Proof. If $M = \varnothing$, there are no charts to compare. Suppose $M \neq \varnothing$. First observe that if two charts in the differentiable structure have nonempty intersection, their model spaces are isomorphic as Banach spaces. Let (U, φ) and (V, ψ) be two charts such that $U \cap V \neq \varnothing$, modeled on the Banach spaces X and Y, respectively. Fix $x \in U \cap V$ and write $\xi := \varphi(x)$. Since the coordinate change $\psi \circ \varphi^{-1}$ is a diffeomorphism of class at least C^1, the operator

$$d(\psi \circ \varphi^{-1})_\xi : X \longrightarrow Y$$

is linear and continuous. Differentiating the identities between the inverse coordinate changes gives

$$d(\varphi \circ \psi^{-1})_{\psi(x)} \circ d(\psi \circ \varphi^{-1})_\xi = \mathrm{id}_X, \qquad d(\psi \circ \varphi^{-1})_\xi \circ d(\varphi \circ \psi^{-1})_{\psi(x)} = \mathrm{id}_Y .$$

Thus $d(\psi \circ \varphi^{-1})_\xi$ is a continuous linear isomorphism with continuous inverse.
Now take a fixed chart (U_0, φ_0), modeled on a Banach space X_0, and define

$$A := \{x \in M \mid \text{there exists a chart around } x \text{ modeled on a space isomorphic to } X_0\}.$$

The set A is nonempty, since $U_0 \subseteq A$, and open: if $x \in A$ and (U, φ) is a chart around x modeled on a space isomorphic to X_0, the same chart works around every point of U, so $U \subseteq A$.
The set $M \setminus A$ is also open. Let $y \in M \setminus A$ and let (V, ψ) be a chart around y modeled on a Banach space Y. If there existed $z \in V \cap A$, there would be a chart around z modeled on a space isomorphic to X_0. This chart would intersect (V, ψ) in an open set containing z, and the first part of the proof would show that Y is isomorphic to X_0. The chart (V, ψ) would then show that $y \in A$, a contradiction. Thus $V \subseteq M \setminus A$.
Hence A is open and closed. Since M is connected and $A \neq \varnothing$, we have $A = M$. Finally, if (V, ψ) is any chart, choose $y \in V$. Since $y \in A$, there exists another chart around y whose model space is isomorphic to X_0; comparing the two charts in a neighborhood of y, the first part of the proof shows that the model space of (V, ψ) is also isomorphic to X_0. This completes the proof. □

This result justifies speaking, when M is connected, of the model space of a Banach manifold up to Banach space isomorphism. For this reason, a Banach manifold is often defined from the outset as a manifold modeled on a fixed Banach space X.

Before introducing the tangent space, we specify the regularity of maps between Banach manifolds.

Definition 24.1.3. Let M and N be Banach manifolds of classes C^k and C^ℓ, respectively, and let $r \in \mathbb{N} \cup \{\infty\}$ be such that $1 \leq r \leq k$ and $1 \leq r \leq \ell$. A map $F : M \longrightarrow N$ is of **class** C^r **at** $p \in M$ if there exist a chart (U, φ) of M around p, a chart (V, ψ) of N around $F(p)$, and an open neighborhood $U_0 \subseteq U$ of p such that $F(U_0) \subseteq V$

and

$$\psi \circ F \circ \varphi^{-1} \colon \varphi(U_0) \longrightarrow \psi(V)$$

is of class C^r. The map F is of **class** C^r if it is of this class at every point of M. When $r = \infty$, we say that F is **smooth**.

This regularity does not depend on the chosen charts. Let $(\widetilde{U}, \widetilde{\varphi})$ and $(\widetilde{V}, \widetilde{\psi})$ be other charts around p and $F(p)$, respectively. The representation $\psi \circ F \circ \varphi^{-1}$ is continuous and $V \cap \widetilde{V}$ is a neighborhood of $F(p)$; we may therefore restrict the domain to a neighborhood of p whose image under F is contained in $V \cap \widetilde{V}$. Restricting also to $U \cap \widetilde{U}$ gives

$$\widetilde{\psi} \circ F \circ \widetilde{\varphi}^{-1} = (\widetilde{\psi} \circ \psi^{-1}) \circ (\psi \circ F \circ \varphi^{-1}) \circ (\varphi \circ \widetilde{\varphi}^{-1}).$$

The maps on either side of the coordinate representation of F are coordinate changes of class at least C^r. The chain rule shows that one coordinate representation of F is of class C^r if and only if every other one is.

Remark 24.1.4. (The structure of lower regularity) Let $\mathcal{A}^k$ be the maximal atlas of a manifold of class C^k, and fix $r \in \mathbb{N} \cup \{\infty\}$ with $1 \le r \le k$. The coordinate changes of $\mathcal{A}^k$ are also of class C^r. This atlas therefore determines a structure of class C^r on the same topological space; denote its maximal atlas by $\mathcal{A}^r$. Its charts are those that are C^r–compatible with the charts of $\mathcal{A}^k$. Any two such charts are compatible with each other: near each point of an overlap, insert a chart of $\mathcal{A}^k$ and write their coordinate change as a composition of two diffeomorphisms of class C^r.

When $r < k$, the atlas $\mathcal{A}^r$ may contain more charts than $\mathcal{A}^k$. A chart in $\mathcal{A}^r$ will be called a *chart of class C^r on M*. The class C^r of a map can be checked in these charts, since the argument for coordinate independence uses only coordinate changes of class C^r. This distinction allows us to construct coordinates adapted to a map with the regularity that the map possesses. In the results on local forms of maps of class C^r, the constructed charts will belong to the underlying structures of class C^r.

Since $r \ge 1$, all these coordinate changes are of class C^1. By the chain rule, two curves have the same velocity in a chart of $\mathcal{A}^k$ if and only if they do in a chart of $\mathcal{A}^r$. Thus passage to the structure of lower regularity preserves the tangent space to be defined next.

To study locally Lipschitz vector fields and their flows, we will also use regularity intermediate between C^1 and C^2.

Definition 24.1.5. (Maps and manifolds of class $C^{1,1}$) Let X, Y be Banach spaces and let $U \subseteq X$ be open. A map $f \colon U \longrightarrow Y$ is of **class** $C^{1,1}$ if it is of class C^1 and, for each $x_0 \in U$, there exist $r, L > 0$ such that $B_X(x_0, r) \subseteq U$ and

$$\|Df(x) - Df(y)\|_{\mathcal{L}(X,Y)} \le L\|x - y\|_X, \qquad x, y \in B_X(x_0, r).$$

The condition on the derivative is local: a single constant L valid on all of U is not required. A diffeomorphism is of class $C^{1,1}$ if both it and its inverse have this regularity.

Two Banach charts are $C^{1,1}$**–compatible** if their intersection is empty or the coordinate change between them is a diffeomorphism of class $C^{1,1}$. An **atlas of class** $C^{1,1}$ is a covering by mutually $C^{1,1}$–compatible charts. A **Banach manifold of class** $C^{1,1}$ is a Hausdorff space equipped with a maximal atlas of that class. Since its coordinate changes are C^1, this atlas determines a Banach manifold structure of class C^1 on the same space.

Proposition 24.1.6. (Stability of $C^{1,1}$ regularity) Every map of class C^2 between open subsets of Banach spaces is of class $C^{1,1}$. The composition of two maps of class $C^{1,1}$, whenever defined, is of class $C^{1,1}$. Moreover, if a diffeomorphism of class C^1 is of class $C^{1,1}$, so is its inverse.

Proof. If f is of class C^2, continuity of $D^2 f$ allows its norm to be bounded by a constant L on a sufficiently small ball around each point of its domain. Theorem 23.1.10, applied to the map Df on this convex ball, gives $\|Df(x) - Df(y)\| \le L\|x - y\|$. This proves the first assertion.

Now let $f\colon U \subseteq X \longrightarrow Y$ and $g\colon V \subseteq Y \longrightarrow Z$ be of class $C^{1,1}$, with $f(U) \subseteq V$. Fix $x_0 \in U$. We can choose a convex ball $B \subseteq U$ around x_0 whose image lies in a convex ball $C \subseteq V$, and constants $M_f, M_g, L_f, L_g > 0$, such that $\|Df\| \le M_f$ on B, $\|Dg\| \le M_g$ on C, and the derivatives are Lipschitz there with constants L_f, L_g, respectively. The mean value inequality gives $\|f(x) - f(y)\| \le M_f\|x - y\|$ for $x, y \in B$. By the chain rule,

$$D(g \circ f)(x) - D(g \circ f)(y) = [Dg(f(x)) - Dg(f(y))]Df(x) + Dg(f(y))[Df(x) - Df(y)].$$

Consequently,

$$\|D(g \circ f)(x) - D(g \circ f)(y)\| \le (L_g M_f^2 + M_g L_f)\|x - y\|, \qquad x, y \in B.$$

The composition is therefore of class $C^{1,1}$.

Finally, let $f\colon U \longrightarrow V$ be a diffeomorphism of class C^1 and suppose f is of class $C^{1,1}$. Write $h = f^{-1}$. Around $y_0 \in V$, choose a convex ball C such that $h(C)$ is contained in a ball on which Df is L–Lipschitz. Since Dh is continuous, we may shrink C so that $\|Dh(y)\| \le M$ there. Then $\|h(y) - h(z)\| \le M\|y - z\|$ for $y, z \in C$. The identity $A^{-1} - B^{-1} = A^{-1}(B - A)B^{-1}$, applied to $A = Df(h(y))$ and $B = Df(h(z))$, gives

$$Dh(y) - Dh(z) = Dh(y)[Df(h(z)) - Df(h(y))]Dh(z).$$

Consequently,

$$\|Dh(y) - Dh(z)\| \le LM^3\|y - z\|, \qquad y, z \in C.$$

This proves that h is of class $C^{1,1}$. □

Stability under composition allows a $C^{1,1}$ atlas to be completed to a unique maximal atlas by adding all charts compatible with the given ones. To compare two added charts around a common point, insert a chart of the original atlas and apply the preceding proposition to the two coordinate changes. Likewise, a map between $C^{1,1}$ manifolds is of class $C^{1,1}$ when its coordinate representations are; the same composition of chart changes shows that it suffices to check this in one chart around each point.

Every manifold of class at least C^2 thus has an underlying $C^{1,1}$ structure obtained by completing its atlas in this category. When working at $C^{1,1}$ regularity, we use charts of this chosen atlas, rather than all charts of the underlying C^1 atlas: a merely C^1 coordinate change need not have locally Lipschitz differential. The admissible curves and the tangent space construction below use only the first-order chain rule, so they also apply to this category through its underlying C^1 structure.

If $U \subseteq M$ is open, we equip it with the Banach manifold structure induced by that of M. Denote by $C^r(U, N)$ the set of maps of class C^r from U to N and write $C^r(U) := C^r(U, \mathbb{R})$. In particular, if $I \subseteq \mathbb{R}$ is an open interval, a curve $\gamma\colon I \longrightarrow M$ is of class C^r if for each $t_0 \in I$ there exist a chart (U, φ) around $\gamma(t_0)$, modeled on X, and an open interval $J \subseteq I$ containing t_0 such that $\gamma(J) \subseteq U$ and $\varphi \circ \gamma\restriction_J\colon J \longrightarrow X$ is of class C^r. By chart independence, it suffices to verify this condition in one chart around each point of the curve.

We now introduce the notion of tangent space. In finite dimensions there are several equivalent constructions, including one based on curves and another formulated through derivations on germs of smooth functions. On Banach manifolds, these two constructions need not agree under the canonical identification, so it is useful to distinguish them before fixing our convention.

Definition 24.1.7. Let M be a Banach manifold of class C^k, with $k \geq 1$, and let $p \in M$. An **admissible curve at** p is a map $\gamma\colon (-\varepsilon,\varepsilon) \longrightarrow M$ of class C^1 such that $\gamma(0) = p$, where $\varepsilon > 0$ may depend on γ.
Two admissible curves γ_1 and γ_2 are **equivalent at** p, and we write $\gamma_1 \sim_p \gamma_2$, if there exists a chart (U,φ) around p such that, after restricting both curves to a sufficiently small common interval around 0,

$$\left.\frac{d}{dt}\right|_{t=0} (\varphi \circ \gamma_1)(t) = \left.\frac{d}{dt}\right|_{t=0} (\varphi \circ \gamma_2)(t).$$

Proposition 24.1.8. Let M be a Banach manifold of class C^k, with $k \geq 1$, and let $p \in M$. The condition in Definition 24.1.7 is independent of the chosen chart and defines an equivalence relation on the set of admissible curves at p.

Proof. Let (U,φ) and (V,ψ) be two charts around p, and let γ_1 and γ_2 be two admissible curves at p. Since $\gamma_1(0) = \gamma_2(0) = p$ and the curves are continuous, there exists $\delta > 0$ such that $\gamma_j((-\delta,\delta)) \subseteq U \cap V$ for $j \in \{1,2\}$. Near 0, we have

$$\psi \circ \gamma_j = (\psi \circ \varphi^{-1}) \circ (\varphi \circ \gamma_j),$$

, and the chain rule gives

$$(\psi \circ \gamma_j)'(0) = d(\psi \circ \varphi^{-1})_{\varphi(p)}\big((\varphi \circ \gamma_j)'(0)\big).$$

The operator $A_{\psi\varphi}(p) := d(\psi \circ \varphi^{-1})_{\varphi(p)}$ is a continuous linear isomorphism, with inverse $d(\varphi \circ \psi^{-1})_{\psi(p)}$. Consequently,

$$(\varphi \circ \gamma_1)'(0) = (\varphi \circ \gamma_2)'(0) \quad \Longleftrightarrow \quad (\psi \circ \gamma_1)'(0) = (\psi \circ \gamma_2)'(0).$$

Thus two curves have the same velocity in one chart around p if and only if they do in every other chart. In particular, in the preceding definition, "there exists a chart" can equivalently be replaced by "for every chart."
Reflexivity and symmetry are immediate. To check transitivity, suppose $\gamma_1 \sim_p \gamma_2$ and $\gamma_2 \sim_p \gamma_3$, and choose any chart (U,φ) around p. By chart independence,

$$(\varphi \circ \gamma_1)'(0) = (\varphi \circ \gamma_2)'(0) = (\varphi \circ \gamma_3)'(0),$$

, so $\gamma_1 \sim_p \gamma_3$. □

Definition 24.1.9. Let M be a Banach manifold of class C^k, with $k \geq 1$, and let $p \in M$. The set of equivalence classes of admissible curves at p is called the **kinematic tangent space** of M at p and is denoted by $T_p^{\mathrm{kin}}M$. The class of an admissible curve γ is denoted by $[\gamma]$.

Proposition 24.1.10. Let M be a Banach manifold of class C^k, with $k \geq 1$, let $p \in M$, and let (U, φ) be a chart around p modeled on a Banach space X. The map

$$\Theta_{\varphi,p} \colon T_p^{\mathrm{kin}} M \longrightarrow X, \qquad \Theta_{\varphi,p}([\gamma]) := \left.\frac{d}{dt}\right|_{t=0} (\varphi \circ \gamma)(t),$$

is a bijection. The vector operations transported from X through $\Theta_{\varphi,p}$ do not depend on the chosen chart. Each chart also determines a complete norm on $T_p^{\mathrm{kin}} M$, and norms determined by different charts satisfy the explicit inequalities in the proof.

Proof. For every admissible curve γ at p, continuity of γ allows its domain to be restricted so that its image lies in U. Chart independence, proved in Proposition 24.1.8, shows that $\Theta_{\varphi,p}$ does not depend on the representative of $[\gamma]$, so it is well defined. If $\Theta_{\varphi,p}([\gamma_1]) = \Theta_{\varphi,p}([\gamma_2])$, then $\gamma_1 \sim_p \gamma_2$ by the definition of the relation itself; thus $\Theta_{\varphi,p}$ is injective.

To prove surjectivity, let $v \in X$ and write $a := \varphi(p)$. Since $\varphi(U)$ is open, there exists $r > 0$ such that $B_X(a, r) \subseteq \varphi(U)$. If $\varepsilon := \frac{r}{1+\|v\|_X}$, then $a + tv \in \varphi(U)$ for $|t| < \varepsilon$. The curve $\gamma_v(t) := \varphi^{-1}(a + tv)$ is admissible at p and satisfies $\Theta_{\varphi,p}([\gamma_v]) = v$.

For $\xi, \eta \in T_p^{\mathrm{kin}} M$ and $\lambda \in \mathbb{R}$, define

$$\xi + \eta := \Theta_{\varphi,p}^{-1}\big(\Theta_{\varphi,p}(\xi) + \Theta_{\varphi,p}(\eta)\big), \qquad \lambda\xi := \Theta_{\varphi,p}^{-1}\big(\lambda\Theta_{\varphi,p}(\xi)\big).$$

Let (V, ψ) be another chart around p modeled on a Banach space Y. The chain rule gives

$$\Theta_{\psi,p} = A_{\psi\varphi}(p) \circ \Theta_{\varphi,p}, \qquad A_{\psi\varphi}(p) := d(\psi \circ \varphi^{-1})_{\varphi(p)}.$$

Since $A_{\psi\varphi}(p)$ is linear, the operations obtained through $\Theta_{\psi,p}$ agree with those obtained through $\Theta_{\varphi,p}$. In particular, $T_p^{\mathrm{kin}} M$ has a well-defined vector space structure; its zero vector is the class of the constant curve $t \longmapsto p$.

Finally, set $\|\xi\|_{\varphi,p} := \|\Theta_{\varphi,p}(\xi)\|_X$. This norm is complete because $\Theta_{\varphi,p}$ is a linear isometry onto X. Moreover,

$$\|\xi\|_{\psi,p} \leq \|A_{\psi\varphi}(p)\|_{\mathcal{L}(X,Y)} \|\xi\|_{\varphi,p}, \qquad \|\xi\|_{\varphi,p} \leq \|A_{\psi\varphi}(p)^{-1}\|_{\mathcal{L}(Y,X)} \|\xi\|_{\psi,p}.$$

Thus the preceding two inequalities show that the norms associated with different charts determine the same topology. The resulting linear structure and Banach topology are independent of the chart, although in general there is no distinguished norm. □

There is also an algebraic construction of the tangent space. To formulate it, we need M to be smooth.

Definition 24.1.11. Let M be a smooth Banach manifold and let $p \in M$. A **germ at p of a smooth real function** is an equivalence class of pairs (U, f), where $U \subseteq M$ is an open neighborhood of p and $f \colon U \longrightarrow \mathbb{R}$ is smooth. Two pairs (U, f) and (V, g) are equivalent if there exists an open neighborhood $W \subseteq U \cap V$ of p such that $f \restriction_W = g \restriction_W$. The set of these germs is denoted by $C_p^\infty(M)$.

The preceding relation is an equivalence relation: reflexivity and symmetry are immediate, and transitivity follows by intersecting two neighborhoods on which the corresponding representatives agree. Addition, multipli-

cation, and scalar multiplication in $C^\infty_p(M)$ are defined by choosing representatives, restricting them to a common neighborhood of p, and performing the usual operations there. These definitions do not depend on the representatives, since equivalent representatives agree on a sufficiently small neighborhood of p. Thus $C^\infty_p(M)$ is a commutative unital real algebra. Evaluation at p is well defined and is an algebra homomorphism. As usual, we use the same symbol f for a germ and any of its representatives when no confusion can arise, and simply write $f(p)$.

Definition 24.1.12. Let M be a smooth Banach manifold and let $p \in M$. An **operational tangent vector at** p is an algebraic linear functional

$$D\colon C^\infty_p(M) \longrightarrow \mathbb{R}$$

satisfying the Leibniz rule

$$D(fg) = D(f)g(p) + f(p)D(g)$$

for any $f, g \in C^\infty_p(M)$. The space of all operational tangent vectors at p is denoted by $T^{\mathrm{op}}_p M$.

No continuity condition is imposed on D, since no topology has been chosen on the germ algebra $C^\infty_p(M)$. With addition and scalar multiplication defined pointwise, $T^{\mathrm{op}}_p M$ is a vector space. Every derivation $D \in T^{\mathrm{op}}_p M$ annihilates constants: $D(1) = D(1 \cdot 1) = 2D(1)$ gives $D(1) = 0$, and linearity gives $D(c) = 0$ for every $c \in \mathbb{R}$.

Proposition 24.1.13. Let M be a smooth Banach manifold and let $p \in M$. Every kinematic tangent vector determines an operational tangent vector. More precisely, there exists a canonical injective linear map

$$\mathcal{J}_p\colon T^{\mathrm{kin}}_p M \longrightarrow T^{\mathrm{op}}_p M, \qquad \mathcal{J}_p([\gamma]) = D_{[\gamma]},$$

, where

$$D_{[\gamma]} f := \frac{d}{dt}\bigg|_{t=0} f(\gamma(t)).$$

Proof. The expression is well defined with respect to the germ. If two representatives f and g agree on a neighborhood W of p, continuity of γ allows its domain to be restricted so that $\gamma(t) \in W$ near 0; then $f(\gamma(t)) = g(\gamma(t))$ near 0, and the two derivatives agree.

It is also independent of the curve representing $[\gamma]$. Fix a chart (U, φ) around p modeled on a Banach space X and write $a := \varphi(p)$. After restricting the representative of f and the chart to a common neighborhood of p, the chain rule gives

$$D_{[\gamma]} f = D(f \circ \varphi^{-1})(a)\big[\Theta_{\varphi,p}([\gamma])\big]. \tag{24.1}$$

The right-hand side depends only on the germ of f and the class $[\gamma]$.

Linearity of $D_{[\gamma]}$ in f follows from linearity of the derivative, and the usual product rule shows that

$$D_{[\gamma]}(fg) = D_{[\gamma]}(f)g(p) + f(p)D_{[\gamma]}(g).$$

Thus $D_{[\gamma]} \in T^{\mathrm{op}}_p M$.

Formula (24.1), linearity of $D(f \circ \varphi^{-1})(a)$, and the definition of the vector operations in $T^{\mathrm{kin}}_p M$ imply that $\mathcal{J}_p$ is linear. To prove injectivity, let $\xi \in T^{\mathrm{kin}}_p M$ be such that $\mathcal{J}_p(\xi) = 0$ and set $v := \Theta_{\varphi,p}(\xi)$. For each $\ell \in X'$,

consider the smooth function $f_\ell\colon U \longrightarrow \mathbb{R}$ defined by $f_\ell(x) := \ell(\varphi(x) - a)$. Then

$$0 = \mathcal{J}_p(\xi)(f_\ell) = \ell(v).$$

Since the continuous dual X' separates points of X, it follows that $v = 0$. Injectivity of $\Theta_{\varphi,p}$ implies $\xi = 0$, so $\mathcal{J}_p$ is injective. □

In finite dimensions, the identification in Definition 1.4.5, completed in Exercise 1.4.13, shows that $\mathcal{J}_p$ is an isomorphism. In infinite dimensions it may fail to be surjective, since the Leibniz rule alone does not force an algebraic derivation to depend only on the first derivative.

Proposition 24.1.14. (The operational tangent space may contain nonkinematic vectors) Let $E := \ell^2(\mathbb{N};\mathbb{R})$ be regarded as a smooth Banach manifold, and let $0 \in E$. Then the canonical map

$$\mathcal{J}_0\colon T_0^{\mathrm{kin}}E \longrightarrow T_0^{\mathrm{op}}E$$

is not surjective. Consequently, under the canonical identification given by $\mathcal{J}_0$, the kinematic tangent space is a proper subspace of the operational tangent space.

Proof. Let $\mathcal{L}^2_s(E;\mathbb{R})$ be the space of continuous symmetric bilinear forms on E, equipped with the norm in Definition 23.2.1, and denote by $\mathcal{F}_s(E)$ the subspace of symmetric forms of finite rank. Proposition B.3.23 identifies each $B \in \mathcal{L}^2_s(E;\mathbb{R})$ isometrically with a continuous self-adjoint linear operator $A_B\colon E \longrightarrow E$ through $B(x,y) = \langle A_B x, y\rangle_E$ and shows that $\overline{\mathcal{F}_s(E)}$ corresponds to the space of compact self-adjoint operators.
Consider the form $B_0(x,y) := \langle x, y\rangle_E$. The operator associated with B_0 is the identity on E, which is not compact because the standard orthonormal basis $(e_n)_{n\in\mathbb{N}}$ lies in the unit ball and satisfies $\|e_n - e_m\|_E = \sqrt{2}$ for $n \neq m$. Thus

$$B_0 \notin \overline{\mathcal{F}_s(E)}.$$

Form the quotient space

$$\mathcal{Q} := \mathcal{L}^2_s(E;\mathbb{R})/\overline{\mathcal{F}_s(E)}$$

and let $\pi\colon \mathcal{L}^2_s(E;\mathbb{R}) \longrightarrow \mathcal{Q}$ be the canonical projection. By Proposition B.2.20, $\mathcal{Q}$ is a normed space and

$$\|\pi(B)\|_{\mathcal{Q}} = \operatorname{dist}_{\mathcal{L}^2_s(E;\mathbb{R})}\big(B, \overline{\mathcal{F}_s(E)}\big).$$

In particular, $b_0 := \pi(B_0)$ is nonzero and $\|b_0\|_{\mathcal{Q}} > 0$.
On the one-dimensional subspace $\operatorname{span}\{b_0\}$, define

$$\lambda_0\colon \operatorname{span}\{b_0\} \longrightarrow \mathbb{R}, \qquad \lambda_0(tb_0) := t.$$

This function is well defined because $b_0 \neq 0$: if $tb_0 = sb_0$, then $(t-s)b_0 = 0$ and therefore $t = s$. Moreover, λ_0 is linear. By absolute homogeneity of the norm, $\|tb_0\|_{\mathcal{Q}} = |t|\,\|b_0\|_{\mathcal{Q}}$, and consequently

$$|\lambda_0(tb_0)| = |t| = \frac{\|tb_0\|_{\mathcal{Q}}}{\|b_0\|_{\mathcal{Q}}}.$$

In particular, for every $t \neq 0$,

$$\frac{|\lambda_0(tb_0)|}{\|tb_0\|_{\mathcal{Q}}} = \frac{1}{\|b_0\|_{\mathcal{Q}}}.$$

Since every nonzero element of $\operatorname{span}\{b_0\}$ has the form tb_0 with $t \neq 0$, we conclude that

$$\|\lambda_0\| = \sup_{\substack{x \in \operatorname{span}\{b_0\} \\ x \neq 0}} \frac{|\lambda_0(x)|}{\|x\|_{\mathcal{Q}}} = \frac{1}{\|b_0\|_{\mathcal{Q}}}.$$

Thus λ_0 is continuous. Corollary B.2.29 gives a continuous linear extension $\widetilde{\lambda}\colon \mathcal{Q} \longrightarrow \mathbb{R}$ of λ_0. Define

$$\Lambda := \widetilde{\lambda} \circ \pi\colon \mathcal{L}^2_s(E;\mathbb{R}) \longrightarrow \mathbb{R}.$$

Then Λ is linear and continuous, annihilates $\overline{\mathcal{F}_s(E)}$, and satisfies $\Lambda(B_0) = 1$.
For a germ $f \in C^\infty_0(E)$, define

$$\mathscr{D}(f) := \Lambda(D^2 f(0)).$$

This definition is independent of the representative, since two representatives of the same germ agree on a neighborhood of 0 and have the same derivatives there. Theorem 23.2.10 ensures that $D^2 f(0) \in \mathcal{L}^2_s(E;\mathbb{R})$. Linearity of the second derivative and of Λ shows that $\mathscr{D}$ is linear.
Let $f, g \in C^\infty_0(E)$ and choose representatives defined on a common open neighborhood of 0. By Proposition 23.2.11,

$$D^2(fg)(0) = f(0)D^2 g(0) + g(0)D^2 f(0) + Df(0) \otimes Dg(0) + Dg(0) \otimes Df(0).$$

Corollary B.3.24 shows that

$$C_{f,g} := Df(0) \otimes Dg(0) + Dg(0) \otimes Df(0)$$

is a symmetric bilinear form of rank at most two. Thus $C_{f,g} \in \mathcal{F}_s(E) \subseteq \overline{\mathcal{F}_s(E)}$ and $\Lambda(C_{f,g}) = 0$. Applying Λ to the preceding formula gives

$$\mathscr{D}(fg) = f(0)\mathscr{D}(g) + g(0)\mathscr{D}(f).$$

Hence $\mathscr{D} \in T_0^{\mathrm{op}} E$.
It remains to prove that $\mathscr{D}$ is not in the image of $\mathcal{J}_0$. Consider $q\colon E \longrightarrow \mathbb{R}$, $q(x) := \|x\|_E^2$. For $x, h \in E$, we have $q(x+h) - q(x) = 2\langle x, h\rangle_E + \|h\|_E^2$, whence

$$Dq(x)[h] = 2\langle x, h\rangle_E, \qquad D^2 q(x)[h,k] = 2\langle h, k\rangle_E.$$

The second derivative is constant and all higher derivatives vanish; in particular, q is smooth, $Dq(0) = 0$, and $D^2 q(0) = 2B_0$. Consequently,

$$\mathscr{D}(q) = 2\Lambda(B_0) = 2.$$

In contrast, if $[\gamma] \in T_0^{\mathrm{kin}} E$ and $v := \gamma'(0)$, the chain rule gives

$$\mathcal{J}_0([\gamma])(q) = \frac{d}{dt}\bigg|_{t=0} q(\gamma(t)) = Dq(0)[v] = 0.$$

Thus $\mathscr{D}$ does not agree with $\mathcal{J}_0([\gamma])$ for any admissible curve γ, and $\mathcal{J}_0$ is not surjective. □

Since $\mathcal{J}_0$ is injective, it canonically identifies $T_0^{\mathrm{kin}}E$ with the subspace $\mathcal{J}_0(T_0^{\mathrm{kin}}E)$ of $T_0^{\mathrm{op}}E$; the proposition shows that this inclusion is proper. This means precisely that there are operational derivations that do not arise from velocities of curves and hence that the two tangent space constructions do not agree canonically in infinite dimensions. Failure of surjectivity of $\mathcal{J}_0$ does not by itself exclude the possible existence of an abstract noncanonical linear isomorphism between the two vector spaces: to rule out that possibility as well, one would need to compare, for example, their algebraic dimensions. Such a stronger assertion is unnecessary here; the geometrically relevant difference is that the natural identification provided by curves does not exhaust the space of derivations.

From now on, unless expressly stated otherwise, "tangent space" means the kinematic tangent space.

Definition 24.1.15. Let M be a Banach manifold of class C^k, with $k \geq 1$, and let $p \in M$. The **tangent space** of M at p is

$$T_pM := T_p^{\mathrm{kin}}M.$$

Its elements are equivalence classes of admissible curves. If (U,φ) is a chart around p modeled on a Banach space X, the associated bicontinuous linear isomorphism is

$$\Theta_{\varphi,p}\colon T_pM \longrightarrow X, \qquad [\gamma] \longmapsto \frac{d}{dt}\bigg|_{t=0} (\varphi\circ\gamma)(t).$$

Definition 24.1.16. Let $F\colon M \longrightarrow N$ be a map of class C^1 between Banach manifolds and let $p \in M$. The **differential of F at p** is the map

$$dF_p\colon T_pM \longrightarrow T_{F(p)}N, \qquad dF_p[\gamma] := [F\circ\gamma].$$

The preceding definition makes sense because $F\circ\gamma$ is a curve of class C^1 and satisfies $(F\circ\gamma)(0) = F(p)$. Moreover, it is independent of the representative of $[\gamma]$. Let (U,φ) be a chart of M around p and (V,ψ) a chart of N around $F(p)$. After restricting the domains, for every admissible curve γ at p we have

$$(\psi\circ F\circ\gamma)'(0) = d(\psi\circ F\circ\varphi^{-1})_{\varphi(p)}\big((\varphi\circ\gamma)'(0)\big).$$

If γ_1 and γ_2 represent the same vector in T_pM, their velocities in the chart φ agree, and the preceding formula shows that $F\circ\gamma_1$ and $F\circ\gamma_2$ have the same velocity in the chart ψ. Thus $[F\circ\gamma_1] = [F\circ\gamma_2]$.

The same formula gives the coordinate representation

$$\Theta_{\psi,F(p)}\circ dF_p\circ\Theta_{\varphi,p}^{-1} = d(\psi\circ F\circ\varphi^{-1})_{\varphi(p)}.$$

In particular, dF_p is a continuous linear operator. The chain rule for maps between open subsets of Banach spaces also implies that, if $G\colon N \longrightarrow P$ is of class C^1, then

$$d(G\circ F)_p = dG_{F(p)}\circ dF_p, \qquad d(\mathrm{id}_M)_p = \mathrm{id}_{T_pM}.$$

24.2 Complementability and linear decompositions

The local forms of submanifolds and maps of regular rank depend on a linear property that goes unnoticed in finite dimensions. A closed subspace of a Banach space need not admit a closed complement. Before studying

immersions and submersions, it is therefore useful to make precise the relation between topological complements, continuous projections, and one-sided inverses.

Definition 24.2.1. Let E be a Banach space and let $Y \subseteq E$ be a closed subspace. We say that Y is **complemented** in E if there exists a closed subspace $Z \subseteq E$ such that

$$E = Y \oplus Z.$$

This means that every $x \in E$ can be written uniquely as $x = y + z$, with $y \in Y$ and $z \in Z$. The subspace Z is called a **topological complement** of Y.

The word "topological" refers to the fact that both summands are Banach spaces with the induced norms and the projections determined by the decomposition are continuous. This last property is not an additional assumption, as the following characterization shows.

Proposition 24.2.2. (Characterization by continuous projections) Let E be a Banach space and $Y \subseteq E$ a closed subspace. The following assertions are equivalent.

(a) The subspace Y is complemented in E.

(b) There exists an operator $P \in \mathcal{L}(E)$ such that $P^2 = P$ and $\mathrm{Ran}(P) = Y$.

If (b) holds, then

$$E = Y \oplus \ker(P).$$

Proof. Suppose $E = Y \oplus Z$, with Y and Z closed. Equip $Y \times Z$ with the norm $\|(y,z)\| := \|y\| + \|z\|$. The operator

$$S \colon Y \times Z \longrightarrow E, \qquad S(y,z) := y + z,$$

is linear, continuous, and bijective. Since $Y \times Z$ and E are Banach spaces, Theorem B.2.17 ensures that S^{-1} is continuous. If pr_Y and pr_Z denote the coordinate projections of $Y \times Z$, the projections determined by the direct sum are

$$P_Y = \mathrm{pr}_Y \circ S^{-1}, \qquad P_Z = \mathrm{pr}_Z \circ S^{-1}.$$

Thus both are continuous. In particular, $P_Y^2 = P_Y$ and $\mathrm{Ran}(P_Y) = Y$.
Conversely, let $P \in \mathcal{L}(E)$ be a projection with range Y. The subspace $\ker(P)$ is closed. For each $x \in E$, we have

$$x = Px + (x - Px),$$

, where $Px \in Y$ and $P(x - Px) = 0$. Thus $E = Y + \ker(P)$. If $x \in Y \cap \ker(P)$, then $x = Py$ for some $y \in E$ and

$$x = Py = P^2 y = P(Py) = Px = 0.$$

The sum is direct and $E = Y \oplus \ker(P)$. □

Definition 24.2.3. (One-sided inverses) Let E and F be Banach spaces and let $T \in \mathcal{L}(E,F)$. An operator $L \in \mathcal{L}(F,E)$ is a **left inverse** of T if $L \circ T = I_E$, and an operator $R \in \mathcal{L}(F,E)$ is a **right inverse** of T if $T \circ R = I_F$. Both are called **one-sided inverses** of T.

Proposition 24.2.4. (One-sided inverses and complementability) Let E and F be Banach spaces and let $T \in \mathcal{L}(E,F)$.

(a) There exists $L \in \mathcal{L}(F,E)$ such that $L \circ T = I_E$ if and only if T is injective and $\mathrm{Ran}(T)$ is a complemented subspace of F.

(b) There exists $R \in \mathcal{L}(F,E)$ such that $T \circ R = I_F$ if and only if T is surjective and $\ker(T)$ is a complemented subspace of E.

In the first case, $T\colon E \longrightarrow \mathrm{Ran}(T)$ is a Banach space isomorphism. In the second, if $E = \ker(T) \oplus E_1$, then $T\restriction_{E_1}\colon E_1 \longrightarrow F$ is an isomorphism.

Proof. First suppose $L \circ T = I_E$. Then T is injective. The operator $P := T \circ L \in \mathcal{L}(F)$ satisfies

$$P^2 = T(LT)L = TL = P.$$

Moreover, $P(F) \subseteq \mathrm{Ran}(T)$ and $P(Tx) = T(LT)x = Tx$ for every $x \in E$. Consequently, $\mathrm{Ran}(T) = \mathrm{Ran}(P) = \ker(I_F - P)$. This subspace is closed, and Proposition 24.2.2 shows that this range is complemented.
Now suppose T is injective and $F = \mathrm{Ran}(T) \oplus Z$. Since the range is closed, $T\colon E \longrightarrow \mathrm{Ran}(T)$ is a continuous bijective linear operator between Banach spaces. Theorem B.2.17 implies that its inverse $T^{-1}\colon \mathrm{Ran}(T) \longrightarrow E$ is continuous. If $P_{\mathrm{Ran}(T)}\colon F \longrightarrow \mathrm{Ran}(T)$ is the continuous projection associated with the decomposition, then

$$L := T^{-1} \circ P_{\mathrm{Ran}(T)}$$

belongs to $\mathcal{L}(F,E)$ and satisfies $L \circ T = I_E$. This proves (a).
Suppose $T \circ R = I_F$. In particular, T is surjective. The operator $Q := R \circ T \in \mathcal{L}(E)$ is a projection, since

$$Q^2 = R(TR)T = RT = Q.$$

If $x \in \ker(Q)$, then $Tx = T(Qx) = 0$. The reverse inclusion is immediate, so $\ker(Q) = \ker(T)$. Likewise, $\mathrm{Ran}(Q) = \mathrm{Ran}(R)$. Since Q is a continuous projection, its range and kernel are closed, and Proposition 24.2.2 gives the topological decomposition

$$E = \ker(T) \oplus \mathrm{Ran}(R).$$

Conversely, suppose T is surjective and $E = \ker(T) \oplus E_1$. The restriction $T_1 := T\restriction_{E_1}\colon E_1 \longrightarrow F$ is injective. It is also surjective: given $y \in F$, choose $x \in E$ with $Tx = y$ and write $x = k + x_1$, with $k \in \ker(T)$ and $x_1 \in E_1$; then $T_1 x_1 = y$. Theorem B.2.17 shows that $T_1^{-1}\colon F \longrightarrow E_1$ is continuous. Composing this inverse with the inclusion $E_1 \hookrightarrow E$ gives a continuous right inverse of T. □

One-sided inverses persist under sufficiently small perturbations. This property explains why the local forms encountered below persist in a neighborhood of the point under consideration.

Corollary 24.2.5. (Stability of one-sided inverses) Let E and F be Banach spaces and let $T, S \in \mathcal{L}(E,F)$.

(a) If $L \in \mathcal{L}(F,E)$ satisfies $LT = I_E$ and $\|L(S-T)\|_{\mathcal{L}(E)} < 1$, then S admits the continuous left inverse

$$(LS)^{-1}L.$$

(b) If $R \in \mathcal{L}(F,E)$ satisfies $TR = I_F$ and $\|(S-T)R\|_{\mathcal{L}(F)} < 1$, then S admits the continuous right inverse

$$R(SR)^{-1}.$$

Proof. In the first case, $LS = I_E + L(S-T)$ is invertible by Theorem B.2.10; hence $(LS)^{-1}LS = I_E$. In the second, $SR = I_F + (S-T)R$ is invertible and $SR(SR)^{-1} = I_F$. □

Proposition 24.2.6. (Complements in the finite-dimensional and Hilbert space cases) Let E be a Banach space.

(a) Every finite-dimensional subspace of E is complemented.

(b) Every closed subspace of finite codimension in E is complemented.

(c) If E is a Hilbert space, every closed subspace of E is complemented.

Proof. Let $Y \subseteq E$ be finite-dimensional and choose a basis $y_1,\dots,y_m$ of Y. The coordinate functionals $\ell_j\colon Y \longrightarrow \mathbb{R}$ are continuous. By Corollary B.2.29, each ℓ_j has a continuous extension $\widetilde{\ell}_j \in E'$. The operator

$$P(x) := \sum_{j=1}^{m} \widetilde{\ell}_j(x) y_j$$

is a continuous projection onto Y. Proposition 24.2.2 proves (a).
Now let $Y \subseteq E$ be closed and of codimension $m < \infty$. Choose $e_1,\dots,e_m \in E$ whose classes form an algebraic basis of E/Y and set $Z := \operatorname{span}\{e_1,\dots,e_m\}$. Then Z is closed, $Y \cap Z = \{0\}$, and every element of E belongs to $Y + Z$. Thus $E = Y \oplus Z$.
Finally, if E is a Hilbert space and Y is closed, Corollary B.3.8 gives $E = Y \oplus Y^{\perp}$. □

24.3 Banach submanifolds

We now turn to the notion of submanifold. In finite dimensions, a subset is a submanifold if it can locally be straightened by a change of coordinates. This principle remains valid in Banach spaces, but an additional topological condition arises: the subspace describing the tangent directions must be complemented. In infinite dimensions, a closed subspace need not have a closed complement, so this property must be part of the definition.

Definition 24.3.1. Let M be a Banach manifold of class C^k and let $1 \le r \le k$. A subset $N \subseteq M$ is an **embedded submanifold of class** C^r if, for each $p \in N$, there exist a chart (U,φ) of class C^r on M around p, in the sense of Remark 24.1.4, with $\varphi(p) = 0$, and a topological decomposition $X = Y \oplus Z$ of the chart's model space into closed subspaces such that, upon identifying X with $Y \times Z$ through $(y,z) \mapsto y + z$,

$$\varphi(U \cap N) = \varphi(U) \cap (Y \times \{0\}).$$

A chart of class C^r with these properties is called an **adapted chart** for N at M. The subspace Y is the local model space of N in this chart.

The condition in Definition 24.3.1 does more than describe the local position of N inside M: it canonically

equips N with a Banach manifold structure.

Proposition 24.3.2. (Induced manifold structure on a submanifold) Let N be an embedded submanifold of class C^r of a Banach manifold M. Then N, with the subspace topology, is a Banach manifold of class C^r. If (U,φ) is an adapted chart, $X = Y \oplus Z$ is the corresponding decomposition, and $\pi_Y : X \longrightarrow Y$ is the canonical projection, then

$$\varphi_N := \pi_Y \circ \varphi \restriction_{U\cap N}$$

is a chart on N. The canonical inclusion $\iota\colon N \hookrightarrow M$ is of class C^r and, for each $p \in N$, the differential $d\iota_p$ identifies T_pN with a closed complemented subspace of T_pM.

Proof. Let (U,φ) be an adapted chart around $p \in N$, with $\varphi(p) = 0$ and $X = Y \oplus Z$. Define

$$V_Y := \{y \in Y \mid (y,0) \in \varphi(U)\}.$$

The linear inclusion $\iota_Y : Y \longrightarrow X$, given by $\iota_Y(y) = (y,0)$, is continuous, and $V_Y = \iota_Y^{-1}(\varphi(U))$. Since $\varphi(U)$ is open in X, the set V_Y is open in Y.
By the adapted chart condition, every point of $\varphi(U \cap N)$ has the form $(y,0)$ with $y \in V_Y$. Consequently, $\varphi_N : U \cap N \longrightarrow V_Y$ is bijective. Its inverse is given by

$$\varphi_N^{-1}(y) = \varphi^{-1}(y,0), \qquad y \in V_Y.$$

Continuity of φ_N follows from continuity of $\varphi \restriction_{U\cap N}$ and Proposition 24.2.2; continuity of φ_N^{-1} follows from continuity of φ^{-1} and ι_Y. Thus φ_N is a homeomorphism for the subspace topology on N.
Consider two adapted charts (U_1,φ_1) and (U_2,φ_2) with decompositions $X_1 = Y_1 \oplus Z_1$ and $X_2 = Y_2 \oplus Z_2$. On the corresponding overlap, the coordinate change between the induced charts on N can be written as

$$\varphi_{N,2} \circ \varphi_{N,1}^{-1} = \pi_{Y_2} \circ \varphi_2 \circ \varphi_1^{-1} \circ \iota_{Y_1}.$$

The inclusions ι_{Y_1} and projections π_{Y_2} are continuous and linear, while $\varphi_2 \circ \varphi_1^{-1}$ is of class C^r. The chain rule shows that the coordinate change is of class C^r. Interchanging the indices gives the same regularity for its inverse. Thus the charts φ_N form a Banach atlas of class C^r on N. Since N is a subspace of a Hausdorff space, it is also Hausdorff, establishing its Banach manifold structure.
In the coordinates of an adapted chart, the canonical inclusion $\iota\colon N \hookrightarrow M$ is represented by the continuous linear operator

$$\iota_Y : Y \longrightarrow Y \oplus Z, \qquad \iota_Y(y) = (y,0).$$

Thus ι is of class C^r. Moreover, $d\iota_p$ is represented by ι_Y, whose image is $Y \times \{0\}$. This subspace is closed and complemented by $\{0\} \times Z$, so T_pN is identified with a closed complemented subspace of T_pM. □

Adapted charts also allow us to recognize when a map with image in N is differentiable as a map into the submanifold itself.

Lemma 24.3.3. (Maps into a submanifold) Let $N \subseteq M$ be an embedded submanifold of class C^r, let P be a Banach manifold of class at least C^s, and suppose $1 \le s \le r$. If $F : P \longrightarrow M$ has image contained in N, then F is of class C^s if and only if its corestriction $\widehat{F} : P \longrightarrow N$ is of class C^s.

Proof. If $\widehat{F}$ is of class C^s, so is $F = \iota \circ \widehat{F}$, since the inclusion $\iota\colon N \longrightarrow M$ is of class C^r. Conversely, suppose F is of class C^s. Since N has the subspace topology, the corestriction $\widehat{F}$ is continuous. Given $p \in P$, choose an adapted chart (U, φ) of M around $F(p)$, with decomposition $X = Y \oplus Z$. On the open set $F^{-1}(U)$, the representation of $\widehat{F}$ in the induced chart φ_N is

$$\varphi_N \circ \widehat{F} = \pi_Y \circ \varphi \circ F.$$

After introducing a chart of P, the right-hand side is a composition of maps of class C^s, since φ is of class C^r and π_Y is continuous and linear. Consequently, $\widehat{F}$ is of class C^s near p. Since p was arbitrary, it is of this class on all of P. □

Remark 24.3.4. By Theorem 23.3.8, the description through adapted charts is equivalent to locally representing the subset, after a change of coordinates, as the graph of a map of class C^r of the form $h\colon A \longrightarrow Z$, where $A \subseteq Y$ is open. The adapted chart description directly displays the tangent space and its complement in the ambient space.

When the complement Z can be chosen of finite dimension m, we say that N has codimension m. In particular, a submanifold of codimension one is locally modeled on the kernel of a nonzero continuous linear functional. This situation arises naturally in regular level sets and variational constraints.

24.4 Fundamental examples of Banach submanifolds

The adapted charts in Definition 24.3.1 can be constructed explicitly in several basic examples. These examples also show how complementability determines the tangent geometry.

Proposition 24.4.1. (Complemented subspaces and their translates) Let E be a Banach space, let $Y \subseteq E$ be a closed complemented subspace, and let $a \in E$. Then $a + Y$ is a smooth embedded submanifold of E. If $\iota\colon a + Y \longrightarrow E$ is the inclusion and $\Theta_{\mathrm{id}_E, x}\colon T_x E \longrightarrow E$ is the bicontinuous linear isomorphism in Proposition 24.1.10, then

$$\Theta_{\mathrm{id}_E, x}\big(d\iota_x(T_x(a + Y))\big) = Y$$

for every $x \in a + Y$.

Proof. Choose a closed complement Z such that $E = Y \oplus Z$. For each $x \in a + Y$, the translation

$$\varphi_x\colon E \longrightarrow E, \qquad \varphi_x(u) := u - x,$$

is a smooth diffeomorphism, $\varphi_x(x) = 0$, and

$$\varphi_x(a + Y) = Y \times \{0\},$$

, where E is identified with $Y \times Z$. Thus φ_x is an adapted chart. In these coordinates, the inclusion of $a + Y$ into E is represented by $y \mapsto (y, 0)$, whose differential has image Y. □

Proposition 24.4.2. (Tangent space to a graph) Let E and F be Banach spaces, let $U \subseteq E$ be open, and let $h \in C^r(U,F)$, with $r \geq 1$. Then

$$\operatorname{graf}(h) := \{(x, h(x)) \in E \times F \mid x \in U\}$$

is an embedded submanifold of class C^r of the open set $U \times F$. Moreover, if $\iota\colon \operatorname{graf}(h) \longrightarrow U \times F$ is the inclusion, then

$$\Theta_{\mathrm{id}_{U\times F},(x,h(x))}\big(d\iota_{(x,h(x))}(T_{(x,h(x))}\operatorname{graf}(h))\big) = \{(v, Dh(x)v) \mid v \in E\}.$$

Proof. The graph description of submanifolds in Remark 24.3.4 can be seen directly. Fix $x_0 \in U$ and consider the diffeomorphism

$$\Phi_{x_0}\colon U \times F \longrightarrow (U - x_0) \times F, \qquad \Phi_{x_0}(x,y) := (x - x_0, y - h(x)).$$

The map Φ_{x_0} is of class C^r, its inverse is given by

$$\Phi_{x_0}^{-1}(\xi, z) = (\xi + x_0, z + h(\xi + x_0)),$$

, and it satisfies

$$\Phi_{x_0}(x_0, h(x_0)) = (0,0), \qquad \Phi_{x_0}(\operatorname{graf}(h)) = (U - x_0) \times \{0\}.$$

Thus Φ_{x_0} is a chart of class C^r compatible with the underlying C^r structure of $U \times F$ and adapted at $(x_0, h(x_0))$. The differential of the parametrization $x \mapsto (x, h(x))$ at x_0 is given by $v \mapsto (v, Dh(x_0)v)$, yielding the tangent space formula, since x_0 was arbitrary. This space is complemented by $\{0\} \times F$, since, for each $(u,w) \in E \times F$,

$$(u,w) = (u, Dh(x_0)u) + (0, w - Dh(x_0)u).$$

□

Example 24.4.3. (Hyperplanes and spheres) Let E be a real Banach space.

(a) If $\ell \in E'$ is nonzero and $c \in \mathbb{R}$, then $\ell^{-1}(c)$ is a smooth embedded submanifold of codimension one. Indeed, if $e \in E$ satisfies $\ell(e) = 1$, then $E = \ker(\ell) \oplus \mathbb{R}e$ and

$$\ell^{-1}(c) = ce + \ker(\ell).$$

Proposition 24.4.1 shows that this affine hyperplane is an embedded submanifold. If $\iota_c\colon \ell^{-1}(c) \longrightarrow E$ is the inclusion, for every $x \in \ell^{-1}(c)$ we have

$$\Theta_{\mathrm{id}_E,x}\big(d(\iota_c)_x(T_x\ell^{-1}(c))\big) = \ker(\ell).$$

(b) Let $r \geq 1$ and suppose the norm on E is of class C^r on $E \setminus \{0\}$. Set

$$S_E := \{x \in E \mid \|x\|_E = 1\}.$$

For each $x \in S_E$, homogeneity of the norm implies

$$D\|\cdot\|_E(x)(x) = \frac{d}{dt}\bigg|_{t=0} \|(1+t)x\|_E = \|x\|_E.$$

Thus $D\|\cdot\|_E(x) \neq 0$ on the unit sphere. To obtain an adapted chart, fix $x \in S_E$ and set $Y := \ker(D\|\cdot\|_E(x))$. We have $E = Y \oplus \mathbb{R}x$. The map

$$F_x \colon \mathcal{O}_x \longrightarrow \mathbb{R}, \qquad F_x(y,t) := \|x + y + tx\|_E - 1,$$

, where $\mathcal{O}_x$ is a sufficiently small open neighborhood of $(0,0)$ in $Y \times \mathbb{R}$ that $x + y + tx \neq 0$, is of class C^r and satisfies $F_x(0,0) = 0$ and $D_2F_x(0,0)(s) = s$. Theorem 23.3.8 locally represents the set $F_x^{-1}(0)$ as the graph of a function of class C^r on Y. If h denotes this function, the derivative formula for the implicit function gives

$$Dh(0) = -D_2F_x(0,0)^{-1} \circ D_1F_x(0,0) = 0,$$

, since $D_1F_x(0,0)$ is the restriction of $D\|\cdot\|_E(x)$ to Y. In particular, the graph has tangent space $Y \times \{0\}$ at the origin. The coordinate change that subtracts this function in the second variable straightens the graph onto $Y \times \{0\}$. Thus S_E is an embedded submanifold of class C^r. Differentiating the identity defining the sphere gives, if $\iota_S \colon S_E \longrightarrow E$ denotes the inclusion,

$$\Theta_{\mathrm{id}_E,x}\big(d(\iota_S)_x(T_xS_E)\big) = \ker\big(D\|\cdot\|_E(x)\big).$$

If E is a real Hilbert space, we may take $q(x) := \|x\|_E^2$; then $Dq(x)v = 2\langle x, v\rangle_E$ and $\Theta_{\mathrm{id}_E,x}\big(d(\iota_S)_x(T_xS_E)\big) = x^\perp$.

Example 24.4.4. (The group of invertible operators) Let E be a Banach space. The set

$$\mathrm{GL}(E) := \{A \in \mathcal{L}(E) \mid A \text{ is invertible}\}$$

is open in the Banach space $\mathcal{L}(E)$ by Proposition 23.3.2. Thus $\mathrm{GL}(E)$ is a smooth Banach manifold, and

$$\Theta_{\mathrm{id}_{\mathrm{GL}(E)},A} \colon T_A\,\mathrm{GL}(E) \longrightarrow \mathcal{L}(E)$$

is a bicontinuous linear isomorphism for every $A \in \mathrm{GL}(E)$. Operator composition is continuous and bilinear and, by Proposition 23.2.4, smooth. The map $A \mapsto A^{-1}$ is also smooth and satisfies

$$D(A \mapsto A^{-1})(A)H = -A^{-1}HA^{-1}.$$

24.5 Immersions, submersions, and embeddings

In finite dimensions, injectivity or surjectivity of the differential alone provides the local inclusion and projection forms. On Banach manifolds, one must also retain the topological information contained in a one-sided inverse. Proposition 24.2.4 allows this condition to be expressed through complemented kernels and images. The resulting local forms are those commonly used in infinite-dimensional differential geometry; more general formulations may be found in [67, 2, 91].

Definition 24.5.1. Let M and N be Banach manifolds of class C^k, let $f\colon M \longrightarrow N$ be a map of class C^r, with $1 \le r \le k$, and let $p \in M$.

(a) We say that f is a **weak immersion at** p if $df_p\colon T_pM \longrightarrow T_{f(p)}N$ is injective.

(b) We say that f is a **split immersion at** p if df_p admits a continuous linear left inverse.

(c) We say that f is a **weak submersion at** p if df_p is surjective.

(d) We say that f is a **split submersion at** p if df_p admits a continuous linear right inverse.

The map f is a weak immersion, a split immersion, a weak submersion, or a split submersion if it has the corresponding property at every point of M. From now on, within the category of Banach manifolds, **immersion** and **submersion** mean the split versions unless expressly stated otherwise.

The condition is intrinsic: differentials of coordinate changes are continuous linear isomorphisms, and existence of a one-sided inverse is preserved under composition on either side with isomorphisms. Proposition 24.2.4 gives the characterizations

$$\begin{aligned} f \text{ is a split immersion at } p &\iff df_p \text{ is injective and } \operatorname{Ran}(df_p) \text{ is complemented},\\ f \text{ is a split submersion at } p &\iff df_p \text{ is surjective and } \ker(df_p) \text{ is complemented}. \end{aligned}$$

In the first equivalence, the image is automatically closed. Thus mere injectivity, injectivity with closed image, and injectivity with closed complemented image are distinct conditions.

Theorem 24.5.2. (Local form of split immersions) Let $f\colon M \longrightarrow N$ be a map of class C^r between Banach manifolds, with $r \ge 1$, and let $p \in M$. The following assertions are equivalent.

(a) The map f is a split immersion at p.

(b) There exist charts of class C^r, (U,φ) of M around p and (V,ψ) of N around $f(p)$, Banach spaces E and Z, and an identification of the model space of V with $E \oplus Z$ such that $\varphi(p) = 0$, $\psi(f(p)) = (0,0)$, and

$$(\psi \circ f \circ \varphi^{-1})(x) = (x, 0)$$

for every $x \in \varphi(U)$.

In particular, if f is a split immersion at p, after shrinking U the map $f\restriction_U$ is injective and is a split immersion at every point of U.

Proof. Suppose (a). Take initial charts around p and $f(p)$. Composing them with translations reduces the problem to a map $F\colon \Omega \subseteq E \longrightarrow \Theta \subseteq H$ of class C^r, where Ω and Θ are open sets containing the origin, such that $F(0) = 0$ and $A := DF(0)$ admits a continuous left inverse. By Proposition 24.2.4, the subspace $R := \operatorname{Ran}(A)$ is closed, and there exists a closed subspace $Z \subseteq H$ such that $H = R \oplus Z$. Denote the continuous projections by $P_R\colon H \longrightarrow R$ and $P_Z\colon H \longrightarrow Z$.
The operator $A\colon E \longrightarrow R$ is an isomorphism. Consider

$$G\colon \Omega \longrightarrow R, \qquad G(x) := P_R F(x).$$

We have $DG(0) = A$. Theorem 23.3.3 gives open sets $\Omega_0 \subseteq \Omega$ and $W \subseteq R$ containing the origin such that $G\restriction_{\Omega_0} : \Omega_0 \longrightarrow W$ is a diffeomorphism of class C^r. In the new coordinate $y = G(x)$, write

$$F\big(G^{-1}(y)\big) = y + h(y), \qquad h(y) := P_Z F\big(G^{-1}(y)\big) \in Z.$$

Since $h(0) = 0$ and Θ is open, there exist open neighborhoods $W_0 \subseteq W$ and $Z_0 \subseteq Z$ of the origin such that

$$W_0 \times Z_0 \subseteq \Theta, \qquad h(W_0) \subseteq Z_0.$$

Shrink Ω_0 to $G^{-1}(W_0)$. The triangular map

$$\Xi\colon W_0 \times Z \longrightarrow W_0 \times Z, \qquad \Xi(y,z) := (y, z - h(y)),$$

is a diffeomorphism of class C^r, with inverse $\Xi^{-1}(y,z) = (y, z + h(y))$. After restricting it to an open neighborhood $W_0 \times Z_0$ of the origin, its image $\Xi(W_0 \times Z_0)$ is open and $\Xi\restriction_{W_0\times Z_0}$ is a diffeomorphism onto that image. Inclusion $h(W_0) \subseteq Z_0$ ensures that the points in the image of F under consideration lie in the domain of this new chart, giving

$$\Xi\Big(F\big(G^{-1}(y)\big)\Big) = (y, 0).$$

Finally, the isomorphism $A\colon E \longrightarrow R$ allows us to postcompose the coordinate G with A^{-1} and the first component of the codomain coordinate with the same isomorphism. In this way, both first factors are identified with the model space E, and the preceding expression becomes $x \mapsto (x, 0)$. Transporting these coordinate changes to M and N gives (b).

