde{G}_{\alpha,k})^a \restriction_{\Omega_\alpha} - f_\alpha^a$. By construction, $h_{\alpha,k}^a \to 0$ in $W^{m,p}(\Omega_\alpha)$. Let us show that also $\eta_\alpha h_{\alpha,k}^a \to 0$ in $W^{m,p}(\Omega_\alpha)$.

Let β be a multi-index with $|\beta| \leq m$. By the Leibniz formula,

$$\partial^\beta (\eta_\alpha h_{\alpha,k}^a) = \sum_{\gamma \leq \beta} \binom{\beta}{\gamma} (\partial^\gamma \eta_\alpha) \partial^{\beta-\gamma} h_{\alpha,k}^a.$$

Since η_α is smooth and supported in $\varphi_\alpha(U_\alpha)$, its derivatives of order $\leq m$ are bounded on Ω_α. Thus, for each β there is a constant $C_\beta > 0$, independent of k, such that

$$\|\partial^\beta (\eta_\alpha h_{\alpha,k}^a)\|_{L^p(\Omega_\alpha)} \leq C_\beta \sum_{\gamma \leq \beta} \|\partial^{\beta-\gamma} h_{\alpha,k}^a\|_{L^p(\Omega_\alpha)}.$$

Summing over all multi-indices $|\beta| \leq m$ gives a constant $C > 0$, independent of k, such that

$$\|\eta_\alpha h_{\alpha,k}^a\|_{W^{m,p}(\Omega_\alpha)} \leq C \|h_{\alpha,k}^a\|_{W^{m,p}(\Omega_\alpha)}.$$

Since $h^a_{\alpha,k} \to 0$ in $W^{m,p}(\Omega_\alpha)$, we conclude that $\eta_\alpha(\widetilde{G}_{\alpha,k})^a \restriction_{\Omega_\alpha} \to f^a_\alpha$ in $W^{m,p}(\Omega_\alpha)$. Thus multiplying the approximating functions by $\chi_\alpha \circ \varphi_\alpha^{-1}$ does not alter the limit.
After this replacement, the supports of the approximating functions in the chart lie in the image of a compact subset of U_α.
In either case, we have constructed smooth functions $(\widetilde{G}_{\alpha,k})^a$ on the corresponding coordinate domain, with the support needed to return to the manifold. Define a smooth section on U_α by

$$\mathbf{G}_{\alpha,k} = \sum_{a=1}^{r} \Big[(\widetilde{G}_{\alpha,k})^a \circ \varphi_\alpha\Big]\mathbf{e}_{a,\alpha}.$$

In a boundary chart, it is understood that we use the approximating functions already multiplied by $\chi_\alpha \circ \varphi_\alpha^{-1}$. By the choice of supports, $\mathbf{G}_{\alpha,k}$ extends by zero outside U_α to define a global smooth section of $\mathbf{E}$.
By the preceding local estimate,

$$\|\mathbf{G}_{\alpha,k} - (\psi_\alpha \mathbf{F})\restriction_{U_\alpha}\|_{W^{m,p}(U_\alpha, \mathbf{E}\restriction_{U_\alpha})} \xrightarrow[k\to\infty]{} 0.$$

Since $\operatorname{supp}(\mathbf{G}_{\alpha,k} - \psi_\alpha \mathbf{F}) \subseteq U_\alpha$ and ∇^s_w is a local operator for each $s \le m$, we have

$$\|\mathbf{G}_{\alpha,k} - (\psi_\alpha \mathbf{F})\restriction_{U_\alpha}\|_{W^{m,p}(U_\alpha, \mathbf{E}\restriction_{U_\alpha})} = \|\mathbf{G}_{\alpha,k} - \psi_\alpha \mathbf{F}\|_{W^{m,p}(M,\mathbf{E})}.$$