Conversely, in the coordinates of (b), the differential of f at p is represented by the inclusion

$$E \longrightarrow E \oplus Z, \qquad v \longmapsto (v, 0),$$

, which admits projection onto E as a left inverse. The chart differentials are isomorphisms, so df_p also admits a continuous left inverse.

The local expression $(x, 0)$ shows both injectivity of $f\restriction_U$ and persistence of the split condition on U. □

Theorem 24.5.3. (Local form of split submersions) Let $f : M \longrightarrow N$ be a map of class C^r between Banach manifolds, with $r \geq 1$, and let $p \in M$. The following assertions are equivalent.

(a) The map f is a split submersion at p.

(b) There exist charts of class C^r, (U, φ) of M around p and (V, ψ) of N around $f(p)$, and a Banach space K, such that the model space of U is identified with $K \oplus F$, where F is the model space of V, and

$$(\psi \circ f \circ \varphi^{-1})(k, y) = y$$

for every $(k, y) \in \varphi(U)$.

In particular, every split submersion is locally open, admits local sections around every point of its image, and remains a split submersion in a neighborhood of the point under consideration.

Proof. Suppose (a) and work in centered charts, so the map is represented by $F\colon \Omega \subseteq E \longrightarrow H$, with $F(0) = 0$. Let $T := DF(0)$. By Proposition 24.2.4, there exists a closed subspace $E_1 \subseteq E$ such that

$$E = K \oplus E_1, \qquad K := \ker(T),$$

and $T_1 := T\restriction_{E_1} : E_1 \longrightarrow H$ is an isomorphism. Let $P_K : E \longrightarrow K$ be the continuous projection and define

$$\Gamma\colon \Omega \longrightarrow K \times H, \qquad \Gamma(x) := (P_K x, F(x)).$$

If $x = k + e_1$, then

$$D\Gamma(0)(k + e_1) = (k, T_1 e_1).$$

This operator is an isomorphism from E onto $K \times H$, with inverse $(k, y) \mapsto k + T_1^{-1} y$. Theorem 23.3.3 shows that Γ is a diffeomorphism of class C^r between neighborhoods of the origin. Since the second component of Γ is F, in the coordinate $(k, y) = \Gamma(x)$ we have

$$F\big(\Gamma^{-1}(k, y)\big) = y.$$

This proves (b).
If (b) holds, the differential is represented by the projection $K \oplus F \longrightarrow F$, which admits the right inverse $y \mapsto (0, y)$. This proves the equivalence.
In these coordinates, the image of any sufficiently small open product is open. Moreover, the map $y \mapsto (0, y)$, transported through the charts, provides a local section. Persistence of the property follows from the same normal form. □

Definition 24.5.4. Let M and N be Banach manifolds. A map $f\colon M \longrightarrow N$ of class C^r, with $r \geq 1$, is called a **split embedding** if it is a split immersion, is injective, and the map

$$f\colon M \longrightarrow f(M)$$

is a homeomorphism when $f(M)$ is equipped with the subspace topology from N.

Proposition 24.5.5. (Embeddings and embedded submanifolds) Let $f\colon M \longrightarrow N$ be a map of class C^r between Banach manifolds, with $r \geq 1$.

(a) If f is a split embedding, then $f(M)$ is an embedded submanifold of class C^r of N, and $f\colon M \longrightarrow f(M)$ is a diffeomorphism.

(b) If $S \subseteq N$ is an embedded submanifold of class C^r, its inclusion $S \hookrightarrow N$ is a split embedding.

(c) If $f(M)$ is an embedded submanifold and $f\colon M \longrightarrow f(M)$ is a diffeomorphism, then f is a split embedding.

Proof. Suppose f is a split embedding and fix $p \in M$. By Theorem 24.5.2, there exist neighborhoods $U \subseteq M$ of p and $V \subseteq N$ of $f(p)$, with charts $\varphi\colon U \longrightarrow \varphi(U) \subseteq E$ and $\psi\colon V \longrightarrow \psi(V) \subseteq E \oplus Z$, in which

$$(\psi \circ f \circ \varphi^{-1})(x) = (x, 0).$$

Since $f\colon M \longrightarrow f(M)$ is a homeomorphism, $f(U)$ is open in $f(M)$. Thus there exists an open set $O \subseteq N$ such that $f(U) = O \cap f(M)$. The set $\psi(V \cap O)$ is an open subset of the space $E \oplus Z$ containing the origin. Choose open neighborhoods $W_E \subseteq E$ and $W_Z \subseteq Z$ of the origin so that

$$W_E \subseteq \varphi(U), \qquad W_E \times W_Z \subseteq \psi(V \cap O).$$

Define

$$U_0 := \varphi^{-1}(W_E), \qquad V_0 := \psi^{-1}(W_E \times W_Z).$$

The local form of f shows that $f(U_0) \subseteq V_0 \cap f(M)$. Conversely, if $q \in V_0 \cap f(M)$, then $q \in O \cap f(M) = f(U)$. Writing $q = f(x)$ with $x \in U$ gives $\psi(q) = (\varphi(x), 0)$. Since $\psi(q) \in W_E \times W_Z$, it follows that $\varphi(x) \in W_E$ and therefore $x \in U_0$. We have proved the equality $f(U_0) = V_0 \cap f(M)$ and consequently

$$\psi(V_0 \cap f(M)) = W_E \times \{0\} = \psi(V_0) \cap (E \times \{0\}).$$

Thus $\psi \restriction_{V_0}$ is an adapted chart for $f(M)$. The same local expression shows that the corestriction of f and its inverse are of class C^r.

The second assertion follows from Proposition 24.3.2: the inclusion is of class C^r, is a homeomorphism onto its image, and its differential is the inclusion of a closed complemented subspace. The third assertion follows by composing the diffeomorphism $M \longrightarrow f(M)$ with the split inclusion $f(M) \hookrightarrow N$. □

Remark 24.5.6. (Phenomena specific to infinite dimensions) The conditions in Definition 24.5.1 cannot be reduced to injectivity or surjectivity of the differential.

(a) The linear inclusion $I\colon \ell^1 \longrightarrow \ell^2$ is continuous and injective, but its image is not closed. If the first N terms of $x^{(N)}$ are equal to $\frac{1}{N}$ and the remaining terms are zero, then

$$\|x^{(N)}\|_{\ell^1} = 1, \qquad \|Ix^{(N)}\|_{\ell^2} = \frac{1}{\sqrt{N}} \longrightarrow 0.$$

If the image were closed, Theorem B.2.17 applied to $I\colon \ell^1 \longrightarrow \operatorname{Ran}(I)$ would give a constant $C > 0$ such that $\|x\|_{\ell^1} \le C\|Ix\|_{\ell^2}$, contradicting this sequence. Thus the image is not closed. In particular, I admits no continuous left inverse and, regarded as a map between Banach manifolds, is a weak immersion that is not a split immersion; indeed, by linearity, $dI_x = I$ at every $x \in \ell^1$.

(b) The subspace $c_0 := \{x = (x_n) \in \ell^\infty \mid x_n \longrightarrow 0\}$ is closed in ℓ^∞, since a uniform limit of sequences tending to zero also tends to zero. However, c_0 is not complemented; this last assertion is the classical theorem of Phillips. Consequently, the inclusion $c_0 \hookrightarrow \ell^\infty$ is a linear map that is a homeomorphism onto its image and has injective differential with closed image, but is not a split immersion. Its differential at every point is the inclusion itself.

Noncomplementability of c_0 in ℓ^∞ is Phillips's Theorem 7.5 [117, p. 539]. Its proof uses the representation of the dual of ℓ^∞ by finitely additive measures and a weak convergence argument that is not needed in the rest of the book. Here it is used only to exhibit a closed subspace whose inclusion is not split; no later result depends on that dual representation.

(c) The canonical projection

$$\pi\colon \ell^\infty \longrightarrow \ell^\infty/c_0$$

is linear, continuous, and surjective. Since c_0 is closed, the quotient ℓ^∞/c_0 is a Banach space by Proposition B.2.20. At each point, the differential of the projection is π and its kernel is c_0. If it admitted a continuous linear right inverse, Proposition 24.2.4 would imply that $\ker(\pi) = c_0$ is complemented in ℓ^∞, which is false. Thus π is a weak submersion that is not a split submersion.

24.6 Constant rank and preimage theorems

For an operator between infinite-dimensional spaces, rank is not adequately described by an integer. The local form corresponding to the rank theorem requires simultaneous control of the kernel, the image, and their complements. The following assumption expresses that, near the basepoint, the images of the differentials retain a common complement in the codomain.

Theorem 24.6.1. (Constant rank with complemented decompositions) Let E and F be Banach spaces, let $\Omega \subseteq E$ be open, and let $f \in C^r(\Omega, F)$, with $r \geq 1$. Fix $a \in \Omega$ and set

$$A := Df(a), \qquad K := \ker(A), \qquad R := \operatorname{Ran}(A).$$

Suppose there exist closed subspaces $X \subseteq E$ and $C \subseteq F$ such that

$$E = K \oplus X, \qquad F = R \oplus C,$$

and these direct sums are topological. Suppose, moreover, that there exists an open neighborhood $\Omega_1 \subseteq \Omega$ of a for which

$$F = \operatorname{Ran}(Df(x)) \oplus C \tag{24.2}$$

is a topological direct sum for every $x \in \Omega_1$. Then there exist open sets $W_R \subseteq R$ and $W_K \subseteq K$ containing the origin, an open set $U_0 \subseteq \Omega_1$ containing a, an open set $V_0 \subseteq F$ containing $f(a)$, and diffeomorphisms of class C^r

$$\alpha \colon U_0 \longrightarrow W_R \times W_K, \qquad \beta \colon V_0 \longrightarrow \beta(V_0) \subseteq R \times C,$$

such that $\alpha(a) = (0,0)$, $\beta(f(a)) = (0,0)$, and

$$(\beta \circ f \circ \alpha^{-1})(y,k) = (y,0)$$

for every $(y,k) \in W_R \times W_K$. The open set V_0 can be chosen inside any previously specified open neighborhood of $f(a)$.

Proof. Denote by $P_K \colon E \longrightarrow K$, $P_X \colon E \longrightarrow X$, $P_R \colon F \longrightarrow R$, and $P_C \colon F \longrightarrow C$ the continuous projections associated with the decompositions in the statement. Since $K = \ker(A)$ and $R = \operatorname{Ran}(A)$, the restriction

$$A_X := A \restriction_X \colon X \longrightarrow R$$

is linear and bijective. Theorem B.2.17 implies that $A_X^{-1} \colon R \longrightarrow X$ is continuous.
Define

$$G \colon \Omega_1 \longrightarrow R \times K, \qquad G(x) := \big(P_R(f(x) - f(a)), P_K(x-a)\big).$$

If $v = k + \xi$, with $k \in K$ and $\xi \in X$, then

$$DG(a)v = (A_X\xi, k).$$

This operator is an isomorphism from E onto $R \times K$; its inverse is $(y,k) \mapsto k + A_X^{-1}y$. By Theorem 23.3.3, after shrinking Ω_1 there exist an open set $U_1 \subseteq \Omega_1$ containing a and an open set $W \subseteq R \times K$ containing $(0,0)$ such that $G\restriction_{U_1} : U_1 \longrightarrow W$ is a diffeomorphism of class C^r. We may choose open balls $W_R \subseteq R$ and $W_K \subseteq K$, centered at the origin, such that $W_R \times W_K \subseteq W$, and replace U_1 by the preimage of this product.
In the coordinates $(y,k) = G(x)$, set

$$\widetilde{f}(y,k) := f\left(G^{-1}(y,k)\right) - f(a).$$

The definition of G implies $P_R\widetilde{f}(y,k) = y$. Thus there exists a map $h \in C^r(W_R \times W_K, C)$ such that

$$\widetilde{f}(y,k) = (y, h(y,k)).$$

Fix $(y,k) \in W_R \times W_K$ and $\eta \in K$. We have

$$D\widetilde{f}(y,k)(0,\eta) = (0, D_2h(y,k)\eta).$$

This vector belongs to C. On the other hand, the chain rule and invertibility of $DG^{-1}(y,k)$ show that

$$\operatorname{Ran}(D\widetilde{f}(y,k)) = \operatorname{Ran}\left(Df\left(G^{-1}(y,k)\right)\right).$$

The direct sum in (24.2) implies that the intersection of this range with C is trivial. It follows that $D_2h(y,k)\eta = 0$ for every $\eta \in K$, and consequently

$$D_2h(y,k) = 0.$$

The ball W_K can be chosen convex. For $y \in W_R$ and $k \in W_K$, the integral mean value formula in Theorem 23.1.11 gives

$$h(y,k) - h(y,0) = \int_0^1 D_2h(y,tk)k\,dt = 0.$$

Thus $h(y,k) = h(y,0)$. Define the triangular change of coordinates

$$\Xi\colon W_R \times C \longrightarrow W_R \times C, \qquad \Xi(y,z) := (y, z - h(y,0)).$$

Its inverse is given by $\Xi^{-1}(y,z) = (y, z + h(y,0))$, so Ξ is a diffeomorphism of class C^r. Moreover,

$$\Xi(\widetilde{f}(y,k)) = (y,0).$$

Since $h(0,0) = 0$, choose an open ball $W_C \subseteq C$ centered at the origin and shrink W_R, if necessary, so that

$$h(y,0) \in W_C$$

for every $y \in W_R$. Given an open neighborhood of $f(a)$ in F in advance, the balls W_R and W_C can also be chosen so that their image under the sum isomorphism $R \times C \longrightarrow F$, translated by $f(a)$, is contained in that neighborhood.

Take

$$U_0 := G^{-1}(W_R \times W_K)$$

and define $\alpha := G \restriction_{U_0}$. Likewise, let

$$V_0 := f(a) + \{y + z \mid y \in W_R,\ z \in W_C\}.$$

This set is open in F because the sum map $R \times C \longrightarrow F$ is a topological isomorphism. The map

$$\beta\colon V_0 \longrightarrow \Xi(W_R \times W_C), \qquad \beta(v) := \Xi\big(P_R(v - f(a)), P_C(v - f(a))\big),$$

is a diffeomorphism of class C^r, satisfies $\beta(f(a)) = (0,0)$, and, for $(y,k) \in W_R \times W_K$, satisfies

$$(\beta \circ f \circ \alpha^{-1})(y,k) = (y,0).$$

These are the required diffeomorphisms. □

Theorem 24.6.2. (Constant rank on Banach manifolds) Let M and N be Banach manifolds and let $f : M \longrightarrow N$ be a map of class C^r, with $r \geq 1$. Fix $p \in M$. Suppose that, in charts centered at p and $f(p)$, a coordinate representation

$$F\colon \Omega \subseteq E \longrightarrow H, \qquad F(0) = 0,$$

has the following property. If

$$A := DF(0), \qquad K := \ker(A), \qquad R := \operatorname{Ran}(A),$$

, there exist closed subspaces $X \subseteq E$ and $C \subseteq H$ such that

$$E = K \oplus X, \qquad H = R \oplus C,$$

as topological direct sums, and C remains a topological complement of $\operatorname{Ran}(DF(x))$ for every x in a neighborhood of the origin. Then there exist charts of class C^r in which f has the form

$$(y,k) \longmapsto (y,0).$$

In particular, locally f factors as the projection $R \times K \longrightarrow R$ followed by the inclusion $R \hookrightarrow R \times C$. Its local image is an embedded submanifold, and its local fibers are embedded submanifolds modeled on K.

Proof. Apply Theorem 24.6.1 to the coordinate representation of f, choosing the open set V_0 inside the image of the initial codomain chart. Composing the resulting diffeomorphisms with the initial charts gives charts of class C^r, as in Remark 24.1.4. The assertions about the image, fibers, and factorization follow directly from the expression $(y,k) \mapsto (y,0)$. □

The common complement assumption in the preceding theorem replaces the numerical constancy of rank used in finite dimensions. A particular fixed complement need not be preserved under a nonlinear change of coordinates. The conclusion, however, is intrinsic: existence of charts in which the map has the form $(y,k) \mapsto (y,0)$ does not depend on the initial charts used to construct them.

Proposition 24.6.3. (Preimage of a submanifold under a submersion) Let M and N be Banach manifolds, let $f : M \longrightarrow N$ be a split submersion of class C^r, with $r \geq 1$, and let $S \subseteq N$ be an embedded submanifold of class C^r. Then $f^{-1}(S)$ is an embedded submanifold of class C^r of M. The restriction

$$f \restriction_{f^{-1}(S)} \colon f^{-1}(S) \longrightarrow S$$

is a split submersion and, for each $p \in f^{-1}(S)$, if $\iota \colon f^{-1}(S) \longrightarrow M$ and $\jmath \colon S \longrightarrow N$ are the inclusions, then

$$d\iota_p\big(T_p(f^{-1}(S))\big) = (df_p)^{-1}\big(d\jmath_{f(p)}(T_{f(p)}S)\big). \tag{24.3}$$

Proof. If $f^{-1}(S) = \varnothing$, all assertions hold vacuously. Thus suppose $f^{-1}(S) \neq \varnothing$. Fix $p \in f^{-1}(S)$ and write $q := f(p)$. Choose a chart (V, ψ) of N adapted to S at q. After translating the origin and identifying the model space with a sum $Y \oplus Z$, we have

$$\psi(V \cap S) = \psi(V) \cap (Y \times \{0\}).$$

Take an initial chart of M around p and represent f in these coordinates, retaining the adapted chart ψ in the codomain. The differential of the representation admits a continuous right inverse. The construction in the proof of Theorem 24.5.3, which leaves the codomain coordinate unchanged, gives a domain chart in which

$$f(k, y, z) = (y, z),$$

, where the domain model space is identified with $K \oplus Y \oplus Z$. In these coordinates,

$$f^{-1}(S) = \{(k, y, 0) \mid (k, y, 0) \text{ belongs to the chart domain}\}.$$

This set is the intersection of the domain with the complemented subspace $K \oplus Y \oplus \{0\}$. Thus the chart is adapted to $f^{-1}(S)$.
The restriction of f is represented by the projection

$$K \oplus Y \longrightarrow Y, \qquad (k, y) \longmapsto y,$$

, which admits the right inverse $y \mapsto (0, y)$. Finally, the differential of f in these coordinates is $(k, y, z) \mapsto (y, z)$, and the preimage of $Y \times \{0\}$ is $K \oplus Y \oplus \{0\}$. This proves (24.3). □

Definition 24.6.4. Let M and N be Banach manifolds and let $f : M \longrightarrow N$ be a map of class C^r, with $r \geq 1$. A point $q \in N$ is called a **split regular value** of f if, for each $p \in f^{-1}(q)$, the differential

$$df_p \colon T_pM \longrightarrow T_qN$$

admits a continuous linear right inverse. Equivalently, df_p is surjective and $\ker(df_p)$ is complemented in T_pM for every $p \in f^{-1}(q)$. If $f^{-1}(q) = \varnothing$, the condition is deemed satisfied.

Theorem 24.6.5. (Preimage theorem) Let M and N be Banach manifolds, let $f\colon M \longrightarrow N$ be a map of class C^r, with $r \geq 1$, and let $q \in N$ be a split regular value of f. Then $f^{-1}(q)$ is an embedded submanifold of class C^r of M and, if $\iota_q\colon f^{-1}(q) \longrightarrow M$ is the inclusion,

$$d(\iota_q)_p\big(T_p(f^{-1}(q))\big) = \ker(df_p)$$

for every $p \in f^{-1}(q)$. If N is finite-dimensional of dimension m, then $f^{-1}(q)$ has codimension m.

Proof. If the fiber is empty, the local condition in Definition 24.3.1 holds vacuously; we adopt the usual convention that the empty submanifold has the indicated codimension. Suppose the fiber is nonempty and let $p \in f^{-1}(q)$. By split regularity and Theorem 24.5.3, there exist charts centered at p and q in which f has the form

$$(k, y) \longmapsto y.$$

Consequently, the fiber of q corresponds in these coordinates to $K \times \{0\}$, where K represents $\ker(df_p)$. This subspace is closed and complemented by $\{0\}\times F$, where F is the model space of the codomain chart. The isomorphism $d\psi_q\colon T_qN \longrightarrow F$ transports the tangent directions of the codomain to this second factor. Thus the resulting charts are adapted charts for $f^{-1}(q)$. Its tangent space at p is K, which under the chart differentials corresponds precisely to $\ker(df_p)$.
If N has dimension m, the normal complement $\{0\} \times F$ has dimension m, since $d\psi_q$ is an isomorphism, and the fiber has codimension m. □

Corollary 24.6.6. (Regular values with finite-dimensional codomain) Let M be a Banach manifold, let N be a finite-dimensional manifold, let $f\colon M \longrightarrow N$ be a map of class C^r, with $r \geq 1$, and let $q \in N$. Set $m := \dim(N)$. If $df_p\colon T_pM \longrightarrow T_qN$ is surjective for every $p \in f^{-1}(q)$, then q is a split regular value. Consequently, $f^{-1}(q)$ is an embedded submanifold of codimension m and, if $\iota_q\colon f^{-1}(q) \longrightarrow M$ is the inclusion, for every $p \in f^{-1}(q)$,

$$d(\iota_q)_p\big(T_p(f^{-1}(q))\big) = \ker(df_p).$$

Proof. If $f^{-1}(q) = \varnothing$, the regularity assumption is vacuous and the conclusion is immediate under the usual convention that the empty set is an embedded submanifold of the indicated codimension; the assertion about tangent spaces is also vacuous. Suppose $f^{-1}(q) \neq \varnothing$. Fix $p \in f^{-1}(q)$ and choose a basis $e_1, \dots, e_m$ of T_qN. By surjectivity of df_p, there exist $v_1, \dots, v_m \in T_pM$ such that $df_p(v_j) = e_j$. The operator

$$R_p\colon T_qN \longrightarrow T_pM, \qquad R_p\left(\sum_{j=1}^{m} a_j e_j\right) := \sum_{j=1}^{m} a_j v_j$$

is linear and continuous because its domain is finite-dimensional, and satisfies $df_p \circ R_p = I_{T_qN}$. Thus q is a split regular value, and Theorem 24.6.5 gives the conclusion. □

Example 24.6.7. (Fibers of linear operators) Let E and F be Banach spaces and let $T \in \mathcal{L}(E, F)$ be surjective. If $\ker(T)$ is complemented, every $y \in F$ is a split regular value of T. For any $x_0 \in T^{-1}(y)$, we have

$$T^{-1}(y) = x_0 + \ker(T).$$

If $\iota_y\colon T^{-1}(y) \longrightarrow E$ is the inclusion, then

$$\Theta_{\mathrm{id}_E,x}\big(d(\iota_y)_x(T_x(T^{-1}(y)))\big) = \ker(T) \quad \text{for every } x \in T^{-1}(y).$$

Indeed, for each $x \in T^{-1}(y)$, the translation

$$\theta_x\colon \ker(T) \longrightarrow T^{-1}(y), \qquad \theta_x(k) := x + k,$$

is an affine diffeomorphism, and its differential is the inclusion $\ker(T) \hookrightarrow E$. Thus the tangent space of the fiber, regarded as a Banach manifold modeled on $\ker(T)$, is identified with $\ker(T)$. If the kernel is complemented, this inclusion admits a continuous left inverse, and the fiber is an embedded submanifold by Proposition 24.4.1. If the kernel is not complemented, the fiber is still a closed affine subspace and a Banach manifold in its own right. If the fiber were an embedded submanifold of E, the differential of its inclusion would have image exactly $\ker(T)$. Indeed, every differentiable curve γ in the fiber satisfies $T \circ \gamma = y$ and therefore $T\gamma'(0) = 0$; conversely, if $k \in \ker(T)$, the curve $t \mapsto x + tk$ remains in the fiber and has velocity k at $t = 0$. Under the assumed embedded submanifold structure, this curve is also of class C^1 as a curve with values in the fiber, by Lemma 24.3.3. Proposition 24.3.2 would then force this tangent image to be complemented in E, contradicting the assumption. Consequently, the fiber is not an embedded submanifold in the sense of Definition 24.3.1.

24.7 Regular level sets

Level sets of real functionals are the most frequent specialization of Theorem 24.6.5. In this case, a nonvanishing differential automatically provides a right inverse and a one-dimensional complement to the kernel. We will develop this situation directly to obtain explicit adapted charts and fix the formulation to be used for variational constraints.

Lemma 24.7.1. Let X be a real Banach space and let $f, g \in X'$ be nonzero functionals. Then $\ker(f)$ and $\ker(g)$ are isomorphic as Banach spaces.

Proof. First prove that there exists $a \in X$ such that $g(a) = 1$ and $f(a) \neq 0$. Since $g \neq 0$, there exists $b \in X$ such that $g(b) \neq 0$. Replacing b by $\frac{b}{g(b)}$, we may assume $g(b) = 1$. If $f(b) \neq 0$, take $a = b$. Thus suppose $f(b) = 0$. Since $f \neq 0$, there exists $x \in X$ such that $f(x) \neq 0$. Define $y := x - g(x)b$. Then $g(y) = g(x) - g(x)g(b) = 0$ and $f(y) = f(x) - g(x)f(b) = f(x) \neq 0$. Thus, taking $a := b + y$, we have $g(a) = g(b) + g(y) = 1$ and $f(a) = f(b) + f(y) = f(y) \neq 0$.

Now define $T\colon \ker(f) \longrightarrow \ker(g)$ by $T(h) := h - g(h)a$. First check that T is well defined. If $h \in \ker(f)$, then $g(T(h)) = g(h) - g(h)g(a) = g(h) - g(h) = 0$. Thus $T(h) \in \ker(g)$.

The operator T is linear and continuous, since it is the restriction to $\ker(f)$ of the continuous linear operator $x \mapsto x - g(x)a$ defined on X. We now prove that T is bijective. To this end, define $S\colon \ker(g) \longrightarrow \ker(f)$ by $S(k) := k - \dfrac{f(k)}{f(a)}a$. This formula is well defined because $f(a) \neq 0$. Moreover, if $k \in \ker(g)$, then $f(S(k)) = f(k) - \dfrac{f(k)}{f(a)}f(a) = 0$, so $S(k) \in \ker(f)$. Thus S is well defined. It is also linear and continuous.

Let us check that S and T are inverses. Let $h \in \ker(f)$. Since $T(h) = h - g(h)a$, we have $f(T(h)) = f(h) - g(h)f(a) = -g(h)f(a)$, because $f(h) = 0$. Then

$$S(T(h)) = T(h) - \frac{f(T(h))}{f(a)}a = h - g(h)a - \frac{-g(h)f(a)}{f(a)}a = h.$$

On the other hand, let $k \in \ker(g)$. Since $S(k) = k - \dfrac{f(k)}{f(a)}a$, we have $g(S(k)) = g(k) - \dfrac{f(k)}{f(a)}g(a) = -\dfrac{f(k)}{f(a)}$, because $g(k) = 0$ and $g(a) = 1$. Thus

$$T(S(k)) = S(k) - g(S(k))a = k - \frac{f(k)}{f(a)}a + \frac{f(k)}{f(a)}a = k.$$

Thus $S = T^{-1}$. Consequently, $T\colon \ker(f) \longrightarrow \ker(g)$ is a continuous linear bijection with continuous linear inverse.
Finally, since f and g are continuous, $\ker(f)$ and $\ker(g)$ are closed subspaces of X. Thus both are Banach spaces with the norm induced from X. We conclude that $\ker(f)$ and $\ker(g)$ are isomorphic as Banach spaces. □

Theorem 24.7.2. (Regular level sets in open subsets of Banach spaces) Let X be a real Banach space, let $\Omega \subseteq X$ be nonempty and open, and let $J\colon \Omega \longrightarrow \mathbb{R}$ be a function of class C^k, with $k \geq 1$. Let $c \in \mathbb{R}$ and suppose the level set $V := \{u \in \Omega \mid J(u) = c\}$ is regular, that is, $DJ(u) \neq 0$ for every $u \in V$. For $u \in \Omega$, the identity chart determines the operator

$$\mathcal{I}_u := \Theta_{\mathrm{id}_\Omega, u}\colon T_u\Omega \longrightarrow X.$$

Proposition 24.1.10 proves that $\mathcal{I}_u$ is linear, bijective, and bicontinuous. Then V is an embedded Banach submanifold of class C^k and codimension 1 of Ω. If $\iota\colon V \longrightarrow \Omega$ is the inclusion, then

$$\mathcal{I}_u\big(d\iota_u(T_uV)\big) = \ker(DJ(u))$$

for every $u \in V$.

Proof. If $V = \varnothing$, the assertion is vacuous. Suppose $V \neq \varnothing$ and fix $u \in V$. Since $DJ(u) \neq 0$, there exists $e \in X$ such that $DJ(u)(e) \neq 0$. Let $Y_u := \ker(DJ(u))$. Then Y_u is closed and

$$X = Y_u \oplus \mathbb{R}e.$$

For each $x \in X$, we have

$$x = \left(x - \frac{DJ(u)(x)}{DJ(u)(e)}e\right) + \frac{DJ(u)(x)}{DJ(u)(e)}e,$$

, where the first summand belongs to Y_u and the intersection $Y_u \cap \mathbb{R}e$ is trivial.
Consider

$$\Phi(y,t) := J(u + y + te) - c$$

on the open subset of $Y_u \times \mathbb{R}$ consisting of pairs (y,t) such that $u + y + te \in \Omega$. Moreover, $\Phi(0,0) = 0$ and $D_2\Phi(0,0)(1) = DJ(u)(e) \neq 0$. By Theorem 23.3.8, there exist open sets $U_0 \subseteq Y_u$ and $I_0 \subseteq \mathbb{R}$ containing 0 and a function $h\colon U_0 \longrightarrow I_0$ of class C^k, with $h(0) = 0$, such that

$$\Phi(y,t) = 0 \quad \Longleftrightarrow \quad t = h(y)$$

for every $(y,t) \in U_0 \times I_0$.
Let $W := \{u + y + te \mid y \in U_0,\ t \in I_0\}$. The linear operator $L_u \colon Y_u \times \mathbb{R} \longrightarrow X$, $L_u(y,t) := y + te$, is a topological isomorphism by Proposition 24.2.2; hence W is open in X. Define

$$\varphi \colon W \longrightarrow Y_u \times \mathbb{R}, \qquad \varphi(u + y + te) := (y, t - h(y)).$$

Its image is the open set

$$\varphi(W) = \{(y,s) \in U_0 \times \mathbb{R} \mid s + h(y) \in I_0\},$$

, and its inverse is given by $\varphi^{-1}(y,s) = u + y + (s + h(y))e$. Consequently, φ is a diffeomorphism of class C^k, $\varphi(u) = (0,0)$, and

$$\varphi(W \cap V) = \varphi(W) \cap (Y_u \times \{0\}).$$

Thus V is an embedded submanifold of class C^k and codimension 1.
To identify the tangent space in the natural coordinates of the open set $\Omega \subseteq X$, differentiate the identity $\Phi(y, h(y)) = 0$ at $y = 0$. For each $\eta \in Y_u$, this gives

$$0 = D\Phi(0,0)\big(\eta, Dh(0)(\eta)\big) = DJ(u)\big(\eta + Dh(0)(\eta)e\big) = Dh(0)(\eta)DJ(u)(e).$$

Since $DJ(u)(e) \neq 0$, it follows that $Dh(0) = 0$. The differential of the inverse adapted chart therefore sends $(\eta, 0)$ to η. Proposition 24.3.2 thus gives

$$\mathcal{I}_u\big(d\iota_u(T_uV)\big) = Y_u = \ker(DJ(u)).$$

Finally, if $u_0 \in V$ is fixed, Lemma 24.7.1 shows that $\ker(DJ(u))$ is isomorphic to $\ker(DJ(u_0))$ for every $u \in V$. Thus, even if V is disconnected, all its local model spaces are isomorphic. □

Lemma 24.7.3. (Differential of a restriction) Let X be a Banach space, let $\Omega \subseteq X$ be open, let $V \subseteq \Omega$ be a Banach submanifold, and let $\varphi \in C^1(\Omega, \mathbb{R})$. Then $\varphi \restriction_V \in C^1(V, \mathbb{R})$ and, for each $u \in V$,

$$d(\varphi \restriction_V)_u(v) = D\varphi(u)\big(\mathcal{I}_u(d\iota_u(v))\big)$$

for every $v \in T_uV$. In particular,

$$d(\varphi \restriction_V)_u = D\varphi(u) \circ \mathcal{I}_u \circ d\iota_u.$$

Proof. Let $\iota \colon V \longrightarrow \Omega$ be the canonical inclusion. Then $\varphi \restriction_V = \varphi \circ \iota$. Proposition 24.3.2 shows that ι is of class C^1, and the chain rule gives

$$d(\varphi \restriction_V)_u = d\varphi_u \circ d\iota_u.$$

Under the bicontinuous isomorphism $\mathcal{I}_u \colon T_u\Omega \longrightarrow X$ defined in Theorem 24.7.2, the differential $d\iota_u$ is represented by the inclusion of $\mathcal{I}_u(d\iota_u(T_uV))$ into X. Moreover, in the identity chart of Ω and the usual coordinate on $\mathbb{R}$, the differential $d\varphi_u$ is represented by the Fréchet derivative $D\varphi(u)$; that is, $d\varphi_u = D\varphi(u) \circ \mathcal{I}_u$, identifying $T_{\varphi(u)}\mathbb{R}$ with $\mathbb{R}$. Thus

$$d(\varphi \restriction_V)_u(v) = D\varphi(u)\big(\mathcal{I}_u(d\iota_u(v))\big)$$

for every $v \in T_u V$, as required. □

24.8 Bump functions and smooth partitions of unity

Constructing global objects from local data requires additional care on Banach manifolds. In finite dimensions, second countability and local compactness give paracompactness, and Euclidean bump functions yield smooth partitions of unity. In an infinite-dimensional Banach space, there are no relatively compact neighborhoods, and existence of bump functions with the prescribed regularity depends on the geometry of the model space. It is therefore useful to separate the topological and differential parts of the argument.

Let E be a topological space. Recall that the support of a continuous function $b\colon E \longrightarrow \mathbb{R}$ is the closed set

$$\operatorname{supp}(b) := \overline{\{x \in E \mid b(x) \neq 0\}}.$$

The closure is taken in E.

Definition 24.8.1. Let E be a real Banach space and let $k \in \mathbb{N} \cup \{\infty\}$. A **bump function of class** C^k on E, also called a **bump of class** C^k, is a function $b \in C^k(E, \mathbb{R})$ that is not identically zero and has bounded support.

In finite dimensions, a closed bounded support is compact, so the preceding definition agrees with the one used in earlier chapters. In infinite dimensions, compact support cannot be required, as the following result shows.

Proposition 24.8.2. Let E be an infinite-dimensional normed space. Every continuous function $b\colon E \longrightarrow \mathbb{R}$ with compact support is identically zero.

Proof. We first use the following elementary consequence of Riesz's lemma. If $Y \subsetneq E$ is a closed subspace and $0 < a < 1$, there exists $x \in E$ such that $\|x\|_E = 1$ and

$$\operatorname{dist}(x, Y) > a.$$

Indeed, take $z \notin Y$ and write $d := \operatorname{dist}(z, Y) > 0$. By the definition of the infimum, there exists $y_0 \in Y$ such that $\|z - y_0\|_E < \frac{d}{a}$. If $x := \frac{z - y_0}{\|z - y_0\|_E}$, then, for every $y \in Y$,

$$\|x - y\|_E = \frac{\|z - (y_0 + \|z - y_0\|_E y)\|_E}{\|z - y_0\|_E} \geq \frac{d}{\|z - y_0\|_E} > a.$$

Applying this observation inductively with $a = \frac{1}{2}$ and $Y_m := \operatorname{span}\{x_1, \dots, x_m\}$ gives a sequence $(x_m)_{m \in \mathbb{N}}$ of unit vectors such that $\|x_m - x_j\|_E > \frac{1}{2}$ whenever $m \neq j$. Here each Y_m is closed because it is finite-dimensional and proper because E is infinite-dimensional. Thus the closed unit ball of E is not compact.

Now suppose b is not identically zero and choose $x_0 \in E$ with $b(x_0) \neq 0$. Continuity gives $r > 0$ such that

$$|b(x)| > \frac{|b(x_0)|}{2} \qquad \text{if } \|x - x_0\|_E < r.$$

Consequently, $\overline{B}_E(x_0, r) \subseteq \operatorname{supp}(b)$. If this support were compact, so would be the closed ball $\overline{B}_E(x_0, r)$. Translation by $-x_0$ and dilation by the factor $\frac{1}{r}$ would then imply compactness of the closed unit ball,

contradicting the preceding paragraph. □

The usual normalization of a bump function remains valid with the notion of bounded support.

Lemma 24.8.3. If E admits a bump function of class C^k, it admits a function $\beta \in C^k(E,\mathbb{R})$ such that

$$0 \le \beta \le 1, \qquad \beta = 1 \text{ on a neighborhood of } 0, \qquad \operatorname{supp}(\beta) \text{ is bounded.}$$

Proof. Let b be a bump function and choose $z \in E$ such that $c := b(z) \neq 0$. There exist disjoint open intervals containing 0 and c, respectively. By Proposition 1.3.6, applied in $\mathbb{R}$, we can choose $\vartheta \in C^\infty(\mathbb{R})$ such that $0 \le \vartheta \le 1$, $\vartheta = 0$ on a neighborhood of 0, and $\vartheta = 1$ on a neighborhood of c. Define

$$\beta(x) := \vartheta(b(x+z)).$$

The function β is of class C^k by the chain rule, equals one on a neighborhood of 0, and takes values in $[0,1]$. Moreover,

$$\{x \in E \mid \beta(x) \neq 0\} \subseteq \operatorname{supp}(b) - z,$$

because $\vartheta(0) = 0$. Since the set on the right is closed and bounded, $\operatorname{supp}(\beta)$ is also bounded. □

Differentiable norms are a direct source of bump functions.

Proposition 24.8.4. Let ν be a norm on a Banach space E and suppose there exist constants $c_\nu, C_\nu > 0$ such that

$$c_\nu \|x\|_E \le \nu(x) \le C_\nu \|x\|_E, \qquad x \in E.$$

If $\nu : E \setminus \{0\} \longrightarrow \mathbb{R}$ is of class C^k, then E admits a bump function of class C^k.

Proof. Choose $\chi \in C^\infty(\mathbb{R})$ such that $0 \le \chi \le 1$, $\chi(t) = 1$ for $t \le 1$, and $\chi(t) = 0$ for $t \ge 2$. The function

$$b(x) := \chi(\nu(x))$$

is of class C^k away from the origin and constant on the neighborhood $\{x \in E \mid \nu(x) < 1\}$ of 0; hence it is of class C^k on all of E. Moreover, $b(0) = 1$ and $\operatorname{supp}(b) \subseteq \{x \in E \mid \nu(x) \le 2\}$; the inequality $c_\nu \|x\|_E \le \nu(x)$ shows that this support is contained in $\left\{x \in E \;\middle|\; \|x\|_E \le \frac{2}{c_\nu}\right\}$. □

Existence of a bump function is necessary for constructing smooth partitions of unity, but the converse implication will not be used without additional assumptions. The precise condition needed in the geometric argument is formulated next.

Definition 24.8.5. Let E be a Banach space and let $k \in \mathbb{N} \cup \{\infty\}$. We say that E **admits partitions of unity of class** C^k if every open cover $\mathscr{U} = (U_\alpha)_{\alpha \in A}$ of E admits a partition of unity $(\psi_\alpha)_{\alpha \in A}$ subordinate to $\mathscr{U}$, in the sense of Definition 1.3.4, such that each ψ_α is of class C^k.

This property includes, in particular, the ability to separate a closed set from an open set by a smooth function.

Lemma 24.8.6. (Cutoff functions in the model space) Suppose E admits partitions of unity of class C^k. If $A \subseteq E$ is closed, $B \subseteq E$ is open, and $A \subseteq B$, there exists $\theta \in C^k(E, \mathbb{R})$ such that

$$0 \le \theta \le 1, \qquad \theta = 1 \text{ on } A, \qquad \operatorname{supp}(\theta) \subseteq B.$$

Proof. Consider the open cover $(B, E \setminus A)$ of E and a subordinate partition of unity (θ, ζ) of class C^k. Subordination gives $\operatorname{supp}(\theta) \subseteq B$ and $\operatorname{supp}(\zeta) \subseteq E \setminus A$. In particular, $\zeta = 0$ on A; since $\theta + \zeta = 1$, it follows that $\theta = 1$ on A. □

Taking $A = \overline{B}_E(0,1)$ and $B = B_E(0,2)$ in the preceding lemma gives a bump function of class C^k. Thus admitting C^k partitions is, a priori, a stronger condition than having a single bump function.

24.8.1 The global construction on a Banach manifold

The topological part of the construction is collected in a shrinking lemma. The paracompactness in its statement is paracompactness of the underlying topological space; it is not part of Definition 24.1.1 and must therefore be imposed explicitly.

Lemma 24.8.7. (Locally finite shrinking) Let X be a paracompact Hausdorff space. Then:

(a) if $F \subseteq U \subseteq X$, where F is closed and U is open, there exists an open set V such that

$$F \subseteq V \subseteq \overline{V} \subseteq U;$$

(b) if $(W_i)_{i \in I}$ is a locally finite open cover of X, there exists an open cover $(V_i)_{i \in I}$ such that

$$\overline{V_i} \subseteq W_i \qquad \text{for every } i \in I.$$

Proof. First prove that X is normal. Fix a point $x \in X$ and a closed set F not containing it. For each $y \in F$, the Hausdorff property gives disjoint open sets A_y and B_y with $x \in A_y$ and $y \in B_y$. The cover

$$\{X \setminus F\} \cup \{B_y \mid y \in F\}$$

admits a locally finite open refinement $(R_j)_{j \in J}$. Let $J_F := \{j \in J \mid R_j \cap F \neq \varnothing\}$. If $j \in J_F$, the set R_j cannot be contained in $X \setminus F$; since this is a refinement, it is contained in some B_y. Consequently, $x \notin \overline{R_j}$. The family $(\overline{R_j})_{j \in J}$ is also locally finite, and hence

$$\overline{\bigcup_{j \in J_F} R_j} \subseteq \bigcup_{j \in J_F} \overline{R_j}.$$

The open set $W := \bigcup_{j \in J_F} R_j$ contains F, while $x \notin \overline{W}$. Thus $X \setminus \overline{W}$ is a neighborhood of x whose closure is disjoint from F. This proves that X is regular.

Now let F_0 and F_1 be disjoint closed sets. For each $x \in F_0$, regularity gives an open set U_x such that $x \in U_x$ and $\overline{U_x} \cap F_1 = \varnothing$. Take a locally finite refinement of the cover

$$\{X \setminus F_0\} \cup \{U_x \mid x \in F_0\}$$

and let G be the union of those elements of the refinement that meet F_0. These elements are contained in some U_x. Local finiteness implies that the closure of their union is contained in the union of their closures; consequently,

$$F_0 \subseteq G, \qquad \overline{G} \cap F_1 = \varnothing.$$

The open sets G and $X \setminus \overline{G}$ separate F_0 and F_1. Thus X is normal. Applying this separation to the closed sets F and $X \setminus U$ gives (a).

To prove (b), well-order I and construct the open sets V_i by transfinite recursion. Suppose the V_j with $j < i$ have been chosen so that the family

$$\{V_j \mid j < i\} \cup \{W_j \mid j \geq i\}$$

covers X. Define

$$K_i := X \setminus \left(\bigcup_{j<i} V_j \cup \bigcup_{j>i} W_j \right).$$

The set K_i is closed, and the inductive property shows that $K_i \subseteq W_i$. By (a), there exists an open set V_i such that $K_i \subseteq V_i$ and $\overline{V_i} \subseteq W_i$. This choice preserves the covering property at the next successor stage.

It also preserves this property at every limit ordinal. Indeed, if a point x belonged neither to any of the already chosen V_j nor to any of the remaining W_j, local finiteness would allow us to take the largest index, among those strictly preceding the limit ordinal, of the sets W_j containing x. The covering property immediately after that index would force x to belong to one of the already chosen V_j, a contradiction. At the end of the recursion, $(V_i)_{i\in I}$ covers X and satisfies $\overline{V_i} \subseteq W_i$. Since $V_i \subseteq W_i$, the family $(V_i)_{i\in I}$ is locally finite. □

In metric spaces, paracompactness follows directly from the distance, without assumptions of separability or local compactness.

Theorem 24.8.8. (Paracompactness of metric spaces) Every open cover of a metric space admits a locally finite open refinement. In particular, every metrizable space and every subspace of it are paracompact.

Proof. Let (X,d) be a metric space and let $(U_\alpha)_{\alpha\in A}$ be an open cover. If $X = \varnothing$, the assertion is immediate. Suppose $X \neq \varnothing$ and choose a well-order on A. For each α, define

$$f_\alpha(x) := \min\{1, d(x, X \setminus U_\alpha)\}, \qquad x \in X,$$

and take $f_\alpha \equiv 1$ when $U_\alpha = X$. Distance to a nonempty set is 1–Lipschitz: from $d(x,z) \leq d(x,y) + d(y,z)$, taking infima over z in the set gives one inequality, and the other follows by interchanging x and y. Since truncation at 1 preserves this property, each f_α is 1–Lipschitz. Moreover, $f_\alpha(x) > 0$ if and only if $x \in U_\alpha$, since U_α is open.

For $n \in \mathbb{N}$, set $r_n := 2^{-n}$ and consider the closed sets

$$F_{\alpha,n} := \{x \in X \mid f_\alpha(x) \geq r_n,\ f_\beta(x) \leq r_n/2 \text{ for every } \beta < \alpha\}.$$

They are closed because they are defined as intersections of closed sets. If $\alpha < \beta$, $x \in F_{\alpha,n}$, and $y \in F_{\beta,n}$, then

$$d(x,y) \geq |f_\alpha(x) - f_\alpha(y)| \geq r_n/2.$$

Moreover, these sets cover X as α and n vary. Indeed, given $x \in X$, let α be the first index for which $x \in U_\alpha$. Then $f_\alpha(x) > 0$ and $f_\beta(x) = 0$ for every $\beta < \alpha$. Choosing n with $r_n \le f_\alpha(x)$ suffices to obtain $x \in F_{\alpha,n}$.
If $F_{\alpha,n} \neq \varnothing$, define the open set

$$V_{\alpha,n} := \{x \in X \mid d(x, F_{\alpha,n}) < r_n/8\};$$

; if $F_{\alpha,n} = \varnothing$, take $V_{\alpha,n} = \varnothing$. For $x \in V_{\alpha,n}$, there exists $u \in F_{\alpha,n}$ with $d(x,u) < r_n/8$, and hence $f_\alpha(x) \ge f_\alpha(u) - d(x,u) > 7r_n/8 > 0$. Thus $V_{\alpha,n} \subseteq U_\alpha$. If $\alpha \neq \beta$, $x \in V_{\alpha,n}$, and $y \in V_{\beta,n}$, choose points in the respective closed sets at distance less than $r_n/8$. Separation of the closed sets and the triangle inequality give $d(x,y) > r_n/4$. Consequently, each ball $B_d(z, r_n/8)$ meets at most one of the sets $V_{\alpha,n}$. For each fixed n, the family $(V_{\alpha,n})_{\alpha\in A}$ is therefore locally finite. Together, these families cover X as n varies.
To obtain local finiteness also with respect to n, set

$$O_n := \bigcup_{1\le k\le n} \bigcup_{\alpha\in A} V_{\alpha,k}, \qquad h_n(x) := \min\{1, d(x, X \setminus O_n)\},$$

, with $h_n \equiv 1$ if $O_n = X$, and define

$$P_0 := \varnothing, \qquad P_n := \{x \in X \mid h_n(x) \ge 2^{-n}\} \quad (n \in \mathbb{N}).$$

The sets O_n are open and increasing. The functions h_n are continuous and satisfy $h_n \le h_{n+1}$; hence the P_n are closed, $P_n \subseteq O_n$, and $P_n \subseteq P_{n+1}$. Their interiors cover X. Indeed, if $x \in O_m$, then $h_m(x) > 0$ and, for sufficiently large n, $n \ge m$ and $h_n(x) \ge h_m(x) > 2^{-n}$. By continuity, this strict inequality persists on a neighborhood of x contained in P_n.
Finally, define

$$W_{\alpha,n} := V_{\alpha,n} \setminus P_{n-1}.$$

Each $W_{\alpha,n}$ is open and contained in U_α. To check that they cover X, given $x \in X$, take the least n such that $x \in V_{\alpha,n}$ for some α. If $n = 1$, we have $x \notin P_0$. If $n > 1$, minimality gives $x \notin O_{n-1}$ and, since $P_{n-1} \subseteq O_{n-1}$, also $x \notin P_{n-1}$. In either case, $x \in W_{\alpha,n}$.
Now fix $x \in X$ and choose N with $x \in \operatorname{Int}(P_N)$. This neighborhood meets no $W_{\alpha,n}$ with $n > N$, because $P_N \subseteq P_{n-1}$. For each of the finitely many levels $1 \le n \le N$, local finiteness of $(V_{\alpha,n})_{\alpha\in A}$ gives a neighborhood of x meeting only finitely many of its elements. The intersection of these neighborhoods with $\operatorname{Int}(P_N)$ meets only finitely many of the $W_{\alpha,n}$. Thus the nonempty members of this family form the required locally finite open refinement. The assertion for metrizable spaces follows by choosing a compatible metric, and the assertion for their subspaces follows by applying what we have proved to the restricted metric. □

Theorem 24.8.9. (Smooth partitions on Banach manifolds) Let M be a Banach manifold of class C^k modeled on a Banach space E, where $k \in \mathbb{N} \cup \{\infty\}$. Suppose the topological space M is paracompact and E admits partitions of unity of class C^k. Then every open cover $\mathscr{U} = (U_\alpha)_{\alpha\in A}$ of M admits a partition of unity of class C^k subordinate to $\mathscr{U}$.

Proof. Lemma 24.8.7 shows, in particular, that M is regular. For each $x \in M$, choose $\alpha(x) \in A$ such that $x \in U_{\alpha(x)}$ and a chart (C_x, φ_x) around x. Applying regularity to the open set $C_x \cap U_{\alpha(x)}$ gives an open set Q_x such that

$$x \in Q_x, \qquad \overline{Q_x} \subseteq C_x \cap U_{\alpha(x)}.$$

Since $\varphi_x(Q_x)$ is an open neighborhood of $\varphi_x(x)$, there exists $r_x > 0$ such that

$$\overline{B}_E(\varphi_x(x), r_x) \subseteq \varphi_x(Q_x).$$

Set

$$P_x := \varphi_x^{-1}\big(B_E(\varphi_x(x), r_x)\big).$$

Since $P_x \subseteq Q_x$ and $\overline{Q_x} \subseteq C_x$, the closure of P_x in M remains inside the chart domain. Thus

$$\overline{P_x} = \varphi_x^{-1}\big(\overline{B}_E(\varphi_x(x), r_x)\big) \subseteq Q_x \subseteq U_{\alpha(x)}. \tag{24.4}$$

Paracompactness gives a locally finite open refinement $(W_i)_{i\in I}$ of the cover $(P_x)_{x\in M}$. For each i, fix a point $x(i)$ such that $W_i \subseteq P_{x(i)}$ and abbreviate

$$C_i := C_{x(i)}, \qquad \varphi_i := \varphi_{x(i)}, \qquad \alpha(i) := \alpha(x(i)).$$

By Lemma 24.8.7, there exists an open cover $(V_i)_{i\in I}$ with

$$\overline{V_i} \subseteq W_i \qquad \text{for every } i \in I. \tag{24.5}$$

Within the model space, consider

$$A_i := \varphi_i(\overline{V_i}), \qquad B_i := \varphi_i(W_i).$$

The set B_i is open and $A_i \subseteq B_i$. Moreover, A_i is closed in E. To verify this last point, first observe that $\overline{V_i}$ is closed in M and contained in C_i, so A_i is closed in the open set $\varphi_i(C_i)$. On the other hand, A_i is contained in the closed ball $\overline{B}_E(\varphi_i(x(i)), r_{x(i)})$, which is a closed subset of E contained in $\varphi_i(C_i)$ by (24.4). If $A_i = F_i \cap \varphi_i(C_i)$ with F_i closed in E, then

$$A_i = F_i \cap \overline{B}_E(\varphi_i(x(i)), r_{x(i)}),$$

, proving the assertion.
Lemma 24.8.6 gives a function $\theta_i \in C^k(E, \mathbb{R})$ such that

$$0 \le \theta_i \le 1, \qquad \theta_i = 1 \text{ on } A_i, \qquad \operatorname{supp}(\theta_i) \subseteq B_i. \tag{24.6}$$

Define $\eta_i : M \longrightarrow \mathbb{R}$ by

$$\eta_i(p) := \begin{cases} \theta_i(\varphi_i(p)), & p \in C_i, \\ 0, & p \notin C_i. \end{cases}$$

This extension by zero is of class C^k. Indeed, the third property in (24.6) implies that the local function vanishes outside a closed set contained in W_i, and $\overline{W_i} \subseteq \overline{P_{x(i)}} \subseteq C_i$ by (24.4); hence it is identically zero on a neighborhood of every point of $M \setminus C_i$. Moreover,

$$\operatorname{supp}(\eta_i) \subseteq W_i, \qquad \eta_i = 1 \text{ on } \overline{V_i}. \tag{24.7}$$

The family $(\operatorname{supp}(\eta_i))_{i\in I}$ is locally finite because it is subordinate to $(W_i)_{i\in I}$. Consequently, the sum

$$h := \sum_{i\in I} \eta_i$$

locally consists of finitely many functions of class C^k and therefore belongs to $C^k(M)$. Given $p \in M$, there exists i with $p \in V_i$; then (24.7) gives $\eta_i(p) = 1$. Thus $h(p) \geq 1$ for every $p \in M$. The functions

$$\rho_i := \frac{\eta_i}{h}$$

are of class C^k, are nonnegative, form a locally finite family, satisfy $\operatorname{supp}(\rho_i) \subseteq W_i$, and obey $\sum_{i\in I} \rho_i = 1$.

Finally, for each $\alpha \in A$, define

$$\psi_\alpha := \sum_{\{i\in I \mid \alpha(i)=\alpha\}} \rho_i.$$

The sum is locally finite, so ψ_α is of class C^k. Moreover,

$$\sum_{\alpha\in A} \psi_\alpha = \sum_{i\in I} \rho_i = 1.$$

To check subordination, note that any subfamily of a locally finite family of closed sets has closed union. Hence

$$\operatorname{supp}(\psi_\alpha) \subseteq \bigcup_{i\in I,\ \alpha(i)=\alpha} \operatorname{supp}(\rho_i) \subseteq \bigcup_{i\in I,\ \alpha(i)=\alpha} W_i \subseteq U_\alpha.$$

The family of these supports is also locally finite, since it is obtained by grouping the locally finite family $(\operatorname{supp}(\rho_i))_{i\in I}$ according to the elements of the original cover. Thus $(\psi_\alpha)_{\alpha\in A}$ is the required partition. □

Definition 24.8.10. A Banach manifold of class C^k is called **C^k–paracompact** if its topological space is paracompact and every open cover admits a subordinate partition of unity of class C^k.

Theorem 24.8.9 states that a paracompact manifold modeled on a space admitting partitions of class C^k is C^k–paracompact. This formulation distinguishes the two assumptions: paracompactness produces locally finite families, while the property of the model space provides differentiable cutoff functions.

24.8.2 Criteria and examples of model spaces

General criteria for passing from a single bump function to partitions of unity belong to the theory of smoothness and renorming of Banach spaces. We introduce the functional assumption appearing in one of the most useful criteria.

Definition 24.8.11. A Banach space E is an **Asplund space** if every closed separable subspace $Y \subseteq E$ has separable dual.

Theorem 24.8.12. (Fry's criterion) Let E be a Banach space and let $k \in \mathbb{N}\cup\{\infty\}$. If E admits a bump function of class C^k and E' is an Asplund space, then E admits partitions of unity of class C^k.

This result is Fry's Theorem 3.1 [63, p. 146]. Its proof uses projectional resolutions in dual spaces and constructs a topological embedding into a space $c_0(\Gamma)$ whose scalar components are of class C^k. Existence of this embedding provides the partitions of unity. The criterion thus combines the regularity of the bump function with the Asplund assumption on the dual. Theorem 24.8.9 explains how to transfer its conclusion to a paracompact manifold. Johanis [86] gives a characterization that brings together and extends several existence criteria.

In that work, sufficiency of a single bump function of class C^k on an arbitrary Banach space is formulated as an open problem. In addition to the bump function, his characterization uses a family of smooth functions that allows each point to be approximated by subspaces determined by its nonzero components. This additional information makes partitions possible in the cases covered by the criterion.

Recall why the Asplund assumption in the preceding criterion holds in the reflexive examples. If E is reflexive, so is E' by Proposition B.11.40. Let $Y \subseteq E'$ be a closed separable subspace. Since closed subspaces of a reflexive space are reflexive, Y is reflexive: indeed, the unit ball of Y is the intersection of the unit ball of E' with the closed convex subspace Y, which is weakly closed by Theorem B.11.16; thus this ball is weakly compact, and Theorem B.11.38 gives reflexivity of Y. Consequently, Y' is also reflexive, and its closed unit ball $B_{Y'}$ is weakly compact.

On the other hand, separability of Y and Theorem B.11.31 show that $B_{Y'}$ is metrizable in the weak-$*$ topology. Since Y is reflexive, the canonical embedding $J_Y\colon Y \longrightarrow Y''$, defined by $J_Y(y)(y') := y'(y)$, is surjective. Consequently, the weak topology $\sigma(Y', Y'')$ and the weak-$*$ topology $\sigma(Y', J_Y(Y))$ agree on Y'; through J_Y, the latter is precisely $\sigma(Y', Y)$. Thus $B_{Y'}$ is a compact metric space. Choose a countable weakly dense subset $D \subseteq B_{Y'}$. Its real convex hull $\operatorname{co}(D)$ has weak closure $B_{Y'}$, since it contains D and is contained in the convex ball $B_{Y'}$. The rational convex hull $\operatorname{co}_{\mathbb{Q}}(D)$ is countable and norm dense in $\operatorname{co}(D)$: simply approximate the coefficients of each finite convex combination by nonnegative rational numbers summing to one. Finally, the norm closure of $\operatorname{co}_{\mathbb{Q}}(D)$ is convex and, by Theorem B.11.16, also weakly closed. Since it contains $\operatorname{co}(D)$, it contains its weak closure, which is $B_{Y'}$; the reverse inclusion is immediate. Consequently, $B_{Y'}$ is norm separable, and so is Y'. This proves that every reflexive space is Asplund and, in particular, the dual of a reflexive space is Asplund.

Example 24.8.13. (Hilbert spaces) Let H be a real Hilbert space. The quadratic function

$$Q\colon H \longrightarrow \mathbb{R}, \qquad Q(x) := \langle x, x\rangle_H,$$

is smooth, and its only nonzero derivatives are

$$DQ(x)h = 2\langle x, h\rangle_H, \qquad D^2Q(x)(h_1, h_2) = 2\langle h_1, h_2\rangle_H.$$

If $\chi \in C^\infty(\mathbb{R})$ satisfies $0 \le \chi \le 1$, $\chi = 1$ on $(-\infty, 1]$, and $\chi = 0$ on $[4, \infty)$, then $\chi \circ Q$ is a smooth bump function. Since H is reflexive, H' is Asplund. Theorem 24.8.12 implies that H admits smooth partitions of unity. Consequently, every smooth paracompact manifold modeled on a Hilbert space admits smooth partitions of unity, without any separability assumption on the model space.

The degree of differentiability available in L^p spaces can be seen directly in the functional defining their norm.

Lemma 24.8.14. Let $(X, \mathcal{A}, \mu)$ be a measure space and $1 < p < \infty$, over real scalars. Define

$$P_p\colon L^p(X) \longrightarrow \mathbb{R}, \qquad P_p(u) := \int_X |u|^p \, d\mu.$$

If p is an even integer, P_p is smooth. If p is not an even integer, P_p is of class C^m for every $m \in \mathbb{N}$ with $m < p$. For $1 \le j < p$, its derivatives are

$$D^j P_p(u)(h_1, \dots, h_j) = \int_X a_{p,j}(u) h_1 \cdots h_j \, d\mu, \tag{24.8}$$

, where

$$a_{p,j}(t) := p(p-1)\cdots(p-j+1)|t|^{p-j}(\operatorname{sgn} t)^j, \qquad a_{p,j}(0) := 0.$$

Proof. First suppose $1 \le j < p$. Hölder's inequality in Proposition B.7.9, with exponents $\frac{p}{p-j}, p, \dots, p$, gives

$$\left| \int_X a_{p,j}(u) h_1 \cdots h_j \, d\mu \right| \le C_{p,j} \|u\|_{L^p(X)}^{p-j} \prod_{\ell=1}^{j} \|h_\ell\|_{L^p(X)}. \tag{24.9}$$

Here and in the following estimates, $C_{p,j} > 0$ depends only on p and j; it does not depend on u, the increments, or the measure space. Thus the right-hand side of (24.8) defines a continuous j–linear form.
The Nemytskii operator

$$L^p(X) \longrightarrow L^{\frac{p}{p-j}}(X), \qquad u \longmapsto a_{p,j}(u), \tag{24.10}$$

is continuous. Indeed, if $r := p - j$, for $0 < r \le 1$ we have the pointwise inequality

$$\left| |s|^r (\operatorname{sgn} s)^j - |t|^r (\operatorname{sgn} t)^j \right| \le C_r |s - t|^r,$$

, while for $r > 1$,

$$\left| |s|^r (\operatorname{sgn} s)^j - |t|^r (\operatorname{sgn} t)^j \right| \le C_r (|s|^{r-1} + |t|^{r-1}) |s - t|.$$

In both inequalities, $C_r > 0$ can be chosen to depend only on r; in particular, it is independent of s and t. Raising to the power $\frac{p}{r}$, integrating, and applying Hölder in the second case gives, respectively,

$$\|a_{p,j}(u) - a_{p,j}(v)\|_{L^{\frac{p}{r}}(X)} \le C_{p,j} \|u - v\|_{L^p(X)}^r$$

and

$$\|a_{p,j}(u) - a_{p,j}(v)\|_{L^{\frac{p}{r}}(X)} \le C_{p,j} (\|u\|_{L^p(X)}^{r-1} + \|v\|_{L^p(X)}^{r-1}) \|u - v\|_{L^p(X)}.$$

This proves continuity of (24.10) and, together with (24.9), norm continuity of the function assigning to u the multilinear form in (24.8).
It remains to verify that these forms are indeed the Fréchet derivatives. Set $a_{p,0}(t) := |t|^p$. If $j + 1 < p$, the fundamental theorem of calculus on $\mathbb{R}$ gives, at almost every point of X,

$$a_{p,j}(u + h) - a_{p,j}(u) - a_{p,j+1}(u)h = \int_0^1 \big(a_{p,j+1}(u + th) - a_{p,j+1}(u) \big) h \, dt.$$

For $j = 0$, interpret the empty product as 1. For each $t \in [0,1]$, Hölder's inequality with exponents $\frac{p}{p-j-1}, p, \dots, p$ controls the $L^1(X)$ norm of the integrand after multiplication by $h_1 \cdots h_j$. Moreover, continuity of the Nemytskii operator makes this integrand depend continuously on t in $L^1(X)$. We may therefore integrate in t in this Banach space and apply the continuous linear functional $v \longmapsto \int_X v \, d\mu$; this operation justifies interchanging the integrals. The preceding scalar identity agrees with this identity in $L^1(X)$: the

integrand vanishes outside the union of the sets $\{|u| \geq 1/n\}$ and $\{|h| \geq 1/n\}$, with $n \in \mathbb{N}$, which have finite measure, so Fubini's theorem applies on this support of σ–finite measure. We thus obtain

$$\left| \int_X \bigl(a_{p,j}(u+h) - a_{p,j}(u) - a_{p,j+1}(u)h\bigr) h_1 \cdots h_j \, d\mu \right|$$
$$\leq \sup_{t\in[0,1]} \|a_{p,j+1}(u+th) - a_{p,j+1}(u)\|_{L^{\frac{p}{p-j-1}}(X)} \|h\|_{L^p(X)} \prod_{\ell=1}^{j} \|h_\ell\|_{L^p(X)}.$$

Continuity of the Nemytskii operator corresponding to $j+1$ shows that the supremum tends to zero as $h \to 0$ in $L^p(X)$: in the two preceding estimates, simply replace v by $u+th$, and the bounds are uniform for $0 \leq t \leq 1$. Thus, for every $\varepsilon > 0$, there exists $\delta > 0$, depending on u, p, j and ε, such that, if $\|h\|_{L^p(X)} < \delta$, the norm of the remainder as a j–linear form is at most $\varepsilon \|h\|_{L^p(X)}$. For $j = 0$, this proves the first derivative formula. Suppose that, for an integer $j \geq 1$ with $j+1 < p$, the form in (24.8) already agrees with $D^j P_p$. The remainder estimate, taken over all $h_\ell \in L^p(X)$ with $\|h_\ell\|_{L^p(X)} \leq 1$ and $\ell \in \{1, \ldots, j\}$, proves differentiability of $D^j P_p$ in the norm of the space of j–linear forms. Through the association in Proposition 23.2.3, its derivative is exactly the form indicated for order $j+1$. Continuity of this form was already established in (24.10). This proves the induction step and hence that P_p is of class C^m for every $m \in \mathbb{N}$ with $m < p$.
If p is an even integer, $|u|^p = u^p$ and

$$(u_1, \ldots, u_p) \longmapsto \int_X u_1 \cdots u_p \, d\mu$$

is a continuous p–linear form by Hölder's inequality. Thus P_p is a continuous homogeneous polynomial of degree p. Proposition 23.2.4, applied to this form, and Corollary 23.2.8, applied to the diagonal map $u \longmapsto (u, \ldots, u)$, show that P_p is smooth. □

Corollary 24.8.15. (The models ℓ^p and L^p) Let $1 < p < \infty$.

(a) If p is an even integer, the real spaces ℓ^p and $L^p(X)$, for every σ–finite measure space $(X, \mathcal{A}, \mu)$, admit smooth partitions of unity.

(b) If p is not an even integer, these spaces admit partitions of unity of class C^m for each $m \in \mathbb{N}$ with $m < p$.

Consequently, Theorem 24.8.9 applies, with the same degree of differentiability, to every paracompact Banach manifold modeled on one of these spaces.

Proof. Let $\chi \in C^\infty(\mathbb{R})$ be such that $0 \leq \chi \leq 1$, equal to one on $(-\infty, 1]$ and zero on $[2, \infty)$. By Lemma 24.8.14, the function $u \mapsto \chi(P_p(u))$ is a smooth bump function if p is even and of class C^m if $m < p$ in the other cases. Theorem B.7.7 shows that the $L^p(X)$ spaces under consideration are reflexive; the case of ℓ^p follows by taking counting measure on $\mathbb{N}$. As we saw before Example 24.8.13, the dual of a reflexive space is Asplund. The conclusion follows from Theorem 24.8.12. □

The differentiability range in the corollary is not a defect of the chosen bump function. The following result shows that, for ℓ^p, the restriction is intrinsic.

Theorem 24.8.16. (Bonic–Frampton) Let $1 < p < \infty$ and suppose p is not an even integer. If $m \in \mathbb{N}$ and $m \geq p$, there exists no nonzero bump function on ℓ^p of class C^m. In particular, ℓ^p admits neither partitions of unity of class C^m for these values of m nor smooth partitions of unity.

The statement is Theorem 1 and its Corollary 1 in Bonic and Frampton [24, Theorem 1 and Corollary 1, pp. 393–394]. Their argument uses the following boundary value principle: if p is not an even integer, $D \subseteq \ell^p$ is open, connected, and bounded, and a real function is continuous on $\overline{D}$ and m times differentiable on D, with $m \geq p$, then its image on $\overline{D}$ is contained in the closure of its image on ∂D. Applied to a bounded connected component of the set where a bump function is nonzero, this principle forces the function to be identically zero. Indeed, the connected components of an open subset of ℓ^p are open, since each point has a convex ball contained in that open set. If D is a component of $\{u \mid b(u) \neq 0\}$, then $b = 0$ on ∂D: otherwise, a connected ball on which b is nonzero would meet D and lie in the same component, contradicting the fact that its center is a boundary point. Thus the closure of $b(\partial D)$ is $\{0\}$, and the cited principle gives $b(D) = \{0\}$, a contradiction. The result shows that the differentiability order in the preceding corollary is optimal. The assertion about partitions follows from Lemma 24.8.6, since a partition with this regularity would produce a bump function of the same order.

There are nonreflexive examples whose construction requires more refined techniques. Haydon proved the following result.

Definition 24.8.17. (The spaces $C(K)$ and $C_0(L)$) If K is compact and Hausdorff, $C(K)$ is the real Banach space of continuous functions $u\colon K \longrightarrow \mathbb{R}$, with the norm $\|u\|_\infty := \sup_{x \in K} |u(x)|$. If L is locally compact and Hausdorff, define

$$C_0(L) := \{u\colon L \longrightarrow \mathbb{R} | u \text{ is continuous and, for every } \varepsilon > 0,\ \{x \in L \mid |u(x)| \geq \varepsilon\} \text{ is compact}\},$$

with the supremum norm. This norm is finite: for $\varepsilon = 1$, we have $|u| < 1$ outside a compact set and, if this set is nonempty, $|u|$ attains a maximum on it. Moreover, $C_0(L)$ is complete. Indeed, a Cauchy sequence for $\|\cdot\|_\infty$ converges uniformly to a continuous bounded function u. Given $\varepsilon > 0$, if $\|u - u_n\|_\infty < \frac{\varepsilon}{2}$, then

$$\{x \in L \mid |u(x)| \geq \varepsilon\} \subseteq \{x \in L \mid |u_n(x)| \geq \frac{\varepsilon}{2}\};$$

; the set on the left is closed and the one on the right is compact, so the former is compact. Its elements are precisely the continuous functions vanishing at infinity.

Theorem 24.8.18. (Haydon) If K is a countable compact Hausdorff space, then $C(K)$ admits a smooth norm ν away from the origin and constants $c_K, C_K > 0$, which may depend on K, such that $c_K\|u\|_\infty \leq \nu(u) \leq C_K\|u\|_\infty$ for every $u \in C(K)$; moreover, it admits smooth partitions of unity. The same holds for $C_0([0,\Omega))$, where Ω is an ordinal and $[0,\Omega)$ has the order topology, with constants that may depend on Ω.

The smooth norm is constructed in Haydon's Theorem 1 and Proposition 2, pp. 457–463; the partition criterion is his Theorem 2, and the two cases in the statement follow from Corollaries 4–5, pp. 464–468 [77]. Haydon's construction uses Talagrand operators, projectional resolutions, and transfinite induction on ordinal spaces. These examples show that the model space assumption in Theorem 24.8.9 can also hold without reflexivity.

24.8.3 Geometric consequences

Partitions of unity allow constructions with values in vector spaces to be globalized. We record a form that will be used frequently.

Proposition 24.8.19. (Gluing functions with linear codomain) Let M be a C^k–paracompact Banach manifold, let $(U_\alpha)_{\alpha\in A}$ be an open cover, and let F be a Banach space. Suppose $f_\alpha\colon U_\alpha \longrightarrow F$ is of class C^k for each α. If $(\psi_\alpha)_{\alpha\in A}$ is a partition of unity of class C^k subordinate to the cover, then

$$f\colon M \longrightarrow F, \qquad f(p) := \sum_{\alpha\in A} \psi_\alpha(p) f_\alpha(p),$$

, where each product is extended by zero outside U_α, is well defined and of class C^k.

Proof. Inclusion $\operatorname{supp}(\psi_\alpha) \subseteq U_\alpha$ ensures that $\psi_\alpha f_\alpha$ extends by zero to a function of class C^k on all of M. Each point has a neighborhood meeting only finitely many supports $\operatorname{supp}(\psi_\alpha)$. The sum defining f is therefore locally finite and locally agrees with a finite sum of functions of class C^k. □

Proposition 24.8.20. (Fine smooth approximation) Let M be a C^k–paracompact Banach manifold, let F be a Banach space, and let $f\colon M \longrightarrow F$ be continuous. For every continuous function $\varepsilon\colon M \longrightarrow (0,\infty)$, there exists $g \in C^k(M,F)$ such that

$$\|g(p) - f(p)\|_F < \varepsilon(p) \qquad \text{for every } p \in M.$$

Proof. For each $x \in M$, continuity of f and ε allows us to choose an open neighborhood U_x of x such that, for every $p \in U_x$,

$$\|f(p) - f(x)\|_F < \frac{\varepsilon(x)}{2}, \qquad \varepsilon(p) > \frac{\varepsilon(x)}{2}.$$

Let $(\psi_x)_{x\in M}$ be a partition of unity of class C^k subordinate to $(U_x)_{x\in M}$. Define

$$g(p) := \sum_{x\in M} \psi_x(p) f(x).$$

The sum is locally finite, and each summand is the product of a function of class C^k and a fixed vector in F; thus g is of class C^k. If $\psi_x(p) \neq 0$, then $p \in \operatorname{supp}(\psi_x) \subseteq U_x$, and the preceding inequalities give

$$\|f(x) - f(p)\|_F < \frac{\varepsilon(x)}{2} < \varepsilon(p).$$

Using $\psi_x(p) \geq 0$ and $\sum_{x\in M} \psi_x(p) = 1$, we conclude that

$$\|g(p) - f(p)\|_F \leq \sum_{x\in M} \psi_x(p) \|f(x) - f(p)\|_F < \varepsilon(p).$$

□

In particular, partitions of class C^k imply fine approximation of continuous functions with linear codomain. Together with Proposition 24.8.4 and Theorem 24.8.12, this makes precise the implications used here: if a norm

that is C^k away from the origin satisfies $c\|x\| \le \nu(x) \le C\|x\|$ with $c, C > 0$, it produces a bump function; under the Asplund assumption on the dual, this function produces C^k partitions; and partitions produce smooth approximations. The converse implications are not needed; they belong to substantially more delicate renorming and approximation problems.

The same argument preserves linear affine relations whenever the local objects take values in a common Banach space. Indeed, if $L\colon F \longrightarrow G$ is continuous and linear, $b \in G$, and the local functions $f_\alpha\colon U_\alpha \longrightarrow F$ satisfy $L \circ f_\alpha = b$, then the glued function $f := \sum_{\alpha\in A} \psi_\alpha f_\alpha$ satisfies

$$L \circ f = \sum_{\alpha\in A} \psi_\alpha L(f_\alpha) = \left(\sum_{\alpha\in A} \psi_\alpha\right) b = b.$$

Thus partitions of unity allow local constructions with linear codomain to be globalized without destroying the affine constraints they satisfy.

There is no analogous operation for maps with values in an arbitrary Banach manifold, since a convex combination of points of a manifold is not defined. Globalizing such maps therefore requires additional geometric constructions. This distinction appears in the global study of submersions and mapping spaces; a modern application of smooth partitions in this setting is the Stacey–Roberts lemma for Banach manifolds, presented in [89].

25

Vector bundles, connections, and flows on Banach manifolds

Vector bundles over Banach manifolds are described by transition maps with values in groups of invertible operators. The topology used on these groups is induced by the operator norm; this choice makes Fréchet calculus applicable and avoids confusing the joint continuity of evaluation with the regularity, in the operator norm, of a family of linear transformations.

The framework of bundles with Banach fibers and the need to distinguish topological tensor products already appear in the classical formulation of infinite-dimensional global analysis [85, §§4(C)–4(G)]. Here we work in the Banach category and use Fréchet differentiability.

Differential geometry with infinite-dimensional fibers

Banach bundles allow each fiber to be a complete infinite-dimensional space. This generalization arises naturally in the study of families of sections, operators, or initial data that vary over a base. The operator norm determines the regularity of transition functions, connections, and parallel transport. We will study these constructions together with the topological conditions they require, some of which hold automatically in finite dimensions.

25.1 Banach vector bundles

Let X and F be real Banach spaces, and let M be a Banach manifold of class C^r, with $r \in \mathbb{N} \cup \{\infty\}$, modeled on X. The space F will be the model fiber. We use the convention of Definition 24.1.1: charts have open images in the model spaces. A continuous bundle is understood to satisfy the same conditions as a C^r bundle, with C^r regularity replaced by continuity in the operator norm. This variant will be used for the tangent bundle of a C^1 manifold.

Proposition 25.1.1. (General linear group of a Banach space) The set

$$\mathrm{GL}(F) := \{A \in \mathcal{L}(F) \mid A \text{ is invertible}\}$$

is an open subset of the Banach algebra $\mathcal{L}(F)$. With this structure, $\mathrm{GL}(F)$ is a Banach Lie group: composition and inversion

$$(A,B)\longmapsto AB, \qquad A\longmapsto A^{-1}$$

are smooth. Moreover,

$$D(A\mapsto A^{-1})(A)H = -A^{-1}HA^{-1}.$$

Proof. Composition is continuous and bilinear, and hence smooth. The openness of the set of invertible operators, the smoothness of inversion, and the formula for its differential are precisely the assertions of Proposition 23.3.2, applied with $X = Y = F$. □

Before taking duals of fibers, it is useful to distinguish two notions that coincide in finite dimensions but not in a general Banach space. For a vector space V, we denote its algebraic dual, consisting of all linear functionals, by V^*. For a Banach space F, we denote its continuous dual, consisting of the continuous linear functionals, by

$$F' := \mathcal{L}(F;\mathbb{R})$$

The latter is a subspace of the algebraic dual F^* and carries the norm

$$\|\lambda\|_{F'} := \sup_{v\in F,\ \|v\|_F\le 1} |\lambda(v)|.$$

Proposition 25.1.2. (Continuous dual and transpose operators) The space F' is a Banach space. If $A \in \mathcal{L}(F,G)$, its transpose

$$A'\colon G' \longrightarrow F', \qquad A'\mu := \mu\circ A,$$

is linear and continuous, and satisfies

$$\|A'\|_{\mathcal{L}(G',F')} = \|A\|_{\mathcal{L}(F,G)}.$$

If $A\colon F\longrightarrow G$ is a topological linear isomorphism, then so is $A'\colon G'\longrightarrow F'$, and $(A')^{-1} = (A^{-1})'$. Moreover, the map

$$\mathcal{L}(F,G)\longrightarrow\mathcal{L}(G',F'), \qquad A\longmapsto A',$$

is an isometric linear embedding.
If F is infinite-dimensional, the inclusion $F'\subseteq F^*$ is strict.

Proof. Let $(\lambda_n)_{n\in\mathbb{N}}$ be a Cauchy sequence in F'. For each $v\in F$, the sequence $(\lambda_n(v))_{n\in\mathbb{N}}$ is Cauchy in $\mathbb{R}$, since

$$|\lambda_n(v)-\lambda_m(v)| \le \|\lambda_n-\lambda_m\|_{F'}\|v\|_F.$$

Define $\lambda(v) := \lim_{n\to\infty}\lambda_n(v)$. Passing to the limit shows that λ is linear. Since every Cauchy sequence is bounded, there exists $C>0$ such that $\|\lambda_n\|_{F'}\le C$ for every $n\in\mathbb{N}$, and then $|\lambda(v)|\le C\|v\|_F$. Therefore, $\lambda\in F'$. Given $\varepsilon>0$, for sufficiently large n,m we have $\|\lambda_n-\lambda_m\|_{F'}<\varepsilon$; letting m tend to infinity in the corresponding pointwise inequality gives $\|\lambda_n-\lambda\|_{F'}\le\varepsilon$. Thus, F' is complete.

The inequality $\|A'\| \le \|A\|$ follows from

$$|(A'\mu)(v)| \le \|\mu\|_{G'}\|A\|\|v\|_F.$$

Conversely, the Hahn–Banach theorem applied to $Av \in G$ yields, for each $v \in F$ with $Av \neq 0$, a functional $\mu_v \in G'$ such that $\|\mu_v\|_{G'} = 1$ and $\mu_v(Av) = \|Av\|_G$. Hence,

$$\|Av\|_G \le \|A'\|\|v\|_F,$$

an inequality that also holds when $Av = 0$. Taking the supremum over the unit ball gives $\|A\| \le \|A'\|$. The assertions about the inverse follow from $(BA)' = A'B'$.

Finally, suppose that F is infinite-dimensional. There exists a linearly independent sequence $(v_n)_{n\in\mathbb{N}}$ of unit vectors. On its linear span, consisting of finite linear combinations of these vectors, we define $\lambda_0(v_n) := n$ for each $n \in \mathbb{N}$ and extend it algebraically to F by extending $(v_n)_{n\in\mathbb{N}}$ to a Hamel basis. The extension $\lambda \in F^*$ is not continuous, because it is not bounded on the unit sphere. Consequently, $\lambda \notin F'$. □

The algebraic dual does not in general carry a canonical Banach topology compatible with evaluation. For this reason, all the dual bundles that appear below are constructed using the continuous dual.

Definition 25.1.3. (Banach vector bundle) Let M be a Banach manifold of class C^r. A **Banach vector bundle of class C^r with model fiber** F over M consists of a Hausdorff topological space $\mathcal{E}$, a continuous surjective map

$$\pi\colon \mathcal{E} \longrightarrow M$$

and a Banach vector space structure on each fiber $\mathcal{E}_p := \pi^{-1}(p)$, together with an open cover $(U_\alpha)_{\alpha\in A}$ of M and homeomorphisms

$$\Phi_\alpha\colon \pi^{-1}(U_\alpha) \longrightarrow U_\alpha \times F$$

satisfying the following conditions:

(a) $\mathrm{pr}_1 \circ \Phi_\alpha = \pi$;

(b) for each $p \in U_\alpha$, the restriction

$$\Phi_{\alpha,p} := \mathrm{pr}_2 \circ \big(\Phi_\alpha \restriction_{\mathcal{E}_p}\big)\colon \mathcal{E}_p \longrightarrow F$$

is a linear and topological isomorphism;

(c) on every nonempty intersection there are maps of class C^r, with respect to the operator norm topology,

$$g_{\beta\alpha}\colon U_\alpha \cap U_\beta \longrightarrow \mathrm{GL}(F)$$

such that

$$\Phi_\beta \circ \Phi_\alpha^{-1}(p, v) = \big(p, g_{\beta\alpha}(p)v\big).$$

The family (U_α, Φ_α) is called a **family of local trivializations**. Two families determine the same C^r bundle if their union satisfies condition (c).

The regularity in Definition 25.1.3 is required in the operator norm. Since evaluation

$$\mathcal{L}(F)\times F \longrightarrow F, \qquad (A,v)\longmapsto Av,$$

is continuous and bilinear, each change of trivialization is of class C^r in the base and fiber coordinates. Combined with an atlas of M, the trivializations equip $\boldsymbol{\mathcal{E}}$ with a Banach manifold atlas modeled on $X\times F$. The projection π is then of class C^r.

Definition 25.1.3 reproduces, with Banach fibers and regularity in the operator norm, the finite-dimensional construction in Definition 1.7.2. In finite rank, continuity of a family of matrices and continuity in the operator norm are the same condition; for a Banach fiber, the latter is the condition that allows Fréchet calculus to be applied directly.

Proposition 25.1.4. (Transition maps and reconstruction) Let M be a Banach manifold of class C^r. The transition maps of a Banach vector bundle satisfy

$$g_{\alpha\alpha}(p)=\mathrm{id}_F, \qquad g_{\alpha\beta}(p)=g_{\beta\alpha}(p)^{-1}, \qquad g_{\gamma\beta}(p)g_{\beta\alpha}(p)=g_{\gamma\alpha}(p)$$

for $\alpha,\beta,\gamma\in A$ and p in the intersection of the corresponding domains.
Conversely, an open cover $(U_\alpha)_{\alpha\in A}$ of M and a family of C^r maps

$$g_{\beta\alpha}\colon U_\alpha\cap U_\beta\longrightarrow \mathrm{GL}(F)$$

satisfying these identities determine, up to a bundle isomorphism of class C^r, a Banach vector bundle with model fiber F.

Proof. The identities follow by composing the changes of trivialization. For the converse, consider the disjoint union

$$\boldsymbol{\mathcal{E}}_0:=\coprod_{\alpha\in A}(U_\alpha\times F)$$

and the relation

$$(\alpha,p,v)\sim(\beta,p,w) \quad\Longleftrightarrow\quad w=g_{\beta\alpha}(p)v.$$

The cocycle identities show that this is an equivalence relation. Let $q\colon \boldsymbol{\mathcal{E}}_0\longrightarrow \boldsymbol{\mathcal{E}}:=\boldsymbol{\mathcal{E}}_0/\!\sim$ be the projection, and equip $\boldsymbol{\mathcal{E}}$ with the quotient topology. For each α, define

$$j_\alpha\colon U_\alpha\times F\longrightarrow\boldsymbol{\mathcal{E}}, \qquad j_\alpha(p,v):=q(\alpha,p,v).$$

The map j_α is injective. Moreover, if $O\subseteq U_\alpha\times F$ is open, then

$$q^{-1}\big(j_\alpha(O)\big)=\coprod_{\beta\in A}\Big\{(\beta,p,g_{\beta\alpha}(p)v)\;\Big|\;(p,v)\in O,\ p\in U_\alpha\cap U_\beta\Big\}.$$

For each β, the set on the right is the image of the open set $O\cap((U_\alpha\cap U_\beta)\times F)$ under the homeomorphism

$$(p,v)\longmapsto(p,g_{\beta\alpha}(p)v).$$

Consequently, $q^{-1}(j_\alpha(O))$ is open, and the definition of the quotient topology implies that $j_\alpha(O)$ is open.

Therefore, j_α is a homeomorphism onto the open set $j_\alpha(U_\alpha \times F)$.
The formula

$$\pi\big(j_\alpha(p,v)\big) := p$$

is well defined, is surjective, and is continuous on each of the open sets $j_\alpha(U_\alpha \times F)$. In fact, $j_\alpha(U_\alpha \times F) = \pi^{-1}(U_\alpha)$: if $q(\beta,p,w)$ projects to $p \in U_\alpha$, it is also represented by $(\alpha,p,g_{\alpha\beta}(p)w)$. We show that $\boldsymbol{\mathcal{E}}$ is Hausdorff. If $e_1,e_2 \in \boldsymbol{\mathcal{E}}$ project to distinct points, choose disjoint open subsets of M containing their projections; their preimages under π separate e_1 and e_2. If $\pi(e_1) = \pi(e_2) = p$, choose α with $p \in U_\alpha$ and write $e_i = j_\alpha(p,v_i)$. The inequality $e_1 \neq e_2$ implies $v_1 \neq v_2$. Two disjoint balls in F about v_1 and v_2, multiplied by an open neighborhood of p contained in U_α and transported by j_α, separate the two points.
On each fiber, the operations are defined by transporting those of F via j_α; the cocycle guarantees that they do not depend on α. The trivializations

$$\Phi_\alpha : j_\alpha(U_\alpha \times F) \longrightarrow U_\alpha \times F, \qquad \Phi_\alpha := j_\alpha^{-1},$$

have as their coordinate changes precisely the maps $(p,v) \mapsto (p, g_{\beta\alpha}(p)v)$. Combining them with charts of M gives the Banach manifold atlas on the total space.
Finally, if $\widetilde{\boldsymbol{\mathcal{E}}} \longrightarrow M$ is another bundle equipped with trivializations $\widetilde{\Phi}_\alpha$ having the same transition maps, the formula

$$j_\alpha(p,v) \longmapsto \widetilde{\Phi}_\alpha^{-1}(p,v)$$

is independent of α. It defines a bundle isomorphism of class C^r, since it is the identity in each trivialization. This proves uniqueness up to isomorphism. □

Two cocycles $(g_{\beta\alpha})$ and $(\widetilde{g}_{\beta\alpha})$ over the same cover are called **equivalent** if there are maps $h_\alpha \in C^r(U_\alpha, \mathrm{GL}(F))$ such that

$$\widetilde{g}_{\beta\alpha}(p) = h_\beta(p)\, g_{\beta\alpha}(p)\, h_\alpha(p)^{-1}. \tag{25.1}$$

In that case, the formula

$$[\alpha,p,v]_g \longmapsto [\alpha,p,h_\alpha(p)v]_{\widetilde{g}}$$

is well defined by (25.1) and provides an isomorphism of the reconstructed bundles. Conversely, the local representations of a bundle isomorphism over M provide a family (h_α) satisfying that identity, after passing to a common cover. Thus, equivalence of cocycles describes exactly the change of trivializations of the same bundle.

Definition 25.1.5. (Bundle homomorphism) Let M and N be Banach manifolds. Let $\pi_{\mathcal{E}} : \boldsymbol{\mathcal{E}} \longrightarrow M$ and $\pi_{\mathcal{H}} : \boldsymbol{\mathcal{H}} \longrightarrow N$ be Banach vector bundles of class C^r, with model fibers F and G, respectively. A **bundle homomorphism of class C^r over** $f \in C^r(M,N)$ is a map $\mathscr{A} : \boldsymbol{\mathcal{E}} \longrightarrow \boldsymbol{\mathcal{H}}$ such that

$$\pi_{\mathcal{H}} \circ \mathscr{A} = f \circ \pi_{\mathcal{E}},$$

whose restrictions

$$\mathscr{A}_p : \boldsymbol{\mathcal{E}}_p \longrightarrow \boldsymbol{\mathcal{H}}_{f(p)}$$

are linear and continuous and whose local representations are C^r families, in the operator norm,

$$A_{\beta\alpha} : U_\alpha \cap f^{-1}(V_\beta) \longrightarrow \mathcal{L}(F,G).$$

A homomorphism over id_M is called a homomorphism over M. It is a **bundle isomorphism** if every fiber operator is invertible and the inverse homomorphism is of class C^r.

Proposition 25.1.6. (Local data of a homomorphism) Let M and N be Banach manifolds, and let $\boldsymbol{\mathcal{E}} \to M$ and $\boldsymbol{\mathcal{H}} \to N$ be Banach vector bundles of class C^r. The local representations of a bundle homomorphism satisfy

$$A_{\delta\gamma}(p) = h_{\delta\beta}(f(p))A_{\beta\alpha}(p)g_{\alpha\gamma}(p), \tag{25.2}$$

whenever all the trivializations involved are defined. Here g and h are the transition maps of $\boldsymbol{\mathcal{E}}$ and $\boldsymbol{\mathcal{H}}$. Conversely, a family of C^r maps with values in $\mathcal{L}(F,G)$ satisfying (25.2) determines a unique bundle homomorphism of class C^r over f. Composition of homomorphisms corresponds to pointwise composition of their local operators.

Proof. The first identity follows by writing a local representation with respect to two different pairs of trivializations. For the converse, let $e \in \boldsymbol{\mathcal{E}}_p$, let Φ_α be a trivialization about p, and choose a trivialization Ψ_β of $\boldsymbol{\mathcal{H}}$ about $f(p)$. If $\Phi_\alpha(e) = (p, v)$, set

$$\mathscr{A}(e) := \Psi_\beta^{-1}\big(f(p), A_{\beta\alpha}(p)v\big).$$

Identity (25.2) shows that the result does not depend on α or β. In each pair of trivializations, $\mathscr{A}$ is represented by $(p,v) \mapsto (f(p), A_{\beta\alpha}(p)v)$, which is of class C^r because evaluation $\mathcal{L}(F,G)\times F \longrightarrow G$ is continuous and bilinear. Uniqueness and the assertion about compositions are immediate in these representations. □

Definition 25.1.7. (Complemented subbundle) Let M be a Banach manifold. Let $\boldsymbol{\mathcal{E}} \longrightarrow M$ be a Banach vector bundle with model fiber F. A **complemented vector subbundle** is a subset $\boldsymbol{\mathcal{S}} \subseteq \boldsymbol{\mathcal{E}}$ such that each $\boldsymbol{\mathcal{S}}_p := \boldsymbol{\mathcal{S}} \cap \boldsymbol{\mathcal{E}}_p$ is a vector subspace and, for each $p \in M$, there exist a trivialization

$$\Phi : \boldsymbol{\mathcal{E}} \restriction_U \longrightarrow U \times F$$

and a closed complemented subspace $F_0 \subseteq F$ for which

$$\Phi(\boldsymbol{\mathcal{S}} \restriction_U) = U \times F_0.$$

Proposition 25.1.8. Let M be a Banach manifold, and let $\boldsymbol{\mathcal{E}} \to M$ be a Banach vector bundle. Every complemented subbundle $\boldsymbol{\mathcal{S}} \subseteq \boldsymbol{\mathcal{E}}$ is a Banach vector bundle and, over each component on which its model fiber is fixed, its inclusion in $\boldsymbol{\mathcal{E}}$ is a split embedded submanifold. In the trivializations of Definition 25.1.7, the local normal bundle is modeled on any closed complement of F_0.

Proof. If two adapted trivializations intersect, their transition map sends F_0 onto the corresponding subfiber model. The restriction is a continuous linear isomorphism. To check regularity in norm, let F_0 and $\widetilde{F}_0$ be the subfiber models, and let $\widetilde{P}\colon F \to \widetilde{F}_0$ be a continuous projection. The restricted operator can be written as $\widetilde{P} \circ g_{\beta\alpha}(p) \restriction_{F_0}$. Restriction and composition with $\widetilde{P}$ are continuous linear operations between the operator spaces; hence this family is C^r. Therefore, the restrictions of the trivializations define the bundle

structure of $\mathcal{S}$. If $F = F_0 \oplus F_1$, the inclusion is locally

$$U \times F_0 \longrightarrow U \times (F_0 \oplus F_1), \qquad (p, v) \longmapsto (p, v, 0).$$

This is the local form of a split embedded submanifold. □

Proposition 25.1.9. (Quotient by a complemented subbundle) Let M be a Banach manifold, and let $\mathcal{E} \to M$ be a Banach vector bundle. If $\mathcal{S} \subseteq \mathcal{E}$ is a complemented subbundle, the union

$$\mathcal{E}/\mathcal{S} := \coprod_{p \in M} \mathcal{E}_p/\mathcal{S}_p$$

restricted to each connected component $C \subseteq M$ has a natural Banach vector bundle structure over C, with a fixed quotient model Q_C. If the spaces Q_C are all isomorphic to a single Banach space Q, the full union is a bundle over M with model fiber Q. On each component, the sequence

$$0 \longrightarrow \mathcal{S} \longrightarrow \mathcal{E} \longrightarrow \mathcal{E}/\mathcal{S} \longrightarrow 0$$

is exact fiberwise and splits locally by homomorphisms of class C^r. If $F = F_0 \oplus F_1$ in an adapted trivialization, the projection $F_1 \longrightarrow F/F_0$ is a topological linear isomorphism. This identification depends on the complement, whereas the quotient bundle is canonical.

Proof. A transition map between adapted trivializations sends the subfiber model onto the corresponding model and therefore induces a continuous linear isomorphism between the quotient spaces. These induced operators depend on the base with C^r regularity. Indeed, if $q_\alpha \colon F \to F/F_{0,\alpha}$ is the quotient projection and $j_\alpha \colon F/F_{0,\alpha} \to F$ a continuous linear section obtained from a complement, the induced operator is $q_\beta g_{\beta\alpha}(p) j_\alpha$. This expression is C^r in the operator norm. Its value does not depend on the chosen section, because two representatives of a class differ by an element of $F_{0,\alpha}$, and the transition map sends that subspace into $F_{0,\beta}$. The cocycle identities follow by applying the operators to equivalence classes. On each connected component C, the Banach isomorphism type of these quotient spaces is locally constant. Indeed, trivialization domains that can be joined by a chain of nonempty intersections have isomorphic quotient models, and the unions corresponding to the different classes of chains would form a partition of C into open sets; connectedness forces there to be only one class. Moreover, C is open because a Banach manifold is locally connected. Fixing a model Q_C and topological linear identifications of the local models with Q_C, the induced operators become a cocycle with values in $\mathrm{GL}(Q_C)$. Proposition 25.1.4 then constructs the quotient bundle. If $F = F_0 \oplus F_1$, the canonical projection restricted to F_1 is bijective and continuous; its inverse is continuous by the continuity of the projections associated with the topological direct sum. This gives the local splitting. □

Definition 25.1.10. (Section) Let M be a Banach manifold, and let $\mathcal{E} \to M$ be a Banach vector bundle. A **section** of $\mathcal{E} \longrightarrow M$ over an open subset $U \subseteq M$ is a map $\mathbf{s} \colon U \longrightarrow \mathcal{E}$ such that $\pi \circ \mathbf{s} = \mathrm{id}_U$. It is of class C^r if, in every local trivialization, there is a map $s_\alpha \in C^r(U \cap U_\alpha, F)$ for which

$$\Phi_\alpha(\mathbf{s}(p)) = (p, s_\alpha(p)).$$

The vector space of global C^r sections is denoted by $\Gamma^r(\mathcal{E})$.

On an intersection we have

$$s_\beta(p) = g_{\beta\alpha}(p)s_\alpha(p),$$

so that the regularity of a section can be checked in any family of trivializations.

Proposition 25.1.11. (Local data and gluing of sections) Let M be a Banach manifold, and let $\mathcal{E} \to M$ be a Banach vector bundle of class C^r. A family of maps $s_\alpha \in C^r(U_\alpha, F)$ determines a unique section $\mathbf{s} \in \Gamma^r(\mathcal{E})$ if and only if

$$s_\beta(p) = g_{\beta\alpha}(p)s_\alpha(p)$$

on each overlap. More generally, sections of class C^r defined over an open cover and agreeing pairwise on overlaps glue to a unique section of class C^r. Moreover, $\Gamma^r(\mathcal{E})$ is a module over $C^r(M)$ under $(f\mathbf{s})(p) := f(p)\mathbf{s}(p)$, and every $e \in \mathcal{E}_p$ is the value at p of a local section of class C^r.

Proof. The compatibility condition allows us to define

$$\mathbf{s}(p) := \Phi_\alpha^{-1}(p, s_\alpha(p))$$

independently of the index α. In each trivialization this section is represented by s_α, so it is of class C^r; the same formula proves uniqueness. The argument for an arbitrary cover is identical. The module operations are checked pointwise and preserve regularity in the local representations. Finally, if $\Phi\colon \mathcal{E}\restriction_U \longrightarrow U \times F$ is a trivialization about p and $\Phi(e) = (p, v)$, the section $q \mapsto \Phi^{-1}(q, v)$ over U takes the value e at p. □

Proposition 25.1.12. (Pullback bundle) Let M and N be Banach manifolds. Let $f\colon N \longrightarrow M$ be a map of class C^r, and let $\mathcal{E} \longrightarrow M$ be a Banach vector bundle of class C^r. The set

$$f^*\mathcal{E} := \{(q, e) \in N \times \mathcal{E} \mid f(q) = \pi(e)\}, \qquad \pi_f(q, e) := q,$$

has a natural Banach vector bundle structure over N, called the **induced bundle** or **pullback**. Its transition maps are

$$g_{\beta\alpha} \circ f$$

over $f^{-1}(U_\alpha \cap U_\beta)$. This structure does not depend on the chosen family of trivializations.

Proof. Over $f^{-1}(U_\alpha)$ define

$$\widetilde{\Phi}_\alpha(q, e) := \big(q, \mathrm{pr}_2\, \Phi_\alpha(e)\big).$$

These bijections and their inverses provide the required local trivializations. On an intersection, the fiber coordinate change is $g_{\beta\alpha}(f(q))$, which is of class C^r. Compatibility with another family of trivializations follows from (25.1): if the change is given by h_α, the induced cocycles are related by $h_\alpha \circ f$. □

Proposition 25.1.13. (Direct sum) Let M be a Banach manifold. Let $\mathcal{E} \longrightarrow M$ and $\mathcal{H} \longrightarrow M$ be Banach

vector bundles of class C^r, with model fibers F and G. The fiberwise union

$$\mathcal{E} \oplus \mathcal{H} := \coprod_{p \in M} (\mathcal{E}_p \oplus \mathcal{H}_p)$$

is a Banach vector bundle with model fiber $F \oplus G$. In simultaneous trivializations, its transition maps are

$$g^{\mathcal{E}}_{\beta\alpha}(p) \oplus g^{\mathcal{H}}_{\delta\gamma}(p).$$

The canonical inclusions and projections are bundle homomorphisms.

Proof. On $F \oplus G$ one may use, for example, the norm $\|(v,w)\| = \|v\|_F + \|w\|_G$. The indicated diagonal operators are invertible and depend on the base in a C^r manner. The cocycle identities hold componentwise. □

If $\mathcal{E}$ and $\mathcal{H}$ are bundles over the same base, we write

$$\mathcal{E} \times_M \mathcal{H} := \{(e,h) \in \mathcal{E} \times \mathcal{H} \mid \pi_{\mathcal{E}}(e) = \pi_{\mathcal{H}}(h)\}$$

for their fiber product. This notation describes the total space underlying the direct sum when the linear operations are taken fiberwise.

Proposition 25.1.14. (Dual bundle) Let M and N be Banach manifolds. Let $\mathcal{E} \longrightarrow M$ be a Banach vector bundle of class C^r, with model fiber F and transition maps $g_{\beta\alpha}$. The union

$$\mathcal{E}' := \coprod_{p \in M} \mathcal{E}'_p$$

has a natural Banach vector bundle structure of class C^r, with model fiber F'. In the dual trivialization of Φ_α,

$$\Phi'_\alpha(\lambda_p) := \big(p, \lambda_p \circ \Phi^{-1}_{\alpha,p}\big),$$

its transition maps are

$$g^{\vee}_{\beta\alpha}(p) := \big(g_{\beta\alpha}(p)^{-1}\big)'. \tag{25.3}$$

Fiberwise evaluation

$$\mathrm{ev} \colon \mathcal{E}' \times_M \mathcal{E} \longrightarrow \mathbb{R}, \qquad (\lambda_p, e_p) \longmapsto \lambda_p(e_p),$$

is of class C^r.
If $\mathscr{A} \colon \mathcal{E} \longrightarrow \mathcal{H}$ is a homomorphism over $f \colon M \longrightarrow N$, there is a natural transpose homomorphism

$$\mathscr{A}' \colon f^*\mathcal{H}' \longrightarrow \mathcal{E}', \qquad \mathscr{A}'_p(\mu_{f(p)}) := \mu_{f(p)} \circ \mathscr{A}_p.$$

In particular, there is a canonical isomorphism

$$\mathfrak{d}_f \colon (f^*\mathcal{H})' \longrightarrow f^*(\mathcal{H}').$$

On the fiber over p, let $\iota_p\colon \mathcal{H}_{f(p)} \longrightarrow (f^*\mathcal{H})_p$ be the isomorphism $\iota_p(h) := (p,h)$. Then

$$(\mathfrak{d}_f)_p(\lambda) := \lambda \circ \iota_p.$$

Its inverse is $\mu \mapsto \mu \circ \iota_p^{-1}$. Both operators are linear and continuous, and in the induced trivializations they are represented by the identity on G'. Therefore, $\mathfrak{d}_f$ and its inverse are bundle homomorphisms of class C^r.

Proof. Proposition 25.1.2 shows that the operators in (25.3) belong to $\mathrm{GL}(F')$ and depend on p with C^r regularity. Moreover,

$$g^\vee_{\gamma\beta} g^\vee_{\beta\alpha} = \big(g^{-1}_{\gamma\beta}\big)'\big(g^{-1}_{\beta\alpha}\big)',$$

and, since $(BA)' = A'B'$, the last expression is

$$\big(g^{-1}_{\beta\alpha} g^{-1}_{\gamma\beta}\big)' = \big((g_{\gamma\beta} g_{\beta\alpha})^{-1}\big)' = g^\vee_{\gamma\alpha},$$

so they satisfy the cocycle identity in the correct order. Proposition 25.1.4 reconstructs the bundle. In the trivializations of $\mathcal{E}'$ and $\mathcal{E}$, evaluation is the continuous bilinear map $F' \times F \longrightarrow \mathbb{R}$; the dual transition law ensures that these local expressions agree on overlaps.
The local representation of $\mathscr{A}'$ is $A_{\beta\alpha}(p)'$. Transposition is continuous and linear in the operator norm, and hence the family is of class C^r; its compatibility follows by transposing (25.2). Finally, the transition maps of $(f^*\mathcal{H})'$ and $f^*(\mathcal{H}')$ are, in both cases,

$$q \longmapsto \big(h_{\delta\beta}(f(q))^{-1}\big)',$$

so the fiberwise identity defines the canonical isomorphism. □

Proposition 25.1.15. (Operator bundles) Let M be a Banach manifold. Let $\mathcal{E} \longrightarrow M$ and $\mathcal{H} \longrightarrow M$ be Banach vector bundles of class C^r, with model fibers F and G. The union

$$\mathcal{L}(\mathcal{E},\mathcal{H}) := \coprod_{p\in M} \mathcal{L}(\mathcal{E}_p, \mathcal{H}_p)$$

is a Banach vector bundle with model fiber $\mathcal{L}(F,G)$. In two pairs of trivializations, the coordinate change is

$$A \longmapsto h_{\delta\beta}(p) A g_{\alpha\gamma}(p). \tag{25.4}$$

Its sections of class C^r are identified with the homomorphisms $\mathcal{E} \longrightarrow \mathcal{H}$ of class C^r over id_M.
In particular,

$$\mathrm{End}(\mathcal{E}) := \mathcal{L}(\mathcal{E},\mathcal{E})$$

has fiber $\mathcal{L}(\mathcal{E}_p)$ and transition maps $A \mapsto g_{\beta\alpha} A g^{-1}_{\beta\alpha}$. Evaluation

$$\mathcal{L}(\mathcal{E},\mathcal{H}) \times_M \mathcal{E} \longrightarrow \mathcal{H}, \qquad (A_p, e_p) \longmapsto A_p e_p,$$

is a bundle map of class C^r and is bilinear in the fiber variables.

Proof. The space $\mathcal{L}(F,G)$ is Banach. Composition of operators is continuous and bilinear, so the maps (25.4) are continuous linear isomorphisms that depend on the point with C^r regularity. The cocycle identities follow from those of g and h, and reconstruction follows from Proposition 25.1.4. The identification of sections with homomorphisms is exactly the compatibility condition (25.2). Evaluation is represented locally by the continuous bilinear map $\mathcal{L}(F,G)\times F \longrightarrow G$. □

25.2 Tangent and cotangent bundles

Let M be a Banach manifold of class C^k, modeled on X, and suppose first that $k \geq 1$. Following Definition 24.1.15, set

$$TM := \coprod_{p\in M} T_pM, \qquad \pi_{TM}(\xi_p) := p.$$

Each chart (U,φ) induces a trivialization

$$\tau_\varphi : TM\restriction_U \longrightarrow U\times X, \qquad \tau_\varphi(\xi_p) := \big(p, \Theta_{\varphi,p}(\xi_p)\big).$$

If (V,ψ) is another chart and $p \in U\cap V$, the change in the fiber is

$$A_{\psi\varphi}(p) := D(\psi\circ\varphi^{-1})(\varphi(p)) \in \mathrm{GL}(X). \tag{25.5}$$

The chain rule gives the cocycle identities.

Proposition 25.2.1. (Regularity of the tangent bundle) If M is a Banach manifold of class C^k, with $2 \leq k < \infty$, the preceding trivializations make TM a Banach vector bundle of class C^{k-1}. If M is smooth, TM is a smooth Banach vector bundle. For a merely C^1 manifold, the same construction produces a continuous vector bundle.

Proof. If the coordinate change $\psi\circ\varphi^{-1}$ is of class C^k, the map assigning to each point its derivative, with values in $\mathcal{L}(X)$ equipped with the operator norm, is of class C^{k-1}. We consider the base with its underlying C^{k-1} structure, described in Remark 24.1.4. The expression (25.5), the openness of $\mathrm{GL}(X)$, and reconstruction from cocycles prove the assertion. When $k=1$, this map is continuous; when $k=\infty$, it is smooth. □

The loss of one derivative in the preceding proposition is part of the structure: for $k<\infty$, one should not in general assign C^k regularity to TM on the basis of an atlas of class C^k.

Definition 25.2.2. (Cotangent bundle) Let M be a Banach manifold of class at least C^1. The **cotangent space** at p is the continuous dual of the kinematic tangent space,

$$T'_pM := (T_pM)'.$$

The **cotangent bundle** is the union

$$T'M := \coprod_{p\in M} T'_pM, \qquad \pi_{T'M}(\alpha_p) := p.$$

In the chart (U,φ) it is trivialized by

$$\tau_{\varphi}^{*}(\alpha_p) = \bigl(p, \alpha_p \circ \Theta_{\varphi,p}^{-1}\bigr) \in U \times X'.$$

Thus, $T'M$ is the continuous dual bundle of TM in the sense of Proposition 25.1.14. We use neither the algebraic dual of T_pM nor the dual of the operational tangent space. This choice ensures that each fiber is a Banach space and that evaluation is continuous. The prime distinguishes this bundle from the finite-dimensional cotangent bundle T^*M and is consistent with the notation X' for the continuous dual of a Banach space.

On an intersection, if $A_{\psi\varphi}$ is the operator in (25.5), the cotangent transition map is

$$\alpha \longmapsto \bigl(A_{\psi\varphi}(p)^{-1}\bigr)'\alpha. \tag{25.6}$$

The map $A \mapsto A'$ is continuous and linear in the operator norm, and inversion in $\mathrm{GL}(X)$ is smooth. Therefore, $T'M$ is a vector bundle modeled on X', of class C^{k-1} when $2 \le k < \infty$, continuous when $k = 1$, and smooth when M is smooth.

Proposition 25.2.3. (Tangent–cotangent evaluation) Let M be a Banach manifold of class at least C^1. The bundle map

$$\mathrm{ev}\colon T'M \times_M TM \longrightarrow \mathbb{R}, \qquad \mathrm{ev}(\alpha_p, \xi_p) := \alpha_p(\xi_p),$$

is natural under coordinate changes. It has the same regularity as the tangent and cotangent bundles; in particular, it is smooth if M is smooth.

Proof. In a trivialization, the map is represented by continuous bilinear evaluation

$$X' \times X \longrightarrow \mathbb{R}, \qquad (\ell, v) \longmapsto \ell(v).$$

Formula (25.6) was chosen precisely to make this expression invariant. □

Definition 25.2.4. (Covector fields and the differential) Let M be a smooth Banach manifold. A **covector field** or a 1-**form** on an open subset $U \subseteq M$ is a smooth section $\boldsymbol{\alpha}\colon U \longrightarrow T'M$. If $f \in C^{\infty}(U)$, its **differential** is the covector field determined by

$$(df)_p(v) := \frac{d}{dt}\bigg|_{t=0} f(\gamma(t)), \qquad v = [\gamma] \in T_pM.$$

The definition does not depend on the representative γ because, in a chart (U,φ), we have

$$(df)_{\varphi}(x) = D(f \circ \varphi^{-1})(x). \tag{25.7}$$

In the same chart, a covector field is represented by

$$\alpha_{\varphi}\colon \varphi(U) \longrightarrow X', \qquad \alpha_{\varphi}(\varphi(p)) := \boldsymbol{\alpha}_p \circ \Theta_{\varphi,p}^{-1},$$

and, if (V,ψ) is another chart, satisfies

$$\alpha_\psi(\psi(p)) = \big(A_{\psi\varphi}(p)^{-1}\big)'\,\alpha_\varphi(\varphi(p)). \tag{25.8}$$

Formula (25.7) shows that df is smooth. More precisely, if M and f are of class C^k, with $1 \le k < \infty$, then $T'M$ and the section df are of class C^{k-1}; the loss comes from differentiating the changes of charts and f.

Proposition 25.2.5. (Elementary properties of the differential) Let M be a smooth Banach manifold. For $f, g \in C^\infty(M)$ we have

$$d(fg) = f\,dg + g\,df.$$

Moreover, every covector is locally the differential of a function at the point: if $p \in M$ and $\lambda_p \in T_p'M$, there exist a neighborhood U of p and $f \in C^\infty(U)$ such that $(df)_p = \lambda_p$.

Proof. The Leibniz rule follows by applying the product rule to (25.7). For the second assertion, let (U,φ) be a chart about p and set

$$\ell := \lambda_p \circ \Theta_{\varphi,p}^{-1} \in X'.$$

The function $f(q) := \ell(\varphi(q) - \varphi(p))$ is smooth on U, and its local representation has constant derivative ℓ. Consequently, $(df)_p = \lambda_p$. □

Definition 25.2.6. (Pullback of covector fields) Let $f\colon M \longrightarrow N$ be a smooth map between Banach manifolds. For a 1-form $\boldsymbol{\alpha}$ on N, define

$$(f^*\boldsymbol{\alpha})_p := \boldsymbol{\alpha}_{f(p)} \circ df_p \in T_p'M.$$

The field $f^*\boldsymbol{\alpha}$ is called the **pullback** of $\boldsymbol{\alpha}$ by f.

Proposition 25.2.7. (Regularity and naturality of pullback) Let M, N, and P be smooth Banach manifolds, and let $f\colon M \to N$ be a smooth map. The pullback of a smooth 1-form is a smooth 1-form. If $g\colon N \longrightarrow P$ is smooth, then

$$(g\circ f)^* = f^* \circ g^*, \qquad \mathrm{id}_M^* = \mathrm{id}, \qquad d(h\circ f) = f^*(dh)$$

for every $h \in C^\infty(N)$.

Proof. Let φ and ψ be charts in M and N, respectively, and write

$$\widehat{f} := \psi \circ f \circ \varphi^{-1}, \qquad \widehat{\alpha} := \alpha_\psi.$$

The local representation of the pullback is

$$(f^*\boldsymbol{\alpha})_\varphi(x) = D\widehat{f}(x)'\,\widehat{\alpha}(\widehat{f}(x)).$$

The map $x \mapsto D\widehat{f}(x)$ is smooth with respect to the operator norm, transposition is continuous and linear, and evaluation is continuous and bilinear. Therefore, the expression is smooth. The three identities follow from the chain rule and the pointwise definition. □

To treat forms of higher degree without choosing a tensor completion, if $m \in \mathbb{N}$ and X_0, Y_0 are Banach spaces,

denote by

$$\mathcal{L}^m_{\mathrm{alt}}(X_0;Y_0)$$

the subspace of continuous m-linear maps $A\colon X_0^m \longrightarrow Y_0$ that are alternating, equipped with the operator norm. It is a closed subspace of $\mathcal{L}^m(X_0;Y_0)$ and therefore is a Banach space. Coordinate changes act by

$$\omega \longmapsto \omega \circ (A^{-1},\dots,A^{-1}).$$

Proposition 25.1.4 thus provides a Banach bundle, denoted by $\bigwedge^m(T'M)$, whose fiber at p is $\mathcal{L}^m_{\mathrm{alt}}(T_pM;\mathbb{R})$.

Definition 25.2.8. (Differential forms) Let M and N be smooth Banach manifolds. A **smooth differential m-form** on M is a smooth section of $\bigwedge^m(T'M)$, for $m\in\mathbb{N}$. The space of these sections is denoted by $\Omega^m(M)$; for $m=0$ we set $\Omega^0(M):=C^\infty(M)$. If $f\colon M\longrightarrow N$ is smooth and $\omega\in\Omega^m(N)$, its pullback is defined by

$$(f^*\omega)_p(v_1,\dots,v_m) := \omega_{f(p)}(df_pv_1,\dots,df_pv_m). \tag{25.9}$$

The same local proof as in Proposition 25.2.7, using continuous multilinear composition, shows that (25.9) defines a smooth m-form and that pullback is functorial. This formulation does not identify continuous forms with a completed tensor product; it thus avoids imposing a tensor norm that is not canonical.