Consequently, $\|\mathbf{G}_{\alpha,k} - \psi_\alpha \mathbf{F}\|_{W^{m,p}(M,\mathbf{E})} \to 0$ as $k \to \infty$.
Now fix $q \in \mathbb{N}$. By the preceding convergence, for each $\alpha \in \mathbb{N}$ there is $k_{\alpha,q} \in \mathbb{N}$ such that $\|\psi_\alpha \mathbf{F} - \mathbf{G}_{\alpha,k_{\alpha,q}}\|_{W^{m,p}(M,\mathbf{E})} < 2^{-(\alpha+q)}$. Since $\operatorname{supp}(\mathbf{G}_{\alpha,k_{\alpha,q}}) \subseteq U_\alpha$ and the family $(U_\alpha)_{\alpha\in\mathbb{N}}$ is locally finite, the sum $\mathbf{G}_q := \sum_{\alpha=1}^{\infty} \mathbf{G}_{\alpha,k_{\alpha,q}}$ is locally finite. It therefore defines a global smooth section $\mathbf{G}_q \in \Gamma(\mathbf{E})$.
Finally, $\mathbf{F} - \mathbf{G}_q = \sum_{\alpha=1}^{\infty} (\psi_\alpha \mathbf{F} - \mathbf{G}_{\alpha,k_{\alpha,q}})$, where the sum is locally finite. Using the triangle inequality,

$$\|\mathbf{F} - \mathbf{G}_q\|_{W^{m,p}(M,\mathbf{E})} \le \sum_{\alpha=1}^{\infty} \|\psi_\alpha \mathbf{F} - \mathbf{G}_{\alpha,k_{\alpha,q}}\|_{W^{m,p}(M,\mathbf{E})} \le \sum_{\alpha=1}^{\infty} \frac{1}{2^{\alpha+q}} = \frac{1}{2^q}.$$

Thus $\mathbf{G}_q \to \mathbf{F}$ in $W^{m,p}(M,\mathbf{E})$ as $q \to \infty$.
Moreover,

$$\|\mathbf{G}_q\|_{W^{m,p}(M,\mathbf{E})} \le \|\mathbf{F}\|_{W^{m,p}(M,\mathbf{E})} + \|\mathbf{F} - \mathbf{G}_q\|_{W^{m,p}(M,\mathbf{E})} \le \|\mathbf{F}\|_{W^{m,p}(M,\mathbf{E})} + 2^{-q} < \infty.$$

Therefore, $\mathbf{G}_q \in H^{m,p}(M,\mathbf{E})$ for every $q \in \mathbb{N}$.
We have proved that every section in $W^{m,p}(M,\mathbf{E})$ can be approximated in the Sobolev norm by smooth sections with finite Sobolev norm. This shows that $W^{m,p}(M,\mathbf{E}) \subseteq H^{m,p}(M,\mathbf{E})$. Together with the initial inclusion, we conclude that $H^{m,p}(M,\mathbf{E}) = W^{m,p}(M,\mathbf{E})$. □

Lemma 9.4.9. (Continuity of multiplication by smooth functions) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{E} \to M$ be a smooth vector bundle equipped with a bundle metric $\mathbf{h}_\mathbf{E}$ and a compatible connection $\nabla^\mathbf{E}$. Let $m \in \mathbb{N}$ and $1 \le p < \infty$. Suppose that $\psi \in C^\infty(M)$ satisfies

$$\|\nabla^q \psi\|_{L^\infty(M, T^{(0,q)}(TM))} < \infty \qquad \text{for every } 0 \le q \le m.$$

Then the operator

$$\mathbf{u} \longmapsto \psi\mathbf{u}$$

is linear and continuous from $W^{m,p}(M,\mathbf{E})$ to itself. In particular, there is a constant $C_{\psi,m} > 0$ such that

$$\|\psi\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \leq C_{\psi,m}\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}$$

for every $\mathbf{u} \in W^{m,p}(M,\mathbf{E})$.
In particular, if M is compact, every function $\psi \in C^\infty(M)$ defines a continuous multiplication operator on $W^{m,p}(M,\mathbf{E})$. More generally, on a noncompact manifold it suffices to take $\psi \in C^\infty_c(M)$.