Definitions 25.2.2 and 25.2.4, together with Proposition 25.2.5, correspond to Definitions 1.7.46 and 1.7.47 and Corollary 1.7.50. The pullback formula is the same as in Definition 1.10.19 and preserves the identities of Proposition 1.10.20. The functional-analytic difference is that here each covector belongs to the continuous dual and all regularity is checked in the operator norm; no finite-dimensional identification with a tensor product is used.

Remark 25.2.9. (Bidual and tensor products) There is a canonical isometric linear injection

$$J_X\colon X\longrightarrow X'',\qquad J_X(v)(\ell):=\ell(v),$$

but it need not be surjective. Hence, if the model space is not reflexive, there is no canonical fiberwise identification between TM and $(T'M)'$.

Nor is there a unique tensor completion implicit in the Banach category. For example, $X'\otimes F$ maps to the space of finite-rank operators from X to F, whereas its projective and injective completions may differ and do not in general coincide with $\mathcal{L}(X,F)$. Consequently, tensor bundles must be defined by specifying a complete tensor norm. When only continuous multilinear maps are required, it is canonical to work directly with fibers such as

$$\mathcal{L}^m(T_pM;\mathbb{R}) \quad\text{or}\quad \mathcal{L}(T_pM,T_pM),$$

without imposing a tensor identification that may fail.

25.3 Vector fields and integral curves

Throughout the rest of this chapter, M will be a smooth Banach manifold modeled on a Banach space X.

Definition 25.3.1. (Vector field) Let M be a smooth Banach manifold. A **vector field** on M is a section $\mathbf{X}\colon M \longrightarrow TM$. In a chart (U,φ) it is represented by

$$X_\varphi\colon \varphi(U) \longrightarrow X, \qquad X_\varphi(\varphi(p)) := \Theta_{\varphi,p}(\mathbf{X}(p)).$$

On the overlap of two charts we have

$$X_\psi(\psi(p)) = D(\psi\circ\varphi^{-1})(\varphi(p))X_\varphi(\varphi(p)). \tag{25.10}$$

The field is continuous, locally Lipschitz, or of class C^r if its coordinate representations have the corresponding property.

We denote by $\mathfrak{X}(U) := \Gamma^\infty(TU)$ the space of smooth vector fields on an open subset $U \subseteq M$. If $f \in C^\infty(U)$ and $\mathbf{X} \in \mathfrak{X}(U)$, the function $\mathbf{X}(f) \in C^\infty(U)$ is defined by

$$\mathbf{X}(f)(p) := (df)_p(\mathbf{X}(p)), \qquad p \in U.$$

If $\mathbf{X},\mathbf{Y} \in \mathfrak{X}(U)$, in a chart we define

$$[\mathbf{X},\mathbf{Y}]_\varphi(x) := DY_\varphi(x)X_\varphi(x) - DX_\varphi(x)Y_\varphi(x). \tag{25.11}$$

Proposition 25.3.2. (Bracket of vector fields) Let M be a smooth Banach manifold, and let $U \subseteq M$ be open. Expression (25.11) is independent of the chart and defines a smooth vector field $[\mathbf{X},\mathbf{Y}]$. Moreover,

$$[\mathbf{X},\mathbf{Y}] = -[\mathbf{Y},\mathbf{X}], \qquad [\mathbf{X},f\mathbf{Y}] = \mathbf{X}(f)\mathbf{Y} + f[\mathbf{X},\mathbf{Y}]$$

for every $f \in C^\infty(U)$, and the bracket satisfies the Jacobi identity.

Proof. Let χ be a coordinate change, and write $\widetilde{X}(\chi(x)) = D\chi(x)X(x)$ and $\widetilde{Y}(\chi(x)) = D\chi(x)Y(x)$. Differentiating and subtracting gives

$$\begin{aligned} &D\widetilde{Y}(\chi(x))\widetilde{X}(\chi(x)) - D\widetilde{X}(\chi(x))\widetilde{Y}(\chi(x)) \\ &\qquad = D\chi(x)\big(DY(x)X(x) - DX(x)Y(x)\big), \end{aligned}$$

because the terms containing $D^2\chi(x)(X(x),Y(x))$ cancel by the symmetry of the second derivative. This is exactly the transformation law for a vector field. The first two identities are checked in coordinates using the product rule. For Jacobi, first consider the action on a function $f \in C^\infty(U)$. If $\widehat{f} = f\circ\varphi^{-1}$, the product rule gives

$$\mathbf{X}(\mathbf{Y}(f)) = D^2\widehat{f}(X_\varphi, Y_\varphi) + D\widehat{f}\big(DY_\varphi[X_\varphi]\big)$$

in the chart coordinates. The symmetry of $D^2\widehat{f}$ implies $[\mathbf{X},\mathbf{Y}](f) = \mathbf{X}(\mathbf{Y}(f)) - \mathbf{Y}(\mathbf{X}(f))$. Applying this identity twice, the three terms of Jacobi act as

$$\begin{aligned} [\mathbf{X},[\mathbf{Y},\mathbf{Z}]](f) &= \mathbf{XYZ}(f) - \mathbf{XZY}(f) - \mathbf{YZX}(f) + \mathbf{ZYX}(f), \\ [\mathbf{Y},[\mathbf{Z},\mathbf{X}]](f) &= \mathbf{YZX}(f) - \mathbf{YXZ}(f) - \mathbf{ZXY}(f) + \mathbf{XZY}(f), \end{aligned}$$

$$[\mathbf{Z},[\mathbf{X},\mathbf{Y}]](f)=\mathbf{ZXY}(f)-\mathbf{ZYX}(f)-\mathbf{XYZ}(f)+\mathbf{YXZ}(f).$$

Each composition appears once with each sign, so the sum is zero. At each point p, every continuous covector is the differential of a local function by Proposition 25.2.5. Since the continuous dual separates points by Hahn–Banach, a vector annihilated by all these differentials is zero. The sum of the three fields is therefore the zero field, which is the Jacobi identity. □

The local Lipschitz condition is independent of the chart. Indeed, let χ be a coordinate change, and let B be a convex ball on which X_φ is L_X-Lipschitz. After shrinking B, the smoothness of χ provides constants $C_0, C_1, C_2 > 0$ such that, for $x, y \in B$,

$$\|D\chi(x)\| \le C_0, \qquad \|D\chi(x)-D\chi(y)\| \le C_1\|x-y\|, \qquad \|x-y\| \le C_2\|\chi(x)-\chi(y)\|.$$

If also $\|X_\varphi(x)\| \le C_X$ on B, the transformation law gives

$$\|X_\psi(\chi(x))-X_\psi(\chi(y))\| \le C_2(C_0L_X + C_1C_X)\|\chi(x)-\chi(y)\|.$$

This transports a Lipschitz constant between charts. In particular, every field of class C^1 is locally Lipschitz, since its derivative is bounded on a sufficiently small ball.

Definition 25.3.3. (Integral curve) Let M be a smooth Banach manifold, and let $\mathbf{X}$ be a vector field on M. If $I \subseteq \mathbb{R}$ is an open interval and $\gamma\colon I \longrightarrow M$ is a curve of class C^1, its velocity at t is

$$\dot\gamma(t) := d\gamma_t(1) \in T_{\gamma(t)}M.$$

The curve γ is an **integral curve** of $\mathbf{X}$ if

$$\dot\gamma(t) = \mathbf{X}(\gamma(t))$$

for every $t \in I$. It is **maximal** if it is not the restriction of an integral curve defined on a strictly larger interval.

In a chart, the integral curve equation becomes the autonomous ODE

$$x'(t) = X_\varphi(x(t)).$$

The transformation law (25.10) and the chain rule ensure that this equation is independent of the coordinates.

Theorem 25.3.4. (Existence and uniqueness of integral curves) Let M be a smooth Banach manifold. Let $\mathbf{X}$ be a continuous, locally Lipschitz field on M. For each $p \in M$ there exists a unique maximal integral curve

$$\gamma_p\colon I_p \longrightarrow M, \qquad 0 \in I_p, \qquad \gamma_p(0) = p.$$

The domain I_p is an open interval. Every integral curve taking the value p at time zero is a restriction of γ_p.

Proof. Theorem B.13.1, applied to a coordinate representation of $\mathbf{X}$, gives a local integral curve. Proposition B.13.2 shows that two integral curves with a common value agree near that time and, by the open-

and-closed argument on the intersection of their intervals, agree on every common component. The local solutions can therefore be glued. The same union argument as in Theorem B.13.3 produces a maximal open interval and a unique integral curve on it. □

25.4 Flows on Banach manifolds

Definition 25.4.1. (Local flow) Let M be a smooth Banach manifold. A **local flow** on M is a continuous map

$$\Phi\colon \mathcal{D} \longrightarrow M,$$

where $\mathcal{D} \subseteq \mathbb{R} \times M$ is open and contains $\{0\} \times M$. For each $p \in M$, we require that

$$\mathcal{D}_p := \{t \in \mathbb{R} \mid (t,p) \in \mathcal{D}\}$$

be an interval containing 0. The map satisfies

$$\Phi(0,p) = p$$

and, if $s \in \mathcal{D}_p$, the exact equivalence of domains

$$t \in \mathcal{D}_{\Phi(s,p)} \quad \Longleftrightarrow \quad t+s \in \mathcal{D}_p,$$

together with the law

$$\Phi(t+s,p) = \Phi(t,\Phi(s,p))$$

whenever those conditions hold. If $\mathcal{D} = \mathbb{R} \times M$, it is called a **global flow**. A flow is of class C^r, with $r \in \mathbb{N}_0 \cup \{\infty\}$, if the map Φ is of that class. It is said to have **generating field $\mathbf{X}$** if each curve $t \mapsto \Phi(t,p)$ is of class C^1 and

$$\left.\frac{\partial}{\partial t}\right|_{t=0} \Phi(t,p) = \mathbf{X}(p)$$

for every $p \in M$. A local flow with generating field $\mathbf{X}$ is **maximal** if every other local flow with generator $\mathbf{X}$ is a restriction of it. In particular, it admits no proper extension with the same generator.

For a field $\mathbf{X}$ as in Theorem 25.3.4, define

$$\mathcal{D}_{\mathbf{X}} := \{(t,p) \in \mathbb{R} \times M \mid t \in I_p\}, \qquad \Phi_{\mathbf{X}}(t,p) := \gamma_p(t).$$

Theorem 25.4.2. (Maximal flow and smooth dependence) Let M be a smooth Banach manifold. Let $\mathbf{X}$ be a continuous, locally Lipschitz field on M. Then $\mathcal{D}_{\mathbf{X}}$ is open, $\Phi_{\mathbf{X}}$ is continuous, and it is the unique maximal local flow whose orbit curves are integral curves of $\mathbf{X}$.
If $\mathbf{X}$ is of class C^r, with $r \in \mathbb{N} \cup \{\infty\}$, then $\Phi_{\mathbf{X}}$ is of class C^r. For any $p \in M$ and $s,t \in \mathbb{R}$ such that $(s,p) \in \mathcal{D}_{\mathbf{X}}$, we have the equivalence

$$(t,\Phi_{\mathbf{X}}(s,p)) \in \mathcal{D}_{\mathbf{X}} \quad \Longleftrightarrow \quad (t+s,p) \in \mathcal{D}_{\mathbf{X}},$$

and, when these conditions hold,

$$\Phi_{\mathbf{X}}(t, \Phi_{\mathbf{X}}(s,p)) = \Phi_{\mathbf{X}}(t+s,p). \tag{25.12}$$

Proof. In a chart and for sufficiently small times, the assertions about openness, continuity, and regularity are those of Theorem B.13.5, taking the initial point as parameter. To reach an arbitrary point $(t_0,p_0) \in \mathcal{D}_{\mathbf{X}}$, cover the compact image of the curve γ_{p_0} between 0 and t_0 by finitely many charts and subdivide the interval so that each segment lies in one of them. The finite composition of the local solution maps shows that $\mathcal{D}_{\mathbf{X}}$ is open about (t_0,p_0) and that $\Phi_{\mathbf{X}}$ has the asserted regularity there. More explicitly, if $t_0 > 0$, choose $0 = t_0' < t_1' < \cdots < t_m' = t_0$ so that each segment belongs to a local solution domain; here $m \in \mathbb{N}$. Start from an initial value p near p_0. Suppose that, after j segments, with $0 \le j < m$, the point reached depends on p with the asserted regularity and remains close to $\gamma_{p_0}(t_j')$. Continuity allows us to shrink the neighborhood of p_0 so that this point belongs to the domain of the next local map. Composition with that map preserves regularity and gives the point of segment $j+1$. This is the induction step, whose initial case is the identity $p \mapsto p$. In the last segment we also allow the final time to vary in a neighborhood of t_0. This gives a solution defined on an open product about (t_0,p_0), with the required regularity. For $t_0 < 0$ we apply this construction to the field $-\mathbf{X}$; at $t_0 = 0$ the local result suffices.

Now fix s with $(s,p) \in \mathcal{D}_{\mathbf{X}}$. The curves

$$t \longmapsto \Phi_{\mathbf{X}}(t, \Phi_{\mathbf{X}}(s,p)) \quad \text{and} \quad t \longmapsto \Phi_{\mathbf{X}}(t+s,p)$$

are integral curves of $\mathbf{X}$ and take the same value at $t = 0$. Uniqueness shows that they agree on their common domain. Maximality of both curves identifies their intervals of definition and proves both the equivalence of domains and (25.12). Finally, any flow with generating field $\mathbf{X}$ consists of integral curves: differentiating $\Phi(t+h,p) = \Phi(h,\Phi(t,p))$ at $h = 0$ gives $\partial_t \Phi(t,p) = \mathbf{X}(\Phi(t,p))$. Uniqueness of integral curves then shows that this flow is a restriction of $\Phi_{\mathbf{X}}$. □

The preceding notions extend Definitions 1.7.40, 1.8.1, and 1.8.13. The proof of Theorem 1.8.15 retains its uniqueness and gluing argument here; the new step is that local existence and dependence on the initial value come from ODEs in Banach spaces, Theorems B.13.1 and B.13.5, without using local compactness.

For each $t \in \mathbb{R}$, let

$$M_t := \{p \in M \mid (t,p) \in \mathcal{D}_{\mathbf{X}}\}.$$

The openness of $\mathcal{D}_{\mathbf{X}}$ implies that M_t is open. The flow law shows that

$$\Phi_{\mathbf{X}}^t := \Phi_{\mathbf{X}}(t,\cdot)\colon M_t \longrightarrow M_{-t}$$

is a homeomorphism with inverse $\Phi_{\mathbf{X}}^{-t}$. If $\mathbf{X}$ is of class C^r, both maps are of class C^r, and hence $\Phi_{\mathbf{X}}^t$ is a C^r diffeomorphism between open sets.

Remark 25.4.3. (Fields and flows with $C^{1,1}$ regularity) Let M be a Banach manifold with the $C^{1,1}$ atlas of Definition 24.1.5. A vector field is a section $\mathbf{X}\colon M \longrightarrow TM$, and we say it is locally Lipschitz if its representations in the charts of that atlas are locally Lipschitz. This property does not depend on the chosen chart. Indeed, the law (25.10) uses only first derivatives. If $\chi = \psi \circ \varphi^{-1}$, we can shrink the domain about the point under consideration so that $D\chi$ is bounded and Lipschitz, $\mathbf{X}_\varphi$ is bounded and Lipschitz, and χ^{-1} is Lipschitz on a ball in its domain. The last property follows from the continuity of $D\chi^{-1}$ and

the mean value inequality. The estimate in Section 25.3 applies with these same bounds and shows that $\mathbf{X}_\psi = (D\chi \cdot \mathbf{X}_\varphi) \circ \chi^{-1}$ is locally Lipschitz.

The definition of an integral curve and the conclusions concerning existence, uniqueness, and a continuous maximal flow in Theorems 25.3.4 and 25.4.2 remain valid at this regularity. To see this, in each chart we apply Theorem B.13.1 to the coordinate field. The chain rule for C^1 changes transforms a coordinate solution into an integral curve independent of the chart. Local uniqueness allows these solutions to be glued and the union of their intervals to be taken, as in Theorem 25.3.4. By Theorem B.13.5, the local solution maps are continuous in time and in the initial value. Composition over a finite partition of a compact segment of the orbit, constructed in the proof of Theorem 25.4.2, proves openness of the flow domain and joint continuity. Uniqueness gives the group law and the time homeomorphisms together with their inverses. No differentiability of the flow with respect to the initial value is asserted here for a field that is only locally Lipschitz.

Proposition 25.4.4. (Generating field) Let M be a smooth Banach manifold. If $\Phi\colon \mathcal{D} \longrightarrow M$ is a local flow of class C^1, then

$$\mathbf{X}_\Phi(p) := \left.\frac{\partial}{\partial t}\right|_{t=0} \Phi(t,p) \in T_pM$$

defines a continuous vector field. Each curve $t \mapsto \Phi(t,p)$ is an integral curve of $\mathbf{X}_\Phi$. If Φ is of class C^r, with $r \geq 1$, then $\mathbf{X}_\Phi$ is of class C^{r-1}; if Φ is smooth, so is $\mathbf{X}_\Phi$.

Proof. The identity $\Phi(0,p) = p$ shows that $\mathbf{X}_\Phi(p) \in T_pM$. Differentiating the flow law

$$\Phi(t+h,p) = \Phi(h,\Phi(t,p))$$

with respect to h at $h = 0$ gives

$$\frac{\partial}{\partial t}\Phi(t,p) = \mathbf{X}_\Phi(\Phi(t,p)).$$

The regularity assertion follows by taking a partial derivative with respect to time. □

Theorem 25.4.5. (Global flow of a bounded field on a Banach space) Let X be a Banach space, regarded as a smooth Banach manifold, and let $\mathbf{V}\colon X \longrightarrow X$ be a continuous, locally Lipschitz field. If there exists $C \geq 0$ such that

$$\|\mathbf{V}(x)\|_X \leq C$$

for every $x \in X$, then its maximal flow is global:

$$\Phi_{\mathbf{V}}\colon \mathbb{R} \times X \longrightarrow X.$$

Moreover,

$$\|\Phi_{\mathbf{V}}(t,x) - x\|_X \leq C|t|$$

for every $(t,x) \in \mathbb{R} \times X$. If $\mathbf{V}$ is of class C^r, with $r \in \mathbb{N} \cup \{\infty\}$, then $\Phi_{\mathbf{V}}$ is of class C^r, and each $\Phi_{\mathbf{V}}^t\colon X \longrightarrow X$ is a diffeomorphism of class C^r, with inverse $\Phi_{\mathbf{V}}^{-t}$.

Proof. Corollary B.13.6, applied to $F(t,x) := \mathbf{V}(x)$, shows that every maximal integral curve is defined for all $t \in \mathbb{R}$ and provides the indicated estimate. Regularity of the flow follows from Theorem B.13.5. The law (25.12) gives

$$\Phi_{\mathbf{V}}^{-t} \circ \Phi_{\mathbf{V}}^{t} = \mathrm{id}_X = \Phi_{\mathbf{V}}^{t} \circ \Phi_{\mathbf{V}}^{-t}.$$

□

The boundedness condition in the preceding theorem uses the distinguished norm of the space X. On an abstract Banach manifold it is not an invariant condition until additional structure is fixed, for example a continuous norm on each fiber of TM with suitable uniform control. The basic intrinsic criterion for continuation remains the analysis, in a final chart, of convergence of the curve and membership of its limit in the domain, as in Theorem B.13.4.

25.5 Linear connections on Banach bundles

Let $\pi\colon \mathcal{E} \longrightarrow M$ be a smooth Banach vector bundle with model fiber F, over a smooth Banach manifold modeled on X. In infinite dimensions it is not enough to require algebraic identities of an operator on sections: one must also require its local coefficients to depend smoothly on the point in the operator norm topology.

Definition 25.5.1. (Linear connection) Let M be a smooth Banach manifold, and let $\mathcal{E} \to M$ be a smooth Banach vector bundle. A **linear connection** on $\mathcal{E}$ is a rule that, for each open set $U \subseteq M$, each $\mathbf{X} \in \mathfrak{X}(U)$, and each $\mathbf{s} \in \Gamma^{\infty}(\mathcal{E}\restriction_U)$, assigns a section

$$\nabla_{\mathbf{X}}\mathbf{s} \in \Gamma^{\infty}(\mathcal{E}\restriction_U),$$

compatibly with restriction to smaller open sets, and satisfies

$$\begin{aligned} \nabla_{f\mathbf{X}+g\mathbf{Y}}\mathbf{s} &= f\nabla_{\mathbf{X}}\mathbf{s} + g\nabla_{\mathbf{Y}}\mathbf{s}, \\ \nabla_{\mathbf{X}}(a\mathbf{s}+b\mathbf{t}) &= a\nabla_{\mathbf{X}}\mathbf{s} + b\nabla_{\mathbf{X}}\mathbf{t}, \\ \nabla_{\mathbf{X}}(f\,\mathbf{s}) &= \mathbf{X}(f)\mathbf{s} + f\nabla_{\mathbf{X}}\mathbf{s} \end{aligned}$$

for $f, g \in C^{\infty}(U)$ and $a, b \in \mathbb{R}$. The following local regularity is also required. If (U,φ) is a chart of M and $\Phi\colon \mathcal{E}\restriction_U \longrightarrow U \times F$ is a trivialization, there is a map smooth in the operator norm,

$$\Gamma_{\varphi,\Phi}\colon \varphi(U) \longrightarrow \mathcal{L}\big(X, \mathcal{L}(F)\big)$$

such that

$$\big(\nabla_{\mathbf{X}}\mathbf{s}\big)_{\varphi,\Phi}(x) = Ds_{\varphi,\Phi}(x)[X_{\varphi}(x)] + \Gamma_{\varphi,\Phi}(x)(X_{\varphi}(x))s_{\varphi,\Phi}(x). \tag{25.13}$$

The map $\Gamma_{\varphi,\Phi}$ is called the **local coefficient of the connection** in the chosen chart and trivialization.

The first identity expresses linearity over $C^{\infty}(U)$ in the direction, whereas the third is the Leibniz rule in the section. The additional local condition ensures that the operation is a continuous differential structure and not merely an algebraic operator.

The algebraic part agrees with Definition 2.4.2. The difference is analytic: in a trivialization with infinite-dimensional fiber, the coefficient must be a smooth map with values in $\mathcal{L}(X, \mathcal{L}(F))$ equipped with the operator

norm. This hypothesis replaces the automatic control of matrix families in finite dimensions and ensures smoothness of the evaluation appearing in (25.13).

Proposition 25.5.2. (Transformation law for a connection) Let M be a smooth Banach manifold, and let $\mathcal{E} \to M$ be a smooth Banach vector bundle with connection ∇. Let (U, φ, Φ) and (V, ψ, Ψ) be two choices of chart and trivialization. On the overlap, write

$$\chi := \psi \circ \varphi^{-1}, \qquad g(x) := g_{\Psi\Phi}(\varphi^{-1}(x)).$$

If Γ and $\widetilde{\Gamma}$ are the corresponding local coefficients, then

$$\widetilde{\Gamma}(\chi(x))(D\chi(x)v) = g(x)\Gamma(x)(v)g(x)^{-1} - Dg(x)[v]g(x)^{-1} \tag{25.14}$$

for every $v \in X$. Conversely, a family of smooth maps with values in $\mathcal{L}(X, \mathcal{L}(F))$ satisfying this law determines a unique linear connection.

Proof. Let $x = \varphi(p)$, $w = s_{\varphi,\Phi}(x)$, and $v = X_\varphi(x)$. In the second coordinates we have

$$s_{\psi,\Psi}(\chi(x)) = g(x)w, \qquad X_\psi(\chi(x)) = D\chi(x)v.$$

The chain rule and product rule give

$$D(s_{\psi,\Psi} \circ \chi)(x)[v] = Dg(x)[v]w + g(x)Ds_{\varphi,\Phi}(x)[v].$$

Since $\nabla_{\mathbf{X}}\mathbf{s}$ is a section of $\mathcal{E}$, its second representation must be $g(x)$ times the first. Substituting (25.13) and canceling the term involving $Ds_{\varphi,\Phi}$ gives

$$\widetilde{\Gamma}(\chi(x))(D\chi(x)v)g(x)w = g(x)\Gamma(x)(v)w - Dg(x)[v]w.$$

Since $w \in F$ is arbitrary, this identity is equivalent to (25.14).
Conversely, define $\nabla_{\mathbf{X}}\mathbf{s}$ by (25.13) in each trivialization. The preceding calculation, read in reverse, shows that the local expressions transform as a section and therefore glue together. The identities in Definition 25.5.1 are checked directly, and the local formula proves uniqueness. □

Theorem 25.5.3. (Existence of connections) Let M be a smooth Banach manifold. Suppose that M admits smooth partitions of unity subordinate to every open cover. Then every smooth Banach vector bundle over M admits a smooth linear connection.

Proof. Simultaneously refining an atlas of M and a family of trivializations, we obtain a cover $(U_\alpha)_{\alpha \in A}$ such that each U_α is the domain of a chart φ_α and a trivialization Φ_α. Choose a smooth partition of unity $(\rho_\alpha)_{\alpha \in A}$ subordinate to it. On $\mathcal{E}\restriction_{U_\alpha}$ there is a local flat connection ∇^α whose coefficient in $(\varphi_\alpha, \Phi_\alpha)$ is zero.
Define the rule on the entire sheaf of sections. Let $W \subseteq M$ be open, let $\mathbf{X} \in \mathfrak{X}(W)$, and let $\mathbf{s} \in \Gamma^\infty(\mathcal{E}\restriction_W)$. On $W \cap U_\alpha$ set

$$T_\alpha(\mathbf{X}, \mathbf{s}) := \rho_\alpha\restriction_W \, \nabla^\alpha_{\mathbf{X}\restriction_{W\cap U_\alpha}}(\mathbf{s}\restriction_{W\cap U_\alpha}).$$

Since $\operatorname{supp}(\rho_\alpha) \subseteq U_\alpha$, this section extends by zero to a smooth section of $\mathcal{E}\restriction_W$: every point of $W \setminus U_\alpha$ has a

neighborhood on which ρ_α vanishes identically. The family of these extensions is locally finite. Therefore, the sum

$$\nabla_{\mathbf{X}}\mathbf{s} := \sum_{\alpha\in A} T_\alpha(\mathbf{X},\mathbf{s})$$

is well defined and smooth on W. The same formula on an open set $W_0 \subseteq W$ is the restriction of the preceding one, so the rule is compatible with restrictions.

Each ∇^α is linear over functions in the direction and linear over $\mathbb{R}$ in the section; multiplication by ρ_α and summation preserve these two properties. For $f \in C^\infty(W)$, on each $W \cap U_\alpha$ we have

$$\begin{aligned}\nabla_{\mathbf{X}}(f\mathbf{s}) &= \sum_{\alpha\in A} \rho_\alpha\big(\mathbf{X}(f)\mathbf{s} + f\nabla^\alpha_{\mathbf{X}}\mathbf{s}\big)\\ &= \mathbf{X}(f)\mathbf{s} + f\nabla_{\mathbf{X}}\mathbf{s},\end{aligned}$$

since $\sum_{\alpha\in A}\rho_\alpha = 1$. Finally, in any chart and trivialization, each local flat connection transforms by (25.14) into a smooth coefficient with values in $\mathcal{L}(X,\mathcal{L}(F))$. The coefficient of ∇ is the locally finite sum of those coefficients multiplied by ρ_α; hence it is smooth in the operator norm. Thus all the conditions of Definition 25.5.1 hold. □

The hypothesis of the preceding theorem is substantive in the Banach category. Paracompactness alone does not produce smooth partitions of unity; the hypotheses on the model space studied in Section 24.8 are required.

Proposition 25.5.4. (Induced connections) Let M and N be smooth Banach manifolds, and let $\mathcal{E} \to M$ be a smooth Banach vector bundle. Let ∇ be a connection on $\mathcal{E}$. Then:

(i) the dual bundle $\mathcal{E}'$ has the dual connection ∇' determined by the identity

$$(\nabla'_{\mathbf{X}}\lambda)(\mathbf{s}) = \mathbf{X}\big(\lambda(\mathbf{s})\big) - \lambda(\nabla_{\mathbf{X}}\mathbf{s}); \tag{25.15}$$

here $U \subseteq M$ is open, $\mathbf{X} \in \mathfrak{X}(U)$, $\lambda \in \Gamma^\infty(\mathcal{E}'\restriction_U)$, and $\mathbf{s} \in \Gamma^\infty(\mathcal{E}\restriction_U)$;

(ii) if $\mathcal{H}$ has a connection $\nabla^{\mathcal{H}}$, the bundle $\mathcal{E}\oplus\mathcal{H}$ has the direct sum connection

$$\nabla^{\oplus}_{\mathbf{X}}(\mathbf{s},\mathbf{t}) = (\nabla_{\mathbf{X}}\mathbf{s}, \nabla^{\mathcal{H}}_{\mathbf{X}}\mathbf{t});$$

(iii) if $f\colon N \longrightarrow M$ is smooth, the bundle $f^*\mathcal{E}$ has a connection $f^*\nabla$. Let (V,ψ) be a chart of N and (U,φ) a chart of M such that $f(V) \subseteq U$, and let $\Phi\colon \mathcal{E}\restriction_U \longrightarrow U\times F$ be a trivialization. Let $\widehat{f} := \varphi\circ f\circ\psi^{-1}$, and denote by Γ the coefficient of ∇ in (φ,Φ). In the induced trivialization, if V and σ also denote their local representations, the connection has the expression

$$\big((f^*\nabla)_V\sigma\big)(y) = D\sigma(y)[V(y)] + \Gamma(\widehat{f}(y))\big(D\widehat{f}(y)[V(y)]\big)\sigma(y). \tag{25.16}$$

Proof. For (25.15) to define a covector, we must first check its dependence on the test section. If $h \in C^\infty(U)$, then

$$\mathbf{X}\big(\lambda(h\mathbf{s})\big) - \lambda(\nabla_{\mathbf{X}}(h\mathbf{s})) = \mathbf{X}\big(h\lambda(\mathbf{s})\big) - \lambda\big(\mathbf{X}(h)\mathbf{s} + h\nabla_{\mathbf{X}}\mathbf{s}\big)$$

$$= h\big(\mathbf{X}(\lambda(\mathbf{s})) - \lambda(\nabla_{\mathbf{X}}\mathbf{s})\big).$$

The right-hand side of (25.15) is therefore $C^\infty(U)$-linear in $\mathbf{s}$. To check also that its value at a point depends only on the fiber, write ℓ and s for the representations of λ and $\mathbf{s}$, and $u = X_\varphi(x)$. The derivative of evaluation, which is continuous and bilinear, gives

$$D\big(\ell(\cdot)(s(\cdot))\big)(x)[u] = D\ell(x)[u](s(x)) + \ell(x)(Ds(x)[u]).$$

Subtracting $\ell(x)(Ds(x)[u] + \Gamma(x)(u)s(x))$ cancels the terms involving Ds. The result depends only on $s(x)$ and is given by the continuous functional

$$D\ell(x)[X_\varphi(x)] - \big(\Gamma(x)(X_\varphi(x))\big)'\ell(x).$$

In particular, it is continuous in the fiber variable and depends smoothly on the point. The coefficient of the dual connection is

$$\Gamma'(x)(v) = -\big(\Gamma(x)(v)\big)',$$

which is smooth in the operator norm because transposition $\mathcal{L}(F) \longrightarrow \mathcal{L}(F')$ is continuous and linear. Differentiating the identity $\langle (g^{-1})'\ell, gw\rangle = \langle \ell, w\rangle$ and using (25.14) gives exactly the transformation law of Γ' for the dual cocycle $(g^{-1})'$. Linearity and the Leibniz rule in λ follow directly from (25.15).

The direct sum connection satisfies the identities componentwise; in simultaneous trivializations its coefficient is the diagonal operator $\Gamma^{\mathcal{E}} \oplus \Gamma^{\mathcal{H}}$.

For the pullback, suppose that N is modeled on a Banach space Y. In the coordinates and induced trivialization of the statement, define

$$\Gamma^f(y)(w) := \Gamma(\widehat{f}(y))\big(D\widehat{f}(y)[w]\big), \qquad w \in Y.$$

Composition and evaluation of operators are smooth, so $\Gamma^f : \psi(V) \longrightarrow \mathcal{L}(Y, \mathcal{L}(F))$ is smooth in the operator norm. If the domain chart, the codomain chart, and the trivialization are changed, substitute (25.14) into this formula and use

$$D(g \circ \widehat{f})(y)[w] = Dg(\widehat{f}(y))[D\widehat{f}(y)[w]].$$

The result is (25.14) for the induced transition map $g \circ \widehat{f}$; hence the local expressions glue together. The resulting local formula is (25.16). Its linearity over functions in the vector direction and the Leibniz rule in σ follow, respectively, from the linearity of $D\widehat{f}(y)$ and the product rule for $D(h\sigma)$. □

The dual connection and the induced connection extend the constructions of Proposition 2.4.27. In finite dimensions the coefficients are matrices; here the same proof additionally requires that transposition, composition, and the coefficients depend continuously in the operator norm.

25.6 Differentiation along curves and parallel transport

Let $\gamma : I \longrightarrow M$ be a curve of class C^1. A field of class C^1 along γ is a section $\mathbf{V} \in \Gamma^1(\gamma^*\boldsymbol{\mathcal{E}})$. If $\gamma(J)$ is contained in the domain of a chart and a trivialization, write $x(t)$ for the representation of γ and $v(t)$ for that of $\mathbf{V}$. The local formula (25.13) shows that $(\nabla_{\mathbf{X}}\mathbf{s})(p)$ depends on $\mathbf{X}$ only through $\mathbf{X}(p)$. Hence, if $u \in T_pM$, we write $\nabla_u\mathbf{s}$ for the

common value of $(\nabla_{\mathbf{X}}\mathbf{s})(p)$ among all local fields $\mathbf{X}$ such that $\mathbf{X}(p) = u$.

Definition 25.6.1. (Covariant derivative along a curve) Let M be a smooth Banach manifold, let $\boldsymbol{\mathcal{E}} \to M$ be a smooth Banach vector bundle with connection, and let $\gamma\colon I \to M$ be a curve of class C^1. The **covariant derivative of $\mathbf{V}$ along** γ is the field $\frac{D^\nabla \mathbf{V}}{dt}$ whose representation in the trivialization Φ is defined locally as follows. For p in the domain of Φ, denote by

$$\Phi_p := \mathrm{pr}_2 \circ \big(\Phi \restriction_{\boldsymbol{\mathcal{E}}_p}\big)\colon \boldsymbol{\mathcal{E}}_p \longrightarrow F$$

the fiber coordinate. Then

$$\Phi_{\gamma(t)}\left(\left(\frac{D^\nabla \mathbf{V}}{dt}\right)(t)\right) = v'(t) + \Gamma(x(t))(x'(t))v(t). \tag{25.17}$$

For γ and $\mathbf{V}$ of class C^1, the covariant derivative is a continuous field along γ. The field $\mathbf{V}$ is **parallel** if $\frac{D^\nabla \mathbf{V}}{dt} = 0$.

Proposition 25.6.2. (Invariance of differentiation along curves) Let M be a smooth Banach manifold, let $\boldsymbol{\mathcal{E}} \to M$ be a smooth Banach vector bundle with connection, and let $\gamma\colon I \to M$ be a curve of class C^1. Expression (25.17) does not depend on the chart or the trivialization. It is linear in $\mathbf{V}$ and satisfies

$$\frac{D^\nabla(a\mathbf{V})}{dt} = a'\mathbf{V} + a\frac{D^\nabla \mathbf{V}}{dt}$$

for every function $a \in C^1(I)$. If $\mathbf{V}(t) = \mathbf{s}(\gamma(t))$ for a smooth local section $\mathbf{s}$, then

$$\frac{D^\nabla \mathbf{V}}{dt}(t) = \nabla_{\dot\gamma(t)}\mathbf{s}.$$

Proof. Under a change of trivialization we have $\widetilde{v}(t) = g(x(t))v(t)$. Therefore,

$$\widetilde{v}'(t) = Dg(x(t))[x'(t)]v(t) + g(x(t))v'(t).$$

Adding the connection term and using (25.14) cancels the two terms containing Dg, and the result is $g(x(t))$ times the right-hand side of (25.17). Invariance under changes of base coordinates is included in the same law. The remaining assertions follow from the product rule and (25.13). □

Theorem 25.6.3. (Existence and uniqueness of parallel transport) Let M be a smooth Banach manifold, let $\boldsymbol{\mathcal{E}} \to M$ be a smooth Banach vector bundle with connection, and let $\gamma\colon I \to M$ be a curve of class C^1. Let $t_0 \in I$ and $e_0 \in \boldsymbol{\mathcal{E}}_{\gamma(t_0)}$. There exists a unique parallel field $\mathbf{V}$ along γ such that $\mathbf{V}(t_0) = e_0$. For $t_0, t_1 \in I$, the map

$$P^\nabla_{\gamma, t_0 \to t_1}\colon \boldsymbol{\mathcal{E}}_{\gamma(t_0)} \longrightarrow \boldsymbol{\mathcal{E}}_{\gamma(t_1)}, \qquad e_0 \longmapsto \mathbf{V}(t_1),$$

is a topological linear isomorphism. Moreover,

$$P^\nabla_{\gamma,t_1\to t_2} \circ P^\nabla_{\gamma,t_0\to t_1} = P^\nabla_{\gamma,t_0\to t_2},$$
$$\big(P^\nabla_{\gamma,t_0\to t_1}\big)^{-1} = P^\nabla_{\gamma,t_1\to t_0}.$$

for any $t_0, t_1, t_2 \in I$.

Proof. In a trivialization over a subinterval $J \subseteq I$, the parallelism condition is equivalent to the linear ODE in F

$$v'(t) = -A(t)v(t), \qquad A(t) := \Gamma(x(t))(x'(t)) \in \mathcal{L}(F). \tag{25.18}$$

The coefficient A is continuous in the operator norm. The existence and uniqueness theorem for ODEs in Banach spaces, Theorem B.13.1, gives a unique local solution. On every compact subinterval contained in J, the function $\|A(t)\|$ is bounded, and the integral equation together with Grönwall's lemma 1.8.19 gives

$$\|v(t)\|_F \le \|v(t_0)\|_F \exp\left(\int_{t_0}^{t} \|A(\tau)\|\, d\tau\right)$$

when $t \ge t_0$, with the analogous estimate in the reverse direction. Therefore, the solution remains bounded on every compact subinterval. If a finite endpoint c of the maximal interval belonged to the interior of J, then, on a compact set containing t_0 and c, A and v would also be bounded. The equation would imply that $v' = -Av$ is bounded; hence v would be uniformly Lipschitz and would have a limit in F as t tends to c, because F is complete. Applying the local theorem again with that limit as initial value would extend the solution beyond c, a contradiction. Thus, the solution exists throughout J. Covering the curve segment between two times by finitely many trivializations and using uniqueness on the overlaps gives a solution on all of I.

The equation is linear in the initial value, and the preceding estimate, combined over finitely many trivializations, proves continuity of the transport operator. Uniqueness shows that transport from t_0 to t_1 followed by transport from t_1 to t_2 produces the same parallel section as direct transport. Taking $t_2 = t_0$ gives the formula for the inverse. □

The notion of a section along a curve and the differentiation formula are those of Definition 2.7.3 and Theorem 2.7.5. Likewise, the composition and inversion laws correspond to Theorem 2.7.12 and Proposition 2.7.14. The new feature here is that the linear equation takes values in a Banach fiber; global existence on the interval follows from the estimate in Grönwall's lemma 1.8.19 and the completeness of the fiber, rather than from finite dimensionality.

Definition 25.6.4. (Curvature of a connection) Let M be a smooth Banach manifold, and let $\mathcal{E} \to M$ be a smooth Banach vector bundle with connection ∇. The **curvature** of ∇ is the operator

$$\mathbf{R}^{\nabla}(\mathbf{X}, \mathbf{Y})\mathbf{s} := \nabla_{\mathbf{X}} \nabla_{\mathbf{Y}} \mathbf{s} - \nabla_{\mathbf{Y}} \nabla_{\mathbf{X}} \mathbf{s} - \nabla_{[\mathbf{X},\mathbf{Y}]} \mathbf{s}.$$

The connection is **flat** if $\mathbf{R}^{\nabla} = 0$.

Proposition 25.6.5. (Tensoriality and local expression of curvature) Let M be a smooth Banach manifold, and let $\mathcal{E} \to M$ be a smooth Banach vector bundle with connection ∇. Curvature is $C^\infty(M)$-linear in $\mathbf{X}$, $\mathbf{Y}$, and $\mathbf{s}$, and alternating in $\mathbf{X}, \mathbf{Y}$. The local expression obtained below also shows that its value at p depends only on $\mathbf{X}(p)$, $\mathbf{Y}(p)$, and $\mathbf{s}(p)$. Thus, for each $p \in M$ it determines a continuous trilinear map

$$\mathbf{R}^{\nabla}_p \colon T_pM \times T_pM \times \mathcal{E}_p \longrightarrow \mathcal{E}_p.$$

Equivalently,

$$\mathbf{R}^{\nabla}_p \in \mathcal{L}^2_{\mathrm{alt}}\big(T_pM; \mathcal{L}(\boldsymbol{\mathcal{E}}_p)\big).$$

In a chart and a trivialization, if x represents p, then

$$\mathbf{R}^{\nabla}_x(u,v)w = \Omega(x)(u,v)w, \tag{25.19}$$

where

$$\begin{aligned}\Omega(x)(u,v) = {} & D\Gamma(x)[u](v) - D\Gamma(x)[v](u) \\ & + \Gamma(x)(u)\Gamma(x)(v) - \Gamma(x)(v)\Gamma(x)(u).\end{aligned}$$

Under a change of chart and trivialization as in Proposition 25.5.2, we have

$$\widetilde{\Omega}(\chi(x))(D\chi(x)u, D\chi(x)v) = g(x)\Omega(x)(u,v)g(x)^{-1}. \tag{25.20}$$

Proof. Antisymmetry is immediate. For $f \in C^\infty(M)$, we use

$$[f\mathbf{X}, \mathbf{Y}] = f[\mathbf{X}, \mathbf{Y}] - \mathbf{Y}(f)\mathbf{X}$$

and the Leibniz rules for the connection to obtain $\mathbf{R}^{\nabla}(f\mathbf{X}, \mathbf{Y})\mathbf{s} = f\mathbf{R}^{\nabla}(\mathbf{X}, \mathbf{Y})\mathbf{s}$. Linearity in the second direction follows from antisymmetry. Likewise, on expanding $\mathbf{R}^{\nabla}(\mathbf{X}, \mathbf{Y})(f\mathbf{s})$, the terms involving first derivatives of f cancel, and the remaining second-order term is

$$\big(\mathbf{X}(\mathbf{Y}(f)) - \mathbf{Y}(\mathbf{X}(f)) - [\mathbf{X}, \mathbf{Y}](f)\big)\mathbf{s} = 0.$$

These identities prove linearity over functions. Pointwise dependence and continuity are checked directly using the coefficients of the connection. Denote by U, V and s the local representations of the two fields and the section; in the following equalities all maps and their derivatives are evaluated at x. Applying (25.13) twice gives

$$\begin{aligned}(\nabla_{\mathbf{X}}\nabla_{\mathbf{Y}}\mathbf{s})_{\varphi,\Phi} = {} & D^2s[U,V] + Ds[DV[U]] + D\Gamma[U](V)s + \Gamma(DV[U])s \\ & + \Gamma(V)Ds[U] + \Gamma(U)Ds[V] + \Gamma(U)\Gamma(V)s.\end{aligned}$$

The expression for $\nabla_{\mathbf{Y}}\nabla_{\mathbf{X}}\mathbf{s}$ is obtained by interchanging U and V. Subtracting them cancels the terms involving D^2s by symmetry, and the two terms in which a derivative of s is multiplied by Γ appear on both sides with the same sign. The terms containing DU or DV sum to

$$Ds[DV[U] - DU[V]] + \Gamma(DV[U] - DU[V])s = (\nabla_{[\mathbf{X},\mathbf{Y}]}\mathbf{s})_{\varphi,\Phi}.$$

Subtracting this last expression leaves (25.19), now obtained for arbitrary fields and sections. They may therefore be replaced by constant fields with the same values without changing the result. For $u, v \in X$ and $w \in F$, the formula gives the bound

$$\|\Omega(x)(u,v)w\|_F \le \big(2\|D\Gamma(x)\| + 2\|\Gamma(x)\|^2\big)\|u\|_X\|v\|_X\|w\|_F.$$

The norms of $\Gamma(x)$ and $D\Gamma(x)$ are those of $\mathcal{L}(X, \mathcal{L}(F))$ and $\mathcal{L}(X, \mathcal{L}(X, \mathcal{L}(F)))$, respectively. This proves trilinear continuity; smoothness in x follows from the smoothness of Γ and continuous bilinear composition of operators. Finally, since $\mathbf{R}^{\nabla}(\mathbf{X}, \mathbf{Y})\mathbf{s}$ is a section and is tensorial in its three arguments, its local representations satisfy (25.20); equivalently, the identity follows by substituting (25.14) and canceling the terms containing derivatives of g and χ. □

The definition and proof of tensoriality correspond to Definition 2.10.1 and Proposition 2.10.2. The algebraic cancellations are exactly the same. What must additionally be checked in the Banach setting is that $D\Gamma(x)[u](v)$ and the operator products in (25.19) depend smoothly on x in the operator norm; this follows from the smoothness of Γ and the continuous bilinearity of evaluation and composition in $\mathcal{L}(F)$.

26

Hilbert geometry and Finsler structures

The existence of a Banach tangent space does not by itself provide a notion of length. It is useful to distinguish three structures that are often confused: a strong Riemannian metric on a Hilbert manifold, a weak Riemannian metric, and a Banach–Finsler structure. The first allows classical Riemannian geometry to be transported locally through the Riesz isomorphism; the second may lack even gradients, a Levi–Civita connection, or a distance that separates points; the third retains the local metric control needed for completeness and deformation flows. At the end we distinguish this theory from classical Finsler geometry, whose vertical convexity leads to the geodesic spray and the Chern connection. Manifolds are understood according to the convention in Definition 24.1.1. In Riemannian geometry and classical Finsler geometry we work with smooth differentiable structures; the lower regularity needed for variational applications will be specified in the Banach–Finsler section.

What remains of Riemannian geometry in infinite dimensions

In finite dimensions, every Riemannian metric identifies vectors and covectors and produces a distance locally equivalent to the coordinate distance. On a Hilbert manifold, that identification may fail if the metric is weak. This difference, studied in modern infinite-dimensional geometry, explains why some gradients do not exist, why the distance can degenerate, and why the Hopf–Rinow theorem loses its usual equivalences. Strong and Banach–Finsler structures recover part of the necessary control, but each conclusion must be proved under its own hypotheses.

26.1 Hilbert manifolds and strong or weak metrics

Definition 26.1.1. A **Hilbert manifold** is a Banach manifold whose model space is a real Hilbert space H. Let M be a Hilbert manifold modeled on H. A **smooth weak Riemannian metric** on M is a family $\mathbf{g} = (\mathbf{g}_x)_{x\in M}$ of continuous positive definite inner products on T_xM such that, in every trivialization of TM, the map

$$x \longmapsto \mathbf{g}_x \in \mathcal{L}^2_s(H;\mathbb{R})$$

is smooth. Its musical homomorphism is

$$\flat_{\mathbf{g}} \colon TM \longrightarrow T'M, \qquad \flat_{\mathbf{g}}(v) = \mathbf{g}(v, \cdot).$$

Here $T'M$ is the bundle of continuous duals from Definition 25.2.2; in coordinates its fibers are modeled on H'. The metric is **strong** if each norm $|v|_{\mathbf{g},x} = \mathbf{g}_x(v,v)^{\frac{1}{2}}$ induces the given topology of T_xM; it is **strictly weak** if it is not strong. Thus, "weak" here means "not necessarily strong." Positivity implies that $\flat_{\mathbf{g},x}$ is injective, but not that it is surjective.

Fix an inner product $\langle \cdot, \cdot \rangle_H$ on the model space of a Hilbert manifold. In a chart there is a unique positive, injective, self-adjoint operator $G(x) \in \mathcal{L}(H)$ such that

$$\mathbf{g}_x(u,v) = \langle G(x)u, v \rangle_H. \tag{26.1}$$

This is the representation in Proposition B.3.23, applied at each point. The map $x \mapsto G(x)$ is smooth. After identifying H' with H by Riesz, $\flat_{\mathbf{g},x}$ is represented by $G(x)$. In particular, its image is dense. Indeed, since $G(x)$ is self-adjoint, $(\operatorname{Ran} G(x))^{\perp} = \ker(G(x)^*) = \ker G(x) = \{0\}$ and hence

$$\overline{\operatorname{Ran} G(x)} = \big(\ker G(x)\big)^{\perp} = H.$$

The range may nevertheless be proper and nonclosed.

Proposition 26.1.2. For a weak Riemannian metric $\mathbf{g}$ on a Hilbert manifold, the following are equivalent:

(i) $\mathbf{g}$ is strong;

(ii) $\flat_{\mathbf{g},x} \colon T_xM \longrightarrow T_x'M$ is a topological isomorphism for every $x \in M$;

(iii) $\flat_{\mathbf{g}} \colon TM \longrightarrow T'M$ is a smooth vector bundle isomorphism;

(iv) about each x_0 there exist a chart and constants $0 < c \le C$ such that

$$c\|v\|_H \le |v|_{\mathbf{g},x} \le C\|v\|_H \quad \text{for every } x \text{ in a neighborhood of } x_0 \text{ and } v \in H.$$

(v) about every point there is a Hilbert chart in which the operator $G(x)$ of (26.1) belongs to $\mathrm{GL}(H)$ for every x in its domain; this property then holds in every chart.

Moreover, if a nonempty Banach manifold admits a strong metric, its model space is isomorphic to a Hilbert space.

Proof. The norm of (26.1) induces the topology of H if and only if there exist $c, C > 0$ such that

$$c^2\|v\|_H^2 \le \langle G(x)v, v \rangle_H \le C^2\|v\|_H^2.$$

The lower inequality is equivalent to invertibility of $G(x)$. Indeed, if it holds, $G(x)^{\frac{1}{2}}$ is bounded below and has closed dense image, so it is surjective. The converse follows from continuity of $G(x)^{-\frac{1}{2}}$. This proves the pointwise equivalences between (i), (ii), and (v).

Since $\mathrm{GL}(H)$ is open and inversion is smooth, continuity of G and G^{-1} gives, after shrinking the chart, uniform bounds for $\|G(x)\|$ and $\|G(x)^{-1}\|$. Specifically, if these bounds are A and B, respectively, we may take $C = A^{\frac{1}{2}}$ and $c = B^{-\frac{1}{2}}$ in (iv). The same observation shows that the fiberwise inverse $\sharp_{\mathbf{g}} := \flat_{\mathbf{g}}^{-1}$ is smooth. Thus, (iii) is equivalent to the preceding conditions.

For the last assertion, denote the model space by X, fix $x_0 \in M$, and transport $\mathbf{g}_{x_0}$ to X. Since the given norm and the inner product norm $|\cdot|_{\mathbf{g},x_0}$ induce the same topology, there exist $c_0, C_0 > 0$ such that

$$c_0\|v\|_X \le |v|_{\mathbf{g},x_0} \le C_0\|v\|_X, \qquad v \in X.$$

If (v_n) is Cauchy in $|\cdot|_{\mathbf{g},x_0}$, the left inequality makes it Cauchy in $\|\cdot\|_X$; it then converges to some $v \in X$, and the right inequality turns this convergence into convergence in $|\cdot|_{\mathbf{g},x_0}$. Consequently, X, equipped with this inner product, is a Hilbert space, and the identity between the two norms is a topological linear isomorphism. □

Example 26.1.3. (Hierarchy of Sobolev metrics) Let $\mathbf{E} \longrightarrow K$ be a real vector bundle of positive finite rank, equipped with a bundle metric and a compatible connection, over a compact Riemannian manifold without boundary K, and let $A = I + (\nabla^{\mathbf{E}})^*\nabla^{\mathbf{E}}$. Suppose that K is nonempty. For $s > 0$ and $0 \le r \le s$, on the Hilbert space $H^s(K,\mathbf{E})$ consider the constant metric

$$\mathbf{g}^{(r)}_{\mathbf{u}}(\mathbf{h},\mathbf{k}) := \left\langle A^{\frac{r}{2}}\mathbf{h}, A^{\frac{r}{2}}\mathbf{k}\right\rangle_{L^2(K,\mathbf{E})}. \tag{26.2}$$

Here we use the spectral norm $\|\mathbf{h}\|_{H^t_A(K,\mathbf{E})} := \|A^{\frac{t}{2}}\mathbf{h}\|_{L^2(K,\mathbf{E})}$. For each $t \ge 0$ there exist constants $c_t, C_t > 0$, depending only on K, the metrics, the connection, and t, such that

$$c_t\|\mathbf{h}\|_{H^t(K,\mathbf{E})} \le \|\mathbf{h}\|_{H^t_A(K,\mathbf{E})} \le C_t\|\mathbf{h}\|_{H^t(K,\mathbf{E})}, \qquad \mathbf{h} \in H^t(K,\mathbf{E}).$$

For even integer orders, these are the estimates of Corollary 11.5.1; the remaining orders follow through the spectral scale and interpolation. Specifically, for $0 < t < 2m$, with $m \in \mathbb{N}$ and parameter $\theta = t/(2m)$, interpolate between $L^2(K,\mathbf{E})$ and the domain of A^m. Proposition 12.4.11 identifies the interpolation space with the domain of $A^{t/2}$, whereas Proposition 13.3.11 identifies it with $H^t(K,\mathbf{E})$. Compactness of K allows the bounded geometry hypotheses of that result to be applied. This is also the case $p = 2$ of Theorem 14.5.6. Continuity of the embedding $H^s(K,\mathbf{E}) \hookrightarrow H^r(K,\mathbf{E})$ shows that $\mathbf{g}^{(r)}$ is a smooth weak metric. For $r = s$ it is strong, since its norm is one of the norms defining $H^s(K,\mathbf{E})$.

Suppose that K has positive dimension. If $A\mathbf{e}_j = \lambda_j\mathbf{e}_j$, with $(\mathbf{e}_j)_{j\in\mathbb{N}}$ orthonormal in $L^2(K,\mathbf{E})$ and $\lambda_j \to \infty$ as $j \to \infty$, then

$$\mathbf{h}_j := \lambda_j^{-\frac{s}{2}}\mathbf{e}_j, \qquad \|\mathbf{h}_j\|_{H^s_A(K,\mathbf{E})} = 1, \qquad |\mathbf{h}_j|_{\mathbf{g}^{(r)}} = \lambda_j^{\frac{r-s}{2}}.$$

Consequently, $\mathbf{g}^{(r)}$ is strictly weak for $r < s$. With respect to the inner product of $H^s(K,\mathbf{E})$, its metric operator is A^{r-s}, which is injective and has dense image, but is not surjective. In particular, there are continuous covectors on $H^s(K,\mathbf{E})$ that have no gradient with respect to $\mathbf{g}^{(r)}$.

Example 26.1.4. (The L^2 metric) The case $r = 0$ of (26.2) is

$$\mathbf{g}^{(0)}_{\mathbf{u}}(\mathbf{h},\mathbf{k}) = \int_K \langle \mathbf{h},\mathbf{k}\rangle_{\mathbf{E}}\, d\lambda_{\mathbf{g}}.$$

Its musical map is the inclusion

$$H^s(K,\mathbf{E}) \longrightarrow H^{-s}(K,\mathbf{E}), \qquad \mathbf{h} \longmapsto \big[\mathbf{k} \longmapsto (\mathbf{h},\mathbf{k})_{L^2(K,\mathbf{E})}\big].$$

If $\dim K > 0$, the image is proper, as checked in the preceding example for $r = 0 < s$. Thus, using an L^2 integral on a configuration space of regularity $H^s(K,\mathbf{E})$ does not automatically make the metric strong. In contrast, the $\mathbf{g}^{(s)}$ metric does identify $H^s(\mathbf{E})$ with its dual through Riesz.

The obstruction from the musical map is independent of the notion of smoothness chosen for function spaces. In particular, passing to convenient calculus on Fréchet spaces, developed in [88], does not make a musical map surjective if it was not already. Convenient theory and strong Hilbert theory solve different problems. A modern comparison of categories of infinite-dimensional calculus and weak Riemannian geometry can be found in [129, Chap. 4 and Appendices C and E]. In this book, however, all maps between open subsets of Banach spaces are interpreted within the Fréchet calculus established in Chapter 23; convenient calculus is not adopted as a premise.

26.2 Connections, geodesics, and variation in the strong case

Let $\mathbf{g}$ be strong, and write $Dg(x)[u](v,w)$ for the derivative of its local representative g. For $x \in U$ and $u,v \in H$, define the covector

$$\mathscr{K}_x(u,v)(w) := \frac{1}{2}\big(Dg(x)[u](v,w) + Dg(x)[v](u,w) - Dg(x)[w](u,v)\big). \tag{26.3}$$

With the multilinear operator norm we have

$$\|\mathscr{K}_x(u,v)\|_{H'} \le \frac{3}{2}\|Dg(x)\|_{\mathcal{L}(H;\mathcal{L}^2_s(H;\mathbb{R}))}\|u\|_H\|v\|_H. \tag{26.4}$$

Indeed, each of the three summands in (26.3) is bounded by the product appearing on the right before the factor $\frac{1}{2}$. Continuous regrouping of multilinear operators then shows that $x \mapsto \mathscr{K}_x \in \mathcal{L}^2_s(H;H')$ is smooth. In particular, the map $(x,u,v) \mapsto \mathscr{K}_x(u,v)$ is smooth, bilinear, and symmetric in (u,v). Since $\flat_{\mathbf{g},x}$ is surjective, there exists a unique vector $\Gamma_x(u,v) = \sharp_{\mathbf{g},x}\mathscr{K}_x(u,v)$ such that

$$2g_x\big(\Gamma_x(u,v),w\big) = Dg(x)[u](v,w) + Dg(x)[v](u,w) - Dg(x)[w](u,v). \tag{26.5}$$

Definition 2.4.8 and Theorem 2.4.10 are the finite-dimensional model for the following construction. Its local expression and coordinate change law appear in Corollary 2.4.11 and Lemma 2.4.12. The Koszul identity and the calculation of chart changes are the same; the new step is that its right-hand side is initially an element of H', and only the strength of the metric allows $\sharp_{\mathbf{g}}$ to be applied to it in the operator norm.