Proof. We first prove the estimate for smooth sections. Let $\mathbf{u} \in \Gamma(\mathbf{E}) \cap W^{m,p}(M,\mathbf{E})$. For each $0 \leq s \leq m$, the iterated Leibniz rule for the induced connection shows that $\nabla^s(\psi\mathbf{u})$ is a finite sum of terms constructed from the covariant derivatives of ψ and $\mathbf{u}$, whose orders sum to s. Consequently, there is a constant $A_s > 0$, depending only on s and the tensor conventions, such that

$$|\nabla^s(\psi\mathbf{u})|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \leq A_s \sum_{t=0}^{s} |\nabla^{s-t}\psi|_{\mathbf{g}}\,|\nabla^t\mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}.$$

Using the boundedness hypothesis on the derivatives of ψ gives

$$|\nabla^s(\psi\mathbf{u})|_{\mathbf{g},\mathbf{h}_\mathbf{E}} \leq A_s \sum_{t=0}^{s} \|\nabla^{s-t}\psi\|_{L^\infty(M,T^{(0,s-t)}(TM))}|\nabla^t\mathbf{u}|_{\mathbf{g},\mathbf{h}_\mathbf{E}}.$$

Taking the $L^p\big(M, T^{(0,s)}(TM)\otimes\mathbf{E}\big)$ norm and using the triangle inequality,

$$\|\nabla^s(\psi\mathbf{u})\|_{L^p(M,T^{(0,s)}(TM)\otimes\mathbf{E})} \leq A_s \sum_{t=0}^{s} \|\nabla^{s-t}\psi\|_{L^\infty(M,T^{(0,s-t)}(TM))}\|\nabla^t\mathbf{u}\|_{L^p(M,T^{(0,t)}(TM)\otimes\mathbf{E})}.$$

Summing over $s \in \{0,\dots,m\}$ gives a constant $C_{\psi,m} > 0$ such that

$$\|\psi\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \leq C_{\psi,m}\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}$$

for every $\mathbf{u} \in \Gamma(\mathbf{E}) \cap W^{m,p}(M,\mathbf{E})$.
Now take $\mathbf{u} \in W^{m,p}(M,\mathbf{E})$. By the Meyers–Serrin theorem for vector bundles (Theorem 9.4.8), there is a sequence $(\mathbf{u}_k)_{k\in\mathbb{N}} \subseteq \Gamma(\mathbf{E}) \cap W^{m,p}(M,\mathbf{E})$ such that $\mathbf{u}_k \to \mathbf{u}$ in $W^{m,p}(M,\mathbf{E})$. By the estimate already proved,

$$\|\psi\mathbf{u}_k - \psi\mathbf{u}_\ell\|_{W^{m,p}(M,\mathbf{E})} \leq C_{\psi,m}\|\mathbf{u}_k - \mathbf{u}_\ell\|_{W^{m,p}(M,\mathbf{E})}.$$

Thus $(\psi\mathbf{u}_k)_{k\in\mathbb{N}}$ is a Cauchy sequence in $W^{m,p}(M,\mathbf{E})$. Define $\psi\mathbf{u}$ as its limit in $W^{m,p}(M,\mathbf{E})$. This definition is independent of the approximating sequence, since, if $\mathbf{u}_k \to \mathbf{u}$ and $\mathbf{v}_k \to \mathbf{u}$, then

$$\|\psi\mathbf{u}_k - \psi\mathbf{v}_k\|_{W^{m,p}(M,\mathbf{E})} \leq C_{\psi,m}\|\mathbf{u}_k - \mathbf{v}_k\|_{W^{m,p}(M,\mathbf{E})} \longrightarrow 0.$$

Moreover, passing to the limit in

$$\|\psi \mathbf{u}_k\|_{W^{m,p}(M,\mathbf{E})} \le C_{\psi,m}\|\mathbf{u}_k\|_{W^{m,p}(M,\mathbf{E})},$$

gives

$$\|\psi \mathbf{u}\|_{W^{m,p}(M,\mathbf{E})} \le C_{\psi,m}\|\mathbf{u}\|_{W^{m,p}(M,\mathbf{E})}.$$