Theorem 26.2.1. (Strong Levi–Civita theorem) Every smooth strong Riemannian metric on a Hilbert manifold has a unique torsion-free connection ∇ compatible with $\mathbf{g}$. If X, Y are the local representatives of the fields $\mathbf{X},\mathbf{Y}$, then

$$(\nabla_{\mathbf{X}}\mathbf{Y})_\varphi(x) = DY(x)X(x) + \Gamma_x(X(x),Y(x)),$$

where Γ is determined by (26.5). Equivalently, for smooth fields $\mathbf{X},\mathbf{Y},\mathbf{Z}$ it satisfies the Koszul formula

$$2\mathbf{g}(\nabla_{\mathbf{X}}\mathbf{Y},\mathbf{Z}) = \mathbf{X}\mathbf{g}(\mathbf{Y},\mathbf{Z}) + \mathbf{Y}\mathbf{g}(\mathbf{X},\mathbf{Z}) - \mathbf{Z}\mathbf{g}(\mathbf{X},\mathbf{Y}) + \mathbf{g}([\mathbf{X},\mathbf{Y}],\mathbf{Z}) - \mathbf{g}([\mathbf{Y},\mathbf{Z}],\mathbf{X}) - \mathbf{g}([\mathbf{X},\mathbf{Z}],\mathbf{Y}).$$

If τ is a coordinate change between open subsets of Hilbert spaces, the corresponding symbols satisfy the full law

$$\widetilde{\Gamma}_{\tau(x)}\big(D\tau(x)u, D\tau(x)v\big) = D\tau(x)\Gamma_x(u,v) - D^2\tau(x)(u,v). \tag{26.6}$$

Equivalently, if $\sigma = \tau^{-1}$ and $y = \tau(x)$,

$$\widetilde{\Gamma}_y(a,b) = D\tau(\sigma(y))\Gamma_{\sigma(y)}\big(D\sigma(y)a, D\sigma(y)b\big) + D\tau(\sigma(y))D^2\sigma(y)(a,b).$$

Proof. In a chart, the musical map depends smoothly on the point and takes values in the open set of linear isomorphisms $H \longrightarrow H'$. Since inversion is smooth on that open set, $x \mapsto \sharp_{\mathbf{g},x} \in \mathcal{L}(H';H)$ is smooth. The preceding construction can be written as

$$\Gamma_x = \sharp_{\mathbf{g},x} \circ \mathscr{K}_x.$$

Continuous composition of operators, together with (26.4), shows that $x \mapsto \Gamma_x \in \mathcal{L}^2_s(H;H)$ is smooth. The local formula explicitly satisfies, for $f, h \in C^\infty(U)$ and $a, b \in \mathbb{R}$,

$$\begin{aligned}
\nabla_{f\mathbf{X}+h\mathbf{Z}}\mathbf{Y} &= f\nabla_{\mathbf{X}}\mathbf{Y} + h\nabla_{\mathbf{Z}}\mathbf{Y},\\
\nabla_{\mathbf{X}}(a\mathbf{Y}+b\mathbf{Z}) &= a\nabla_{\mathbf{X}}\mathbf{Y} + b\nabla_{\mathbf{X}}\mathbf{Z},\\
\nabla_{\mathbf{X}}(f\mathbf{Y}) &= \mathbf{X}(f)\mathbf{Y} + f\nabla_{\mathbf{X}}\mathbf{Y},
\end{aligned}$$

since DY is linear in the direction, Γ_x is bilinear, and, if $\widehat{f} = f \circ \varphi^{-1}$, the product rule gives $D(\widehat{f}Y)[X] = D\widehat{f}[X]Y + \widehat{f}DY[X]$. These are therefore exactly the axioms of Definition 25.5.1, once invariance of the local expressions has been checked.

Now let the representatives of the fields in the second coordinates be $\widetilde{X}(y) = D\tau(\sigma(y))X(\sigma(y))$ and $\widetilde{Y}(y) = D\tau(\sigma(y))Y(\sigma(y))$. The chain rule gives

$$\begin{aligned}
D\widetilde{Y}(\tau(x))\widetilde{X}(\tau(x)) = {}& D^2\tau(x)(X(x),Y(x))\\
&+ D\tau(x)DY(x)X(x).
\end{aligned}$$

Therefore, the equality $\widetilde{\nabla}_{\widetilde{X}}\widetilde{Y} = D\tau(\nabla_X Y)$ between local expressions is equivalent precisely to (26.6). To verify it from the metric, fix x and set $y = \tau(x)$, $A = D\tau(x)$, and $B = D^2\tau(x)$. The metric transformation is $g_x(v,w) = \widetilde{g}_y(Av, Aw)$. Differentiating in the direction u,

$$\begin{aligned}
Dg(x)[u](v,w) = {}& D\widetilde{g}(y)[Au](Av,Aw)\\
&+ \widetilde{g}_y(B(u,v),Aw) + \widetilde{g}_y(Av,B(u,w)).
\end{aligned}$$

In the combination defining $2\mathscr{K}_x(u,v)(w)$, the terms involving $B(u,w)$ cancel those involving $B(w,u)$, and those involving $B(v,w)$ cancel those involving $B(w,v)$. The two remaining terms are equal by symmetry of B. Hence,

$$\mathscr{K}_x(u,v)(w) = \widetilde{\mathscr{K}_y}(Au,Av)(Aw) + \widetilde{g}_y(B(u,v),Aw).$$

Substituting $\mathscr{K}_x(u,v)(w) = g_x(\Gamma_x(u,v),w)$ and the analogous equality for $\widetilde{\mathscr{K}}$ gives

$$\widetilde{g}_y\big(A\Gamma_x(u,v) - \widetilde{\Gamma}_y(Au,Av) - B(u,v), Aw\big) = 0.$$

Since A is surjective and $\widetilde{g}_y$ is nondegenerate, the first argument must be zero. This is (26.6); thus the local expressions glue together and define a connection.
Symmetry of Γ_x shows, in coordinates, that

$$(\nabla_{\mathbf{X}}\mathbf{Y} - \nabla_{\mathbf{Y}}\mathbf{X})_\varphi = DY[X] - DX[Y] = [\mathbf{X},\mathbf{Y}]_\varphi,$$

so the torsion vanishes. On the other hand, the product rule gives

$$(\mathbf{X}\mathbf{g}(\mathbf{Y},\mathbf{Z}))\circ\varphi^{-1} = Dg[X](Y,Z) + g(DY[X],Z) + g(Y,DZ[X]).$$

Adding the identities (26.5) for (X,Y,Z) and (X,Z,Y), the terms $Dg[Y](X,Z)$ and $Dg[Z](X,Y)$ appear once with each sign; by symmetry of g they cancel, leaving

$$Dg[X](Y,Z) = g(\Gamma(X,Y),Z) + g(Y,\Gamma(X,Z)).$$

The last two formulas prove metric compatibility. Conversely, compatibility and the absence of torsion imply the Koszul formula through the same algebraic calculation as in Theorem 2.4.10. If ∇ and $\widetilde{\nabla}$ had the same properties, the Koszul formula would give $\mathbf{g}((\nabla_{\mathbf{X}} - \widetilde{\nabla}_{\mathbf{X}})\mathbf{Y},\mathbf{Z}) = 0$ for every field $\mathbf{Z}$; nondegeneracy of $\mathbf{g}$ establishes uniqueness. □

Proposition 26.2.2. (Musical criterion in the weak case) Let $\mathbf{g}$ be a weak Riemannian metric on a Hilbert manifold. A Levi–Civita connection for $\mathbf{g}$ exists if and only if, in an atlas, the covectors in (26.3) belong to $\operatorname{Im}\flat_{\mathbf{g},x}$ and their unique preimages

$$\Gamma_x(u,v) := \flat_{\mathbf{g},x}^{-1}\mathscr{K}_x(u,v)$$

depend smoothly on (x,u,v). Equivalently, smoothness of $x \mapsto \Gamma_x$ with values in $\mathcal{L}^2_s(H;H)$ equipped with its operator norm is required. When the connection exists, it is unique.

Proof. Necessity follows by applying the Koszul formula to constant fields in a chart. We check the equivalence of the two formulations of smoothness. A family smooth in norm produces smooth joint evaluation through continuous multilinear evaluation. Conversely, if $H_0(x,u,v) := \Gamma_x(u,v)$ is smooth and bilinear in (u,v), then

$$\Gamma_x(u,v) = D_v D_u H_0(x,0,0)[u,v].$$

The Fréchet derivative on the right depends smoothly on x in the bilinear operator norm. Hence Γ has exactly the regularity required in Definition 25.5.1. The hypothesis therefore allows coefficients of a connection to be defined. Under a change of coordinates, both sides of (26.6) agree, after application of $\flat_{\mathbf{g}}$, by the chain rule. Since $\flat_{\mathbf{g}}$ is injective, this law holds and the local expressions define a connection. The proof of Theorem 26.2.1 establishes compatibility, absence of torsion, and uniqueness from the Koszul formula and injectivity of the musical map. □

The criterion explains exactly the difficulty in the weak case. The constant metric $\mathbf{g}^{(r)}$ of Example 26.1.3 has $D\mathbf{g}^{(r)} = 0$ and therefore admits the flat connection $\Gamma = 0$, although it is strictly weak when $r < s$. For a varying weak metric, however, $\mathscr{K}_x(u,v)$ may lie outside the image of the musical map. There is then no vector that can play the role of $\Gamma_x(u,v)$.

Let $\gamma\colon [a,b] \longrightarrow M$ be a C^1 curve, and let $\mathbf{V}$ be a C^1 field along γ. Apply Definition 25.6.1 to the bundle TM

and write $\nabla_t \mathbf{V} := \frac{D^{\nabla}\mathbf{V}}{dt}$. In a chart,

$$\nabla_t \mathbf{V} := \dot{V}(t) + \Gamma_{\gamma(t)}(\dot{\gamma}(t), V(t)),$$

Independence of the chart and the Leibniz rule are given by Proposition 25.6.2. Metric compatibility adds, for every field $\mathbf{W}$ along γ, the second of the rules

$$\nabla_t(f\mathbf{V}) = f'\mathbf{V} + f\nabla_t\mathbf{V}, \qquad \frac{d}{dt}\mathbf{g}(\mathbf{V},\mathbf{W}) = \mathbf{g}(\nabla_t\mathbf{V},\mathbf{W}) + \mathbf{g}(\mathbf{V},\nabla_t\mathbf{W}).$$

Theorem 25.6.3, applied to TM, gives existence and uniqueness of fields satisfying $\nabla_t\mathbf{V} = 0$, as well as the topological linear isomorphisms

$$P^{\gamma}_{s,t} := P^{\nabla}_{\gamma,s\to t}\colon T_{\gamma(s)}M \longrightarrow T_{\gamma(t)}M, \qquad P^{\gamma}_{r,t}P^{\gamma}_{s,r} = P^{\gamma}_{s,t}, \qquad (P^{\gamma}_{s,t})^{-1} = P^{\gamma}_{t,s}.$$

To identify the additional property supplied by Levi–Civita, let $\mathbf{U}$ and $\mathbf{V}$ be the parallel fields with initial values u and v at time s. Metric compatibility gives

$$\frac{d}{dt}\mathbf{g}_{\gamma(t)}(\mathbf{U}(t),\mathbf{V}(t)) = \mathbf{g}(\nabla_t\mathbf{U},\mathbf{V}) + \mathbf{g}(\mathbf{U},\nabla_t\mathbf{V}) = 0.$$

Consequently, for $s,t \in [a,b]$ and $u,v \in T_{\gamma(s)}M$, $\mathbf{g}_{\gamma(t)}(P^{\gamma}_{s,t}u, P^{\gamma}_{s,t}v) = \mathbf{g}_{\gamma(s)}(u,v)$ and parallel transport is an isometry. This is the same deduction that, in finite dimensions, completes Theorems 2.7.5 and 2.7.12 and Proposition 2.7.14; existence and invertibility in the present case instead come from the linear ODE on the Banach space proved in the preceding chapter.

If $\mathbf{T}_{\gamma} := \dot{\gamma}$ denotes the tangent field, a curve C^2 is an **affine geodesic** if $\nabla_t\mathbf{T}_{\gamma} = 0$. In coordinates, this condition is

$$\ddot{\gamma} + \Gamma_{\gamma}(\dot{\gamma},\dot{\gamma}) = 0. \tag{26.7}$$

Every affine geodesic has constant speed, since $\frac{d}{dt}|\mathbf{T}_{\gamma}|^2_{\mathbf{g}} = 2\mathbf{g}(\nabla_t\mathbf{T}_{\gamma},\mathbf{T}_{\gamma}) = 0$. This definition and its local expression are the analogues of Definition 2.8.1; the subsequent analytic novelty is solving the equation in a Banach space, not the calculation that produces it.

Definition 26.2.3. (Spray) Let M be a smooth Banach manifold. Let $h_t\colon TM \longrightarrow TM$ be the fiberwise homothety $h_t(v) = tv$. A **spray** is a smooth vector field $\mathbf{S}$ on TM satisfying

$$T\pi \circ \mathbf{S} = \mathrm{id}_{TM}, \qquad \mathbf{S}(h_t(v)) = Th_t\big(t\mathbf{S}(v)\big)$$

for every $t \in \mathbb{R}$ and $v \in TM$. In a chart it is written as

$$\mathbf{S}(x,v) = \big((x,v),(v,Q_x(v))\big), \qquad Q_x(tv) = t^2Q_x(v).$$

Smoothness at the zero section implies that $Q_x(v)$ is the diagonal of a continuous symmetric bilinear form. Indeed, for fixed v, $Q_x(tv) = t^2Q_x(v)$ implies, by differentiating twice at $t = 0$,

$$Q_x(v) = \frac{1}{2}D^2_vQ_x(0)(v,v).$$

The second derivative is symmetric, bilinear, and continuous; moreover, it depends smoothly on x in the operator norm by Fréchet calculus. A field that satisfies only the first condition is called a second-order

field.

The Levi–Civita spray is given by

$$\mathbf{S}_{\mathbf{g}}(x,v) = \big((x,v),(v,-\Gamma_x(v,v))\big). \tag{26.8}$$

Law (26.6) is exactly what ensures that these expressions glue together. A curve γ satisfies (26.7) if and only if $t \mapsto \dot\gamma(t)$ is an integral curve of $\mathbf{S}_{\mathbf{g}}$.

Proposition 26.2.4. Let $(M,\mathbf{g})$ be a Hilbert manifold with a strong Riemannian metric. For each $v \in T_xM$, there exists a unique maximal geodesic γ_v with $\gamma_v(0) = x$ and $\dot\gamma_v(0) = v$. Its domain is an open interval containing 0, and its dependence on (t,v) is smooth on the maximal domain. The set

$$\mathcal{D} := \{v \in TM \mid \gamma_v \text{ is defined on } [0,1]\}$$

is open, contains the zero section, and the map

$$\exp\colon \mathcal{D} \longrightarrow M, \qquad \exp(v) := \gamma_v(1)$$

is smooth. Moreover, $d(\exp_x)_0 = \mathrm{id}_{T_xM}$; therefore, $\exp_x$ is a diffeomorphism between neighborhoods of the origin and x.

Proof. In coordinates, (26.7) is equivalent to the first-order system $(\dot x, \dot v) = (v, -\Gamma_x(v,v))$. Theorem 25.4.2 applied to the spray gives existence, uniqueness, openness of the maximal domain, and smooth dependence on the initial values. Homogeneity of the spray and uniqueness give the scaling identity

$$\gamma_v(t) = \gamma_{tv}(1) = \exp_x(tv) \tag{26.9}$$

whenever the two sides are defined. In particular,

$$d(\exp_x)_0(v) = \frac{d}{dt}\Big|_{t=0} \exp_x(tv) = \dot\gamma_v(0) = v.$$

The scaling equality is the same geometric step as in Lemma 2.8.5. Theorem 23.3.3 concludes that $\exp_x$ is a diffeomorphism between neighborhoods of 0 and x. In finite dimensions, the geodesic field, maximal existence, and exponential map appear in Proposition 2.8.2, Theorem 2.8.3, and Definition 2.8.6, with their properties in Proposition 2.8.7. The differential argument is identical; here we use the flow and inverse function theorem in Banach spaces. □

For an absolutely continuous curve whose velocity has integrable norm, we define its length; if $|\dot\gamma|_{\mathbf{g}}^2$ is also integrable, we define its energy by

$$L_{\mathbf{g}}(\gamma) = \int_a^b |\dot\gamma|_{\mathbf{g}}\, dt, \qquad E_{\mathbf{g}}(\gamma) = \frac{1}{2}\int_a^b |\dot\gamma|_{\mathbf{g}}^2\, dt.$$

The Cauchy–Schwarz inequality gives

$$L_{\mathbf{g}}(\gamma)^2 \le 2(b-a)E_{\mathbf{g}}(\gamma), \tag{26.10}$$

with equality if and only if the speed is constant almost everywhere.

Proposition 26.2.5. (First variation) Let $(M, \mathbf{g})$ be a Hilbert manifold with a strong Riemannian metric and Levi–Civita connection. Let $\alpha\colon (-\varepsilon,\varepsilon)\times[a,b] \longrightarrow M$ be a smooth variation, $\mathbf{T} = \partial_t\alpha$, $\mathbf{V} = \partial_s\alpha$, and $\gamma = \alpha_0$. On the following right-hand sides, $\mathbf{T}$ and $\mathbf{V}$ are evaluated at $s = 0$. Then

$$\left.\frac{d}{ds}\right|_{s=0} E_{\mathbf{g}}(\alpha_s) = \big[\mathbf{g}(\mathbf{V},\mathbf{T})\big]_a^b - \int_a^b \mathbf{g}\big(\mathbf{V},\nabla_t\mathbf{T}\big)\,dt.$$

The same formulas hold for variations of class C^2. If $\mathbf{T}$ does not vanish along γ, we also have

$$\left.\frac{d}{ds}\right|_{s=0} L_{\mathbf{g}}(\alpha_s) = \left[\frac{\mathbf{g}(\mathbf{V},\mathbf{T})}{|\mathbf{T}|_{\mathbf{g}}}\right]_a^b - \int_a^b \mathbf{g}\left(\mathbf{V},\nabla_t\frac{\mathbf{T}}{|\mathbf{T}|_{\mathbf{g}}}\right)dt. \tag{26.11}$$

Consequently, a curve C^2 is critical for energy with fixed endpoints if and only if it is an affine geodesic. A regular curve is critical for length with fixed endpoints if and only if its arc length parametrization is an affine geodesic.

Proof. Fix $0 < \delta < \varepsilon$ and restrict the variation to the compact rectangle $[-\delta,\delta]\times[a,b]$. The function $(s,t) \mapsto \mathbf{g}_{\alpha(s,t)}(\mathbf{T}(s,t),\mathbf{T}(s,t))$ is smooth and, for a C^2 variation, is at least C^1. Differentiation under the integral sign is therefore justified by uniform continuity of its partial derivative. Metric compatibility gives

$$\left.\frac{d}{ds}\right|_{s=0} E_{\mathbf{g}}(\alpha_s) = \int_a^b \mathbf{g}(\nabla_s\mathbf{T},\mathbf{T})\,dt.$$

Absence of torsion and the equality $[\partial_s,\partial_t] = 0$ on the parameter domain imply $\nabla_s\mathbf{T} = \nabla_t\mathbf{V}$. Using metric compatibility a second time,

$$\int_a^b \mathbf{g}(\nabla_t\mathbf{V},\mathbf{T})\,dt = \int_a^b \left(\frac{d}{dt}\mathbf{g}(\mathbf{V},\mathbf{T}) - \mathbf{g}(\mathbf{V},\nabla_t\mathbf{T})\right)dt = \big[\mathbf{g}(\mathbf{V},\mathbf{T})\big]_a^b - \int_a^b \mathbf{g}(\mathbf{V},\nabla_t\mathbf{T})\,dt,$$

which is the energy formula, including its boundary terms.

If $\mathbf{T}$ does not vanish along γ, compactness of $[a,b]$ and continuity allow us to shrink ε so that $|\mathbf{T}|_{\mathbf{g}}$ remains bounded away from zero. We can again differentiate under the integral sign, and

$$\partial_s|\mathbf{T}|_{\mathbf{g}} = \frac{\mathbf{g}(\nabla_s\mathbf{T},\mathbf{T})}{|\mathbf{T}|_{\mathbf{g}}} = \mathbf{g}\left(\nabla_t\mathbf{V},\frac{\mathbf{T}}{|\mathbf{T}|_{\mathbf{g}}}\right).$$

The identity

$$\frac{d}{dt}\mathbf{g}\left(\mathbf{V},\frac{\mathbf{T}}{|\mathbf{T}|_{\mathbf{g}}}\right) = \mathbf{g}\left(\nabla_t\mathbf{V},\frac{\mathbf{T}}{|\mathbf{T}|_{\mathbf{g}}}\right) + \mathbf{g}\left(\mathbf{V},\nabla_t\frac{\mathbf{T}}{|\mathbf{T}|_{\mathbf{g}}}\right)$$

and integration over $[a,b]$ prove (26.11).

To justify the variational consequence without assuming that every field along γ comes from a global variation, fix a compact subinterval $J \subset (a,b)$ whose image is contained in a chart $\varphi\colon U \longrightarrow H$. If $\mathbf{W}$ is a smooth field along γ, with support contained in the interior of J, for small $|s|$ we define on J

$$\alpha(s,t) := \varphi^{-1}\big(\varphi(\gamma(t)) + s\,d\varphi_{\gamma(t)}\mathbf{W}(t)\big)$$

and set $\alpha(s,t) = \gamma(t)$ outside J. Compactness of the support allows the same interval of values of s to be

chosen, and vanishing of $\mathbf{W}$ in a neighborhood of the endpoints of J makes the gluing smooth. If the central curve is only C^2, take C^2 fields along it, and the same gluing produces a C^2 variation; the first variation formula remains applicable. This variation has variational field $\mathbf{W}$ and fixed endpoints.
If the first variation of energy vanishes for all these variations, fix $z \in H$ and take

$$\mathbf{W}(t) = \chi(t)(d\varphi_{\gamma(t)})^{-1} z, \qquad \chi \in C_c^\infty(\mathring{J}).$$

The formula already proved and the fundamental lemma of the calculus of variations imply

$$\mathbf{g}_{\gamma(t)}\big((d\varphi_{\gamma(t)})^{-1} z, \nabla_t \mathbf{T}(t)\big) = 0, \qquad t \in \mathring{J}.$$

Since z is arbitrary and $d\varphi_{\gamma(t)}$ is an isomorphism, nondegeneracy of $\mathbf{g}$ gives $\nabla_t \mathbf{T} = 0$. For length, the same argument applied to $\nabla_t\big(\frac{\mathbf{T}}{|\mathbf{T}|_{\mathbf{g}}}\big)$ gives $\nabla_t\big(\frac{\mathbf{T}}{|\mathbf{T}|_{\mathbf{g}}}\big) = 0$. Upon parametrizing by arc length, this last field is the tangent vector, and the identity becomes the affine geodesic equation. The converses follow directly from the variation formulas.
Metric compatibility and differentiation along curves are those of Definition 2.4.8 and Theorem 2.7.5; the differentiation and integration argument is the same in finite dimensions. The construction of variations uses a Hilbert chart and cutoff functions on the parameter interval; it therefore remains valid even when the manifold is not locally compact. □

For p, q in the same connected component, let

$$d_{\mathbf{g}}(p,q) := \inf\{L_{\mathbf{g}}(\gamma) \mid \gamma \text{ is a piecewise } C^1 \text{ curve from } p \text{ to } q\}.$$

Proposition 26.2.6. On each connected component of a strong Riemannian Hilbert manifold, $d_{\mathbf{g}}$ is a finite distance inducing the manifold topology.

Proof. Fix x_0 and a chart $\varphi\colon U \longrightarrow H$ with $\varphi(x_0) = 0$. By Proposition 26.1.2, after shrinking U there exist $c, C > 0$ such that

$$c\|w\|_H \le |d\varphi_x^{-1} w|_{\mathbf{g},x} \le C\|w\|_H$$

for every $x \in U$ and $w \in H$. Choose $r > 0$ so that $B_H(0,3r) \subseteq \varphi(U)$ and set $V := \varphi^{-1}(B_H(0, \frac{r}{2}))$. If $x, y \in V$, the segment joining their coordinates remains in $B_H(0, \frac{r}{2})$, and its lift has length at most $C\|\varphi(y) - \varphi(x)\|_H$.
Now let γ be a piecewise C^1 curve from x to y. As long as γ remains in $\varphi^{-1}(B_H(0,2r))$, the chain rule gives

$$c\|\varphi(\gamma(t_1)) - \varphi(\gamma(t_0))\|_H \le L_{\mathbf{g}}\big(\gamma \restriction_{[t_0,t_1]}\big). \tag{26.12}$$

We justify that a curve leaving this ball reaches its coordinate sphere before leaving the chart. Let t_1 be the endpoint of the initial interval during which the curve remains in the ball. For $s < t < t_1$, (26.12) bounds the difference of its coordinates by c^{-1} times the length of the segment $[s,t]$. That length tends to zero as $s, t \nearrow t_1$, because the speed is integrable. The coordinates therefore have a limit in the complete space H, of norm at most $2r$. This limit belongs to $\varphi(U)$, since $\overline{B_H(0,2r)} \subset B_H(0,3r) \subset \varphi(U)$. Continuity of φ^{-1} and γ, together with the Hausdorff property of M, identifies $\gamma(t_1)$ with the preimage of the limit. If an exit occurs, its norm must be $2r$: a smaller norm would allow the interval to be extended inside the ball.
If the curve does not leave this ball, taking its endpoints gives $L_{\mathbf{g}}(\gamma) \ge c\|\varphi(y) - \varphi(x)\|_H$. If it does, continuity

of $\|\varphi\circ\gamma\|_H$ gives a first time t_1 at which its value is $2r$. Since $\|\varphi(x)\|_H < \frac{r}{2}$, inequality (26.12) implies

$$L_{\mathbf{g}}(\gamma) \geq c\big(2r - \|\varphi(x)\|_H\big) > \frac{3cr}{2}.$$

On the other hand, $\|\varphi(y)-\varphi(x)\|_H < r$, so this last bound is greater than $c\|\varphi(y)-\varphi(x)\|_H$. Taking the infimum over all curves gives

$$c\|\varphi(y)-\varphi(x)\|_H \leq d_{\mathbf{g}}(x,y) \leq C\|\varphi(y)-\varphi(x)\|_H$$

for $x, y \in V$. To control also the points outside V, apply the same exit argument to the ball of radius $r/2$, with initial point x_0. Every curve from x_0 to a point of $M \setminus V$ has length at least $cr/2$. Consequently, $B_{d_{\mathbf{g}}}(x_0, cr/2) \subseteq V$. The local upper inequality proves that convergence in coordinates implies convergence in distance; this inclusion and the lower inequality prove the converse. They also separate x_0 from every other point. Symmetry follows by reversing curves and the triangle inequality by concatenating them. Classes of points joined by piecewise C^1 curves are open; connectedness of the component shows that there is only one and proves finiteness.

The corresponding finite-dimensional definition and metric conclusion are found in Definition 2.9.2 and Theorem 2.9.4. The coordinate segment gives the upper bound; the first exit argument gives the lower bound through local comparison of norms, without requiring compact balls. □

For a weak metric, in general one obtains only a pseudodistance: positivity of the length of every curve does not prevent the existence of curves between two distinct points with arbitrarily small lengths.

The local part of Riemannian geometry survives in the strong case; the global part does not do so automatically.

Proposition 26.2.7. (The surviving implication of Hopf–Rinow) Every metrically complete strong Riemannian manifold is geodesically complete.

Proof. Let $\gamma\colon [0,b) \longrightarrow M$ be a maximal geodesic with $b < \infty$. Its speed is constant, so $d_{\mathbf{g}}(\gamma(s),\gamma(t)) \leq |t-s|\|\dot\gamma(0)|_{\mathbf{g}}$. By completeness, $\gamma(t)$ converges to a point q as $t \nearrow b$. Choose a chart $\varphi\colon U \longrightarrow H$ about q. After shrinking it, there exist $c, C, K > 0$ such that

$$c\|w\|_H \leq |d\varphi_x^{-1} w|_{\mathbf{g},x} \leq C\|w\|_H, \qquad \|\Gamma_x\|_{\mathcal{L}^2_s(H;H)} \leq K$$

for $x \in U$ and $w \in H$. For t sufficiently close to b, the curve remains in this chart. If its constant speed is a, then $\|(\varphi\circ\gamma)'(t)\|_H \leq \frac{a}{c}$ and the geodesic equation gives

$$\|(\varphi\circ\gamma)''(t)\|_H \leq K(\frac{a}{c})^2.$$

Thus, $(\varphi\circ\gamma)'(t)$ is Cauchy as $t \nearrow b$ and converges to some $v \in H$. In the coordinate trivialization, the state converges to $(\varphi(q), v)$; therefore, $(\gamma(t), \dot\gamma(t))$ converges to $(q, (d\varphi_q)^{-1}v) \in TM$. Local existence for the spray extends the geodesic beyond b, a contradiction.

In finite dimensions, this is one of the implications in Theorem 2.9.9. Here we reuse only constant speed and local existence for the ODE; we do not use compactness of closed balls, which fails in an infinite-dimensional Hilbert space. □

Example 26.2.8. (Completeness without a minimizing geodesic) Let $(e_n)_{n\in\mathbb{N}}$ be the standard basis of ℓ^2, let $a_1 = 1$ and $a_n = 1 + 2^{-n}$ for $n \geq 2$, and consider the ellipsoid

$$\mathcal{E} := \left\{ x = (x_n) \in \ell^2 \;\middle|\; \sum_{n=1}^{\infty} \frac{x_n^2}{a_n^2} = 1 \right\}$$

with the metric induced by ℓ^2. It is a Hilbert submanifold: the function $f(x) = \sum_{n=1}^{\infty} x_n^2/a_n^2$ is a continuous quadratic form, hence smooth, and $Df(x)[x] = 2$ on the level $f = 1$. Its differential there is surjective onto $\mathbb{R}$ and has complemented kernel. The regular value theorem in Chapter 24 provides the submanifold structure. The induced metric is strong, because it uses the norm of ℓ^2 on each closed tangent subspace. The operator $A(x_n) = (a_n x_n)$ is a bounded linear isomorphism, maps the unit sphere onto $\mathcal{E}$, and satisfies

$$\|v\|_{\ell^2} \leq \|Av\|_{\ell^2} \leq (1 + 2^{-2})\|v\|_{\ell^2}.$$

If $d_{\mathbb{S}}$ is the intrinsic distance on the unit sphere and $d_{\mathcal{E}}$ that on $\mathcal{E}$, comparison of lengths gives, for x, y on the sphere,

$$d_{\mathbb{S}}(x,y) \leq d_{\mathcal{E}}(Ax, Ay) \leq \frac{5}{4} d_{\mathbb{S}}(x,y).$$

The Hilbert sphere is complete: the ambient distance satisfies $\|x - y\|_{\ell^2} \leq d_{\mathbb{S}}(x,y)$ and, if $\|x - y\|_{\ell^2} < 1$, the great-circle arc contained in $\operatorname{span}\{x,y\}$ has length $2\arcsin\left(\frac{\|x-y\|_{\ell^2}}{2}\right) \leq 2\|x-y\|_{\ell^2}$. Hence an intrinsic Cauchy sequence converges first in ℓ^2 to a point of the sphere and then in the intrinsic distance. The preceding inequalities prove that $\mathcal{E}$ is metrically complete, and Proposition 26.2.7 proves its geodesic completeness. Every piecewise C^1 curve $c\colon [0,1] \to \mathbb{S}$ joining e_1 to $-e_1$ has length at least π. To see this, set $a(t) = \langle c(t), e_1 \rangle$. Since $\langle \dot{c}(t), c(t) \rangle = 0$,

$$|a'(t)| = |\langle \dot{c}(t), e_1 - a(t)c(t) \rangle| \leq \|\dot{c}(t)\|_{\ell^2} \sqrt{1 - a(t)^2}.$$

For $0 < \delta < 1$, the function $\theta_\delta(t) = \arccos((1-\delta)a(t))$ satisfies $|\theta_\delta'(t)| \leq \|\dot{c}(t)\|_{\ell^2}$ on each segment. Integrating and letting $\delta \to 0^+$, we obtain $\pi \leq L(c)$. Moreover,

$$\|A\dot{c}(t)\|_{\ell^2}^2 - \|\dot{c}(t)\|_{\ell^2}^2 = \sum_{n=2}^{\infty} (a_n^2 - 1)|\langle \dot{c}(t), e_n \rangle|^2 \geq 0.$$

If $L(A \circ c) = L(c)$, the nonnegative difference of the speeds vanishes almost everywhere. Since $a_n > 1$ for each $n \geq 2$, each component $\langle \dot{c}(t), e_n \rangle$ with that index vanishes almost everywhere; the fundamental theorem of calculus gives $\langle c(t), e_n \rangle = 0$ for every $t \in [0,1]$. The curve would remain in $\mathbb{S} \cap \mathbb{R}e_1 = \{e_1, -e_1\}$, where there is no continuous curve between those endpoints. Hence, $L(A \circ c) > L(c)$. In contrast, the semicircles

$$c_n(t) = \cos(\pi t) e_1 + \sin(\pi t) e_n$$

are considered for $n \geq 2$ and $t \in [0,1]$, and satisfy

$$L(A \circ c_n) = \pi \int_0^1 \sqrt{\sin^2(\pi t) + a_n^2 \cos^2(\pi t)}\, dt \longrightarrow \pi.$$

The integrand converges uniformly, since $a_n \to 1$; this also follows by dominated convergence with bound

5/4. Thus $d_{\mathcal{E}}(e_1,-e_1)=\pi$, but no curve realizes that distance. This is Grossman's ellipsoid [70].

Remark 26.2.9. (Limitations of Hopf–Rinow) Proposition 26.2.7 does not restore the finite-dimensional equivalences. Metric completeness does not imply that every pair of points can be joined by a minimizing geodesic, as Example 26.2.8 shows. Nor does metric completeness force $\exp_p$ to be surjective: this is Atkin's counterexample in [12]. The converse implication from global geodesic completeness to metric completeness also fails, but this belongs to a later work of Atkin.[a] These assertions distinguish three properties: continuation of every geodesic, convergence of Cauchy sequences, and existence of minimizing curves. In infinite dimensions one lacks the local compactness of closed balls that relates them in the classical theorem.

There are important partial results. Ekeland proved that, for fixed p on a strong, connected, metrically complete manifold, the set of points that can be joined to p by a unique minimizing geodesic contains a dense G_δ [58, Thm. B]. Under global hypotheses of nonpositive curvature, conclusions of Cartan–Hadamard type can also be recovered. None of these assertions justifies using the finite-dimensional Hopf–Rinow theorem without checking its additional hypotheses.

26.3 Banach–Finsler structures

Definition 26.3.1. Let M be a Banach manifold of class at least C^1, modeled on X. A **Banach–Finsler structure** is a family of norms $F_x\colon T_xM\longrightarrow[0,\infty)$ satisfying:

(i) F_x is a complete norm inducing the given topology of T_xM for every x;

(ii) $(x,v)\mapsto F_x(v)$ is continuous on TM;

(iii) for each x_0 there is a chart $\varphi\colon U\longrightarrow X$ such that, if $\|w\|_x:=F_x((d\varphi_x)^{-1}w)$, for every $\varepsilon>0$ we can shrink U so that

$$(1+\varepsilon)^{-1}\|w\|_{x_0}\le\|w\|_x\le(1+\varepsilon)\|w\|_{x_0},\qquad x\in U,\ w\in X. \tag{26.13}$$

The structure F is called **reversible** if $F_x(-v)=F_x(v)$ for every $x\in M$ and every $v\in T_xM$. This property concerns the structure F, not the Banach manifold without that structure. Here "norm" has its usual meaning, so absolute homogeneity implies this equality: all Banach–Finsler structures in this definition are reversible. Differentiability of F at the zero section is not required. Classical nonreversible Finsler metrics will be introduced later through Minkowski functionals and are not instances of this definition.

Condition (26.13), sometimes called **admissibility**, is the Palais condition. It is stronger than requiring that, for each x, there exist constants $c_x,C_x>0$ such that $c_x\|w\|_X\le F_x((d\varphi_x)^{-1}w)\le C_x\|w\|_X$ for every $w\in X$: in infinite dimensions, pointwise continuity in w does not by itself provide uniformity on the unit ball. Taking $\|\cdot\|_X=\|\cdot\|_{x_0}$ and $C=1+\varepsilon$ gives

$$C^{-1}\|w\|_X\le\|w\|_x\le C\|w\|_X,\qquad x\in U,\quad w\in X. \tag{26.14}$$

The definition does not depend on the chosen admissible chart. Indeed, if ψ is another chart and $\tau=\psi\circ\varphi^{-1}$,

then

$$\|z\|_{x,\psi} = \left\| D\tau(\varphi(x))^{-1} z \right\|_{x,\varphi}.$$

Set

$$A_x := D\tau(\varphi(x))^{-1} D\tau(\varphi(x_0)).$$

Continuity of inversion in the general linear group implies $\|A_x - I\|_{\mathcal{L}(X)} \to 0$, where the operator norm is calculated with $\|\cdot\|_{x_0,\varphi}$. Given $\eta > 0$, choose $\varepsilon, \delta > 0$ so that

$$(1+\varepsilon)(1+\delta) \le 1+\eta, \qquad (1+\varepsilon)^{-1}(1-\delta) \ge (1+\eta)^{-1}.$$

After shrinking the domain, admissibility in the chart φ holds with ε and $\|A_x - I\| \le \delta$. For $w = D\tau(\varphi(x_0))^{-1} z$ we then obtain

$$\|z\|_{x,\psi} = \|A_x w\|_{x,\varphi} \le (1+\varepsilon)(1+\delta)\|w\|_{x_0,\varphi},$$
$$\|z\|_{x,\psi} \ge (1+\varepsilon)^{-1}(1-\delta)\|w\|_{x_0,\varphi}.$$

Since $\|w\|_{x_0,\varphi} = \|z\|_{x_0,\psi}$, this is (26.13) in the chart ψ, with constant $1+\eta$.

Proposition 26.3.2. If $\mathbf{g}$ is a strong Riemannian metric on a Hilbert manifold, then $F_x(v) := |v|_{\mathbf{g},x}$ is a Banach–Finsler structure. Its length and distance agree with $L_{\mathbf{g}}$ and $d_{\mathbf{g}}$.

Proof. Only admissibility needs to be checked. In a chart, fix x_0 and conjugate $G(x)$ by $G(x_0)^{-\frac{1}{2}}$. The positive operator

$$B(x) := G(x_0)^{-\frac{1}{2}} G(x) G(x_0)^{-\frac{1}{2}}$$

converges to I in norm as $x \to x_0$. For $w \in H$, set $z = G(x_0)^{\frac{1}{2}} w$. Then $\|w\|_{x_0}^2 = \|z\|_H^2$ and $\|w\|_x^2 = \langle B(x) z, z\rangle_H$. If $\|B(x) - I\| < \delta < 1$, it follows that

$$(1-\delta)\|w\|_{x_0}^2 \le \|w\|_x^2 \le (1+\delta)\|w\|_{x_0}^2.$$

Given $\varepsilon > 0$, a choice of $\delta > 0$ satisfying $1+\delta \le (1+\varepsilon)^2$ and $1-\delta \ge (1+\varepsilon)^{-2}$ gives (26.13). Equality of lengths and distances follows from the definitions. □

Definition 26.3.3. Let (M, F) be a Banach–Finsler manifold. The **dual Finsler norm** of $\xi \in T_x'M$ is

$$F_x^*(\xi) := \sup\{|\xi(v)| \mid v \in T_xM,\ F_x(v) \le 1\}.$$

For $I \in C^1(M, \mathbb{R})$ we write $\|dI(x)\|_{F,*} := F_x^*(dI(x))$.

Proposition 26.3.4. Let (M, F) be a Banach–Finsler manifold modeled on X. In a chart satisfying (26.13), for $\lambda \in X'$ and x in a smaller domain where (26.14) holds,

$$C^{-1}\|\lambda\|_{X'} \le F_x^*(\lambda \circ d\varphi_x) \le C\|\lambda\|_{X'},$$

where the norm of X' is dual to $\|\cdot\|_X = \|\cdot\|_{x_0}$. In particular, $x \mapsto \|dI(x)\|_{F,*}$ is continuous for $I \in C^1(M)$.

Proof. From (26.14) we obtain the inclusions

$$C^{-1}B_X \subseteq B_x \subseteq CB_X, \qquad B_x := \{w \in X \mid \|w\|_x \le 1\}.$$

Here $B_X := \{w \in X \mid \|w\|_X \le 1\}$ is the closed unit ball. Taking suprema of $|\lambda|$ over these sets gives the dual estimate.

For continuity, fix x_0 and $\eta > 0$. Admissibility allows the chart to be shrunk so that the dual norms at x and x_0 differ by a factor between $(1+\eta)^{-1}$ and $1+\eta$. If $\lambda_x := dI(x) \circ (d\varphi_x)^{-1}$, then $\lambda_x \to \lambda_{x_0}$ in X' and

$$\begin{aligned}\big|\|\lambda_x\|_{x,*} - \|\lambda_{x_0}\|_{x_0,*}\big| &\le \|\lambda_x - \lambda_{x_0}\|_{x,*} \\ &\quad + \big|\|\lambda_{x_0}\|_{x,*} - \|\lambda_{x_0}\|_{x_0,*}\big|.\end{aligned}$$

The precise dual comparison is

$$(1+\eta)^{-1}\|\mu\|_{x_0,*} \le \|\mu\|_{x,*} \le (1+\eta)\|\mu\|_{x_0,*}, \qquad \mu \in X'.$$

Therefore, the first term on the preceding right-hand side does not exceed $(1+\eta)\|\lambda_x - \lambda_{x_0}\|_{x_0,*}$ and the second does not exceed $\eta\|\lambda_{x_0}\|_{x_0,*}$. First choose η and then x; both terms can be made arbitrarily small. This proves continuity. □

For a piecewise C^1 curve, set

$$L_F(\gamma) = \int_a^b F_{\gamma(t)}(\dot\gamma(t))\,dt, \qquad d_F(x,y) = \inf\{L_F(\gamma) \mid \gamma \text{ is a piecewise } C^1 \text{ curve from } x \text{ to } y\}.$$

Length is invariant under increasing piecewise C^1 reparametrizations. Symmetry of the norms implies $L_F(\gamma^{-1}) = L_F(\gamma)$.

Theorem 26.3.5. On each connected component of a Banach–Finsler manifold, d_F is a finite distance inducing the manifold topology. More precisely, for each x_0 there exist a chart $\varphi\colon U \longrightarrow X$, a neighborhood $V \subseteq U$ of x_0, and $C \ge 1$ such that, for $x, y \in V$,

$$C^{-1}\|\varphi(y) - \varphi(x)\|_X \le d_F(x,y) \le C\|\varphi(y) - \varphi(x)\|_X.$$

Proof. Translating coordinates, suppose that $\varphi(x_0) = 0$. First shrink U so that (26.14) holds there, and then choose $r > 0$ so that $B_X(0,3r) \subseteq \varphi(U)$. Let

$$V := \varphi^{-1}(B_X(0, \frac{r}{2})).$$

If $x, y \in V$, the segment $z(t) = (1-t)\varphi(x) + t\varphi(y)$ remains in $B_X(0, \frac{r}{2})$, and its lift $\sigma = \varphi^{-1} \circ z$ satisfies

$$L_F(\sigma) \le C\int_0^1 \|z'(t)\|_X\,dt = C\|\varphi(y) - \varphi(x)\|_X.$$

This is the upper bound.

Now let γ be any curve from x to y. While its image remains in $\varphi^{-1}(B_X(0,2r))$, the chain rule and (26.14)

give

$$\|\varphi(\gamma(t_1))-\varphi(\gamma(t_0))\|_X \le C L_F(\gamma\restriction_{[t_0,t_1]}). \tag{26.15}$$

If γ does not leave that ball, apply the inequality to its endpoints and obtain $L_F(\gamma)\ge C^{-1}\|\varphi(y)-\varphi(x)\|_X$. If it does, there is a first time t_1 at which the norm of its coordinate equals $2r$. Indeed, estimate (26.15) makes the coordinates a Cauchy family as the endpoint of the initial segment is approached. Completeness of X provides a limit in $\overline{B_X(0,2r)}$, which is contained in $\varphi(U)$. Continuity of the curve and the Hausdorff property of M identify that limit with the coordinate of $\gamma(t_1)$. If its norm were less than $2r$, the curve would remain in the ball a little longer. This is the exit argument of Proposition 26.2.6, based on finite length and completeness of the model. Since $\|\varphi(x)\|_X<\frac{r}{2}$, the same inequality gives

$$L_F(\gamma)\ge C^{-1}\frac{3r}{2}\ge C^{-1}\|\varphi(y)-\varphi(x)\|_X,$$

because the distance between two points of $B_X(0,\frac{r}{2})$ is less than r. Taking the infimum over γ gives the lower bound, even against curves that leave the chart.

Nonnegativity, symmetry, and the triangle inequality follow, respectively, from the definition, reversing curves, and concatenating them. To include points outside V, the same argument in the ball of radius $r/2$ proves that every curve from x_0 to $M\setminus V$ has length at least $r/(2C)$. Thus, $B_{d_F}(x_0,r/(2C))\subseteq V$. This inclusion and the lower bound inside V separate x_0 from all other points and show that a sequence converging to x_0 in distance eventually enters V and converges in coordinates. The upper bound proves the converse. Finally, the relation of accessibility by piecewise C^1 curves partitions M into open sets: from an accessible point one can reach every point of a sufficiently small convex chart. By connectedness, each connected component is a single accessibility class, so d_F is finite on it. The two local bounds show that the balls of d_F and the coordinate neighborhoods generate the same topology. □

Definition 26.3.6. A Banach–Finsler manifold is **metrically complete** if each component, equipped with the restriction of d_F, is a complete metric space.

Definition 26.3.7. ($C^{1,1}$ regularity and regularity of the norm) Let (M,F) be a Banach–Finsler manifold. We say it is of class $C^{1,1}$ when M is equipped with a $C^{1,1}$ atlas in the sense of Definition 24.1.5; regularity of coordinate representations will be checked in this atlas. This condition does not impose Lipschitz regularity on the family of norms F_x. A Banach–Finsler structure is **locally Lipschitz in the base** if, for each x_0, there exist a smaller admissible chart and $L>0$ such that

$$\big|\|w\|_x-\|w\|_y\big|\le L\|\varphi(x)-\varphi(y)\|_X\,\|w\|_{x_0},\qquad x,y\in U,\quad w\in X. \tag{26.16}$$

These two conditions are independent: the first concerns the atlas and the second the family of norms. The second is expressed in charts of the chosen $C^{1,1}$ atlas, since transformation of a tangent norm contains the differential of the chart change.

The term "Finsler manifold of class $C^{1,1}$" sometimes groups together different hypotheses. The Palais–Struwe arguments use the following ingredients:

(a) M is a paracompact Banach manifold with a $C^{1,1}$ atlas;

(b) F is a continuous admissible structure in the sense of Definition 26.3.1;

(c) the covers involved admit partitions of unity locally Lipschitz in the charts of the $C^{1,1}$ atlas.

In this construction, the partitions in the last item do not constitute an additional hypothesis on the model space. On each component, Theorem 26.3.5 and Theorem 24.8.8 allow Lemma 24.8.7 to be applied. Distances to the complements of the shrunk open sets, divided by their positive, locally finite sum, produce these partitions. The construction is developed in Theorem 31.4.4. When differentiable partitions are required, one instead uses Theorem 24.8.9, with the regularity and model space hypotheses stated there.

Continuity and admissibility of F suffice for the topology of d_F and for transporting strict inequalities from one fiber to nearby fibers. The $C^{1,1}$ atlas and locally Lipschitz partitions are the ingredients that allow local fields to be glued and an ODE with uniqueness to be obtained. The additional condition (26.16) is invoked only when the norm itself needs to vary with Lipschitz control. None of these hypotheses asserts that $v \mapsto F_x(v)^2$ has a vertical Hessian or that a Chern connection exists. This is the setting of the deformation theory of Palais and Struwe [138, §II.3.7].

Example 26.3.8. (Complete submanifolds of a Banach space) Let N be a closed split submanifold of a Banach space X. The norm induced by X on each T_xN defines a complete Banach–Finsler structure. In a local parametrization $\theta\colon V \subseteq X_0 \longrightarrow N$, continuity of $D\theta$ in the operator norm and the fact that $D\theta(y_0)$ is an isomorphism onto its image allow us to use $\|w\|_0 := \|D\theta(y_0)w\|_X$. This norm is complete because $D\theta(y_0)$ is a topological isomorphism onto the closed subspace $T_{\theta(y_0)}N$. Given $\varepsilon > 0$, shrink V so that

$$\|D\theta(y) - D\theta(y_0)\|_{0,X} < \frac{\varepsilon}{1+\varepsilon}.$$

Here $\|\cdot\|_{0,X}$ is the operator norm from the space $(X_0, \|\cdot\|_0)$ to $(X, \|\cdot\|_X)$. The triangle inequality and its reverse form then give

$$(1+\varepsilon)^{-1}\|w\|_0 \le \|D\theta(y)w\|_X \le (1+\varepsilon)\|w\|_0,$$

which is exactly admissibility of the induced norms. To prove completeness, first observe that, for every curve γ in N,

$$\|\gamma(b) - \gamma(a)\|_X \le L_F(\gamma),$$

so an intrinsic Cauchy sequence is Cauchy in X. Its limit belongs to N because N is closed. In an adapted submanifold chart, the local parametrization and its differential are bounded after shrinking the chart. The coordinate segment then gives $d_F(x,p) \le C_0\|\psi(x) - \psi(p)\|_{X_0}$ for x close to the limit p, where $C_0 > 0$ depends on the smaller chart. Therefore, convergence in X, and with it convergence in the chart, implies intrinsic convergence. Global closedness and local control of lengths play different roles in this argument.

Proposition 26.3.9. (Continuation criterion) Let (M, F) be a complete Banach–Finsler manifold, and let $\mathbf{X}$ be a field defined on all of M, continuous and locally Lipschitz in coordinates. Suppose the atlas of M is at least $C^{1,1}$. If there exists $A \ge 0$ such that $F_x(\mathbf{X}(x)) \le A$ for every x, every maximal integral curve of $\mathbf{X}$ is defined on $\mathbb{R}$. The global flow is continuous, and its time maps are homeomorphisms with inverse Φ_{-t}. If the atlas is C^{r+1} and $\mathbf{X}$ is C^r, with $r \in \mathbb{N}$, the flow and its time maps are C^r; if the atlas and field are smooth, so is the flow.

Proof. If the maximal right endpoint were $b < \infty$, then, for $s < t < b$, $d_F(\gamma(s), \gamma(t)) \le L_F(\gamma\restriction_{[s,t]}) \le A(t-s)$. The curve is Cauchy and, by completeness, converges to a point p. Since d_F induces the manifold topology, the tail of γ enters a chart about p. Remark 25.4.3, applied with initial value p at time b, produces a local

solution. To check gluing at b, write the integral equation in the final chart and let the upper endpoint tend to b. The field is continuous and the curve has a limit, so the integral equation also holds with the limiting initial value; its derivative at b is the field value at p. Local uniqueness identifies this continuation with the solution starting at p. This gives an integral curve beyond b, contradicting maximality. The left endpoint is treated in the same way, or by applying the argument to $-\mathbf{X}$.

The chart argument of Theorem 25.4.2 remains applicable: changes in a $C^{1,1}$ atlas preserve the local Lipschitz condition on fields, by the estimate in Section 25.3. The continuous dependence theorem in the appendix gives continuity of the flow. If the atlas is C^{r+1}, its tangent changes are C^r, and the same construction gives the asserted C^r dependence. Uniqueness gives $\Phi_{t+s} = \Phi_t \circ \Phi_s$ and $\Phi_t^{-1} = \Phi_{-t}$; C^r dependence on the initial values gives the last assertion. □

Remark 26.3.10. (Gradient versus pseudogradient) For a strong metric, $\operatorname{grad} I = \sharp_{\mathbf{g}}(dI)$ and $dI(\operatorname{grad} I) = |\operatorname{grad} I|_{\mathbf{g}}^2$. In a Banach–Finsler structure there is generally no canonical choice of a vector that realizes the dual norm, and in a nonreflexive Banach space the supremum may not be attained. At a point where $dI \neq 0$, deformation only requires choosing locally, by the definition of the supremum, directions v with $F(v) \leq 1$ and $dI(v) > \theta \|dI\|_{F,*}$, $0 < \theta < 1$. One may also leave a strict margin in the norm. Fixing x_0, choose $\theta < \theta_1 < 1$ and $v_0 \in T_{x_0}M$ with $F_{x_0}(v_0) \leq 1$ and $dI_{x_0}(v_0) > \theta_1 \|dI(x_0)\|_{F,*}$. Multiply v_0 by $a \in (\theta/\theta_1, 1)$. Then $F_{x_0}(av_0) < 1$ and $dI_{x_0}(av_0) > \theta \|dI(x_0)\|_{F,*}$. Extend av_0 as a field with constant components in a chart. Continuity of F, dI, and the dual norm preserves both strict inequalities in a neighborhood of x_0. In a $C^{1,1}$ atlas, this field is locally Lipschitz in the other charts as well, without having to divide it by a norm that is only continuous. To glue the directions without losing this inequality, one needs a nonnegative locally finite partition of unity of the required regularity. To obtain a locally Lipschitz pseudogradient, one uses the partitions constructed from distances in Theorem 31.4.4; their existence rests on Theorem 24.8.8 and Lemma 24.8.7. The model space need not admit differentiable bump functions. Theorem 24.8.9 concerns the different problem of obtaining differentiable partitions. None of these constructions enters the definition of F or the proof that d_F induces the topology. This is the functional-analytic reason for the pseudogradient vector fields used in variational deformations.

26.4 Classical Finsler geometry in finite dimensions

26.4.1 Minkowski functionals and vertical tensors

Definition 26.4.1. (Minkowski functional) Let V be a finite-dimensional real vector space. A **Minkowski functional** is a continuous function $F\colon V \longrightarrow [0,\infty)$, smooth on $V \setminus \{0\}$, positive away from 0, and positively homogeneous, $F(\lambda v) = \lambda F(v)$ for $\lambda > 0$, such that

$$\mathbf{g}_v(u,w) := \frac{1}{2} D^2(F^2)_v(u,w)$$

is an inner product for every $v \neq 0$. It is **reversible** if $F(-v) = F(v)$.

Definition 26.4.2. On a finite-dimensional smooth manifold M, a **classical Finsler metric** is a function

$F\colon TM \longrightarrow [0,\infty)$, continuous at the zero section and smooth on the slit bundle

$$0_M := \{0_x \in T_xM \mid x \in M\}, \qquad \widetilde{TM} := TM \setminus 0_M,$$

such that each restriction $F_x := F\restriction_{T_xM}$ is a Minkowski functional. In coordinates $(x^1,\dots,x^n,v^1,\dots,v^n)$, where $n = \dim M$, the indices i,j,k range over $\{1,\dots,n\}$. The **fundamental tensor** and **Cartan tensor** are

$$g_{ij}(x,v) = \frac{1}{2}\frac{\partial^2 F^2}{\partial v^i \partial v^j}(x,v), \qquad C_{ijk}(x,v) = \frac{1}{4}\frac{\partial^3 F^2}{\partial v^i \partial v^j \partial v^k}(x,v).$$

Intrinsically, $\mathbf{g}_v = \frac{1}{2}D_v^2(F_x^2)$ and $\mathbf{C}_v = \frac{1}{4}D_v^3(F_x^2)$, where the derivatives D_v and $d(F_x)_v$ appearing in this section are always vertical; that is, they are computed in the fixed fiber T_xM.

Proposition 26.4.3. (Euler identities and the Legendre transformation) Let (M,F) be a finite-dimensional classical Finsler manifold. For $v \neq 0$ and $u,w \in T_xM$ we have

$$d(F_x)_v(u) = \frac{\mathbf{g}_v(v,u)}{F(v)}, \qquad \mathbf{g}_v(v,v) = F(v)^2, \qquad \mathbf{C}_v(v,u,w) = 0.$$

The Legendre transformation

$$\mathcal{L}_x\colon T_xM \setminus \{0\} \longrightarrow T_x^*M \setminus \{0\}, \qquad \mathcal{L}_x(v) := d\left(\frac{1}{2}F_x^2\right)_v = \mathbf{g}_v(v,\cdot),$$

is a positively homogeneous diffeomorphism.

Proof. The function F_x^2 is homogeneous of degree two. Euler's theorem gives $d(F_x^2)_v(v) = 2F_x(v)^2$. Differentiating this identity in the direction u gives

$$D^2(F_x^2)_v(v,u) = d(F_x^2)_v(u),$$

which proves the first two formulas. Since $\mathbf{g}_{\lambda v} = \mathbf{g}_v$, its radial derivative is zero, yielding $\mathbf{C}_v(v,u,w) = 0$. The vertical derivative of $\mathcal{L}_x$ at v is the isomorphism $u \mapsto \mathbf{g}_v(u,\cdot)$, so $\mathcal{L}_x$ is a local diffeomorphism. To justify injectivity also on segments passing through the origin, fix a Euclidean norm $|\cdot|$ on T_xM and set $L = \frac{1}{2}F_x^2$. Homogeneity and compactness of the Euclidean sphere give $L(v) \le C|v|^2$ and $\|dL_v\| \le C'|v|$ for constants $C, C' > 0$. Hence L is C^1 on all of T_xM, with $dL_0 = 0$. If $u \neq v$, the function $h(t) := L(u + t(v-u))$ has a continuous derivative on $[0,1]$ and

$$h''(t) = \mathbf{g}_{u+t(v-u)}(v-u, v-u) > 0$$

except, at most, at the unique parameter where the segment passes through zero. On each side of that parameter, h' is strictly increasing, and continuity prevents a jump when crossing it. Therefore, $h'(1) > h'(0)$, that is, $\big(dL_v - dL_u\big)(v-u) > 0$. This proves strict convexity of L and injectivity of its differential. Given $\xi \in T_x^*M \setminus \{0\}$, the function ξ attains a positive maximum on the compact sphere $F_x(v) = 1$. This constraint is regular, since Euler's identity gives $d(F_x)_v(v) = F_x(v) = 1$. Theorem 23.4.2 provides $\xi = \lambda\, d(F_x)_v = \lambda\mathcal{L}_x(v)$ with $\lambda > 0$; the last equality uses $F_x(v) = 1$, and positivity follows by evaluation at v. By homogeneity, $\xi = \mathcal{L}_x(\lambda v)$; thus, $\mathcal{L}_x$ is surjective. A bijection that is a local diffeomorphism has a smooth inverse. □

Strong convexity includes the triangle inequality. Indeed, the preceding Euler identities and the quotient rule give, for $v \neq 0$,

$$D^2F_v(w,w) = \frac{\mathbf{g}_v(w,w)F(v)^2 - \mathbf{g}_v(v,w)^2}{F(v)^3} \geq 0$$

by Cauchy–Schwarz for $\mathbf{g}_v$. The restriction of F to any line is convex away from the possible parameters where it passes through the origin; homogeneity describes the only missing point: on a line tw through the origin, the left slope is $-F(-w)$ and the right slope is $F(w)$. The former is smaller than the latter, so convexity is preserved across the origin as well. Therefore, F is convex on all of V, and convexity and homogeneity imply $F(u+w) \leq F(u)+F(w)$. Thus, a reversible Minkowski functional is a norm, whereas a nonreversible one is a directed norm.

The Cartan tensor measures directional dependence of the fundamental tensor. If $\mathbf{g}_v$ does not depend on v, then $\mathbf{C}_v = 0$. Conversely, if $\dim M \geq 2$, each slit fiber $T_xM \setminus \{0\}$ is connected and $\mathbf{C} = 0$ implies that $\mathbf{g}_v$ is independent of v; therefore, F_x^2 is a quadratic form. In dimension one, the same conclusion additionally requires reversibility: without it, the two rays of a slit fiber may carry different quadratic forms. If F is reversible, it satisfies Definition 26.3.1. In finite dimensions, fix a chart φ and the norm $\|w\|_0 := F_{x_0}((d\varphi_{x_0})^{-1}w)$. On the compact sphere $\{w \in \mathbb{R}^n \mid \|w\|_0 = 1\}$, uniform continuity of $F_x((d\varphi_x)^{-1}w)$ implies that, given $\varepsilon > 0$, after shrinking the chart,

$$(1+\varepsilon)^{-1}\|w\|_0 \leq F_x((d\varphi_x)^{-1}w) \leq (1+\varepsilon)\|w\|_0$$

for every w and every x in the smaller chart. This is admissibility; the compactness used in the argument is exactly what is missing from the unit ball of an infinite-dimensional Banach model.

Example 26.4.4. (Minkowski spaces) A finite-dimensional vector space equipped with a constant Minkowski functional is a Finsler manifold. Its geodesics are straight lines, and the nonlinear and Chern connections introduced below have zero coefficients in linear coordinates. The Cartan tensor may be nonzero: vanishing of the connection expresses that the geometry is locally Minkowski, not that the functional is Euclidean.

26.4.2 Spray, nonlinear connection, and Chern connection

Write $n := \dim M \geq 1$. All Latin and Greek coordinate indices in this section range over $\{1,\dots,n\}$ unless another set is specified. The matrix $(g^{ij})_{i,j=1}^n$ is the inverse of $(g_{ij})_{i,j=1}^n$. Free indices remain fixed in each equality; summed indices will be indicated in the corresponding sum.

For $L = \frac{1}{2}F^2$, the extremals satisfy

$$\frac{d}{dt}\frac{\partial L}{\partial v^i}(\gamma,\dot\gamma) - \frac{\partial L}{\partial x^i}(\gamma,\dot\gamma) = 0. \tag{26.17}$$

Since $\frac{\partial^2 L}{\partial v^i \partial v^j} = g_{ij}$, the preceding equation becomes

$$\ddot x^i + 2G^i(x,\dot x) = 0, \tag{26.18}$$

where

$$G^i(x,v) = \frac{1}{4}\sum_{\ell=1}^n g^{i\ell}(x,v)\left(\sum_{k=1}^n \frac{\partial^2 F^2}{\partial x^k \partial v^\ell}(x,v)v^k - \frac{\partial F^2}{\partial x^\ell}(x,v)\right). \tag{26.19}$$

The coefficients G^i are smooth on $\widetilde{TM}$ and homogeneous of degree two. Under a coordinate change $y = \tau(x)$ they

satisfy

$$\widetilde{G}^{\alpha}(y, D\tau(x)v) = \sum_{i=1}^{n} \frac{\partial \tau^{\alpha}}{\partial x^{i}}(x) G^{i}(x,v) - \frac{1}{2} \sum_{i,j=1}^{n} \frac{\partial^{2} \tau^{\alpha}}{\partial x^{i} \partial x^{j}}(x) v^{i} v^{j}, \tag{26.20}$$

as can be checked by transforming (26.18). Hence they define the **geodesic spray on the slit tangent bundle**

$$\mathbf{S}_{F}(x,v) = \sum_{i=1}^{n} v^{i} \partial_{i} - 2 \sum_{i=1}^{n} G^{i}(x,v) \partial_{v^{i}}$$

on $\widetilde{TM}$. It is a second-order field and satisfies the homogeneity identity of Definition 26.2.3 for $\lambda > 0$:

$$\mathbf{S}_{F}(h_{\lambda}(v)) = T h_{\lambda}\big(\lambda \mathbf{S}_{F}(v)\big), \qquad v \in \widetilde{TM}, \quad \lambda > 0.$$

The restriction to positive scalars is essential when F is not reversible. In general, $\mathbf{S}_{F}$ does not extend smoothly to the zero section; hence it is not a smooth spray on all of TM in the sense of that definition, and constant curves are included separately.

Definition 26.4.5. (Canonical nonlinear connection) Let (M, F) be a finite-dimensional classical Finsler manifold. The coefficients

$$N^{i}_{j}(x,v) := \frac{\partial G^{i}}{\partial v^{j}}(x,v)$$

define the **canonical nonlinear connection**. Denote the restricted tangent projection by $\widetilde{\pi}\colon \widetilde{TM} \to M$. The vertical distribution is

$$\mathcal{V}_{(x,v)} := \ker T_{(x,v)} \widetilde{\pi} = \operatorname{span}\{\partial_{v^{i}} \mid 1 \le i \le n\},$$

and the horizontal distribution is spanned by the fields

$$\boldsymbol{\delta}_{x^{j}} := \partial_{j} - \sum_{i=1}^{n} N^{i}_{j} \partial_{v^{i}},$$

and the adapted vertical coforms are written as

$$\boldsymbol{\delta v}^{i} := \mathbf{d} v^{i} + \sum_{j=1}^{n} N^{i}_{j} \mathbf{d} x^{j}.$$

In particular, $\boldsymbol{\delta v}^{i}(\boldsymbol{\delta}_{x^{j}}) = 0$ and $\boldsymbol{\delta v}^{i}(\partial_{v^{j}}) = \delta^{i}_{j}$. If $\mathcal{H}_{(x,v)}$ denotes the subspace spanned by $\boldsymbol{\delta}_{x^{j}}$, then $T_{(x,v)}\widetilde{TM} = \mathcal{H}_{(x,v)} \oplus \mathcal{V}_{(x,v)}$.

Law (26.20), differentiated with respect to v, gives the explicit transformation

$$\sum_{\beta=1}^{n} \widetilde{N}^{\alpha}_{\beta}(y, D\tau(x)v) \frac{\partial y^{\beta}}{\partial x^{j}} = \sum_{i=1}^{n} \frac{\partial y^{\alpha}}{\partial x^{i}} N^{i}_{j}(x,v) - \sum_{k=1}^{n} \frac{\partial^{2} y^{\alpha}}{\partial x^{j} \partial x^{k}} v^{k}. \tag{26.21}$$

This identity shows that the horizontal distribution is intrinsic, although the coefficients N^{i}_{j} are not those of a linear connection on TM. Homogeneity gives $\sum_{j=1}^{n} N^{i}_{j} v^{j} = 2G^{i}$.

The local flow of $\mathbf{S}_F$ produces a maximal geodesic γ_v for each $v \neq 0$. Homogeneity gives $\gamma_v(t) = \gamma_{tv}(1)$ for $t > 0$ whenever both sides are defined. Adding the constant geodesics gives a star-shaped domain $\mathcal{D}_p \subseteq T_pM$ and the exponential map

$$\exp_p \colon \mathcal{D}_p \longrightarrow M, \qquad \exp_p(v) := \gamma_v(1).$$

It is smooth on $\mathcal{D}_p \setminus \{0\}$, of class C^1 on 0, and

$$d(\exp_p)_0 = \mathrm{id}_{T_pM}.$$

To quantify this assertion, choose coordinates $\varphi \colon U \longrightarrow \mathbb{R}^n$ with $\varphi(p) = 0$ and use $d\varphi_p$ to identify T_pM with $\mathbb{R}^n$. Let $\widehat{\exp}_p := \varphi \circ \exp_p \circ (d\varphi_p)^{-1}$. Take $\rho > 0$ with $\overline{B(0,\rho)} \subseteq \varphi(U)$. Compactness of $\overline{B(0,\rho)} \times S^{n-1}$ provides numbers $M_0, M_x, M_v \geq 0$ bounding, respectively,

$$|G(x,u)|, \qquad \|D_xG(x,u)\|, \qquad \|D_vG(x,u)\|, \qquad |u| = 1.$$

By homogeneity, for $w \neq 0$ these bounds become

$$|G(x,w)| \leq M_0|w|^2, \quad \|D_xG(x,w)\| \leq M_x|w|^2, \quad \|D_vG(x,w)\| \leq M_v|w|.$$

Choose $0 < r \leq 1$ so that $2r < \rho$ and $8M_0r \leq \frac{1}{2}$. If $0 < |v| < r$, the solution x_v of $x_v'' = -2G(x_v, x_v')$, $x_v(0) = 0$, $x_v'(0) = v$ satisfies $|x_v'(t)| \leq 2|v|$ for $0 \leq t \leq 1$. Indeed, while this bound holds,

$$|x_v'(t) - v| \leq 2M_0 \int_0^t |x_v'(s)|^2 ds \leq 8M_0|v|^2 \leq \frac{1}{2}|v|,$$

which improves the initial bound and also gives $|x_v'(t)| \geq \frac{|v|}{2}$; moreover, $|x_v(t)| \leq 2|v| < \rho$. For fixed v, the state (x_v, x_v') thus remains in a compact set contained in the domain of the spray on the slit tangent bundle. Theorem B.13.4 rules out a maximal endpoint before 1, and the argument reaches all of $[0,1]$. Integrating once more gives

$$|\widehat{\exp}_p(v) - v| \leq C_0|v|^2, \qquad C_0 := 8M_0. \tag{26.22}$$

For the derivative with respect to the initial value, set $J_v(t) := D_v x_v(t)$. The variational equation is

$$J_v'' = -2D_xG(x_v, x_v')J_v - 2D_vG(x_v, x_v')J_v', \qquad J_v(0) = 0, \quad J_v'(0) = I. \tag{26.23}$$

The preceding bounds give $\|D_xG(x_v, x_v')\| \leq 4M_x|v|^2$ and $\|D_vG(x_v, x_v')\| \leq 2M_v|v|$. Applying Grönwall's lemma 1.8.19 to the first-order system for (J_v, J_v') and comparing it with (tI, I) gives

$$\|D\widehat{\exp}_p(v) - I\| \leq C_1|v|, \qquad C_1 := (8M_xr + 4M_v)\exp(1 + 8M_xr^2 + 4M_vr). \tag{26.24}$$

In detail, set $E_0 := \exp(1 + 8M_xr^2 + 4M_vr)$. Grönwall's lemma 1.8.19 applied to the sum norm of the system gives $\|J_v(t)\| + \|J_v'(t)\| \leq E_0$ for $t \in [0,1]$. Integrating (26.23), we obtain

$$\|J_v'(t) - I\| \leq \int_0^t \left(8M_x|v|^2\|J_v(s)\| + 4M_v|v|\|J_v'(s)\|\right) ds \leq (8M_xr + 4M_v)E_0|v|t.$$

Integrating again and using $J_v(0) = 0$ yields

$$\|J_v(t) - tI\| \le \frac{1}{2}(8M_x r + 4M_v)E_0|v|t^2.$$

At $t = 1$ this bound implies (26.24) with the indicated value of C_1. Estimates (26.22) and (26.24) extend the differential continuously to the origin with value I and prove that $d(\exp_p)_0 = \mathrm{id}_{T_pM}$. In general, $\exp_p$ is not C^2 at 0, reflecting that F^2 and the spray on the slit tangent bundle need not be smooth at the zero section. The constants C_0, C_1 are independent of the direction v and depend only on r and the bounds M_0, M_x, M_v on the chosen coordinate neighborhood and unit sphere. The inverse function theorem, applied to this C^1 map, also shows that $\exp_p$ restricts to a C^1 diffeomorphism between neighborhoods of 0 and p; away from 0 both the map and its local inverse are smooth.

On the slit tangent bundle, consider the **pullback bundle**

$$\widetilde{\pi}^*TM = \{((x,v),w) \mid v \in T_xM \setminus \{0\},\ w \in T_xM\}.$$

The fundamental tensor is a metric on this bundle: on the fiber over (x,v) we use $\mathbf{g}_v$. The tautological section is $\boldsymbol{\mathcal{Y}}(x,v) = v$.

Theorem 26.4.6. (Chern connection) Let (M,F) be a finite-dimensional classical Finsler manifold. There exists a unique linear connection ∇^{Ch} on $\widetilde{\pi}^*TM$ whose connection forms $\omega^i_j = \sum_{k=1}^{n} \Gamma^i_{jk}(x,v)\,\mathbf{d}x^k$ satisfy

$$\sum_{j=1}^{n} \mathbf{d}x^j \wedge \omega^i_j = 0, \tag{26.25}$$

$$\mathbf{d}g_{ij} - \sum_{k=1}^{n}\left(g_{kj}\omega^k_i + g_{ik}\omega^k_j\right) = 2\sum_{k=1}^{n} C_{ijk}\,\boldsymbol{\delta v}^k. \tag{26.26}$$

Its coefficients are given by

$$\Gamma^i_{jk} = \frac{1}{2}\sum_{\ell=1}^{n} g^{i\ell}\left(\boldsymbol{\delta}_{x^j} g_{\ell k} + \boldsymbol{\delta}_{x^k} g_{j\ell} - \boldsymbol{\delta}_{x^\ell} g_{jk}\right), \qquad \boldsymbol{\delta}_{x^j} = \partial_j - \sum_{m=1}^{n} N^m_j \partial_{v^m}. \tag{26.27}$$

If $y = \tau(x)$ is a coordinate change, its full transformation law is

$$\sum_{\beta,\gamma=1}^{n} \widetilde{\Gamma}^{\alpha}_{\beta\gamma}(y, D\tau(x)v)\frac{\partial y^\beta}{\partial x^i}\frac{\partial y^\gamma}{\partial x^j} = \sum_{k=1}^{n}\frac{\partial y^\alpha}{\partial x^k}\Gamma^k_{ij}(x,v) - \frac{\partial^2 y^\alpha}{\partial x^i \partial x^j}. \tag{26.28}$$

Moreover,

$$N^i_j = \sum_{k=1}^{n}\Gamma^i_{jk}v^k, \qquad 2G^i = \sum_{j,k=1}^{n}\Gamma^i_{jk}v^j v^k. \tag{26.29}$$

If F comes from a Riemannian metric, $\mathbf{C} = 0$ and ∇^{Ch} is the lift of the Levi–Civita connection.

Proof. The first condition is equivalent to $\Gamma^i_{jk} = \Gamma^i_{kj}$. Since $\frac{\partial g_{ij}}{\partial v^k} = 2C_{ijk}$, the vertical components of (26.26)

hold automatically. Its horizontal components are

$$\delta_{x^k} g_{ij} = \sum_{m=1}^{n} \bigl(g_{mj}\Gamma^m_{ik} + g_{im}\Gamma^m_{jk} \bigr).$$

Fix $i, j, k \in \{1, \dots, n\}$. The three required identities are

$$\begin{aligned}
\delta_{x^j} g_{ik} &= \sum_{m=1}^{n} \bigl(g_{mk}\Gamma^m_{ij} + g_{im}\Gamma^m_{kj} \bigr), \\
\delta_{x^k} g_{ij} &= \sum_{m=1}^{n} \bigl(g_{mj}\Gamma^m_{ik} + g_{im}\Gamma^m_{jk} \bigr), \\
\delta_{x^i} g_{jk} &= \sum_{m=1}^{n} \bigl(g_{mk}\Gamma^m_{ji} + g_{jm}\Gamma^m_{ki} \bigr).
\end{aligned}$$

Adding the first two and subtracting the third, symmetry in the lower indices cancels the terms involving g_{mk} and g_{mj}. What remains is $2\sum_{m=1}^{n} g_{im}\Gamma^m_{jk}$. Multiplication by the inverse matrix of g gives (26.27). This proves local uniqueness. Conversely, the formula is symmetric in j, k and, on substituting it into the horizontal identity, the two pairs of terms with opposite signs cancel, leaving $\delta_{x^k} g_{ij}$. The vertical components have already been checked; thus the local connection also exists.

To justify gluing, consider on $\widetilde{\pi}^{*}TM$ the fiber-valued form that sends a tangent vector Z to $T\widetilde{\pi}(Z)$. Its components are $\mathbf{d}x^i$. The first equation expresses that its exterior covariant derivative is zero, so it is invariant under coordinate changes. For the second, the vertical projection determined by the horizontal distribution has components δv^i. Law (26.21) shows that these components change by the Jacobian of the coordinate change. The tensor $\mathbf{C}$, obtained by three derivatives in a fiber where the change is linear, is covariant of order three. Hence the right-hand side of (26.26) and the covariant derivative of $\mathbf{g}$ are tensorial forms of the same type. Both conditions are preserved under coordinate changes. The change of basis in the fiber depends only on x, so it introduces no $\mathbf{d}v$ components into the connection forms. Local uniqueness gives the gluing. Finally, differentiating the change of components of a field along a curve produces $D^2\tau(\dot\gamma, X)$; moving it to the other side gives the negative sign in (26.28). This is the same transformation rule already proved in (26.6).

We prove the contraction with the tautological section $\mathcal{Y}(x, v) = v$. Write $L = \tfrac{1}{2}F^2$. The Euler identities give

$$L_{v^i} = \sum_{k=1}^{n} g_{ik} v^k, \qquad \frac{\partial g_{ik}}{\partial v^m} = 2C_{ikm}, \qquad \sum_{k=1}^{n} C_{ikm} v^k = 0.$$

The Euler–Lagrange equation, written using the spray, is

$$2\sum_{\ell=1}^{n} g_{i\ell} G^\ell = \sum_{k=1}^{n} L_{x^k v^i} v^k - L_{x^i}. \tag{26.30}$$

Differentiating it with respect to v^j gives

$$2\sum_{\ell=1}^{n} g_{i\ell} N^\ell_j = L_{x^j v^i} - L_{x^i v^j} + \sum_{k=1}^{n} \frac{\partial g_{ij}}{\partial x^k} v^k - 4\sum_{m=1}^{n} C_{ijm} G^m. \tag{26.31}$$

We abbreviate $j \in \{1,\dots,n\}$ by $\delta_j := \boldsymbol{\delta}_{x^j}$. On the other hand, contracting (26.27) in the index k with $\boldsymbol{\mathcal{Y}}^k = v^k$ gives

$$2\sum_{\ell,k=1}^{n} g_{i\ell}\Gamma^{\ell}_{jk}v^k = \sum_{k=1}^{n}\big(\delta_j g_{ik} + \delta_k g_{ij} - \delta_i g_{jk}\big)v^k$$
$$= L_{x^j v^i} - L_{x^i v^j} + \sum_{k=1}^{n}\frac{\partial g_{ij}}{\partial x^k}v^k - 4\sum_{m=1}^{n} C_{ijm}G^m.$$

The second equality used $\sum_{k=1}^{n} C_{ikm}v^k = 0$ and $\sum_{k=1}^{n} N^m_k v^k = 2G^m$. Comparison with (26.31) and invertibility of (g_{ij}) prove $N^i_j = \sum_{k=1}^{n}\Gamma^i_{jk}v^k$. The second equality in (26.29) follows by contracting once more and using $\sum_{j=1}^{n} N^i_j v^j = 2G^i$. In the Riemannian case, g_{ij} does not depend on v and (26.27) is the usual Christoffel formula. □

If γ is a regular curve and $\mathbf{W}$ is a nonvanishing field along γ, the Chern connection defines

$$D_t^{\mathbf{W}}\mathbf{X} = \sum_{i=1}^{n}\left(\dot{X}^i + \sum_{j,k=1}^{n}\Gamma^i_{jk}(\gamma,\mathbf{W})\dot{\gamma}^j X^k\right)\partial_i. \tag{26.32}$$

Almost compatibility is expressed by

$$\frac{d}{dt}\mathbf{g}_{\mathbf{W}}(\mathbf{X},\mathbf{Y}) = \mathbf{g}_{\mathbf{W}}(D_t^{\mathbf{W}}\mathbf{X},\mathbf{Y}) + \mathbf{g}_{\mathbf{W}}(\mathbf{X},D_t^{\mathbf{W}}\mathbf{Y}) + 2\mathbf{C}_{\mathbf{W}}(\mathbf{X},\mathbf{Y},D_t^{\mathbf{W}}\mathbf{W}). \tag{26.33}$$

In particular, if $\mathbf{T}_\gamma := \dot{\gamma}$ is the tangent field, a regular curve is a geodesic if and only if $D_t^{\mathbf{T}_\gamma}\mathbf{T}_\gamma = 0$; by (26.29), this is precisely (26.18).

26.4.3 First variation and directed distance

For a regular curve, set

$$E_F(\gamma) := \frac{1}{2}\int_a^b F(\dot{\gamma})^2\,dt, \qquad L_F(\gamma) := \int_a^b F(\dot{\gamma})\,dt.$$

Proposition 26.4.7. (Finsler first variation) Let (M,F) be a finite-dimensional classical Finsler manifold. Let $\alpha\colon (-\varepsilon,\varepsilon)\times[a,b] \longrightarrow M$ be a smooth variation through regular curves, let $\mathbf{T} = \partial_t\alpha$, $\mathbf{V} = \partial_s\alpha$, and let $\gamma = \alpha_0$. On the right-hand sides, $\mathbf{T}$ and $\mathbf{V}$ are evaluated at $s = 0$. Then

$$\frac{d}{ds}\Big|_0 \frac{1}{2}\int_a^b F(\dot{\alpha}_s)^2\,dt = \left[\sum_{i=1}^{n}\frac{\partial L}{\partial v^i}V^i\right]_a^b + \int_a^b\sum_{i=1}^{n}\left(\frac{\partial L}{\partial x^i} - \frac{d}{dt}\frac{\partial L}{\partial v^i}\right)V^i\,dt.$$

Equivalently,

$$\frac{d}{ds}\Big|_0 E_F(\alpha_s) = \big[\mathbf{g}_{\mathbf{T}}(\mathbf{V},\mathbf{T})\big]_a^b - \int_a^b \mathbf{g}_{\mathbf{T}}(\mathbf{V},D_t^{\mathbf{T}}\mathbf{T})\,dt. \tag{26.34}$$

For length we have

$$\left.\frac{d}{ds}\right|_0 L_F(\alpha_s) = \left[\frac{\mathbf{g}_{\mathbf{T}}(\mathbf{V},\mathbf{T})}{F(\mathbf{T})}\right]_a^b - \int_a^b \mathbf{g}_{\mathbf{T}}\left(\mathbf{V}, D_t^{\mathbf{T}}\frac{\mathbf{T}}{F(\mathbf{T})}\right) dt. \tag{26.35}$$

Thus, the energy extremals with fixed endpoints are geodesics with an affine parameter. The regular length extremals are curves whose arc length parametrization is a geodesic.

Proof. Fix $0 < \delta < \varepsilon$ and restrict the variation to $[-\delta,\delta]\times[a,b]$. Since it is regular and this rectangle is compact, the map $(s,t)\mapsto(\alpha(s,t),\mathbf{T}(s,t))$ has compact image in $\widetilde{TM}$; the derivatives of $L=\frac{1}{2}F^2$ are continuous and bounded on that image. Cover the central curve by finitely many charts and subdivide $[a,b]$ so that, after shrinking ε, each strip of the variation lies in one of them. Differentiation under the integral sign is therefore justified and gives on each subinterval

$$\left.\frac{d}{ds}\right|_0 E_F(\alpha_s) = \int_a^b \sum_{i=1}^n \left(\frac{\partial L}{\partial x^i}V^i + \frac{\partial L}{\partial v^i}\dot{V}^i\right) dt.$$

Integration by parts is written explicitly as

$$\int_a^b \sum_{i=1}^n \frac{\partial L}{\partial v^i}\dot{V}^i\,dt = \left[\sum_{i=1}^n \frac{\partial L}{\partial v^i}V^i\right]_a^b - \int_a^b \sum_{i=1}^n \frac{d}{dt}\left(\frac{\partial L}{\partial v^i}\right)V^i\,dt,$$

and proves the first formula on summing over the subintervals: the interior boundary terms cancel because $\sum_{i=1}^n L_{v^i}V^i = d_vL(\mathbf{V})$ is the intrinsic evaluation of a covector. Now $L_{v^i} = \sum_{j=1}^n g_{ij}v^j$ and (26.30) imply

$$\frac{d}{dt}L_{v^i} - L_{x^i} = \sum_{j=1}^n g_{ij}\left(\dot{x}^j + 2G^j(x,\dot{x})\right) = \sum_{j=1}^n g_{ij}(D_t^{\mathbf{T}}\mathbf{T})^j.$$

The last equality uses (26.29). Since the boundary term is $\sum_{i=1}^n L_{v^i}V^i = \mathbf{g}_{\mathbf{T}}(\mathbf{T},\mathbf{V})$, this proves (26.34).

For length, the Euler identity in Proposition 26.4.3 gives $d(F_x)_{\mathbf{T}}(\mathbf{W}) = \frac{\mathbf{g}_{\mathbf{T}}(\mathbf{T},\mathbf{W})}{F(\mathbf{T})}$. Symmetry of the lower indices of Γ^i_{jk}, together with $\partial_s\mathbf{T} = \partial_t\mathbf{V}$, produces the zero-torsion identity along the variation

$$D_s^{\mathbf{T}}\mathbf{T} = D_t^{\mathbf{T}}\mathbf{V}.$$

Applying (26.33) with reference $\mathbf{T}$ eliminates the Cartan term because one of its arguments is $\mathbf{T}$; therefore,

$$\partial_s F(\mathbf{T}) = \mathbf{g}_{\mathbf{T}}\left(D_t^{\mathbf{T}}\mathbf{V}, \frac{\mathbf{T}}{F(\mathbf{T})}\right).$$

The same almost compatibility formula, now in the direction t, gives

$$\frac{d}{dt}\mathbf{g}_{\mathbf{T}}\left(\mathbf{V}, \frac{\mathbf{T}}{F(\mathbf{T})}\right) = \mathbf{g}_{\mathbf{T}}\left(D_t^{\mathbf{T}}\mathbf{V}, \frac{\mathbf{T}}{F(\mathbf{T})}\right) + \mathbf{g}_{\mathbf{T}}\left(\mathbf{V}, D_t^{\mathbf{T}}\frac{\mathbf{T}}{F(\mathbf{T})}\right),$$

since $\mathbf{C}_{\mathbf{T}}\left(\mathbf{V}, \frac{\mathbf{T}}{F(\mathbf{T})}, D_t^{\mathbf{T}}\mathbf{T}\right) = 0$. Integrating this identity proves (26.35), with the indicated boundary terms. It remains to justify that the fundamental lemma applies to all the required local fields. Let $J\subset(a,b)$ be a

compact subinterval contained in a chart $\varphi\colon U \longrightarrow \mathbb{R}^n$ in the sense that $\gamma(J) \subseteq U$, and let $\mathbf{W}$ be a smooth field along γ supported in the interior of J. For small $|s|$,

$$\alpha(s,t) := \varphi^{-1}\Big(\varphi(\gamma(t)) + s\, d\varphi_{\gamma(t)}\mathbf{W}(t)\Big)$$

on J, extended by γ outside J, is a smooth variation. Compactness of the support allows a uniform choice of s, the gluing is smooth because $\mathbf{W}$ vanishes near the endpoints of J, and regularity of γ ensures that nearby curves remain regular after shrinking $|s|$.

For fixed endpoints the boundary terms disappear. Fixing $z \in \mathbb{R}^n$ and $\chi \in C_c^\infty(\mathring{J})$, choose $\mathbf{W}(t) = \chi(t)(d\varphi_{\gamma(t)})^{-1}z$. The energy formula and the fundamental lemma imply

$$\mathbf{g}_{\mathbf{T}}\big((d\varphi_{\gamma(t)})^{-1}z, D_t^{\mathbf{T}}\mathbf{T}\big) = 0 \qquad \text{on } \mathring{J}.$$

The arbitrariness of z and positivity of $\mathbf{g}_{\mathbf{T}}$ give $D_t^{\mathbf{T}}\mathbf{T} = 0$, which by (26.29) is (26.18). Applied to the length formula, the same argument gives $D_t^{\mathbf{T}}\left(\frac{\mathbf{T}}{F(\mathbf{T})}\right) = 0$; after arc length parametrization, this is the affine geodesic equation. The converses follow directly from the formulas.

Metric differentiation and integration by parts agree with the Levi–Civita calculation of the finite-dimensional chapter, whose connection and derivative along curves are given in Theorem 2.4.10 and Theorem 2.7.5. Here we also use the identity $\mathbf{C}_{\mathbf{T}}(\mathbf{T},\cdot,\cdot) = 0$: it eliminates the additional terms in Chern almost compatibility and allows the first variation to be expressed through covariant acceleration. □

The **forward directed distance** is

$$d_F^+(p,q) := \inf\{L_F(\gamma) \mid \gamma \text{ is a piecewise } C^1 \text{ curve from } p \text{ to } q\}. \tag{26.36}$$

It satisfies $d_F^+(p,q) > 0$ for $p \neq q$ and the triangle inequality, but is not necessarily symmetric. The reverse metric

$$\overleftarrow{F}(v) := F(-v)$$

satisfies $d_{\overleftarrow{F}}^+(p,q) = d_F^+(q,p)$. We denote this last distance by $d_F^-(p,q)$. The functions

$$d_F^{\max}(p,q) := \max\{d_F^+(p,q), d_F^-(p,q)\}, \qquad d_F^{\mathrm{sum}}(p,q) := d_F^+(p,q) + d_F^-(p,q)$$

are finite symmetric distances on each connected component. For points in different components, we adopt the value $+\infty$; the metric assertions apply componentwise.

Proposition 26.4.8. (Topology of the directed distance) Let (M,F) be a finite-dimensional classical Finsler manifold. Forward directed balls, backward directed balls, and balls of $d_F^{\max}$ and d_F^{sum} induce the topology of M.

Proof. Fix a Euclidean norm $|\cdot|$ in a chart about x_0. By compactness of the unit sphere and continuity of F, after shrinking the chart there exist $0 < m \le M$ such that

$$m|v| \le F_x(v) \le M|v|, \qquad m|v| \le F_x(-v) \le M|v|$$

for every x in the chart and every v. The first exit argument in the proof of Theorem 26.3.5, applied

separately to F and $\overleftarrow{F}$, gives a coordinate ball V such that, for $x, y \in V$,

$$m|\varphi(y) - \varphi(x)| \le d_F^+(x,y) \le M|\varphi(y) - \varphi(x)|$$

and the same inequalities with d_F^- in place of d_F^+. Finally,

$$d_F^{\max}(x,y) \le d_F^{\mathrm{sum}}(x,y) \le 2 d_F^{\max}(x,y).$$

These estimates prove all four topological assertions. □

Definition 26.4.9. (Directed and geodesic completeness) Let (M,F) be a classical Finsler manifold. A sequence $(x_n)_{n\in\mathbb{N}}$ is **forward Cauchy** if, for every $\varepsilon > 0$, there exists $N \in \mathbb{N}$ such that

$$d_F^+(x_i, x_j) < \varepsilon \qquad \text{if } i, j \in \mathbb{N},\ j \ge i \ge N.$$

The manifold is **forward metrically complete** if every forward Cauchy sequence converges. Backward metric completeness is defined by replacing F by $\overleftarrow{F}$. It is **forward geodesically complete** if every maximal geodesic with nonzero initial velocity is defined for all positive times; the backward notion is defined analogously.

Convergence in the preceding definition can be expressed in the topology of M, by $d_F^+(x_n, x) \to 0$, or by $d_F^-(x, x_n) \to 0$. Indeed, the last two quantities are equal by definition, and in a smaller chart the preceding proof gives constants $m, M > 0$ such that

$$m|\varphi(x_n) - \varphi(x)| \le d_F^+(x_n, x) \le M|\varphi(x_n) - \varphi(x)|$$

when x_n and x belong to that chart. Forward completeness does not in general imply backward completeness. If F is reversible, both distances agree and ordinary metric completeness is recovered.

Example 26.4.10. (Randers metrics) If a is Riemannian and β is a 1-form with $|\beta|_a < 1$, then

$$F(v) = \sqrt{a(v,v)} + \beta(v)$$

is classical Finsler. It is reversible if and only if $\beta = 0$. The condition $|\beta|_a < 1$ is precisely pointwise positivity preventing F from vanishing in a nonzero direction. Over a noncompact base, a uniform bound requires the additional condition $\|\beta\|_{L^\infty(M,a)} < 1$. To check vertical convexity, fix a fiber and write $\alpha(v) = \sqrt{a(v,v)}$. If $v \neq 0$, then

$$\frac{1}{2} D^2(F^2)_v(w,w) = \big(d\alpha_v(w) + \beta(w)\big)^2 + \frac{F(v)}{\alpha(v)}\left(a(w,w) - \frac{a(v,w)^2}{a(v,v)}\right).$$

The second summand is nonnegative by Cauchy–Schwarz and vanishes only when w is proportional to v. In that case, if $w = tv \neq 0$, the first summand is $t^2 F(v)^2 > 0$. If they are not proportional, the second summand is positive. Thus, the Hessian is positive definite for every $v \neq 0$. Moreover, if $b(x) := |\beta_x|_a < 1$, we have $(1 - b(x))\alpha(v) \le F(v) \le (1 + b(x))\alpha(v)$; this distinguishes pointwise positivity from uniform comparison over the whole base.

Example 26.4.11. (Funk metric) On the Euclidean ball B^n, the formula

$$F_x(v) = \frac{\sqrt{(1-|x|^2)|v|^2 + \langle x, v\rangle^2} + \langle x, v\rangle}{1-|x|^2}$$

defines a nonreversible metric. It is a Randers metric: its Riemannian part and its 1-form are

$$a_x(v,v) = \frac{|v|^2}{1-|x|^2} + \frac{\langle x, v\rangle^2}{(1-|x|^2)^2}, \qquad \beta_x(v) = \frac{\langle x, v\rangle}{1-|x|^2}.$$

The inverse matrix of a_x is $(1-|x|^2)(I - xx^{\mathsf{T}})$, so $|\beta_x|^2_{a_x} = |x|^2 < 1$. The preceding example ensures strong vertical convexity. Along a radius directed toward the boundary, $F_{te_1}(e_1) = \frac{1}{1-t}$, whose integral diverges; in the opposite direction one obtains $F_{te_1}(-e_1) = \frac{1}{1+t}$. More generally, if the ray starting at x and passing through y meets the boundary at b, we have

$$d_F^+(x,y) = \log \frac{|x-b|}{|y-b|}.$$

To verify the formula, fix $x \neq y$ and that point $b \in \partial B^n$, and set $h_b(z) = 1 - \langle b, z\rangle > 0$. For $w \neq 0$, the formula for $F_z(w)$ is the positive solution of $|z + w/F_z(w)| = 1$. Taking the inner product with b gives

$$F_z(w) \geq \frac{\langle b, w\rangle}{h_b(z)} = -d(\log h_b)_z(w).$$

The inequality also holds for $w = 0$. Every curve from x to y therefore has length at least $\log(h_b(x)/h_b(y))$. On the oriented segment from x to y equality holds, because the tangent ray meets the sphere precisely at b. Since x, y, b are collinear, $h_b(x)/h_b(y) = |x-b|/|y-b|$, proving the distance formula. In particular,

$$d_F^+(0,y) = -\log(1-|y|), \qquad \overline{B}^+(0,R) = \{y \in B^n \mid |y| \leq 1 - e^{-R}\}, \qquad R \geq 0.$$

These balls are compact. A forward Cauchy sequence lies in one of them by the triangle inequality and has a subsequence converging to $y \in B^n$. To check convergence of the whole sequence, fix $\varepsilon > 0$ and an index N beyond which $d_F^+(x_i, x_j) < \varepsilon/2$ if $j \geq i \geq N$. For each $i \geq N$, take subsequence indices greater than i and pass to the limit; continuity of the distance gives $d_F^+(x_i, y) \leq \varepsilon/2$. The topology of backward balls implies $x_i \to y$. This gives forward completeness. For the reverse metric, however, the radius $t \mapsto te_1$ has length

$$\int_0^1 F_{te_1}(-e_1)\,dt = \log 2 < \infty.$$

Thus, a sequence along this radius converging to the boundary is Cauchy for the reverse distance and does not converge in B^n; the metric is not backward complete.

Theorem 26.4.12. (Finite-dimensional Finsler Hopf–Rinow theorem) Let (M, F) be a connected finite-dimensional classical Finsler manifold. The following are equivalent:

(i) (M, F) is forward metrically complete;

(ii) (M, F) is forward geodesically complete;

(iii) $\exp_p$ is defined on all of T_pM for each $p \in M$;

(iv) every forward closed ball $\overline{B}^{+}(p,r) = \{q \in M \mid d_F^{+}(p,q) \le r\}$ is compact;

(v) every forward bounded closed subset, that is, one contained in some ball $B^{+}(p,r)$, is compact.

Under these conditions, for any $p, q \in M$ there exists a directed geodesic from p to q whose length is $d_F^{+}(p,q)$. The analogous assertions hold backward, applied to $\overleftarrow{F}$. If F is reversible, the two versions agree and give the same completeness equivalences as the Riemannian Hopf–Rinow theorem; a reversible metric need not come from an inner product.

A proof can be found in [19, §6.6, Thm. 6.6.1]; it combines local existence of geodesics with compactness arguments for minimizing sequences and properties of directed balls. Finite dimensionality is essential both for compactness of indicatrices and for the local compactness used in the argument, and cannot be omitted in view of Remark 26.2.9. The result relates, in each orientation separately, metric completeness, geodesic completeness, and existence of minimizing geodesics. It does not identify forward completeness with backward completeness.

26.5 Global results and distinctions between theories

A smooth spray on all of TM determines the symmetric connection used in the following result. In coordinates we write, as in Definition 26.2.3,

$$\mathbf{S}(x,v) = \big((x,v),(v,Q_x(v))\big).$$

Smoothness at the zero section and homogeneity for all scalars imply that Q_x is quadratic. Its polarization defines

$$\Gamma_x(u,v) := -\frac{1}{2}\big(Q_x(u+v) - Q_x(u) - Q_x(v)\big), \qquad Q_x(v) = -\Gamma_x(v,v). \tag{26.37}$$

The transformation law for the spray gives (26.6) for these coefficients, without using an inner product; hence they define a symmetric linear connection on TM. Its parallel transport is that of Theorem 25.6.3. We say that the spray is **compatible** with a Banach–Finsler structure F if this transport, along each geodesic segment, preserves the norms F_x.

Theorem 26.5.1. (Neeb's Cartan–Hadamard theorem) Let M be a connected smooth Banach manifold equipped with a Banach–Finsler structure F and a smooth spray on all of TM, compatible with F in the preceding sense. Suppose it has nonpositive curvature in the following sense: for every $x \in M$ and every $v \in \mathcal{D}_x$, where $\mathcal{D}_x$ is the domain of $\exp_x$, and every $w \in T_xM$,

$$(d\exp_x)_v \colon T_xM \longrightarrow T_{\exp_x(v)}M \quad \text{is an isomorphism and} \quad F_{\exp_x(v)}\big((d\exp_x)_v w\big) \ge F_x(w).$$

Under these hypotheses, geodesic completeness is equivalent to completeness of (M, d_F). If either holds, then for every $x \in M$ the map $\exp_x \colon T_xM \longrightarrow M$ is a covering map. If M is also simply connected, $\exp_x$ is a global diffeomorphism. In this last case radial geodesics minimize distance between their endpoints.

The notions and results that follow come from Neeb [107, pp. 118–124]. Compatible tangent norms and compatible sprays are introduced in his Definitions 1.3–1.4, pp. 118–120. The implication from metric completeness to geodesic completeness is his Lemma 1.8, and the path lifting argument is his Theorem 1.9, pp. 121–123.

The covering property of the exponential map is Theorem 1.10, and equivalence of the completeness notions is Corollary 1.11, pp. 123–124; the diffeomorphism and minimization in the simply connected case appear in Corollary 1.12, p. 124. Neeb's argument constructs path lifts with length control, extends geodesics, and verifies the covering map criterion. The estimate making that argument possible is

$$F_x\big(((d\exp_x)_v)^{-1}z\big) \le F_{\exp_x(v)}(z), \qquad z \in T_{\exp_x(v)}M.$$

Thus, the length of a lift does not exceed that of its projection; in the complete domain T_xM, a lift of finite length has a limit on reaching a finite endpoint, and a local inverse allows it to be continued. This is the path continuation mechanism used in Chapter 23. The condition on $d\exp_x$ contains two independent assertions, invertibility and expansiveness, neither of which follows from continuity of F alone. In turn, a continuous Banach–Finsler structure does not by itself determine a compatible spray.

Proof. Suppose first that (M, d_F) is complete. If a maximal geodesic γ had a finite right endpoint b, compatibility of the spray would make its speed $F_{\gamma(t)}(\dot\gamma(t)) = a$ constant. Indeed, its velocity is parallel for the connection associated with the spray, and transport along the geodesic itself preserves F. Hence, $d_F(\gamma(s),\gamma(t)) \le a|t-s|$, and completeness provides a limit q as $t \nearrow b$.
In a chart about q, local comparison of norms gives $c > 0$ such that $c\|w\|_X \le F_z((d\varphi_z)^{-1}w)$. Smoothness of the connection coefficients allows the chart to be shrunk so that $\|\Gamma_z\| \le K$, with $K > 0$. If $u(t) = \varphi(\gamma(t))$, on the tail of the curve we have

$$\|u'(t)\|_X \le a/c, \qquad \|u''(t)\|_X \le K(a/c)^2.$$

Hence u' has a limit in X as $t \nearrow b$. The state (u, u') converges to a point of the spray domain; the ODE continuation criterion in the appendix extends the geodesic. This contradicts maximality. The same proof at the left endpoint gives geodesic completeness. This is the argument of Proposition 26.2.7, with constant speed and Finsler comparison in place of Riemannian compatibility.
Now suppose geodesic completeness, fix $x \in M$, and write $E := T_xM$, with the complete norm F_x, and $f := \exp_x\colon E \to M$. The differential of f is an isomorphism at every point, so the inverse function theorem makes it a local diffeomorphism. If $c\colon [0,1] \to M$ is a piecewise C^1 curve and $v_0 \in E$ satisfies $f(v_0) = c(0)$, a local inverse starts a lift v of c with $v(0) = v_0$. Two lifts with the same value agree near that time by local injectivity of f; the open-and-closed argument extends agreement to their common interval.
On every segment where the lift is defined, the chain rule and expansiveness give

$$F_x(v'(t)) = F_x\big((df_{v(t)})^{-1}c'(t)\big) \le F_{c(t)}(c'(t)).$$

If its initial domain had an endpoint $b \le 1$, then, for $s < t < b$,

$$F_x(v(t) - v(s)) \le \int_s^t F_{c(\tau)}(c'(\tau))\,d\tau.$$

The right-hand side tends to zero as $s, t \nearrow b$. Completeness of E provides a limit v_b, and continuity of f gives $f(v_b) = c(b)$. A local inverse about v_b continues the lift, or defines it at $t = 1$ if $b = 1$. Thus, every piecewise C^1 curve has a unique lift on all of $[0,1]$ with the prescribed initial value. Since connectedness of M allows $x = f(0)$ to be joined to any point by a curve of this class, f is surjective.
We verify the covering map property. Let $q \in M$ and choose a chart $\psi\colon V \to B_X(0,r)$ with $\psi(q) = 0$ whose

image is an open ball. For $y \in V$, let $c_y(t) := \psi^{-1}(t\psi(y))$. For each $e \in f^{-1}(q)$, define $s_e(y)$ to be the endpoint of the lift of c_y starting at e. Then $f \circ s_e = \mathrm{id}_V$. These maps are smooth. To check this near a point $y_0 \in V$, cover the compact lift of c_{y_0} by finitely many domains of local inverses of f. Subdivide $[0,1]$ so that each segment lifts into one of them. On the first segment use the inverse that takes q to e. If the first j segments have been constructed for y near y_0, continuity of the endpoint and openness of the next domain allow that neighborhood of y_0 to be shrunk and the next local inverse to be used. Joint continuity of $(t,y) \mapsto c_y(t)$ and compactness of each interval of the subdivision allow this choice to be made for the entire segment at once. Uniqueness makes the two expressions agree at their common time. Repeating this step finitely many times expresses the endpoint through smooth local inverses. This proves smoothness of s_e.

Each $s_e(V)$ is open. Indeed, about $s_e(y)$ take a domain O on which f is a diffeomorphism; by continuity of s_e, there is an open set $W \subseteq V$ about y with $s_e(W) \subseteq O$. There $s_e = (f\restriction_O)^{-1}$, so $s_e(W)$ is open. If $s_e(y) = s_{e'}(y)$, lifting the reverse curve of c_y from that point, uniqueness gives $e = e'$. Hence the images of two distinct sections are disjoint. Finally, given $z \in f^{-1}(V)$, lift from z the reverse curve of $c_{f(z)}$; its endpoint is some $e \in f^{-1}(q)$, and uniqueness gives $z = s_e(f(z))$. We have proved

$$f^{-1}(V) = \coprod_{e \in f^{-1}(q)} s_e(V), \qquad f\restriction_{s_e(V)} \colon s_e(V) \to V \text{ is a diffeomorphism.}$$

This is the covering map condition.

The same lifting estimate proves metric completeness. Let $(q_j)_{j\in\mathbb{N}}$ be a Cauchy sequence in M. Choose a subsequence $(q_{j_k})_{k\in\mathbb{N}}$ such that $d_F(q_{j_k}, q_{j_{k+1}}) < 2^{-k-1}$. By the definition of distance, there exists a curve from q_{j_k} to $q_{j_{k+1}}$ of length less than 2^{-k}. Take $v_1 \in f^{-1}(q_{j_1})$ and lift these curves successively, using the endpoint of each as the initial value of the next. If v_k is the lift of q_{j_k}, then

$$F_x(v_\ell - v_k) \le \sum_{m=k}^{\ell-1} 2^{-m} \le 2^{1-k}, \qquad k,\ell \in \mathbb{N}, \quad \ell > k.$$

Thus, v_k converges in E to a point v. Continuity of f and agreement of the topology of M with that of d_F imply $q_{j_k} \to f(v)$ in distance. A Cauchy sequence with a convergent subsequence converges to the same limit, so (M, d_F) is complete.

If M is simply connected, the preceding covering has a single sheet, because E is connected. This can be seen through lifts: a path in E between two points in the same fiber projects to a contractible loop. Lifting a contraction with fixed endpoints makes the lifted endpoint vary continuously in the discrete fiber, so it remains constant. The lift of the constant loop ends where it begins; the two points of the fiber must coincide. The lift of that contraction is constructed in the evenly covered neighborhoods in the same way as for paths, subdividing the compact parameter square into finitely many rectangles. Thus, f is bijective and its local inverses form a global smooth inverse.

It remains to prove minimization. In the simply connected case, let $\Gamma = \exp_x^{-1} \circ \gamma$ be the lift of a curve from x to y; then $\Gamma(0) = 0$. Expansiveness gives

$$L_F(\gamma) \ge \int_0^1 F_x(\dot\Gamma(t))\,dt \ge F_x(\Gamma(1)).$$

The radial curve $t \mapsto \exp_x(t\Gamma(1))$ is a geodesic, and its velocity is parallel; compatibility of the spray with F shows that its length is $F_x(\Gamma(1))$. Therefore, it is minimizing. □

Remark 26.5.2. (Four levels that must be distinguished) (a) A strong Riemannian metric exists only on Hilbertizable models and provides $\sharp_{\mathbf{g}}$, Levi–Civita, and a smooth spray.

(b) A strictly weak Riemannian metric may be geometrically natural, such as L^2 on mapping spaces of positive regularity. Its musical map fails to be surjective on at least one fiber; being weak, in this chapter's convention, does not rule out being strong.

(c) A Palais–Struwe Banach–Finsler structure is a locally uniform family of norms; it requires neither a vertical Hessian nor a Chern connection, and is the appropriate structure for completeness and deformations.

(d) A classical Finsler metric requires smoothness away from zero and strong vertical convexity. The results developed here also use compactness of spheres and finite dimensionality of the vertical tensors; their Banach analogues require additional smoothness and uniform convexity hypotheses and do not follow from an arbitrary norm.

No tensor product, musical duality, or identification of a space with its dual is regarded as canonical without first fixing the structure that produces it.

27

Uniform geometry and geometric function spaces

The preceding chapters established differential calculus and the basic geometric structures on Banach manifolds. To apply them to spaces of functions and sections, an additional difficulty remains: charts, metrics, and connections must be compatible with the chosen functional regularity, and their estimates must remain controlled as the basepoint varies.

In a mapping space, a chart is constructed pointwise using a local addition or the exponential map of the target space. In spaces of metrics and connections, the structure comes from open subsets or affine spaces of tensor sections. Gauge and diffeomorphism groups also introduce nonlinear operations with different regularity: the gauge action requires one derivative of the group element, whereas diffeomorphism composition loses derivatives in one variable. These differences determine which objects form Hilbert manifolds at fixed regularity and which must be studied through a Sobolev scale or an ILH structure.

The aim of this chapter is to bring these constructions together in a uniform framework. We will identify the charts, tangent spaces, and natural actions, while specifying in each case the regularity assumptions that make the operations well defined and smooth. This precision will be essential in the next chapter: many geometric energies use an L^2 metric that is weak relative to the Sobolev topology, and their differential gradients lower regularity. Infinite-dimensional geometry must therefore retain both the geometric structure and the analytic scale in which the equations live.

Eichhorn, Amann, and control at infinity

Noncompact geometry requires distinguishing local closeness, uniform control, and global distance. Eichhorn developed uniformities for comparing geometric objects and studying their finite-distance components; Amann organized uniformly regular atlases adapted to the analysis of function spaces. Although both languages share uniform estimates, they address different questions: one describes configuration spaces, while the other allows operators and norms to be localized without the constants deteriorating as one escapes to infinity.

27.1 Uniform control of the base manifold: uniform regularity and bounded geometry

The spaces $BC^j(U,F)$ and $BUC^j(U,F)$, including the conventions for a half-box and for $j=0,\infty$, were defined in Definition 6.4.1. Normalized and shrinkable atlases, their multiplicity, and uniformly regular atlases and structures were defined in Definitions 13.2.1 and 13.2.2. For a chart $\kappa\colon U_\kappa \longrightarrow Q_\kappa$, the coordinate representation of the metric is, by definition, $g_\kappa = (\kappa^{-1})^* g$. The uniform ellipticity constants and BUC^j bounds for g_κ and g_κ^{-1} appear explicitly in (13.8), (13.9), and (13.11); none depends on the chart.

Theorem 13.2.4 and Corollary 14.4.7 prove the direction used in this chapter, without and with boundary. In the first case, the constants depend only on the dimension, a common normal radius, and bounds on curvature derivatives of the required order. In the second, one adds the collar width, the normal radius of the boundary, and bounds on the second fundamental form and its derivatives. The full comparisons and precise references for their converses are stated in Theorems 13.2.5 and 14.4.8, respectively.

Amann's localization system was constructed in Proposition 13.2.6. Without boundary, for the analysis operators $\mathcal{S}_{\mathfrak{K}}$ and synthesis operators $\mathcal{R}_{\mathfrak{K}}$ defined in Corollary 13.3.12, we have $\mathcal{R}_{\mathfrak{K}}\mathcal{S}_{\mathfrak{K}} = \mathrm{id}$ and, for each $s\in\mathbb{R}$ and $1<p<\infty$, there exist constants $c_{s,p}, C_{s,p}, D_{s,p}>0$ such that

$$c_{s,p}\|u\|_{H^{s,p}(M)} \le \|\mathcal{S}_{\mathfrak{K}}u\|_{\ell^p(I;H^{s,p}(\mathbb{R}^m))} \le C_{s,p}\|u\|_{H^{s,p}(M)}$$

, as well as $\|\mathcal{R}_{\mathfrak{K}}v\|_{H^{s,p}(M)} \le D_{s,p}\|v\|_{\ell^p(I;H^{s,p}(\mathbb{R}^m))}$. The three constants depend only on m,s,p, the multiplicity, and the uniform bounds on coordinate changes and cutoff functions through the required orders; they do not depend on the chart or on u or v. The same corollary records Triebel–Lizorkin comparisons and, when the indices allow, Besov comparisons with explicit constants.

With boundary, Corollary 14.4.12 replaces the preceding sequence space by $\mathbb{H}^{s,p}_{\partial}(\mathfrak{K})$, whose components are modeled on $\mathbb{R}^m$ for interior charts and on $\mathbb{R}^m_+$ for boundary charts. The operators $\mathcal{S}_{\partial,\mathfrak{K}}$ and $\mathcal{R}_{\partial,\mathfrak{K}}$ satisfy $\mathcal{R}_{\partial,\mathfrak{K}}\mathcal{S}_{\partial,\mathfrak{K}} = \mathrm{id}$ and estimates (14.38)– (14.39), with positive constants $c^{\partial}_{s,p}, C^{\partial}_{s,p}, D^{\partial}_{s,p}$. These depend only on m,s,p, overlap bounds, and uniform bounds on coordinate changes and cutoff functions through the required order; they do not depend on the chart or the localized element. This transfers Euclidean embeddings, multipliers, and local operators to the charts with uniform constants. This is the role of Amann's uniform regularity in this book: to provide a coordinate formulation of bounded geometry adapted to function spaces, rather than an alternative geometry or a uniformity on a configuration space.

27.2 Uniform spaces and Eichhorn uniformities

27.2.1 Uniform structures

If X is a set and $U, V \subseteq X\times X$, write

$$U^{-1} := \{(y,x) \mid (x,y)\in U\},$$
$$U\circ V := \{(x,z)\in X\times X \mid \text{there exists } y\in X \text{ with } (x,y)\in V,\ (y,z)\in U\}.$$

The diagonal of $X\times X$ is denoted by $\Delta_X := \{(x,x)\mid x\in X\}$.

Definition 27.2.1. (Uniform structure) A *uniform structure* on X is a nonempty family $\varnothing \neq \mathscr{U} \subseteq \mathcal{P}(X \times X)$ satisfying:

(i) if $U \in \mathscr{U}$ and $U \subseteq V \subseteq X \times X$, then $V \in \mathscr{U}$;

(ii) if $U, V \in \mathscr{U}$, then $U \cap V \in \mathscr{U}$;

(iii) $\Delta_X \subseteq U$ for every $U \in \mathscr{U}$;

(iv) if $U \in \mathscr{U}$, then $U^{-1} \in \mathscr{U}$;

(v) for each $U \in \mathscr{U}$, there exists $V \in \mathscr{U}$ such that $V \circ V \subseteq U$.

The elements of $\mathscr{U}$ are called *uniform neighborhoods*; they are also known by the French name *entourages*. The pair $(X, \mathscr{U})$ is a *uniform space*. It is separated if $\bigcap_{U \in \mathscr{U}} U = \Delta_X$.

Definition 27.2.2. (Base and cofinality) A family $\mathscr{B} \subseteq \mathscr{U}$ is a *base* for the uniformity $\mathscr{U}$ if, for each $U \in \mathscr{U}$, there exists $B \in \mathscr{B}$ such that $B \subseteq U$. Two bases $\mathscr{B}_1$ and $\mathscr{B}_2$ are *cofinal* if each element of either contains an element of the other.
A nonempty family $\mathscr{B} \subseteq \mathcal{P}(X \times X)$ generates a uniformity if all its elements contain Δ_X and the following conditions hold: for $B_1, B_2 \in \mathscr{B}$, there exists $B_3 \in \mathscr{B}$ with $B_3 \subseteq B_1 \cap B_2$; for $B \in \mathscr{B}$, there exist $B', B'' \in \mathscr{B}$ such that $(B')^{-1} \subseteq B$ and $B'' \circ B'' \subseteq B$. The generated uniformity consists of the subsets of $X \times X$ containing some element of $\mathscr{B}$.

Definition 27.2.3. (Metrizable uniformity) A uniformity is *metrizable* if a finite-valued metric generates it. A base is *countable* if it has a countable cofinal subfamily.

For $x \in X$ and $U \in \mathscr{U}$, set $U[x] := \{y \in X \mid (x, y) \in U\}$. The sets $U[x]$ form a neighborhood base for a topology on X. The uniform structure contains more information than this topology: it allows points to be compared without first choosing a basepoint.

Definition 27.2.4. (Uniform continuity) Let $(X, \mathscr{U}_X)$ and $(Y, \mathscr{U}_Y)$ be uniform spaces. A map $F\colon X \longrightarrow Y$ is *uniformly continuous* if, for each $V \in \mathscr{U}_Y$, there exists $U \in \mathscr{U}_X$ such that

$$(F \times F)(U) \subseteq V.$$

Two uniform structures are equivalent if the identity is uniformly continuous in both directions.