This proves continuity of the multiplication operator. □

Definition 9.4.10. (Sobolev spaces with zero trace) Let $(M,\mathbf{g})$ be a Riemannian manifold with nonempty boundary and $\mathbf{E}\to M$ a smooth vector bundle equipped with a bundle metric $\mathbf{h}_\mathbf{E}$ and a smooth connection $\nabla^\mathbf{E}$. Let $m\in\mathbb{N}$ and $1\le p<\infty$.
Define the Sobolev space with zero trace by

$$W_0^{m,p}(M,\mathbf{E}) := \overline{\Gamma_{c,\mathrm{Int}(M)}(\mathbf{E})}^{\|\cdot\|_{W^{m,p}(M,\mathbf{E})}}.$$

That is, $W_0^{m,p}(M,\mathbf{E})$ is the closure, in the Sobolev norm, of the space of smooth sections with compact support contained in the interior of M.

Before formulating the trace theorem, we must fix the connection to be used on the bundle restricted to the boundary. If $\mathbf{u}$ is a smooth section of $\mathbf{E}$, then $\mathbf{u}\restriction_{\partial M}$ is a smooth section of $\mathbf{E}\restriction_{\partial M}$. To measure the Sobolev regularity of this restriction, it does not suffice to regard $\mathbf{E}\restriction_{\partial M}$ simply as a vector bundle: we also need a connection on it. The natural connection is obtained by restricting the connection of $\mathbf{E}$ to directions tangent to the boundary.

Lemma 9.4.11. (Induced connection on the restricted bundle) Let $(M,\mathbf{g})$ be a Riemannian manifold with nonempty boundary, and let $\mathbf{E}\to M$ be a smooth vector bundle equipped with a connection $\nabla^\mathbf{E}$. Then there is a connection on the restricted bundle $\mathbf{E}\restriction_{\partial M}\to\partial M$, denoted by $\nabla^{\mathbf{E}\restriction_{\partial M}}$, defined as follows.
If $\mathbf{X}\in\mathfrak{X}(\partial M)$ and $\mathbf{u}\in\Gamma(\mathbf{E}\restriction_{\partial M})$, take smooth extensions $\widetilde{\mathbf{X}}\in\mathfrak{X}(M)$ and $\widetilde{\mathbf{u}}\in\Gamma(\mathbf{E})$ such that $\widetilde{\mathbf{X}}\restriction_{\partial M}=\mathbf{X}$ and $\widetilde{\mathbf{u}}\restriction_{\partial M}=\mathbf{u}$, and define

$$\nabla^{\mathbf{E}\restriction_{\partial M}}_{\mathbf{X}}\mathbf{u} := (\nabla^\mathbf{E}_{\widetilde{\mathbf{X}}}\widetilde{\mathbf{u}})\restriction_{\partial M}.$$

This definition is independent of the chosen extensions. Moreover, if $\nabla^\mathbf{E}$ is compatible with the bundle metric $\mathbf{h}_\mathbf{E}$, then $\nabla^{\mathbf{E}\restriction_{\partial M}}$ is compatible with the restricted bundle metric $\mathbf{h}_\mathbf{E}\restriction_{\mathbf{E}\restriction_{\partial M}}$.

Proof. We first prove independence of the chosen extensions. Let $\widetilde{\mathbf{X}}_1,\widetilde{\mathbf{X}}_2\in\mathfrak{X}(M)$ be two extensions of $\mathbf{X}$ and let $\widetilde{\mathbf{u}}_1,\widetilde{\mathbf{u}}_2\in\Gamma(\mathbf{E})$ be two extensions of $\mathbf{u}$. We want to prove that

$$(\nabla^\mathbf{E}_{\widetilde{\mathbf{X}}_1}\widetilde{\mathbf{u}}_1)\restriction_{\partial M} = (\nabla^\mathbf{E}_{\widetilde{\mathbf{X}}_2}\widetilde{\mathbf{u}}_2)\restriction_{\partial M}.$$

By linearity,