Definition 27.2.5. (Filters and uniform completeness) A *filter* on X is a nonempty family $\mathscr{F}$ of subsets of X that does not contain $\varnothing$, is closed under finite intersections, and contains every superset of each of its elements. A filter $\mathscr{F}$ on X is *Cauchy* if, for every $U \in \mathscr{U}$, there exists $A \in \mathscr{F}$ such that $A \times A \subseteq U$. It converges to $x \in X$ if $U[x] \in \mathscr{F}$ for every $U \in \mathscr{U}$. The uniform space is *complete* if every Cauchy filter converges.

Lemma 27.2.6. (Filters and sequences for a countable base) Suppose $\mathscr{U}$ has a countable base. A sequence (x_n) is called *Cauchy* if, for each $U \in \mathscr{U}$, there exists n_0 such that $(x_m, x_n) \in U$ whenever $m, n \geq n_0$. Then the space is complete in the sense of Definition 27.2.5 if and only if every Cauchy sequence converges.

Proof. If every Cauchy filter converges, apply the assumption to the filter of tails of a Cauchy sequence; convergence of this filter is equivalent to convergence of the sequence.
Conversely, let $\mathscr{F}$ be a Cauchy filter and let $(\mathscr{B}_k)_{k\in\mathbb{N}}$ be a countable cofinal base. For each k, there exists $A_k \in \mathscr{F}$ such that $A_k \times A_k \subseteq \mathscr{B}_k$. The sets $C_k := A_1 \cap \cdots \cap A_k$ belong to $\mathscr{F}$ and are nonempty; choose $x_k \in C_k$. Given $U \in \mathscr{U}$, there exists j with $\mathscr{B}_j \subseteq U$. If $m, n \geq j$, then $x_m, x_n \in C_j \subseteq A_j$ and therefore $(x_m, x_n) \in U$. The sequence (x_k) is Cauchy and converges, by assumption, to some $x \in X$.
Fix $U \in \mathscr{U}$. There exists a symmetric entourage V such that $V \circ V \subseteq U$: intersect an entourage whose square is contained in U with its inverse. Choose j with $\mathscr{B}_j \subseteq V$ and then $n \geq j$ with $(x, x_n) \in V$. For $y \in A_j$, we have $(x_n, y) \in \mathscr{B}_j \subseteq V$, so $(x, y) \in U$. Consequently, $A_j \subseteq U[x]$ and $U[x] \in \mathscr{F}$. This holds for each U, so $\mathscr{F}$ converges to x. □

Proposition 27.2.7. (Metric uniformity) Let (X, d) be a metric space. The sets

$$U_\varepsilon := \{(x, y) \in X \times X \mid d(x, y) < \varepsilon\}, \qquad \varepsilon > 0,$$

form a base for a separated uniform structure. Its topology is the metric topology, its Cauchy sequences are the usual ones, and the uniform space is complete if and only if (X, d) is complete.

Proof. The diagonal is contained in each U_ε and $U_\varepsilon^{-1} = U_\varepsilon$. The triangle inequality gives $U_{\frac{\varepsilon}{2}} \circ U_{\frac{\varepsilon}{2}} \subseteq U_\varepsilon$. Moreover, $U_\varepsilon[x] = B_d(x, \varepsilon)$, so the induced topology is the metric topology. Finally, $\{x_j\}$ is Cauchy for the uniformity if and only if, given $\varepsilon > 0$, there exists j_0 such that $(x_i, x_j) \in U_\varepsilon$ for $i, j \geq j_0$, which is precisely the usual metric condition. Lemma 27.2.6, applied to the base $\left(U_{\frac{1}{k}}\right)_{k\geq 1}$, identifies completeness by filters with metric completeness. □

Proposition 27.2.8. (Completion in the metrizable case) Every separated metrizable uniform space $(X, \mathscr{U})$ admits a metric completion: there exist a separated, metrizable, complete uniform space $\widehat{X}$ and a uniform embedding $\iota\colon X \longrightarrow \widehat{X}$ with dense image. Here *uniform embedding* means that ι is injective and both ι and its inverse on $\iota(X)$ are uniformly continuous. The completion is unique among separated metrizable completions: if $\jmath\colon X \longrightarrow Y$ is another, there exists a unique uniform isomorphism $\Phi\colon \widehat{X} \longrightarrow Y$ such that $\Phi \circ \iota = \jmath$.

Proof. Choose a metric d generating $\mathscr{U}$. Consider Cauchy sequences in X and identify two of them, (x_j) and (y_j), when $d(x_j, y_j) \to 0$. If $[x_j]$ denotes the resulting class, the formula

$$\widehat{d}([x_j], [y_j]) := \lim_{j\to\infty} d(x_j, y_j)$$

is well defined, since

$$\left|d(x_j, y_j) - d(x_k, y_k)\right| \leq d(x_j, x_k) + d(y_j, y_k).$$

This inequality shows that the scalar sequence is Cauchy and its limit is unchanged when representatives are replaced. Positivity, symmetry, and the triangle inequality pass to the limit, and $\widehat{d}([x_j], [y_j]) = 0$ is equivalent to the relation defining the classes. Thus $\widehat{d}$ is a metric. The map

$$\iota\colon X \longrightarrow \widehat{X}, \qquad x \longmapsto [(x, x, \ldots)],$$

is isometric and hence a uniform embedding. If (x_j) represents $\xi \in \widehat{X}$, then

$$\widehat{d}(\iota(x_j), \xi) = \lim_{k\to\infty} d(x_j, x_k) \longrightarrow 0 \quad \text{as } j \longrightarrow \infty,$$

, so $\iota(X)$ is dense.
Let (ξ_k) be a Cauchy sequence in $\widehat{X}$. Choose a subsequence (η_j) such that $\widehat{d}(\eta_j, \eta_{j+1}) < 2^{-j-2}$ and, by density, points $z_j \in X$ such that $\widehat{d}(\iota(z_j), \eta_j) < 2^{-j-2}$. The triangle inequality gives $d(z_j, z_{j+1}) < 2^{-j}$; consequently, for $q > p$,

$$d(z_p, z_q) < \sum_{j=p}^{q-1} 2^{-j},$$

, and (z_j) is Cauchy. Let $\zeta := [z_j]$. Then

$$\widehat{d}(\eta_j, \zeta) \le 2^{-j-2} + \sum_{r=j}^{\infty} 2^{-r} \longrightarrow 0.$$

The subsequence (η_j) converges to ζ and, since (ξ_k) is Cauchy, we also have $\xi_k \to \zeta$. Thus $\widehat{X}$ is complete.
For uniqueness, we use the following construction, which also explains extension to a completion. If $F\colon X \longrightarrow Y$ is uniformly continuous and (Y, e) is a complete metric space, define, for $\xi = [x_j]$,

$$\widehat{F}(\xi) := \lim_{j\to\infty} F(x_j).$$

Uniform continuity makes $(F(x_j))$ a Cauchy sequence. If $d(x_j, y_j) \to 0$, given $\varepsilon > 0$, choose $\delta > 0$ such that $d(x, y) < \delta$ implies $e(F(x), F(y)) < \frac{\varepsilon}{2}$; for large j, we obtain $e(F(x_j), F(y_j)) < \frac{\varepsilon}{2}$. Thus the limit is independent of the representative. The same criterion shows uniform continuity of $\widehat{F}$: if $\widehat{d}(\xi, \eta) < \frac{\delta}{2}$, choose representatives (x_j) and (y_j) and, for sufficiently large j, $d(x_j, y_j) < \delta$; passage to the limit gives $e(\widehat{F}(\xi), \widehat{F}(\eta)) \le \frac{\varepsilon}{2} < \varepsilon$. The extension is unique because Y is separated and $\iota(X)$ is dense.
Now let $\jmath\colon X \longrightarrow Y$ be another separated metrizable completion. The uniform identity between $\iota(X)$ and $\jmath(X)$ extends to uniformly continuous maps $\Phi\colon \widehat{X} \longrightarrow Y$ and $\Psi\colon Y \longrightarrow \widehat{X}$. Their compositions fix the corresponding dense subsets; the preceding uniqueness gives $\Psi \circ \Phi = \mathrm{id}_{\widehat{X}}$ and $\Phi \circ \Psi = \mathrm{id}_Y$. Moreover, $\Phi \circ \iota = \jmath$, and the same density shows that no other isomorphism has this property. □

Definition 27.2.9. (Extended metric) An *extended metric* on a set X is a map

$$d\colon X \times X \longrightarrow [0, +\infty]$$

satisfying the metric axioms, with the arithmetic convention $a + (+\infty) = +\infty$.

Definition 27.2.10. (Finite-distance component) If d is an extended metric and $x \in X$, the *finite-distance component* of x is

$$X_x := \{y \in X \mid d(x, y) < +\infty\}.$$

The restriction $d \restriction_{X_x}$ is an ordinary metric. The relation defined by the condition $d(x, y) < +\infty$ is an equivalence relation, and its classes are the finite-distance components.

Proposition 27.2.11. (Decomposition into finite-distance components) Finite-distance components are open and closed in the topology generated by balls of finite radius. The completion of (X,d) is the disjoint union of the metric completions of these components.

Proof. If $y \in X_x$, every ball of finite radius centered at y is contained in X_x by the triangle inequality; hence X_x is open. Its complement is the union of the other components and is also open. A Cauchy sequence eventually lies in a single component, since for some finite radius all sufficiently late pairs have distance less than that radius. Consequently, completing each component and taking the disjoint union produces, and characterizes, the completion of the extended metric. □

Proposition 27.2.12. (Metrization by chains) Let $(V_n)_{n\in\mathbb{N}_0}$ be a decreasing cofinal base of symmetric entourages of a separated uniform space X, and suppose

$$V_{n+1} \circ V_{n+1} \circ V_{n+1} \subseteq V_n, \qquad n \geq 0.$$

Define the cost of an edge by

$$\omega(x,y) := \inf\big(\{2^{-n} \mid n \in \mathbb{N}_0,\ (x,y) \in V_n\} \cup \{+\infty\}\big)$$

and, for chains $(x_i)_{i=0}^{N}$ with all vertices in X, define the chain metric by

$$d_{\mathrm{cad}}(x,y) := \inf\left\{ \sum_{i=0}^{N-1} \omega(x_i, x_{i+1}) \,\middle|\, N \in \mathbb{N},\ x = x_0,\ x_N = y \right\}. \tag{27.1}$$

If there is no chain of finite cost, the infimum is $+\infty$. Then, for $n \geq 1$,

$$V_n \subseteq \{(x,y) \mid d_{\mathrm{cad}}(x,y) \leq 2^{-n}\} \quad \text{and} \quad \{(x,y) \mid d_{\mathrm{cad}}(x,y) < 2^{-n}\} \subseteq V_{n-1}.$$

In particular, d_{cad} is an extended metric generating the uniformity on each finite-distance component, and $\min\{1, d_{\mathrm{cad}}\}$ is a finite-valued metric generating the uniformity on the entire space.

Proof. The first inclusion follows by using a chain with one edge. For the second, we prove simultaneously for every $n \in \mathbb{N}$ the following implication: a chain of N edges with cost less than 2^{-n} has its endpoints in V_{n-1}. If $N = 1$, the definition of the cost and the dyadic nature of its values give $(x_0, x_1) \in V_{n+1} \subseteq V_{n-1}$. An edge of zero cost joins equal points, since the pair belongs to all V_j and the uniformity is separated.
Now suppose the implication holds for every chain with fewer than N edges. If the total cost c is zero, all vertices agree. If $c > 0$, choose the first edge for which the accumulated cost reaches or exceeds $c/2$. The preceding subchain has cost less than $c/2$, and the following one has cost at most $c/2$. Since $c < 2^{-n}$, both costs are less than $2^{-(n+1)}$. Each subchain has fewer than N edges, so the induction hypothesis, applied at index $n+1$, places its endpoints in V_n. If a subchain is empty, its endpoints agree and belong to the diagonal of V_n. The central edge has cost less than 2^{-n}, so it belongs to $V_{n+1} \subseteq V_n$. Inclusion $V_n \circ V_n \circ V_n \subseteq V_{n-1}$ completes the induction step.
Symmetry and the triangle inequality for d_{cad} follow by reversing and concatenating chains, respectively. If its value is zero, the second inclusion places the pair in every V_n; separation implies that the points agree.

The two inclusions show that balls and entourages are cofinal. Finally, truncation at one preserves all balls of radius less than one and assigns distance one to pairs in distinct components. □

In particular, every separated uniformity with a countable base is metrizable: intersect each base element with its inverse and refine recursively to obtain the triple-composition condition in the proposition.

27.2.2 Eichhorn uniformities

The preceding uniform regularity is a property of the base manifold and an atlas. The uniformities introduced now, by contrast, live on a set of sections, maps, metrics, or diffeomorphisms. Their role is to compare two objects globally, even when the base is noncompact. The general uniform framework and its use on complete noncompact manifolds without boundary are developed in [51]; the specific analytic constructions are formulated below.

The linear model

Let $(M,\mathbf{g})$ be a complete Riemannian manifold without boundary, and let $\mathbf{E}\longrightarrow M$ be a smooth real vector bundle of finite rank, equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla:=\nabla^{\mathbf{E}}$. For $1\le p<\infty$ and $r\in\mathbb{N}_0$, set

$$\|\mathbf{u}\|_{p,r;\nabla}:=\left(\sum_{j=0}^{r}\int_M |\nabla^j\mathbf{u}|^p_{\mathbf{g},\mathbf{h}_{\mathbf{E}}}\,d\lambda_{\mathbf{g}}\right)^{\frac{1}{p}}.$$

On the space $L^0(M,\mathbf{E})$ of classes of measurable sections modulo almost everywhere equality, define the extended metric

$$d_{p,r;\nabla}(\mathbf{u},\mathbf{v}):=\begin{cases}\|\mathbf{u}-\mathbf{v}\|_{p,r;\nabla}, & \mathbf{u}-\mathbf{v}\in W^{r,p}(M,\mathbf{E}),\\ +\infty, & \mathbf{u}-\mathbf{v}\notin W^{r,p}(M,\mathbf{E}).\end{cases}\tag{27.2}$$

Proposition 27.2.13. (Linear components) Let $(M,\mathbf{g})$ be a complete Riemannian manifold without boundary, and let $\mathbf{E}\to M$ be a smooth real vector bundle of finite rank, equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a compatible connection $\nabla:=\nabla^{\mathbf{E}}$. Fix $1\le p<\infty$ and $r\in\mathbb{N}_0$. Then the sets

$$V_\varepsilon:=\{(\mathbf{u},\mathbf{v})\mid d_{p,r;\nabla}(\mathbf{u},\mathbf{v})<\varepsilon\},\qquad \varepsilon>0,$$

form a base for a separated metrizable uniformity. The finite-distance component of $\mathbf{u}_0$ is the affine space $\mathbf{u}_0+W^{r,p}(M,\mathbf{E})$, which is complete when $W^{r,p}(M,\mathbf{E})$ is. If ∇' is another connection, if the spaces of sections with integrable weak derivatives of order at most r are the same for both connections, and if there exist $c_\nabla,C_\nabla>0$ such that

$$c_\nabla\|\mathbf{u}\|_{p,r;\nabla}\le\|\mathbf{u}\|_{p,r;\nabla'}\le C_\nabla\|\mathbf{u}\|_{p,r;\nabla}\qquad(\mathbf{u}\in W^{r,p}(M,\mathbf{E})),$$

, then both connections induce the same uniformity.

Proof. Symmetry and the triangle inequality for $d_{p,r;\nabla}$ are inherited from the norm on each finite-distance component. Hence $V_{\frac{\varepsilon}{2}}\circ V_{\frac{\varepsilon}{2}}\subseteq V_\varepsilon$; moreover, $V_\varepsilon^{-1}=V_\varepsilon$, $\Delta_{L^0(M,\mathbf{E})}\subseteq V_\varepsilon$, and $V_{\min\{\varepsilon,\delta\}}\subseteq V_\varepsilon\cap V_\delta$. These are all the conditions in Definition 27.2.2. The function $\min\{1,d_{p,r;\nabla}\}$ is a finite-valued metric generating the same entourages of radius less than one, proving metrizability. On the other hand, $d_{p,r;\nabla}(\mathbf{u}_0,\mathbf{u})<\infty$ is equivalent to $\mathbf{u}-\mathbf{u}_0\in W^{r,p}(M,\mathbf{E})$, identifying the component. The translation $\mathbf{u}\mapsto\mathbf{u}-\mathbf{u}_0$ is an isometry from this component onto $W^{r,p}(M,\mathbf{E})$, which gives completeness. Finally, two norms satisfying the explicit

inequalities in the statement have the same uniform balls after changing the radius by the factors c_∇, C_∇ and hence cofinal bases of entourages. □

If $\nabla' - \nabla = \mathbf{a} \in \Omega^1(\operatorname{End}\mathbf{E})$ and $\mathbf{a}, \nabla\mathbf{a}, \dots, \nabla^{r-1}\mathbf{a}$ are uniformly bounded, the Leibniz rule expresses $(\nabla')^j\mathbf{u}$, in the weak sense of Chapter 9, as $\nabla^j\mathbf{u}$ plus a sum of products of derivatives of $\mathbf{a}$ and lower-order derivatives of $\mathbf{u}$. We obtain $\|\mathbf{u}\|_{p,r;\nabla'} \le C_\nabla \|\mathbf{u}\|_{p,r;\nabla}$, where C_∇ depends on r and the bounds on $\mathbf{a}, \nabla\mathbf{a}, \dots, \nabla^{r-1}\mathbf{a}$. If the corresponding derivatives of $-\mathbf{a} = \nabla - \nabla'$ are bounded with respect to ∇', we obtain $c_\nabla \|\mathbf{u}\|_{p,r;\nabla} \le \|\mathbf{u}\|_{p,r;\nabla'}$. The same identities, applied to locally integrable sections in the distributional sense, prove both inclusions between the Sobolev domains; comparing the norms on just one of them is insufficient. In the step from order j to order $j+1$, the Leibniz rule in Proposition 9.1.40 differentiates one of the existing factors, and the term $\mathbf{a}*$ adds a new factor of order zero. Starting from $\nabla'\mathbf{u} = \nabla\mathbf{u} + \mathbf{a} * \mathbf{u}$, this describes all terms for $j \in \{0, \dots, r\}$. This observation explains why, in bounded geometry, admissible reference connections produce the same linear uniformity. For connections on a fixed bundle, the difference of two connections is already a section of $T^*M \otimes \operatorname{End}\mathbf{E}$, and (27.2) applies directly to that difference.

Maps and exponential comparison

Definition 27.2.14. (Conditions (I) and (B_k)) Let $(M, \mathbf{g})$ be a complete Riemannian manifold without boundary. We say that $(M, \mathbf{g})$ satisfies (I) if there exists $i_0 > 0$ such that $\operatorname{inj}(M, \mathbf{g}) \ge i_0$, and that it satisfies (B_k) if there exist constants $K_0, \dots, K_k > 0$ such that

$$\|\nabla^j \operatorname{Rm}_{\mathbf{g}}\|_\infty \le K_j, \qquad 0 \le j \le k.$$

In this section, *bounded geometry of order k* means that (I) and (B_k) hold. Constants in estimates will refer to $i_0, K_0, \dots, K_k$ and the other data specified in each statement.

In what follows, $(M, \mathbf{g})$ and $(N, \mathbf{h}_N)$ denote complete manifolds without boundary satisfying the conditions in Definition 27.2.14 to the required order.

If $\mathbf{E} \longrightarrow M$ is a smooth real vector bundle of finite rank, equipped with a bundle metric $\mathbf{h}_\mathbf{E}$ and a connection $\nabla := \nabla^\mathbf{E}$, and $j \in \mathbb{N}_0$, set

$$C^j_b(M, \mathbf{E}) := \left\{ \mathbf{u} \in C^j(M, \mathbf{E}) \,\middle|\, \|\mathbf{u}\|_{C^j_b(M,\mathbf{E})} := \sum_{\ell=0}^{j} \sup_{x \in M} |\nabla^\ell \mathbf{u}(x)|_{\mathbf{g}, \mathbf{h}_\mathbf{E}} < +\infty \right\}.$$

For $j = 0$, only continuity and boundedness of $\mathbf{u}$ are required. On the pullback bundle f^*TN, use the connection induced by f and the Levi–Civita connection of N.

For $q \in \mathbb{N}$, denote by $C^{\infty,q}_b(M, N)$ the set of smooth maps $f : M \longrightarrow N$ such that $\|\nabla^j df\|_\infty < +\infty$ for $0 \le j \le q-1$. When uniform constants are needed, fix $\mathbf{B} = (B_0, \dots, B_{q-1}) \in (0, +\infty)^q$ and write

$$C^{\infty,q}_{b,\mathbf{B}}(M, N) := \left\{ f \in C^{\infty,q}_b(M, N) \,\middle|\, \|\nabla^j df\|_\infty \le B_j,\ 0 \le j \le q-1 \right\}.$$

The constants will be common to all maps in a class with $\mathbf{B}$ fixed. Allowing each map its own bound does not give a common constant; this distinction matters when checking the axioms of a uniformity.

If $\mathbf{X} \in \Gamma(f^*TN)$ and $\|\mathbf{X}\|_{C^0(M, f^*TN; f^*\mathbf{h}_N)} < i_0(N)$, set $(\operatorname{Exp}_f \mathbf{X})(x) := \exp_{f(x)} \mathbf{X}(x)$ and measure its derivatives with

the induced connection on f^*TN by

$$\|\mathbf{X}\|_{b,r;f} := \sum_{j=0}^{r} \|\nabla^j \mathbf{X}\|_\infty.$$

For $0 < \varepsilon < i_0(N)/2$, define

$$\mathcal{V}_\varepsilon^{b,r} := \left\{ (f,h) \middle| h = \operatorname{Exp}_f \mathbf{X} \text{ for some } \mathbf{X} \in \Gamma(f^*TN),\ \|\mathbf{X}\|_{b,r;f} < \varepsilon \right\}. \tag{27.3}$$

Now suppose $1 < p < \infty$ and $r \in \mathbb{N}$ with $r > \dim(M)/p + 1$, and fix $0 < \rho < i_0(N)/2$. In the Sobolev regime, we use

$$\mathcal{V}_{\varepsilon,\rho}^{p,r} := \left\{ (f,h) \middle| \begin{array}{l} h = \operatorname{Exp}_f \mathbf{X} \text{ for some } \mathbf{X} \in W^{r,p}(M, f^*TN), \\ \|\mathbf{X}\|_{W^{r,p}(M,f^*TN)} < \varepsilon, \quad \|\mathbf{X}\|_{C^0(M,f^*TN;f^*\mathbf{h}_N)} < \rho \end{array} \right\}. \tag{27.4}$$

The pointwise condition keeps the comparison inside a common normal ball. For $q \geq r$, on $C^{\infty,q}_{b,\mathbf{B}}(M,N)$, localization results and Sobolev embedding give a constant $C_S = C_S(M,N,p,r,\rho,\mathbf{B}) > 0$ such that

$$\|\mathbf{X}\|_{C^0(M,f^*TN;f^*\mathbf{h}_N)} \leq C_S \|\mathbf{X}\|_{W^{r,p}(M,f^*TN)}.$$

Thus, in a class with fixed data, the condition $\|\mathbf{X}\|_{C^0(M,f^*TN;f^*\mathbf{h}_N)} < \rho$ follows from $\varepsilon < \rho/C_S$.

The central property is that inversion and composition of exponential comparisons preserve control. If $h = \operatorname{Exp}_f \mathbf{X}$, denote by $P_{\mathbf{X}} \colon f^*TN \longrightarrow h^*TN$ parallel transport along $t \mapsto \exp_{f(x)}(t\mathbf{X}(x))$.

Lemma 27.2.15. (Uniform comparison estimates) Let $(M,\mathbf{g})$ and $(N,\mathbf{h}_N)$ be complete Riemannian manifolds without boundary satisfying (I) and (B_k) to the required order. Fix a radius $\rho > 0$ small enough that balls of radius 4ρ lie in uniform normal domains and the vertical differentials of the exponential map and their inverses have common bounds. It may be chosen in terms of $i_0(N)$ and the curvature bound, with $4\rho < i_0(N)$. Also fix a profile $\mathbf{B}$ bounding the derivatives of the maps under consideration through the necessary order. For each $0 \leq j \leq r$, there exist continuous polynomials P_j, Q_j with nonnegative coefficients and no constant term, depending only on the dimensions, j, ρ, the uniform geometric data of M and N through order r, and $\mathbf{B}$, and satisfying:

(i) if $h = \operatorname{Exp}_f \mathbf{X}$, then

$$\|\nabla^j (P_{\mathbf{X}}\mathbf{X})\|_{C^0(M,T^{(0,j)}(TM)\otimes h^*TN;\mathbf{g},h^*\mathbf{h}_N)} \leq P_j\left(\|\mathbf{X}\|_{C^0(M,f^*TN;f^*\mathbf{h}_N)}, \dots, \|\nabla^j \mathbf{X}\|_{C^0(M,T^{(0,j)}(TM)\otimes f^*TN;\mathbf{g},f^*\mathbf{h}_N)} \right);$$

; since $f = \operatorname{Exp}_h(-P_{\mathbf{X}}\mathbf{X})$, this bound controls inversion;

(ii) if $h = \operatorname{Exp}_f \mathbf{X}$ and $\ell = \operatorname{Exp}_h \mathbf{Y}$ remain in a common normal ball, there exists a unique $\mathbf{Z} \in \Gamma(f^*TN)$ with $\ell = \operatorname{Exp}_f \mathbf{Z}$, and $\|\nabla^j \mathbf{Z}\|_{C^0(M,T^{(0,j)}(TM)\otimes f^*TN;\mathbf{g},f^*\mathbf{h}_N)} \leq Q_j(\|\mathbf{X}\|_{b,j;f}, \|\mathbf{Y}\|_{b,j;h})$.

We may take $P_0(t) = t$ and $Q_0(a,b) = a + b$. Moreover, given $\eta > 0$, there exists $\delta > 0$, depending only on the preceding data, such that $Q_j(a,b) < \eta$ whenever $a + b < \delta$. If $r > \dim(M)/p + 1$, there exist polynomials $\widehat{P}_r, \widehat{Q}_r$ with the same dependencies, together with the Sobolev module and embedding constants, for which

$$\|P_{\mathbf{X}}\mathbf{X}\|_{W^{r,p}(M,h^*TN)} \leq \widehat{P}_r(\|\mathbf{X}\|_{W^{r,p}(M,f^*TN)}), \qquad \|\mathbf{Z}\|_{W^{r,p}(M,f^*TN)} \leq \widehat{Q}_r\left(\|\mathbf{X}\|_{W^{r,p}(M,f^*TN)}, \|\mathbf{Y}\|_{W^{r,p}(M,h^*TN)}\right),$$

if the corresponding norms in $C^0(M, f^*TN; f^*\mathbf{h}_N)$ and $C^0(M, h^*TN; h^*\mathbf{h}_N)$ are less than ρ.

Proof. At order zero, parallel transport is isometric, so $|P_{\mathbf{X}}\mathbf{X}|_{h^*\mathbf{h}_N} = |\mathbf{X}|_{f^*\mathbf{h}_N}$. If two successive geodesic segments determine $\mathbf{Z}$, the triangle inequality gives $|\mathbf{Z}|_{f^*\mathbf{h}_N} \le |\mathbf{X}|_{f^*\mathbf{h}_N} + |\mathbf{Y}|_{h^*\mathbf{h}_N}$ after transporting the vectors to the same tangent space along the segments.

At first order, let $x(s)$ be a curve with $x(0) = x$ and $x'(0) = \mathbf{V}$, and consider $c(s,t) = \exp_{f(x(s))}(t\mathbf{X}(x(s)))$. The field $\mathbf{J}(t) = \partial_s c(0,t)$ satisfies

$$\frac{D^2\mathbf{J}}{dt^2} + \mathrm{Rm}_{\mathbf{h}_N}(\mathbf{J},\dot\gamma)\dot\gamma = 0, \qquad \mathbf{J}(0) = df(\mathbf{V}), \qquad \frac{D\mathbf{J}}{dt}(0) = \nabla_{\mathbf{V}}\mathbf{X}. \tag{27.5}$$

In a parallel frame, the integral form of this equation and Grönwall's lemma 1.8.19 imply $\sup_{t\in[0,1]} |\mathbf{J}(t)|_{\mathbf{h}_N} \le e^{K_0(N)\rho^2}(|df(\mathbf{V})|_{\mathbf{h}_N} + |\nabla_{\mathbf{V}}\mathbf{X}|_{\mathbf{h}_N})$. Integrating the Jacobi equation once gives

$$\sup_{t\in[0,1]} \left|\frac{D\mathbf{J}}{dt}(t)\right|_{\mathbf{h}_N} \le |\nabla_{\mathbf{V}}\mathbf{X}|_{\mathbf{h}_N} + K_0(N)|\mathbf{X}|^2_{f^*\mathbf{h}_N} e^{K_0(N)\rho^2}\left(|df(\mathbf{V})|_{\mathbf{h}_N} + |\nabla_{\mathbf{V}}\mathbf{X}|_{\mathbf{h}_N}\right). \tag{27.6}$$

Since the connection is torsion-free, $\nabla_{\mathbf{V}}(P_{\mathbf{X}}\mathbf{X}) = D_t\mathbf{J}(1)$, and the preceding bound proves the case $j = 1$.

To compose two exponential comparisons, write $\widetilde{\mathbf{Y}} := P_{\mathbf{X}}^{-1}\mathbf{Y} \in \Gamma(f^*TN)$. On the common normal domain, consider the smooth map

$$\Psi(p,v,y) := \exp_p^{-1}\left(\exp_{\exp_p v}(P_v y)\right), \qquad p \in N, \quad v,y \in T_pN,$$

, where $P_v\colon T_pN \longrightarrow T_{\exp_p v}N$ is parallel transport along $t \mapsto \exp_p(tv)$. The section directly comparing $\ell = \mathrm{Exp}_h\mathbf{Y}$ with f is then $\mathbf{Z}(x) = \Psi(f(x),\mathbf{X}(x),\widetilde{\mathbf{Y}}(x))$. Differentiating this identity produces the preceding Jacobi fields and the linear equation for parallel transport. In particular, there exists a constant A_1 depending only on $\dim N$, ρ, and $K_0(N)$ such that

$$|\nabla\mathbf{Z}|_{\mathbf{g},f^*\mathbf{h}_N} \le A_1\left[(1 + |\mathbf{X}|_{f^*\mathbf{h}_N} + |\widetilde{\mathbf{Y}}|_{f^*\mathbf{h}_N})(|\nabla\mathbf{X}|_{\mathbf{g},f^*\mathbf{h}_N} + |\nabla\widetilde{\mathbf{Y}}|_{\mathbf{g},f^*\mathbf{h}_N}) + (|\mathbf{X}|_{f^*\mathbf{h}_N} + |\widetilde{\mathbf{Y}}|_{f^*\mathbf{h}_N})|df|_{\mathbf{g},f^*\mathbf{h}_N}\right].$$

Derivatives of $\widetilde{\mathbf{Y}} = P_{\mathbf{X}}^{-1}\mathbf{Y}$ are estimated using the same parallel transport equation; their bounds depend polynomially on the derivatives of $\mathbf{X}$ and $\mathbf{Y}$ and introduce no constant term.

To make the induction step precise, suppose bounds have been obtained through order $j-1$, with $2 \le j \le r$. Differentiate equation (27.5) a total of $j-1$ times. The recurrence (13.4)– (13.5) separates the order-j unknown from the source: the operator acting on this unknown remains the Jacobi operator, and each source term contains only variation fields of lower orders and curvature derivatives of the orders indicated there. Proposition 9.1.40 allows the contractions to be differentiated without changing their nature. Differentiating a curvature factor raises its order by one; differentiating a field raises the order of that field by one. These are exactly the two operations in the recurrence, and the weight identity prevents the source from containing a second unknown of order j. Its factors are therefore controlled by the induction hypothesis and the fixed data.

We must also preserve vanishing when $\mathbf{X} = 0$. To do so, subtract from the differentiated equation the one corresponding to the constant variation $c(x,t) = f(x)$. The terms containing only $df,\dots,\nabla^{j-1}df$ cancel. Every remaining term contains at least one factor among $\mathbf{X},\nabla\mathbf{X},\dots,\nabla^j\mathbf{X}$. Integrating the linear equation and applying Grönwall gives the order-j bound for the final vector $P_{\mathbf{X}}\mathbf{X}$, with a polynomial having no constant term. This completes the step $j-1 \longrightarrow j$, starting from the zero and first orders already computed.

For composition, proceed with the map Ψ and the parallel transport equation. Here subtract the identity

$\Psi(p,0,0)=0$. Differentiating it with respect to p again eliminates all terms containing only derivatives of the center. The chain rule of order j leaves products of derivatives of $\mathbf{X}$ and $\mathbf{Y}$ whose total order is at most j; their coefficients are bounded by the same Jacobi recurrence and the bound for the inverse differential of the exponential map. The sum of their bounds defines Q_j and retains the absence of a constant term.
To pass to Sobolev norms, use the uniform trivializations and the norm equivalence of Proposition 13.3.14. Each term has at least one integrable factor. Products of derivatives of the sections are estimated by Hölder and Sobolev embeddings, assigning to each factor the order it retains after differentiation; the sum of the differentiation orders does not exceed r. The order-zero factors are controlled by embedding into C^1_b, and the coefficient derivatives by the geometric data and $\mathbf{B}$. The product estimate in the regime $r > m/p+1$ thus gives a polynomial in the $W^{r,p}$ norms of the sections, without a term that would require integrating a constant over M. Finite multiplicity of the cover allows the p powers of the local bounds to be summed with a common constant. This gives $\widehat{P}_r$ and $\widehat{Q}_r$.

□

Proposition 27.2.16. (Uniformity with fixed control data) Let $(M,\mathbf{g})$ and $(N,\mathbf{h}_N)$ be complete Riemannian manifolds without boundary satisfying (I) and (B_k) to the required order. For a fixed profile $\mathbf{B}$, the families $\mathcal{V}^{b,r}_\varepsilon$ restricted to $C^{\infty,r}_{b,\mathbf{B}}(M,N)$ form a base for a separated uniformity. The same holds in the Sobolev regime for $\mathcal{V}^{p,r}_{\varepsilon,\rho}$ after choosing $\varepsilon<\rho/C_S(\mathbf{B})$.

Proof. The diagonal belongs to every entourage, and monotonicity in ε controls intersections. Part (i) of the lemma allows us, for each $\varepsilon>0$, to choose $\delta>0$ such that $(\mathcal{V}^{b,r}_\delta)^{-1}\subseteq\mathcal{V}^{b,r}_\varepsilon$; part (ii) allows δ to be decreased to obtain $\mathcal{V}^{b,r}_\delta\circ\mathcal{V}^{b,r}_\delta\subseteq\mathcal{V}^{b,r}_\varepsilon$. The constants are uniform because $\mathbf{B}$ is fixed. Separation follows from pointwise control. The same argument, using the Sobolev estimates and the condition $C_S(\mathbf{B})\delta<\rho$, proves the second assertion. □

Theorem 27.2.17. (Metrization in a class with common bounds) Let $(M,\mathbf{g})$ and $(N,\mathbf{h}_N)$ be complete, without boundary, and of bounded geometry of order k. For $q\in\{1,\dots,k\}$, fix a profile $\mathbf{B}\in(0,+\infty)^q$. The sets (27.3), with $r=q$, restricted to $C^{\infty,q}_{b,\mathbf{B}}(M,N)$, generate a separated uniformity with a countable base. If $1<p<\infty$ and $k\geq r>m/p+1$, the same holds for (27.4) on $C^{\infty,r}_{b,\mathbf{B}}(M,N)$. Both uniformities are metrizable and are unchanged when the common normal radius is decreased.

Proof. Proposition 27.2.16 verifies the uniformity axioms. Positive rational radii suffice to give a countable base. Separation and metrization follow from Proposition 27.2.12. If the normal radius is decreased, Sobolev embedding with a common constant shows that entourages of sufficiently small radius in the original base belong to the new base. The reverse inclusion is immediate; the bases are cofinal. □

The need to fix the bounds can be seen directly. Take $M=S^1\times\mathbb{R}$ and $N=S^2\times\mathbb{R}$ with their product metrics, and, for $n\in\mathbb{N}$, define

$$f_n(\theta,t)=(\cos(n\theta),\sin(n\theta),0,t),\qquad \theta\in\mathbb{R}/(2\pi\mathbb{Z}),\quad t\in\mathbb{R}.$$

Let $\chi\in C^\infty_c(\mathbb{R})$ equal one on $[-1,1]$, with $0\leq\chi\leq1$, and fix $0<\alpha<\rho$. The field $\mathbf{X}_n=\alpha\chi(t)(0,0,1,0)$ along f_n has C^r_b and $W^{r,p}$ norms equal to a constant times α, independently of n: the vertical vector of the sphere is parallel along the equator, and only the factors χ are differentiated. Writing $a(t)=\alpha\chi(t)$,

$$h_n=\operatorname{Exp}_{f_n}\mathbf{X}_n=(\cos a\cos(n\theta),\cos a\sin(n\theta),\sin a,t).$$

The vector giving the inverse comparison is

$$\mathbf{Y}_n = \log_{h_n} f_n = a(\sin a\cos(n\theta), \sin a\sin(n\theta), -\cos a, 0).$$

On $S^1 \times [-1,1]$, we have $|\nabla_{\partial_\theta}\mathbf{Y}_n| = n\alpha\sin\alpha$. Consequently, the direct comparison can be arbitrarily small with a radius independent of n, whereas the inverse is not bounded with that radius. Each f_n has bounded derivatives, but the family has no common profile. Constant-radius exponential entourages on the union of all classes do not by themselves satisfy the inversion axiom. The local construction of mapping manifolds used below retains the bounds of the center of each chart; see also the chart construction in [49, §5].

In the following construction, write r for the order of either norm. Fix a class with profile $\mathbf{B}$ and one of the two uniformities in the theorem. Abbreviate its exponential entourages by $\mathcal{V}_\varepsilon$. The inversion and composition estimates allow us to choose recursively a decreasing rational sequence $\varepsilon_n \to 0^+$ such that the symmetric entourages

$$\mathcal{W}_n := \mathcal{V}_{\varepsilon_n} \cap \mathcal{V}_{\varepsilon_n}^{-1}$$

are cofinal and satisfy $\mathcal{W}_{n+1} \circ \mathcal{W}_{n+1} \circ \mathcal{W}_{n+1} \subseteq \mathcal{W}_n$. Define

$$\omega(f,h) := \inf\big(\{2^{-n} \mid n \in \mathbb{N}_0,\ (f,h) \in \mathcal{W}_n\} \cup \{+\infty\}\big)$$

and, for a chain $f = f_0, f_1, \dots, f_N = h$ whose vertices f_i, with $i \in \{0,\dots,N\}$, belong to the fixed class, set

$$d_{\mathrm{cad}}(f,h) := \inf\left\{ \sum_{i=0}^{N-1} \omega(f_i, f_{i+1}) \,\middle|\, N \in \mathbb{N},\ f = f_0,\ f_N = h \right\}, \tag{27.7}$$

, with value $+\infty$ when there is no chain of finite cost. Proposition 27.2.12 gives

$$\mathcal{W}_n \subseteq \{(f,h) \mid d_{\mathrm{cad}}(f,h) \le 2^{-n}\} \quad \text{and} \quad \{(f,h) \mid d_{\mathrm{cad}}(f,h) < 2^{-n}\} \subseteq \mathcal{W}_{n-1}, \qquad n \ge 1.$$

Thus (27.7) generates the uniformity on each finite-distance component, and its truncation at one metrizes it on the entire space. The construction does not presuppose that an entire component fits inside a single exponential chart.

Definition 27.2.18. (Slice, equivariant tube, and orbit types) Let G be a Banach Lie group acting smoothly on a Banach manifold $\mathcal{X}$, and let $x \in \mathcal{X}$. Suppose the stabilizer G_x is a closed split Banach Lie subgroup, so that the associated quotient below has its manifold structure. A *slice* at x is a submanifold $S \subseteq \mathcal{X}$ containing x, invariant under the stabilizer G_x, and such that the map

$$G \times_{G_x} S \longrightarrow \mathcal{X}, \qquad [g,s] \longmapsto g \cdot s,$$

is a diffeomorphism onto a G–invariant neighborhood of the orbit $G\cdot x$. Here $G \times_{G_x} S$ is the quotient of $G \times S$ by $(g,s) \sim (gh^{-1}, h\cdot s)$, with $h \in G_x$. The image of this diffeomorphism is called an *equivariant tube* of the orbit.

We will also use the topological version of this notion: if G is a topological group acting continuously, the same associated map is required to be a homeomorphism onto an invariant open set, giving a *topological slice*. Differentiable regularity of S or the tube is added as a separate conclusion. This distinction allows

slices to be formulated for Sobolev diffeomorphisms, whose operations lose derivatives and which do not form a Banach Lie group at a fixed level.

A *quasistratification by orbit types* is a partition $\mathcal{X} = \coprod_{(H)} \mathcal{X}_{(H)}$, where $\mathcal{X}_{(H)} := \{y \in \mathcal{X} \mid G_y \text{ is conjugate to } H\}$, satisfying the following conditions: each $\mathcal{X}_{(H)}$ is a locally closed submanifold; slices provide local models for the partition; and the frontier condition holds:

$$\mathcal{X}_{(K)} \cap \overline{\mathcal{X}_{(H)}} \neq \varnothing \quad \Longrightarrow \quad H \text{ is conjugate to a subgroup of } K.$$

The prefix *quasi* indicates that local finiteness of the family of types is not required. When an external result adds regularity or second countability to the strata and quotient, these properties will be stated as part of its assumptions and conclusions.

Lemma 27.2.19. (Products, derivatives, and approximation in the Hilbert scale) Let M be a smooth compact manifold of dimension m, with or without boundary, and let $\mathbf{E}, \mathbf{F}, \mathbf{G} \to M$ be smooth vector bundles of finite rank, equipped with smooth bundle metrics and connections. The following properties hold.

(a) For $a > m/2$, $0 \le r \le a$, and a smooth homomorphism $B : \mathbf{E} \otimes \mathbf{F} \to \mathbf{G}$, there exists $C > 0$ such that

$$\|B(\mathbf{v} \otimes \mathbf{z})\|_{H^r(M,\mathbf{G})} \le C \|\mathbf{v}\|_{H^a(M,\mathbf{E})} \|\mathbf{z}\|_{H^r(M,\mathbf{F})}. \tag{27.8}$$

(b) For $r \ge 0$, the covariant derivative is a continuous linear operator

$$\nabla : H^r(M,\mathbf{E}) \longrightarrow H^{r-1}(M, T^*M \otimes \mathbf{E}).$$

In particular, if $s > m/2 + 1$, contraction of this derivative satisfies

$$\|\nabla_{\mathbf{v}} \mathbf{z}\|_{H^{s-1}(M,TM)} \le C \|\mathbf{v}\|_{H^s(M,TM)} \|\mathbf{z}\|_{H^s(M,TM)}. \tag{27.9}$$

(c) For every $r \ge 0$, $\Gamma(\mathbf{E})$ is dense in $H^r(M,\mathbf{E})$. If $r_0, r_1 \ge 0$ and $0 < \theta < 1$, then

$$[H^{r_0}(M,\mathbf{E}), H^{r_1}(M,\mathbf{E})]_\theta = H^{(1-\theta)r_0 + \theta r_1}(M,\mathbf{E})$$

with equivalent norms.

Proof. Fix a finite cover by interior and boundary charts, smooth frames, and a subordinate partition of unity $(\rho_i)_{i=1}^N$. Choose cutoff functions χ_i supported in the same charts, with $\chi_i = 1$ on a neighborhood of $\operatorname{supp} \rho_i$. Local norm equivalence for bundles and the constructions in Theorems 6.5.2 and 14.5.9 allow $\rho_i \mathbf{v}$ to be represented continuously by functions in $H^r(\mathbb{R}^m, \mathbb{K}^{\operatorname{rank} \mathbf{E}})$: in boundary charts use the half-space extension, and in interior charts extend by zero after multiplication by the cutoff function. To return to M, restrict to the chart and multiply by χ_i. The sum of these operations recovers $\mathbf{v}$.

First prove the scalar product estimate on $\mathbb{R}^m$. For $a > m/2$, Cauchy–Schwarz gives

$$\|\widehat{v}\|_{L^1(\mathbb{R}^m)} \le \left(\int_{\mathbb{R}^m} \langle \xi \rangle^{-2a} \, d\xi \right)^{1/2} \|v\|_{H^a(\mathbb{R}^m)}.$$

The integral is finite. The inequality $\langle \xi \rangle^a \le C_a(\langle \xi - \zeta \rangle^a + \langle \zeta \rangle^a)$, the Fourier formula for products, and Young's

convolution inequality imply, initially for Schwartz functions,

$$\|vz\|_{H^a(\mathbb{R}^m)} \le C_a\big(\|v\|_{H^a(\mathbb{R}^m)}\|\widehat{z}\|_{L^1(\mathbb{R}^m)} + \|\widehat{v}\|_{L^1(\mathbb{R}^m)}\|z\|_{H^a(\mathbb{R}^m)}\big) \le C\|v\|_{H^a(\mathbb{R}^m)}\|z\|_{H^a(\mathbb{R}^m)}.$$

Density of Schwartz functions in Proposition 6.1.6 extends this product: if $v_j \to v$ and $z_j \to z$ in $H^a(\mathbb{R}^m)$, applying the inequality to $(v_j - v_k)z_j + v_k(z_j - z_k)$ proves that $(v_j z_j)$ is Cauchy. Embedding into $C^0(\mathbb{R}^m)$ identifies its limit with vz. On the other hand, $\|vz\|_{L^2(\mathbb{R}^m)} \le \|v\|_{L^\infty(\mathbb{R}^m)}\|z\|_{L^2(\mathbb{R}^m)}$. Interpolate these two bounds for the linear operator $z \mapsto vz$, holding v fixed; Theorem 6.3.11, with $p = q = 2$, gives the bound in $H^r(\mathbb{R}^m)$ for $0 \le r \le a$. Apply it componentwise and to the localized smooth coefficients of B. The finitely many localization operations above prove (a).

In a local frame, $\nabla_j \mathbf{v}$ has components $\partial_j v^b + \sum_{c=1}^{\operatorname{rank}\mathbf{E}} \Gamma^b_{jc} v^c$. Euclidean differentiation from the same proposition and continuity of smooth multipliers prove (b). For the final estimate, take $a = r = s - 1 > m/2$ in (a), use $H^s(M, TM) \hookrightarrow H^{s-1}(M, TM)$, and contract $\mathbf{v} \otimes \nabla \mathbf{z}$.

For (c), represent each $\rho_i \mathbf{v}$ by an extension V_i as at the beginning of the proof. Take $V_{i,j} \in \mathcal{S}(\mathbb{R}^m, \mathbb{K}^{\operatorname{rank}\mathbf{E}})$ with $V_{i,j} \to V_i$ in the indicated space H^r. Restricting, reconstructing in the frames, and multiplying by χ_i gives smooth sections $\mathbf{v}_j$ on all of M, including the boundary charts, and

$$\|\mathbf{v}_j - \mathbf{v}\|_{H^r(M,\mathbf{E})} \le C \sum_{i=1}^{N} \|V_{i,j} - V_i\|_{H^r(\mathbb{R}^m, \mathbb{K}^{\operatorname{rank}\mathbf{E}})} \longrightarrow 0.$$

Finally, the localization and reconstruction operators can be chosen simultaneously for r_0 and r_1: the Euclidean extension operator is universal. They are therefore a coretraction and a retraction between the section spaces and finite products of Euclidean spaces. Interpolating both identities through Theorem 6.3.11 proves the equality in (c). □

27.3 Sobolev mapping manifolds

Let $(M^m, \mathbf{g})$ and $(N^n, \mathbf{h}_N)$ be smooth finite-dimensional Riemannian manifolds, with N without boundary; M may have boundary. Let $1 < p < \infty$, $r \in \mathbb{N}$. The basic condition

$$rp > m \tag{27.10}$$

ensures that $W^{r,p}$ classes have continuous representatives. This continuity is indispensable: without it, one cannot require two maps to take values in a common normal neighborhood pointwise.

Definition 27.3.1. (Sobolev maps) Let M be a smooth compact manifold with or without boundary and let N be a smooth manifold without boundary. A continuous map $f : M \longrightarrow N$ is of class $W^{r,p}$ if, for finite collections of charts in the base and target adapted to the image of f, its coordinate representations belong to $W^{r,p}$. The resulting space is denoted by $W^{r,p}(M, N)$.

If f is only Sobolev, f^*TN is initially a continuous bundle. The notation $W^{r,p}(M, f^*TN)$ is defined using trivializations induced by charts of N: their transition matrices are smooth superpositions of f and belong locally to $W^{r,p}$. Since $rp > m$, multiplication by these matrices and their inverses is continuous in $W^{r,p}$. A finite partition of

unity thus gives equivalent norms on the section space. No smoothness is attributed to f^*TN before its construction. If the center f is smooth, this definition agrees with the covariant norm in the chapter on Sobolev spaces on bundles, by Lemma 9.1.28.

Fix $f \in W^{r,p}(M,N)$ with M compact. The map

$$\mathcal{E}\colon TN \supset \mathcal{O} \longrightarrow N \times N, \qquad v \longmapsto \big(\pi(v), \exp_{\pi(v)} v\big),$$

is a local diffeomorphism along the zero section. Since $f(M)$ is compact, there exist a neighborhood $\mathcal{O}_f$ of the zero section over $f(M)$ and a number $\rho_f > 0$ such that $|v|_{\mathbf{h}_N} < \rho_f$ implies $v \in \mathcal{O}_f$ and $\mathcal{E}$ is injective on this set. By Sobolev embedding,

$$\mathcal{V}_f := \{\mathbf{X} \in W^{r,p}(M, f^*TN) \mid \|\mathbf{X}\|_{C^0(M, f^*TN; f^*\mathbf{h}_N)} < \rho_f\}$$

is open. Define

$$\operatorname{Exp}_f(\mathbf{X})(x) := \exp^N_{f(x)} \mathbf{X}(x). \tag{27.11}$$

Lemma 27.3.2. (Superposition in the algebra regime) Let M be a smooth compact manifold with or without boundary, let $U \subseteq \mathbb{R}^a$ be open, and let $F\colon U \longrightarrow \mathbb{R}^b$ be smooth. If $rp > m$, the superposition map $u \mapsto F \circ u$ is smooth on the open set $\{u \in W^{r,p}(M,\mathbb{R}^a) \mid u(M) \subseteq U\}$. On each neighborhood whose values lie in a compact set $K \Subset U$, the estimates depend only on the geometry of M, r, p, a bound on the $W^{r,p}$ norm of the arguments, and bounds on the derivatives of F on a neighborhood of K. Its differential is

$$D(F_*)(u)v = (DF \circ u)v.$$

Proof. Since $rp > m$, Sobolev embedding gives each class a continuous representative; below we identify the class with this representative. Set

$$\mathcal{U} := \{u \in W^{r,p}(M,\mathbb{R}^a) \mid u(M) \subseteq U\}.$$

First check that $\mathcal{U}$ is open. If $u \in \mathcal{U}$, compactness of M and continuity of u imply that $u(M)$ is a compact set contained in U. If $U \neq \mathbb{R}^a$, set $d_u := \operatorname{dist}(u(M), \mathbb{R}^a \setminus U) > 0$; if $U = \mathbb{R}^a$, simply fix $d_u := 1$. Let $C_{\mathrm{emb}} > 0$ be a constant for the embedding $W^{r,p}(M,\mathbb{R}^a) \hookrightarrow C^0(M,\mathbb{R}^a)$. If $\|v\|_{W^{r,p}(M,\mathbb{R}^a)} < \frac{d_u}{2C_{\mathrm{emb}}}$, then $\|v\|_{C^0(M,\mathbb{R}^a)} < \frac{d_u}{2}$ and $(u+v)(M) \subseteq U$. Thus $\mathcal{U}$ is open.

Now fix a bounded subset $\mathcal{B} \subseteq \mathcal{U}$ whose images lie in a common compact set $K \Subset U$. Choose another compact set $K_1 \Subset U$ whose interior contains K. Decreasing $\delta > 0$, the preceding embedding ensures that, if $u \in \mathcal{B}$ and $\|v\|_{W^{r,p}(M,\mathbb{R}^a)} < \delta$, then $(u + tv)(M) \subseteq K_1$ for every $t \in [0,1]$.

For a smooth function $G\colon U \longrightarrow \mathbb{R}^c$, the Faà di Bruno formula in Theorem 1.1.19, applied in charts, expresses each derivative of order at most r of $G \circ u$ as a finite sum of terms of the form

$$(D^\ell G \circ u)\big[D^{\alpha_1}u, \dots, D^{\alpha_\ell}u\big], \qquad 1 \le \ell \le r, \quad |\alpha_1| + \cdots + |\alpha_\ell| \le r, \quad \alpha_i \in \mathbb{N}_0^m, \quad |\alpha_i| \ge 1 \quad (1 \le i \le \ell).$$

To estimate each product, work on a bounded coordinate domain $\Omega \subseteq \mathbb{R}^m$ with fixed cutoff functions, and write u for its local representation. If $d_i = |\alpha_i|$, choose $q_i = rp/d_i$. The Sobolev embedding of order $r - d_i$ gives

$$\|D^{\alpha_i} u\|_{L^{q_i}(\Omega,\mathbb{R}^a)} \le C \|u\|_{W^{r,p}(\Omega,\mathbb{R}^a)}.$$

Indeed, $1/p-(r-d_i)/m \le d_i/(rp)$ because $rp > m$; if $d_i = r$, simply use $q_i = p$. Since $\sum_{i=1}^{\ell} 1/q_i = \sum_{i=1}^{\ell} d_i/(rp) \le 1/p$, Hölder's inequality and the finite measure of the region control the product in L^p. The factor $D^\ell G \circ u$ is controlled by its supremum on K_1. This argument, also applied to Leibniz's rule, proves the algebra bound

$$\|vw\|_{W^{r,p}(M)} \le C\|v\|_{W^{r,p}(M)}\|w\|_{W^{r,p}(M)}.$$

Summing over the multi-indices and finitely many charts gives a constant $C = C(M, r, p, \mathcal{B}, K_1, G) > 0$ such that

$$\|G \circ u\|_{W^{r,p}(M,\mathbb{R}^c)} \le C \qquad (u \in \mathcal{B}), \tag{27.12}$$

and, if $u_0, u_1 \in \mathcal{B}$ and the segment joining their values remains in K_1,

$$\|G \circ u_1 - G \circ u_0\|_{W^{r,p}(M,\mathbb{R}^c)} \le C\|u_1 - u_0\|_{W^{r,p}(M,\mathbb{R}^a)}. \tag{27.13}$$

Indeed, for smooth functions the first bound follows term by term from the preceding formula. For the second, write

$$G \circ u_1 - G \circ u_0 = \int_0^1 (DG \circ (u_0 + t(u_1 - u_0)))(u_1 - u_0)\, dt$$

and apply the same product estimates. To extend the bounds, let $u \in \mathcal{B}$ and choose, by Meyers–Serrin 9.4.8 if there is boundary and 9.1.48 if there is none, a sequence $u_j \in C^\infty(M, \mathbb{R}^a)$ with $u_j \to u$ in $W^{r,p}(M, \mathbb{R}^a)$. Embedding into $C^0(M, \mathbb{R}^a)$ gives uniform convergence. After discarding finitely many terms, the values of u_j lie in K_1 and their Sobolev norms have a common bound. The segments joining $u_j(x)$ and $u_k(x)$ remain in a compact neighborhood of K contained in U when the approximation is sufficiently close. By the inequality already proved for smooth arguments,

$$\|G \circ u_j - G \circ u_k\|_{W^{r,p}(M,\mathbb{R}^c)} \le C\|u_j - u_k\|_{W^{r,p}(M,\mathbb{R}^a)} \longrightarrow 0.$$

The limit exists by completeness and agrees with $G \circ u$ by uniform convergence. Taking norms and limits gives (27.12). For two arguments u_0, u_1, choose both approximations in the same compact set and apply the smooth bound to their differences; their limits give (27.13). The constants depend on the stated Sobolev bounds and the derivatives of G on the chosen compact neighborhood, independently of j and k.
For $q \in \mathbb{N}_0$, define

$$A_q(u)[v_1, \dots, v_q] := (D^q F \circ u)[v_1, \dots, v_q],$$

, with the convention $A_0(u) = F \circ u$. The product estimate and (27.12), applied to $G = D^q F$, show that $A_q(u)$ is a continuous q–linear operator from $W^{r,p}(M, \mathbb{R}^a)^q$ to $W^{r,p}(M, \mathbb{R}^b)$ and that $u \mapsto A_q(u)$ is continuous in the operator norm. Moreover, for any $w_1, \dots, w_q \in W^{r,p}(M, \mathbb{R}^a)$, the fundamental theorem of calculus gives, pointwise,

$$\big(A_q(u+v) - A_q(u) - A_{q+1}(u)[v]\big)[w_1, \dots, w_q] = \int_0^1 (1-t)(D^{q+2} F \circ (u + tv))[v, v, w_1, \dots, w_q]\, dt.$$

Taking the operator norm and applying the preceding bounds again, there exist $\delta, C_q > 0$ such that

$$\|A_q(u+v) - A_q(u) - A_{q+1}(u)[v]\|_{\mathcal{L}^q(W^{r,p}(M,\mathbb{R}^a); W^{r,p}(M,\mathbb{R}^b))} \le C_q \|v\|^2_{W^{r,p}(M,\mathbb{R}^a)}$$

for $u \in \mathcal{B}$ and $\|v\|_{W^{r,p}(M,\mathbb{R}^a)} < \delta$. For $q = 0$, division of the remainder by $\|v\|_{W^{r,p}(M,\mathbb{R}^a)}$ proves that $DF_* = A_1$. If $D^q F_* = A_q$ has been identified, the same operator norm estimate proves that A_q is differentiable with differential A_{q+1}; the continuity already established gives $F_* \in C^{q+1}$. This step, for each $q \in \mathbb{N}_0$, identifies $A_q = D^q F_*$ at all orders. In particular,

$$D(F_*)(u)v = (DF \circ u)v,$$

, and F_* is smooth on $\mathcal{U}$. □

Corollary 27.3.3. (Superposition at real Hilbert orders) The preceding lemma holds with $W^{r,p}$ replaced by H^s for every real index $s > m/2$. Consequently, the compact constructions in this chapter using H^s also admit noninteger indices.

Proof. We explain the estimate that handles these indices. Localize in a chart using cutoff functions and use the extension operator from the trace chapter when the chart meets the boundary. It suffices to estimate superposition on functions in $H^s(\mathbb{R}^m)$, multiplying the result by a fixed cutoff function χ. Around a given argument, all values lie in a compact subset of U. Extend F from a neighborhood of this compact set to a smooth map on all of $\mathbb{R}^a$ with bounded derivatives; the extension does not change the superposition under study.

Take the low-frequency operators S_j and the blocks $\Delta_j = S_{j+1} - S_j$, for $j \in \mathbb{N}_0$, of an inhomogeneous dyadic decomposition. Convergence $S_j u \to u$ in C^0 and H^s gives the telescoping identity

$$F(u) = F(S_0 u) + \sum_{j=0}^{\infty} a_j \Delta_j u, \qquad a_j(x) = \int_0^1 DF\big(S_j u(x) + t\Delta_j u(x)\big)\, dt.$$

For each $N \in \mathbb{N}_0$, Bernstein's inequality and the chain rule give

$$\|D^\alpha a_j\|_\infty \le C_N 2^{j|\alpha|}, \qquad j \in \mathbb{N}_0, \quad \alpha \in \mathbb{N}_0^m, \quad |\alpha| \le N.$$

Here C_N depends on a bound for $\|u\|_\infty$ and the derivatives of F through order $N+1$. Applying Leibniz's rule to the product and Bernstein's inequality to the block $\Delta_j u$ gives $\|D^\alpha(\chi a_j \Delta_j u)\|_{L^2(\mathbb{R}^m,\mathbb{R}^b)} \le C_N 2^{j|\alpha|}\|\Delta_j u\|_{L^2(\mathbb{R}^m,\mathbb{R}^a)}$. If $k > j$, the vanishing moments of the kernel of Δ_k allow subtraction of the Taylor polynomial of order $N-1$ of the product. The integral Taylor remainder, together with the preceding bound, gives

$$\|\Delta_k(\chi a_j \Delta_j u)\|_{L^2(\mathbb{R}^m,\mathbb{R}^b)} \le C_N \min\{1, 2^{-N(k-j)}\}\|\Delta_j u\|_{L^2(\mathbb{R}^m,\mathbb{R}^a)}, \qquad j,k \in \mathbb{N}_0.$$

For $k \le j$, we have simply used the L^1 bound on the kernel of Δ_k and the uniform bound on a_j. Choose an integer $N > s$. After multiplication by 2^{ks}, the two regions produce the factors $2^{-(N-s)(k-j)}$ and $2^{-s(j-k)}$, respectively. Both sequences are summable. The convolution inequality in $\ell^2(\mathbb{N}_0)$ and the characterization $H^s = F^s_{2,2}$ from the chapter on intermediate regularity imply

$$\|\chi F(u)\|_{H^s(\mathbb{R}^m,\mathbb{R}^b)} \le C\big(1 + \|u\|_{H^s(\mathbb{R}^m,\mathbb{R}^a)}\big).$$

The low-frequency term is estimated by differentiating $\chi F(S_0 u)$ through order N; compact support of χ makes its L^2 norm finite.

Apply this bound also to $DF, D^2F, \ldots$. Since H^s is an algebra, the integral identity for $F(u+v) - F(u)$ gives

local Lipschitz continuity, and the second-order integral remainder gives differentiability with differential $(DF \circ u)v$. For each $q \in \mathbb{N}_0$, applying the same remainder to $D^q F$ identifies the differential of A_q with A_{q+1}, exactly as in the preceding proof. The estimates are local in the H^s norm and the cover of M is finite; combining them gives the asserted smoothness. □

Theorem 27.3.4. (Exponential charts) Let M be a smooth compact manifold with or without boundary and N a smooth finite-dimensional Riemannian manifold without boundary, and suppose $rp > m$. For sufficiently small ρ_f, the map (27.11) is a diffeomorphism from $\mathcal{V}_f$ onto an open subset of $W^{r,p}(M,N)$. These charts define a Banach manifold independent of the auxiliary metric on N. The operator

$$J_f := D(\operatorname{Exp}_f^{-1})_f \colon T_f W^{r,p}(M,N) \longrightarrow W^{r,p}(M, f^*TN)$$

is a continuous linear isomorphism with inverse $D\operatorname{Exp}_f(0)$. In particular,

$$T_f W^{r,p}(M,N) \cong W^{r,p}(M, f^*TN) \tag{27.14}$$

canonically.

The construction goes back to [85, Sections 6–8] and [111, Chapters II–III].

Proof. Let $\mathcal{W}_f := \mathcal{E}(\mathcal{O}_f)$. The inverse of Exp_f on the set of h for which $(f(x), h(x)) \in \mathcal{W}_f$ for every x is

$$\log_f(h)(x) := \mathcal{E}^{-1}(f(x), h(x)) = \exp_{f(x)}^{-1} h(x).$$

The condition on (f,h) is open in the C^0 topology because M is compact and the graph of (f,h) is compact inside $\mathcal{W}_f$; by $W^{r,p} \hookrightarrow C^0$, it is also open in the Sobolev topology.
To prove smoothness, choose a finite cover of M over which f^*TN is trivialized, and charts of N containing the relevant compact sets. In these coordinates, $\mathbf{X} \mapsto \operatorname{Exp}_f \mathbf{X}$ and $h \mapsto \log_f h$ are superposition operators given by smooth maps whose derivatives are bounded on a compact set. Lemma 27.3.2 proves that they are smooth; a finite partition of unity combines the local expressions.
If the charts are centered at f and g, the coordinate change has the intrinsic expression

$$\Theta_{gf}(\mathbf{X})(x) := \exp_{g(x)}^{-1}\big(\exp_{f(x)} \mathbf{X}(x)\big). \tag{27.15}$$

The preceding argument, applied to the smooth map $(y,z,v) \mapsto \exp_z^{-1}(\exp_y v)$ on its domain of definition, proves that (27.15) is smooth. This directly verifies compatibility of the atlas. If the auxiliary metric is changed, the same formula with the two exponential maps shows that the identity between the two atlases is smooth in both directions. Finally, $D\operatorname{Exp}_f(0)\mathbf{X} = \mathbf{X}$ pointwise. Since Exp_f and its inverse are smooth, their differentials are continuous; differentiating the two inverse identities gives $J_f D\operatorname{Exp}_f(0) = \mathrm{id}$ and $D\operatorname{Exp}_f(0) J_f = \mathrm{id}$. This identification is independent of the chart and gives (14). □

Proposition 27.3.5. (Evaluation and composition) Let M be a smooth compact manifold with or without boundary and let N and P be smooth manifolds without boundary. Under the remaining assumptions of the preceding theorem:

(i) for each $x \in M$, evaluation $\operatorname{ev}_x(f) = f(x)$ is smooth;

(ii) joint evaluation $\mathrm{ev}\colon W^{r,p}(M,N)\times M\longrightarrow N$ is continuous;

(iii) if $r>\frac{m}{p}+j$, joint evaluation is of class C^j;

(iv) if $H\colon N\longrightarrow P$ is smooth, the map $f\mapsto H\circ f$ is smooth on open sets where the required derivatives of H are uniformly bounded;

(v) the map $(f,\eta)\mapsto f\circ\eta$ loses derivatives: in the Hilbert case, for $s>\frac{m}{2}+1$,

$$H^{s+j}(M,N)\times \mathrm{Diff}^s(M)\longrightarrow H^s(M,N),\qquad (f,\eta)\longmapsto f\circ\eta,$$

is of class C^j, whereas at the same level $H^s\times\mathrm{Diff}^s\longrightarrow H^s$ only continuity is asserted in general.

The composition estimates used in the last item are those of [46, Section 2].

Proof. In exponential coordinates, evaluation has the form $(\mathbf{X},x)\mapsto \exp_{f(x)}\mathbf{X}(x)$. The continuous embedding $W^{r,p}\hookrightarrow C^0$ makes point evaluation continuous, and if $r>\frac{m}{p}+j$, embedding $W^{r,p}\hookrightarrow C^j$ allows this formula to be differentiated j times with respect to x and $\mathbf{X}$; each differential is a finite sum of evaluations of derivatives of $\mathbf{X}$ multiplied by smooth coefficients of the exponential map. This proves the first three items. The fourth is Lemma 27.3.2. For the last, the first formal derivative with respect to η contains

$$D_\eta(f\circ\eta)\mathbf{Y}=(df\circ\eta)\mathbf{Y},$$

and uses one derivative of f. Iteration uses j derivatives. The cited composition estimates prove continuity and the C^j assertions with these exact domains. □

On a noncompact base, charts require common estimates in the spatial variable, but their constants may depend on the center. It is useful to construct the atlas first and keep this issue separate from completion of a class with fixed profile.

Fix $k\ge r>m/p+1$ and a normal radius ρ as in Lemma 27.2.15. For each smooth center $f\in C^{\infty,r}_b(M,N)$, set

$$\mathcal{V}_f=\{\mathbf{X}\in W^{r,p}(M,f^*TN)\mid \|\mathbf{X}\|_\infty<\rho\},\qquad \mathcal{U}_f=\mathrm{Exp}_f(\mathcal{V}_f),\qquad \Omega^{p,r}(M,N)=\bigcup_{f\in C^{\infty,r}_b(M,N)}\mathcal{U}_f.$$

The elements of this union are actual maps; if two exponential images agree pointwise, they represent the same element. Give the union the topology of these charts. Compatibility and openness of overlaps are checked in the following proof.

Theorem 27.3.6. (Sobolev charts on a complete noncompact base) Let $(M^m,\mathbf{g})$ and $(N^n,\mathbf{h})$ be smooth, complete, without boundary, and of bounded geometry of order k. Let $1<p<\infty$ and $k\ge r>m/p+1$, with $k,r\in\mathbb{N}$. The preceding charts equip $\Omega^{p,r}(M,N)$ with a Banach manifold structure of class C^{k+1-r}, and a Hilbert manifold structure if $p=2$. In the case of bounded geometry of all orders, the atlas is smooth. If $\Phi_f(\mathbf{Y})=\mathrm{Exp}_f\mathbf{Y}$ is a chart centered at f, then

$$J_f:=D(\Phi_f^{-1})_f:\ T_f\Omega^{p,r}(M,N)\longrightarrow W^{r,p}(M,f^*TN)$$

is linear and bicontinuous, with inverse $D\Phi_f(0)$.

Proof. The Sobolev norm controls the uniform norm, so $\mathcal{V}_f$ is open. The exponential map is injective on this set by the choice of ρ. The localization estimates in the bounded geometry chapter allow us to work in balls and trivializations of a common size; their constants now depend on bounds on the derivatives of the center f.

In these representations, a superposition has the form $\mathbf{X} \mapsto F(x, \mathbf{X}(x))$. The required mixed derivatives of F are uniformly bounded on the normal domain. Through spatial order r and order $k+1-r$ of differentiation with respect to the section, these bounds follow from the Jacobi and transport equations with the recurrence (13.4); this is also the local estimate used in [49, Theorem 5.2]. Differentiating r times in x, the chain rule uses only derivatives of the center through order r and mixed derivatives of the exponential map through order $r + (k+1-r) = k+1$.

On a base of infinite volume, a constant cannot be estimated by its L^p norm. The superposition argument is therefore applied to differences. If $F(x,0) = 0$, the identity

$$F(x, \mathbf{X}(x)) = \int_0^1 D_v F(x, t\mathbf{X}(x))\mathbf{X}(x)\, dt$$

ensures that each term of its spatial derivative contains a derivative of $\mathbf{X}$, even when all remaining derivatives fall on x. Sobolev products and uniform coefficient bounds give a $W^{r,p}$ bound on each ball. The sum of the p powers of these bounds converges by finite multiplicity of the cover. For a nonzero center $\mathbf{X}_0$, use the analogous identity with $F(x,\mathbf{X}) - F(x,\mathbf{X}_0)$ and the factor $\mathbf{X} - \mathbf{X}_0$. The integral Taylor remainder in the variable v proves differentiability; repeating it for $D_v^a F$, with $a \in \{0, \dots, k-r\}$, gives the successive orders. At the last order, continuity follows from uniform continuity of the coefficients on the normal domain and the same product estimates. This yields C^{k+1-r} without integrating any constant term.

Consider an overlap and write $h = \operatorname{Exp}_f \mathbf{X}_0 = \operatorname{Exp}_g \mathbf{Y}_0$, with smooth centers f, g. Then $d(f(x), g(x)) < 2\rho$ for every x. The transition function is

$$\Psi(x, v) = \log_{g(x)}\bigl(\exp_{f(x)} v\bigr).$$

A sufficiently small neighborhood of $\mathbf{X}_0$ in $W^{r,p}$ keeps the arguments in the normal domain. To justify integrability of the transition, write

$$\Psi(x, \mathbf{X}(x)) - \Psi(x, \mathbf{X}_0(x)) = \int_0^1 D_v \Psi\bigl(x, \mathbf{X}_0(x) + t(\mathbf{X}(x) - \mathbf{X}_0(x))\bigr)(\mathbf{X}(x) - \mathbf{X}_0(x))\, dt.$$

The second term on the left is precisely $\mathbf{Y}_0 \in W^{r,p}(M, g^*TN)$. The preceding argument shows that the difference belongs to this space and depends on $\mathbf{X}$ with the stated regularity. Shrinking the neighborhood makes its uniform norm less than $\rho - \|\mathbf{Y}_0\|_\infty$. This positive margin proves openness of the overlap. Interchanging f and g gives the inverse transition.

Point evaluations are continuous in each chart. Two distinct maps differ at some point of M, and two disjoint neighborhoods of their values in N separate them; the constructed space is Hausdorff. This verifies the requirements for a Banach manifold in Definition 24.1.1.

If h has Sobolev regularity, sections of h^*TN are defined in Sobolev trivializations, as in the compact case, or transported from a smooth center of a chart containing h. The transport matrices and changes of trivialization are multipliers in $W^{r,p}$ by the preceding estimates. The resulting norms are equivalent. This allows charts to be recentered at h without assuming h^*TN is a smooth bundle. Finally, $D\Phi_h(0)\mathbf{X} = \mathbf{X}$ pointwise; differentiating the inverse identities gives the two continuous operators in the statement. □

Smooth centers are locally dense: approximate a section $\mathbf{X} \in \mathcal{V}_f$ by smooth compactly supported sections in $W^{r,p}(M, f^*TN)$. Uniform embedding keeps the approximations inside $\mathcal{V}_f$, and their images under Exp_f converge to the initial map. Chart radii and transition constants may vary with the center. This local assertion does not assign a constant-radius uniformity to all maps with bounded derivatives.

27.4 Spaces of metrics, connections, and gauge theory

27.4.1 Riemannian metrics

Let M^m be a smooth compact manifold with or without boundary and let $s > \frac{m}{2}$. Define

$$\mathrm{Met}^s(M) := \{\mathbf{g} \in H^s(M, S^2T^*M) \mid \mathbf{g}_x \text{ is positive definite for every } x \in M\}.$$

Proposition 27.4.1. (Openness of positivity) Let M^m be a smooth compact manifold with or without boundary and let $s > \frac{m}{2}$. Then $\mathrm{Met}^s(M)$ is an open subset of the Hilbert space $H^s(M, S^2T^*M)$. In particular, it is a Hilbert manifold and $T_{\mathbf{g}}\,\mathrm{Met}^s(M) = H^s(M, S^2T^*M)$.

Proof. By compactness, the smallest eigenvalue of $\mathbf{g}$ relative to an auxiliary metric $\mathbf{g}_0$ has a minimum $c_{\mathbf{g}} > 0$. The embedding

$$H^s(M, S^2T^*M) \hookrightarrow C^0(M, S^2T^*M; \mathbf{g}_0)$$

gives $C > 0$ such that

$$\|\mathbf{h}\|_{C^0(M,S^2T^*M;\mathbf{g}_0)} \le C\|\mathbf{h}\|_{H^s(M,S^2T^*M)}.$$

If $\|\mathbf{h}\|_{H^s(M,S^2T^*M)} < \frac{c_{\mathbf{g}}}{2C}$, then $(\mathbf{g}+\mathbf{h})(v,v) \ge (\frac{c_{\mathbf{g}}}{2})|v|^2_{\mathbf{g}_0}$ for every $v \in T_xM$. Thus the corresponding ball lies in $\mathrm{Met}^s(M)$. Since this set is open, its tangent space is the model space. □

On a noncompact manifold, the smallest eigenvalue may tend to zero at infinity; positivity is not open in an absolute Sobolev topology. For example, on $\mathbb{R}$ the metric $\mathbf{g} = e^{-2x^2}(\mathbf{d}x)^2$ is positive, but there exist cutoff functions χ_j translated toward j, with uniformly bounded derivatives, such that $\mathbf{h}_j = -2e^{-2x^2}\chi_j dx^2$ tends to zero in every H^s while $\mathbf{g}+\mathbf{h}_j$ is negative where $\chi_j = 1$. This difficulty disappears when working within a uniform equivalence class.

Two metrics $\mathbf{g}$ and $\mathbf{g}'$ are *quasi-isometric* if there exists $C \ge 1$ such that

$$C^{-1}\mathbf{g} \le \mathbf{g}' \le C\mathbf{g} \tag{27.16}$$

in the sense of Definition 2.1.5; that is, a common constant C satisfies

$$C^{-1}\mathbf{g}_x(v,v) \le \mathbf{g}'_x(v,v) \le C\mathbf{g}_x(v,v) \qquad (x \in M,\ v \in T_xM).$$

Equivalently, the tangent norms satisfy

$$C^{-1/2}|v|_{\mathbf{g}} \le |v|_{\mathbf{g}'} \le C^{1/2}|v|_{\mathbf{g}} \qquad (x \in M,\ v \in T_xM).$$

This condition controls the values of the metrics on all fibers with common constants; control of the connections is added in the following functional. If $\nabla^{\mathbf{g}}$ and $\nabla^{\mathbf{g}'}$ are their Levi–Civita connections, define the comparison

functional

$$\delta_{b,q;\mathbf{g}}(\mathbf{g},\mathbf{g}') := \|\mathbf{g}-\mathbf{g}'\|_{\infty;\mathbf{g}} + \sum_{j=0}^{q-1} \|(\nabla^{\mathbf{g}})^j(\nabla^{\mathbf{g}'}-\nabla^{\mathbf{g}})\|_{\infty;\mathbf{g}}. \tag{27.17}$$

The infinity norms use the metrics on the indicated bundles; when confusion could arise, the metric is added after a semicolon. The difference of connections is a tensor of type $(1,2)$, so all terms are intrinsically defined.

For $k \in \mathbb{N}_0$, denote by $\mathrm{Met}(I,B_k)(M)$ the set of smooth Riemannian metrics $\mathbf{g}$ satisfying conditions (I) and (B_k) in Definition 27.2.14; that is, there exist constants $i_{\mathbf{g}}, K_0(\mathbf{g}), \dots, K_k(\mathbf{g}) > 0$ such that

$$\mathrm{inj}(M,\mathbf{g}) \geq i_{\mathbf{g}}, \qquad \|(\nabla^{\mathbf{g}})^j \mathbf{R}_{\mathbf{g}}\|_{\infty;\mathbf{g}} \leq K_j(\mathbf{g}) \quad (0 \leq j \leq k).$$

The first condition implies that $(M,\mathbf{g})$ is complete. In the following Sobolev construction, both metrics of each pair belong to this set.

If $\mathbf{T}$ is a tensor field of fixed type and $j \in \mathbb{N}_0$, we use $\|\mathbf{T}\|_{b,j;\mathbf{g}} := \sum_{a=0}^{j} \|(\nabla^{\mathbf{g}})^a \mathbf{T}\|_{\infty;\mathbf{g}}$. For $1 < p < \infty$, we also set

$$\|\mathbf{T}\|_{p,j;\mathbf{g}} := \left(\sum_{a=0}^{j} \int_M |(\nabla^{\mathbf{g}})^a \mathbf{T}|_{\mathbf{g}}^p \, d\lambda_{\mathbf{g}} \right)^{\frac{1}{p}}.$$

Both notations are used only when the right-hand side is finite.

Theorem 27.4.2. (Uniform comparison of metrics) Let M^m be smooth and without boundary. For $q \in \mathbb{N}$, the sets

$$\mathcal{U}_{\varepsilon}^{b,q} := \{(\mathbf{g},\mathbf{g}') \mid \mathbf{g} \text{ and } \mathbf{g}' \text{ are quasi-isometric and } \delta_{b,q;\mathbf{g}}(\mathbf{g},\mathbf{g}') < \varepsilon\}$$

generate a separated metrizable uniformity on the smooth complete metrics. In the Sobolev regime, fix a reference metric $\mathbf{g}_0 \in \mathrm{Met}(I,B_k)(M)$, $1 < p < \infty$, and $k \geq r > m/p + 1$. The intrinsic comparison is written as

$$\delta_{p,r;\mathbf{g}}(\mathbf{g},\mathbf{g}')^p := \int_M \left(|\mathbf{g}-\mathbf{g}'|_{\mathbf{g}}^p + \sum_{j=0}^{r-1} |(\nabla^{\mathbf{g}})^j(\nabla^{\mathbf{g}'}-\nabla^{\mathbf{g}})|_{\mathbf{g}}^p \right) d\lambda_{\mathbf{g}}. \tag{27.18}$$

On the affine space $\mathbf{g}_0 + W^{r,p}(M, S^2T^*M; \mathbf{g}_0)$, we use the distance

$$d_{\mathbf{g}_0}(\mathbf{g},\mathbf{g}') := \|\mathbf{g}'-\mathbf{g}\|_{p,r;\mathbf{g}_0}.$$

On every set of smooth metrics satisfying, for fixed numbers $\lambda > 0$ and $R > 0$,

$$\mathbf{g} \geq \lambda \mathbf{g}_0, \qquad \|\mathbf{g}-\mathbf{g}_0\|_{p,r;\mathbf{g}_0} \leq R,$$

, there exist $c, C > 0$ common to all pairs such that

$$c\, d_{\mathbf{g}_0}(\mathbf{g},\mathbf{g}') \leq \delta_{p,r;\mathbf{g}}(\mathbf{g},\mathbf{g}') \leq C\, d_{\mathbf{g}_0}(\mathbf{g},\mathbf{g}').$$

The constants depend on λ, R, p, r and the data of $\mathbf{g}_0$.

Proof. If $\|\mathbf{g}' - \mathbf{g}\|_{\infty;\mathbf{g}} < 1/2$, for every $x \in M$ and $v \in T_xM$, Cauchy–Schwarz in the tensor inner product gives

$$|(\mathbf{g}' - \mathbf{g})_x(v,v)| \le |\mathbf{g}' - \mathbf{g}|_{\mathbf{g}}(x)|v|^2_{\mathbf{g}} \le \frac{1}{2}\mathbf{g}_x(v,v).$$

Adding $\mathbf{g}_x(v,v)$ gives

$$\frac{1}{2}\mathbf{g}_x(v,v) \le \mathbf{g}'_x(v,v) \le \frac{3}{2}\mathbf{g}_x(v,v).$$

By Proposition 7.1.9, the pointwise tensor norms are comparable with constants depending only on the tensor type. The change-of-connection formula (27.21), proved below, expresses derivatives in the new connection as finite sums of products of derivatives of the connection difference. Applied to $\mathbf{g}' - \mathbf{g}$ and $\nabla^{\mathbf{g}'} - \nabla^{\mathbf{g}}$, it gives polynomials with no constant term controlling inversion. For three metrics, add their connection differences and apply the same formula when changing connection in the second summand. This gives corresponding composition polynomials independent of the metrics. This verifies the inversion and composition axioms; the other axioms follow from the diagonal and order-zero control. Rational radii and metrization by chains complete the argument, also formulated in [50, Proposition 2.1].

For Sobolev norms, the embedding gives $\|\mathbf{g} - \mathbf{g}_0\|_{\infty;\mathbf{g}_0} \le C_S R$. The same evaluation on (v,v) gives $\mathbf{g}_x(v,v) \le (1 + C_S R)(\mathbf{g}_0)_x(v,v)$ for every x and v. Together with the lower bound in the statement and Proposition 7.1.9, this implies

$$(1 + C_S R)^{-1}\mathbf{g}_0^{-1} \le \mathbf{g}^{-1} \le \lambda^{-1}\mathbf{g}_0^{-1}, \qquad \lambda^{m/2} \le \frac{d\lambda_{\mathbf{g}}}{d\lambda_{\mathbf{g}_0}} \le (1 + C_S R)^{m/2}.$$

Comparison of the inverse metrics is evaluated on covectors, and the ratio of measures is the positive function described in that proposition. These bounds are common to all metrics in the set under consideration. The Koszul formula (27.19) expresses the connection difference in terms of one metric's inverse and the first derivative of the other. Differentiating the identity $\mathbf{g}^{-1}\mathbf{g} = I$ gives $\nabla\mathbf{g}^{-1} = -\mathbf{g}^{-1}(\nabla\mathbf{g})\mathbf{g}^{-1}$; at each subsequent order, Leibniz's rule differentiates one of the existing factors. Thus, through order $r-1$, derivatives of the inverse and the connection difference are controlled by λ, R and the product estimates. In particular, $\nabla^{\mathbf{g}} - \nabla^{\mathbf{g}_0}$ is bounded in $W^{r-1,p}$ in terms of these data.

Set $\mathbf{h} = \mathbf{g}' - \mathbf{g}$ and $\mathbf{D} = \nabla^{\mathbf{g}'} - \nabla^{\mathbf{g}}$. Koszul's formula and the product estimates give $\|\mathbf{D}\|_{p,r-1;\mathbf{g}_0} \le C\|\mathbf{h}\|_{p,r;\mathbf{g}_0}$. For the reverse inequality, use the metric compatibility identity

$$(\nabla^{\mathbf{g}}_{\mathbf{X}}\mathbf{h})(\mathbf{Y},\mathbf{Z}) = \mathbf{g}'(\mathbf{D}(\mathbf{X},\mathbf{Y}),\mathbf{Z}) + \mathbf{g}'(\mathbf{Y},\mathbf{D}(\mathbf{X},\mathbf{Z})).$$

Starting at order zero for $\mathbf{h}$, differentiate this identity through order $r-1$. In the step from order j to $j+1$, terms in which $\mathbf{g}' = \mathbf{g} + \mathbf{h}$ is differentiated contain derivatives of $\mathbf{h}$ of order at most j, already controlled; the remaining terms contain a derivative of $\mathbf{D}$ of order at most j. The module estimate for $W^{r-1,p}$, valid because $r - 1 > m/p$, controls all these products. The change-of-connection formula allows each norm to be expressed using $\mathbf{g}_0$, and the volume ratios are bounded. We obtain $\|\mathbf{h}\|_{p,r;\mathbf{g}_0} \le C(\|\mathbf{h}\|_{p,0;\mathbf{g}} + \|\mathbf{D}\|_{p,r-1;\mathbf{g}})$, which is the remaining inequality. □

The fixed reference is essential in the Sobolev assertion. On S^1, with $\theta \in \mathbb{R}/(2\pi\mathbb{Z})$, take $\mathbf{g}_a = a^2 d\theta^2$ and $\mathbf{h}_a = a^6 d\theta^2$, for $0 < a < 1$. Their connections agree, and both metrics are complete and of bounded geometry, though their data are not common as a varies. For $p = 2$ and any integer order $r \ge 1$,

$$\delta_{2,r;\mathbf{g}_a}(\mathbf{g}_a,\mathbf{h}_a) = \sqrt{2\pi}\,a^{1/2}(1 - a^4), \qquad \delta_{2,r;\mathbf{h}_a}(\mathbf{h}_a,\mathbf{g}_a) = \sqrt{2\pi}\,a^{-5/2}(1 - a^4).$$

The first side tends to zero and the second to infinity. Thus the condition $\delta_{p,r;\mathbf{g}} < \varepsilon$ on all metrics without common data does not satisfy the inversion axiom. The distance $d_{\mathbf{g}_0}$ is symmetric and satisfies the triangle inequality; the preceding comparison allows the intrinsic expressions to be used in each neighborhood with fixed bounds.

Proposition 27.4.3. (Comparison of tensor norms in a component) Let M be a smooth manifold without boundary, let $\mathbf{g}$ and $\mathbf{g}'$ be smooth quasi-isometric metrics, and let $\mathbf{T}$ be a tensor field of fixed type.

(i) If $\delta_{b,q;\mathbf{g}}(\mathbf{g},\mathbf{g}') < \infty$, then, for each $0 \le j \le q$, there exist constants $c_{b,j}, C_{b,j} > 0$ such that

$$c_{b,j}\|\mathbf{T}\|_{b,j;\mathbf{g}} \le \|\mathbf{T}\|_{b,j;\mathbf{g}'} \le C_{b,j}\|\mathbf{T}\|_{b,j;\mathbf{g}}.$$

(ii) If $\mathbf{g},\mathbf{g}'$ belong to the affine space based at $\mathbf{g}_0$ in the preceding theorem and have a positive lower bound relative to $\mathbf{g}_0$, then, for each $0 \le j \le r$, there exist constants $c_{p,j}, C_{p,j} > 0$ such that

$$c_{p,j}\|\mathbf{T}\|_{p,j;\mathbf{g}} \le \|\mathbf{T}\|_{p,j;\mathbf{g}'} \le C_{p,j}\|\mathbf{T}\|_{p,j;\mathbf{g}}.$$

The constants depend on the tensor type, a quasi-isometry constant between $\mathbf{g}$ and $\mathbf{g}'$, and the norms of $(\nabla^{\mathbf{g}})^a(\nabla^{\mathbf{g}'} - \nabla^{\mathbf{g}})$ through the required order, but not on $\mathbf{T}$.

Proof. Set $\mathbf{D} := \nabla^{\mathbf{g}'} - \nabla^{\mathbf{g}}$. The Koszul identity gives

$$2\mathbf{g}'\big(\mathbf{D}(\mathbf{X},\mathbf{Y}),\mathbf{Z}\big) = (\nabla^{\mathbf{g}}_{\mathbf{X}}\mathbf{g}')(\mathbf{Y},\mathbf{Z}) + (\nabla^{\mathbf{g}}_{\mathbf{Y}}\mathbf{g}')(\mathbf{X},\mathbf{Z}) - (\nabla^{\mathbf{g}}_{\mathbf{Z}}\mathbf{g}')(\mathbf{X},\mathbf{Y}). \tag{27.19}$$

If $C^{-1}\mathbf{g} \le \mathbf{g}' \le C\mathbf{g}$, Proposition 7.1.9, applied with constants C^{-1} and C, gives, for a tensor of type (a,b),

$$C^{-(a+b)/2}|\mathbf{T}|_{\mathbf{g}} \le |\mathbf{T}|_{\mathbf{g}'} \le C^{(a+b)/2}|\mathbf{T}|_{\mathbf{g}}, \tag{27.20}$$

, and the ratio of volume elements satisfies

$$C^{-m/2} \le \rho(x) := \frac{\sqrt{\det(\mathbf{g}'_x)}}{\sqrt{\det(\mathbf{g}_x)}} \le C^{m/2}.$$

The determinants are computed in a common chart, and the ratio is independent of it. For $1 \le p < \infty$, we have

$$\|\mathbf{T}\|^p_{L^p(M,\mathbf{g}')} = \int_M |\mathbf{T}|^p_{\mathbf{g}'}\rho\, d\lambda_{\mathbf{g}}.$$

Raising (27.20) to the power p, multiplying by the bounds on ρ, and integrating gives

$$C^{-(a+b)/2-m/(2p)}\|\mathbf{T}\|_{L^p(M,\mathbf{g})} \le \|\mathbf{T}\|_{L^p(M,\mathbf{g}')} \le C^{(a+b)/2+m/(2p)}\|\mathbf{T}\|_{L^p(M,\mathbf{g})}.$$

For the uniform norm, simply take suprema in the pointwise comparison. These estimates compare the same tensor $\mathbf{T}$; the next step compares the derivatives obtained using the two connections.
The local expansion of the covariant derivative in Lemma 9.1.28 and the Leibniz rule in Proposition 9.1.40

allow us to write, for $j \in \mathbb{N}$,

$$(\nabla^{\mathbf{g}'})^j \mathbf{T} = (\nabla^{\mathbf{g}})^j \mathbf{T} + \sum_{\ell=1}^{j} \sum_{i_0+\cdots+i_\ell=j-\ell} C_{j,\boldsymbol{i}} (\nabla^{\mathbf{g}})^{i_1} \mathbf{D} * \cdots * (\nabla^{\mathbf{g}})^{i_\ell} \mathbf{D} * (\nabla^{\mathbf{g}})^{i_0} \mathbf{T}. \tag{27.21}$$

In the inner sum, $\boldsymbol{i} = (i_0, \dots, i_\ell)$ ranges over $\mathbb{N}_0^{\ell+1}$ subject to the indicated restriction. The coefficients are universal; each term with $*$ represents the finite sum of contractions and permutations specified by the tensor type. The endomorphisms appearing here are not assumed to commute. For $j = 1$, we obtain $\nabla^{\mathbf{g}'}\mathbf{T} = \nabla^{\mathbf{g}}\mathbf{T} + \mathbf{D} * \mathbf{T}$; on differentiating again, the derivative may act on any existing factor or introduce a new factor $\mathbf{D}$. In the first case, one of the i_a, with $a \in \{0, \dots, \ell\}$, increases by one, and the index sum changes from $j-\ell$ to $(j+1)-\ell$. In the second, ℓ increases by one and a zero index is added; the sum remains equal to $(j+1)-(\ell+1)$. These are all the terms of order $j+1$, and their orders and types are those in the formula. This completes the induction step.

In the b, q uniformity, supremum bounds on the derivatives of $\mathbf{D}$ and (27.20) control (27.21) term by term. In the Sobolev uniformity, $r > m/p + 1$ implies that $W^{r-1,p}$ is an algebra and its sections act as multipliers on lower orders. The product and module theorems, applied to each contraction, give the upper bound in part (ii). Interchanging $\mathbf{g}$ and $\mathbf{g}'$ gives the reverse inequalities in both cases. □

For fixed $\mathbf{g}_0 \in \mathrm{Met}(I, B_k)(M)$, denote by $\mathrm{Met}^{p,r}_{\mathbf{g}_0}(M)$ the set

$$\left\{ \mathbf{g}_0 + \mathbf{h} \;\middle|\; \mathbf{h} \in W^{r,p}(M, S^2T^*M; \mathbf{g}_0), \quad \mathbf{g}_0 + \mathbf{h} \geq c\mathbf{g}_0 \text{ for some } c > 0 \right\}.$$

This is the positive affine component considered when writing $\mathrm{Met}^{p,r}(I, B_k)(M)$ with a fixed reference. The complete affine space is $\mathbf{g}_0 + W^{r,p}$; uniform positivity selects an open subset of it, which need not be complete for the affine distance. In the uniform version, let $B^q_{\mathbf{g}_0}$ be the completion of the smooth sections bounded through order q in $\|\cdot\|_{b,q;\mathbf{g}_0}$. Define $\mathrm{Met}^{b,q}_{\mathbf{g}_0}(M)$ by requiring $\mathbf{h} \in B^q_{\mathbf{g}_0}$ and the same uniform positive inequality.

Theorem 27.4.4. (Affine manifolds of metrics) Let M^m be smooth, complete, and without boundary with respect to $\mathbf{g}_0 \in \mathrm{Met}(I, B_k)(M)$. If $1 < p < \infty$ and $k \geq r > m/p + 1$, the space $\mathrm{Met}^{p,r}_{\mathbf{g}_0}(M)$ is an open convex subset of $\mathbf{g}_0 + W^{r,p}(M, S^2T^*M; \mathbf{g}_0)$. It is a smooth Banach manifold, and a Hilbert manifold if $p = 2$. For the affine chart $\Phi_{\mathbf{g}}(\mathbf{g}') = \mathbf{g}' - \mathbf{g}$,

$$J_{\mathbf{g}} := D\Phi_{\mathbf{g}}(\mathbf{g}) : T_{\mathbf{g}} \mathrm{Met}^{p,r}_{\mathbf{g}_0}(M) \longrightarrow H^{r,p}(M, S^2T^*M; \mathbf{g}_0)$$

is the linear bicontinuous identity. Here we use equivalence of the $W^{r,p}$ and $H^{r,p}$ norms for integer orders from the bounded geometry chapter. The uniform construction is an open convex subset modeled on $B^q_{\mathbf{g}_0}$.

Proof. If $\mathbf{g} \geq c\mathbf{g}_0$, the uniform embedding gives $\|\mathbf{k}\|_{\infty;\mathbf{g}_0} \leq C_S \|\mathbf{k}\|_{p,r;\mathbf{g}_0}$. The condition $\|\mathbf{k}\|_{p,r;\mathbf{g}_0} < c/(2C_S)$ implies $\mathbf{g} + \mathbf{k} \geq (c/2)\mathbf{g}_0$, proving openness. A convex combination of two metrics with lower bounds $c_1, c_2 > 0$ has lower bound $(1-t)c_1 + tc_2 > 0$ for $t \in [0,1]$; thus the set is convex. Changes between affine charts are translations with identity differential. The uniform assertion is proved in the same way, using the fact that the $B^q_{\mathbf{g}_0}$ norm controls the infinity norm.

In the Sobolev component, pointwise positivity already implies a uniform lower bound. To see this, $\mathbf{h} \in W^{r,p}$ has bounded first derivative and tends uniformly to zero at infinity. If the latter assertion failed, there would exist $\varepsilon > 0$ and points x_j escaping every compact set, with $|\mathbf{h}(x_j)| \geq \varepsilon$. The bound on $\nabla\mathbf{h}$ and parallel

transport would give $|\mathbf{h}| \geq \varepsilon/2$ on balls of a common positive radius around these points. A disjoint family of balls can be extracted; their volumes have a common lower bound by bounded geometry. Then the sum of the integrals of $|\mathbf{h}|^p$ would be infinite, a contradiction. Thus, outside a compact set, $\mathbf{g}_0 + \mathbf{h} \geq \frac{1}{2}\mathbf{g}_0$. Inside it, continuity and positivity give a positive minimum for the smallest eigenvalue.
Smooth compactly supported sections approximate $\mathbf{h}$ in $W^{r,p}$. Uniform convergence ensures that the approximations retain a positive lower bound. The resulting smooth metrics agree with $\mathbf{g}_0$ outside a compact set, are complete, and satisfy (I) and (B_k), with constants that may depend on the approximation. This relates the affine model to approximation by smooth metrics. It does not assert that the limit retains curvature bounds of order k: that would require control of additional metric derivatives. □

Affine charts are those used in studying spaces of metrics on open manifolds; see [50]. Proposition 27.4.3 explains why, within each neighborhood with common bounds, one may use intrinsic norms for another metric in the component. The fixed reference metric makes explicit the topology used for completion and openness of positivity.

On a compact base, or in a Hilbert Sobolev component of a noncompact base, the Ebin metric is defined by

$$G_{\mathbf{g}}(\mathbf{h}, \mathbf{k}) := \int_M \operatorname{tr}_{\mathbf{g}}(\mathbf{h} \circ \mathbf{k})\, d\lambda_{\mathbf{g}}. \tag{27.22}$$

In the noncompact case, tangent vectors belong to L^2 and the metrics are uniformly equivalent to the reference; Hölder's inequality thus ensures that the integral is finite. For a $W^{r,p}$ component with $p \neq 2$, this integrability must additionally be required. In an H^s topology with $s > 0$, this metric controls only the L^2 norm and is therefore weak. Existence of a connection or an exponential map cannot be deduced from the Koszul formula alone.

27.4.2 Connections and gauge transformations

Let $\mathbf{P} \longrightarrow M$ be a principal bundle with compact structure group G and Lie algebra $\mathfrak{g}$ equipped with a Ad–invariant inner product. Denote by h_{ad} the induced metric on the adjoint bundle and by $\operatorname{ad}\mathbf{P} := \mathbf{P} \times_{\mathrm{Ad}} \mathfrak{g}$ the adjoint bundle.

Proposition 27.4.5. (Affine structure of the space of connections) Let M be a smooth manifold with or without boundary and let $\mathbf{P} \longrightarrow M$ be a smooth principal bundle. For a fixed smooth connection A_0, every smooth connection can be written uniquely as $A_0 + \mathbf{a}$, with $\mathbf{a} \in \Omega^1(M, \operatorname{ad}\mathbf{P})$. Consequently, for every Sobolev index s for which the completion has been fixed,

$$\mathcal{A}^s(\mathbf{P}) := A_0 + H^s(M, T^*M \otimes \operatorname{ad}\mathbf{P})$$

is an affine space and

$$T_A\mathcal{A}^s(\mathbf{P}) = H^s(M, T^*M \otimes \operatorname{ad}\mathbf{P}).$$

Proof. The smooth assertion is Theorem 2.6.23: the difference of two principal connection forms is horizontal and Ad–equivariant and therefore descends to a unique form with values in $\operatorname{ad}\mathbf{P}$. Completing the model vector space in H^s gives the second assertion. No identification of a principal connection with an arbitrary connection on a vector bundle is made here. □

Proposition 27.4.6. (Right gauge action and curvature) Let M be a smooth manifold with or without boundary and let $\mathbf{P} \longrightarrow M$ be a smooth principal bundle. The convention fixed in (2.49) defines a right action:

$$A \triangleleft \mathbf{u} := \mathrm{Ad}_{\mathbf{u}^{-1}} A + \mathbf{u}^{-1} d\mathbf{u}, \qquad (A \triangleleft \mathbf{u}) \triangleleft \mathbf{v} = A \triangleleft (\mathbf{u}\mathbf{v}). \tag{27.23}$$

In a matrix representation, the first formula is written as $A \triangleleft \mathbf{u} = \mathbf{u}^{-1} A \mathbf{u} + \mathbf{u}^{-1} d\mathbf{u}$. Moreover,

$$\mathbf{F}_{A+\mathbf{a}} = \mathbf{F}_A + d_A \mathbf{a} + \frac{1}{2}[\mathbf{a} \wedge \mathbf{a}], \tag{27.24}$$

$$\mathbf{F}_{A \triangleleft \mathbf{u}} = \mathrm{Ad}_{\mathbf{u}^{-1}} \mathbf{F}_A. \tag{27.25}$$

For the Sobolev extension on a compact base, fix $s > m/2$; on a noncompact base, impose the assumptions for the gauge component constructed below. If

$$\Phi \colon \mathcal{A}^s(\mathbf{P}) \times \mathcal{G}^{s+1}(\mathbf{P}) \longrightarrow \mathcal{A}^s(\mathbf{P}), \qquad \Phi(A, \mathbf{u}) = A \triangleleft \mathbf{u},$$

and we trivialize $T_{\mathbf{u}} \mathcal{G}^{s+1}(\mathbf{P})$ by left translation, writing a tangent vector as $\mathbf{u}\xi$, then

$$D\Phi_{(A,\mathbf{u})}(\mathbf{a}, \mathbf{u}\xi) = \mathrm{Ad}_{\mathbf{u}^{-1}} \mathbf{a} + d_{A \triangleleft \mathbf{u}} \xi. \tag{27.26}$$

Proof. The first two identities are Propositions 2.6.35 and 2.6.21, written in a local section. In particular, the order of $\mathbf{u}\mathbf{v}$ in (27.23) is not an implicit convention: it comes from the right action already established. To compute the differential, take a curve $A(t)$ with $A(0) = A$, $\dot{A}(0) = \mathbf{a}$, and the exact curve $\mathbf{u}(t) = \mathbf{u} \exp_G(t\xi)$. By the action law,

$$A(t) \triangleleft \mathbf{u}(t) = \big(A(t) \triangleleft \mathbf{u}\big) \triangleleft \exp_G(t\xi).$$

The variation of the first factor is $\mathrm{Ad}_{\mathbf{u}^{-1}} \mathbf{a}$, while the derivative of $B \triangleleft \exp_G(t\xi)$ at $t = 0$ is $d_B \xi$. Taking $B = A \triangleleft \mathbf{u}$ gives (27.26). □

Theorem 27.4.7. (Sobolev gauge group and compact Coulomb slice) Let $(M^m, \mathbf{g})$ be a smooth compact connected Riemannian manifold without boundary; let G be compact, let $\mathbf{P} \to M$ be a right principal bundle, and let A be a smooth connection. If $s > \frac{m}{2}$, then

$$\mathcal{G}^{s+1}(\mathbf{P}) := H^{s+1}(M, \mathrm{Ad}(\mathbf{P}))$$

is a Hilbert Lie group modeled on $H^{s+1}(M, \mathrm{ad}\,\mathbf{P})$, and its right action on $\mathcal{A}^s(\mathbf{P})$ is smooth. The infinitesimal action is

$$\xi \longmapsto d_A \xi. \tag{27.27}$$

Set

$$K_A := \ker\big(d_A : H^{s+1}(M, \mathrm{ad}\,\mathbf{P}) \longrightarrow H^s(M, T^*M \otimes \mathrm{ad}\,\mathbf{P})\big)$$

and, using the L^2 inner product induced by $\mathbf{g}$ and the Ad–invariant metric on $\mathrm{ad}\,\mathbf{P}$, define

$$X_A^{s+1} := H^{s+1}(M, \mathrm{ad}\,\mathbf{P}) \cap K_A^{\perp_{L^2}}, \qquad Y_A^{s-1} := \Big\{ \mathbf{f} \in H^{s-1}(M, \mathrm{ad}\,\mathbf{P}) \,\Big|\, \langle \mathbf{f}, \zeta \rangle_{\mathcal{D}', \mathcal{D}} = 0 \text{ for every } \zeta \in K_A \Big\}.$$

When $s \geq 1$, the last space is precisely $H^{s-1}(M, \mathrm{ad}\,\mathbf{P}) \cap K_A^{\perp_{L^2}}$; the annihilator formulation remains meaningful

if $s-1<0$, since K_A consists of smooth sections. Then

$$\Delta_A^{(0)} := d_A^* d_A : X_A^{s+1} \xrightarrow{\cong} Y_A^{s-1} \tag{27.28}$$

is a Hilbert space isomorphism and

$$H^s(M, T^*M \otimes \operatorname{ad}\mathbf{P}) = d_A X_A^{s+1} \oplus \ker\bigl(d_A^* : H^s(M, T^*M \otimes \operatorname{ad}\mathbf{P}) \longrightarrow H^{s-1}(M, \operatorname{ad}\mathbf{P})\bigr). \tag{27.29}$$

The stabilizer

$$\operatorname{Stab}(A) := \{\mathbf{u} \in \mathcal{G}^{s+1}(\mathbf{P}) \mid A \triangleleft \mathbf{u} = A\}$$

is a compact finite-dimensional Lie group with Lie algebra K_A. More precisely, if $p \in \mathbf{P}$ and $\operatorname{Hol}_p(A) \subseteq G$ is the holonomy group based at p, evaluation at p induces a Lie group isomorphism

$$\operatorname{Stab}(A) \xrightarrow{\cong} Z_G\bigl(\operatorname{Hol}_p(A)\bigr). \tag{27.30}$$

Finally, if

$$\mathcal{S}_A^s := A + \ker\bigl(d_A^* : H^s(M, T^*M \otimes \operatorname{ad}\mathbf{P}) \to H^{s-1}(M, \operatorname{ad}\mathbf{P})\bigr),$$

, there exist an open neighborhood $\mathcal{U}_A$ of A in $\mathcal{A}^s(\mathbf{P})$ and an open neighborhood $\mathcal{W}_A$ of $[A, e]$ in $\mathcal{S}_A^s \times_{\operatorname{Stab}(A)} \mathcal{G}^{s+1}(\mathbf{P})$ for which the restriction of the map

$$\mathcal{W}_A \longrightarrow \mathcal{U}_A, \qquad [B, \mathbf{u}] \longmapsto B \triangleleft \mathbf{u}, \tag{27.31}$$

is a diffeomorphism. Here the equivalence relation is induced by

$$(B, \mathbf{u}) \cdot \mathbf{h} = (B \triangleleft \mathbf{h}, \mathbf{h}^{-1}\mathbf{u}), \qquad \mathbf{h} \in \operatorname{Stab}(A).$$

Moreover, one can choose an open $\operatorname{Stab}(A)$-invariant neighborhood $\mathcal{S}_0$ of A in $\mathcal{S}_A^s$ such that

$$\mathcal{S}_0 \times_{\operatorname{Stab}(A)} \mathcal{G}^{s+1}(\mathbf{P}) \longrightarrow \mathcal{A}^s(\mathbf{P}), \qquad [B, \mathbf{u}] \longmapsto B \triangleleft \mathbf{u},$$

is a diffeomorphism onto an invariant open set containing the orbit of A. Every connection sufficiently close to A has a representative in $\mathcal{S}_0$, unique modulo $\operatorname{Stab}(A)$. Uniqueness refers to representatives in this Coulomb neighborhood, rather than the entire affine hyperplane $\mathcal{S}_A^s$.

Proof. Since $s > \frac{m}{2}$, we have $s+1 > \frac{m}{2}+1$ and, in particular,

$$H^{s+1}(M, \operatorname{ad}\mathbf{P}) \hookrightarrow C^0(M, \operatorname{ad}\mathbf{P}; h_{\mathrm{ad}}).$$

The Lie exponential is Ad–equivariant and therefore induces a bundle map

$$\operatorname{Exp}\colon \operatorname{ad}\mathbf{P} \longrightarrow \operatorname{Ad}(\mathbf{P}), \qquad [p, \xi] \longmapsto [p, \exp_G \xi].$$

With respect to the Ad–invariant inner product, choose an Ad–invariant ball $\mathcal{O} \subset \mathfrak{g}$ on which $\exp_G$ is a

diffeomorphism onto its image. For each section $\mathbf{u}$ of the group bundle, the formula

$$\Theta_{\mathbf{u}}(\xi) := \mathbf{u}\,\mathrm{Exp}(\xi), \qquad \|\xi\|_{C^0(M,\mathrm{ad}\,\mathbf{P};h_{\mathrm{ad}})} < \mathrm{rad}(\mathcal{O}),$$

has the pointwise inverse $v \mapsto \log_G(\mathbf{u}^{-1}v)$. In a finite cover trivializing both bundles, the two formulas are superposition operators. Lemma 27.3.2 proves that they are smooth in $H^{s+1}(M,\mathrm{ad}\,\mathbf{P})$; equivalently, the differential at zero is the identity, and Theorem 23.3.3 provides the same local inverse. These charts, translated by each $\mathbf{u}$, construct the Hilbert Lie group structure and the identification $T_{\mathbf{u}}\mathcal{G}^{s+1}(\mathbf{P}) = \mathbf{u}H^{s+1}(M,\mathrm{ad}\,\mathbf{P})$.
In these charts, multiplication and inversion are superpositions of the smooth finite-dimensional maps of G and are therefore smooth. Likewise,

$$H^{s+1}(M,\mathrm{End}(\mathrm{ad}\,\mathbf{P}))\cdot H^s(M,T^*M\otimes\mathrm{ad}\,\mathbf{P}) \longrightarrow H^s(M,T^*M\otimes\mathrm{ad}\,\mathbf{P}), \qquad \mathbf{u}\longmapsto \mathbf{u}^{-1}d_A\mathbf{u} : \mathcal{G}^{s+1}(\mathbf{P}) \longrightarrow H^s(M,T^*M\otimes\mathrm{ad}\,\mathbf{P})$$

are smooth maps in charts. Here $\mathbf{u}^{-1}d_A\mathbf{u} := A\triangleleft\mathbf{u} - A$ is a global form with values in $\mathrm{ad}\,\mathbf{P}$. The term $\mathbf{u}^{-1}d\mathbf{u}$ alone is used in a local trivialization: it combines with the connection potential to give that global form. For real indices, apply Corollary 27.3.3. This constructs the Lie group and proves smoothness of the action. Formula (27.26), with $\mathbf{u} = e$, gives (27.27).
The operator $\Delta_A^{(0)} = d_A^*d_A$ is elliptic, formally self-adjoint, and nonnegative. Its self-adjoint realization and domain follow from Corollary 11.4.5; on the closed manifold, Proposition 15.7.2 proves that its resolvent is compact. By the spectral theorem, $K_A = \ker\Delta_A^{(0)}$ is finite-dimensional, consists of smooth sections, and there exists $\lambda_A > 0$ such that

$$\langle\Delta_A^{(0)}\xi,\xi\rangle_{L^2(M,\mathrm{ad}\,\mathbf{P})} \geq \lambda_A\|\xi\|^2_{L^2(M,\mathrm{ad}\,\mathbf{P})}, \qquad \xi\in H^2(M,\mathrm{ad}\,\mathbf{P})\cap K_A^{\perp_{L^2}}.$$

The elliptic estimate and elliptic regularity, applied at each Sobolev level, prove that (27.28) is bijective with continuous inverse.
For $\mathbf{a}\in H^s(M,T^*M\otimes\mathrm{ad}\,\mathbf{P})$, define

$$\xi := (\Delta_A^{(0)}|_{X_A^{s+1}})^{-1}d_A^*\mathbf{a}, \qquad \mathbf{b} := \mathbf{a} - d_A\xi.$$

Since, for $\zeta\in K_A$, $\langle d_A^*\mathbf{a},\zeta\rangle = \langle\mathbf{a},d_A\zeta\rangle = 0$, we have $d_A^*\mathbf{a}\in Y_A^{s-1}$; the formula is well defined and $d_A^*\mathbf{b} = 0$. If $d_A\xi$ also belongs to $\ker d_A^*$, then $\Delta_A^{(0)}\xi = 0$; since $\xi\perp K_A$, it follows that $\xi = 0$. This proves the direct sum in (27.29). The preceding formula also shows that its projections are continuous.
We prove that every element of the Sobolev stabilizer is smooth. If $\mathbf{u}\in\mathcal{G}^{s+1}(\mathbf{P})$ satisfies $A\triangleleft\mathbf{u} = A$, the local formula (27.23) gives, in the weak sense,

$$\mathbf{u}^{-1}d\mathbf{u} = A - \mathrm{Ad}_{\mathbf{u}^{-1}}A.$$

Since $s+1 > \frac{m}{2}+1$, the section $\mathbf{u}$ is continuous. In a trivialization of the group bundle, denote its local representation by $\widehat{u}$. In group coordinates, the last equality is a system $\partial_j\widehat{u} = F_j(x,\widehat{u})$ with F_j smooth. To gain one derivative, suppose $\widehat{u}\in H^{s+1+j}_{\mathrm{loc}}$, with $j\in\mathbb{N}_0$. Smooth superposition, applied to the map $(x,z)\mapsto F_i(x,z)$ in a relatively compact chart, gives $F_i(x,\widehat{u})\in H^{s+1+j}_{\mathrm{loc}}$ for each $i\in\{1,\dots,m\}$. The equation then provides all first derivatives of $\widehat{u}$ in this space; the local Sobolev characterization by derivatives implies $\widehat{u}\in H^{s+2+j}_{\mathrm{loc}}$. Cutoff functions in slightly smaller charts justify each step. Starting from $j = 0$, this implication increases regularity by one at each stage. A finite cover and Sobolev embeddings give $\mathbf{u}\in C^\infty$. The equality is

then classical, and Theorem 2.6.36 shows that $\mathbf{u}$ is a parallel section and evaluation induces the group isomorphism (27.30). Conversely, a smooth parallel section belongs to H^{s+1} because M is compact, so no element is lost.

Point evaluation is smooth in H^{s+1} by embedding into C^0. In the opposite direction, the extension of $c \in Z_G(\mathrm{Hol}_p(A))$ is written in a trivialization as $h(x)^{-1} c\, h(x)$, where $h(x)$ depends smoothly on the locally chosen parallel transport. Thus the inverse is also smooth, and (27.30) is a Lie group isomorphism. Proposition 1.9.16 shows that the centralizer is a closed Lie subgroup of the compact group G and is therefore compact and finite-dimensional. Finally, (2.52) identifies its Lie algebra with K_A.

Now apply the implicit function theorem. For small $\mathbf{a}$ and ξ, with $\xi \in X_A^{s+1}$, set

$$\mathscr{F}(\mathbf{a}, \xi) := d_A^*\big((A + \mathbf{a}) \triangleleft \exp_G(-\xi) - A\big) \in Y_A^{s-1}.$$

The image belongs to Y_A^{s-1} because d_A^* takes values orthogonal to K_A. The differential formula for the action gives

$$D_\xi \mathscr{F}(0,0)\eta = -d_A^* d_A \eta = -\Delta_A^{(0)} \eta, \tag{27.32}$$

with no undetermined sign. By (27.28), Theorem 23.3.8 produces a unique smooth function $\mathbf{a} \mapsto \xi(\mathbf{a}) \in X_A^{s+1}$ such that

$$d_A^*\big((A + \mathbf{a}) \triangleleft \exp_G(-\xi(\mathbf{a})) - A\big) = 0.$$

Equivalently, the map

$$\Psi(\mathbf{b}, \xi) := (A + \mathbf{b}) \triangleleft \exp_G(\xi) - A, \qquad d_A^* \mathbf{b} = 0, \qquad \xi \in X_A^{s+1},$$

has differential

$$D\Psi_{(0,0)}(\mathbf{b}, \xi) = \mathbf{b} + d_A \xi,$$

, which is an isomorphism by (27.29). Theorem 23.3.3 gives the unique local parametrization by $(\mathbf{b}, \xi)$.

It remains to incorporate the stabilizer without confusing it with the directions K_A. Abbreviate

$$H := \mathrm{Stab}(A), \qquad \mathfrak{h} := K_A, \qquad X := X_A^{s+1}.$$

The affine Coulomb space $\mathcal{S}_A^s$ is H–invariant: if $\mathbf{h}$ is parallel, then

$$(A + \mathbf{b}) \triangleleft \mathbf{h} = A + \mathrm{Ad}_{\mathbf{h}^{-1}} \mathbf{b}, \qquad d_A^* \mathrm{Ad}_{\mathbf{h}^{-1}} \mathbf{b} = \mathrm{Ad}_{\mathbf{h}^{-1}} d_A^* \mathbf{b}.$$

The same identity shows that $\mathrm{Ad}_{\mathbf{h}}$ commutes with d_A. Since $\mathbf{h}$ is parallel and the inner product on $\mathfrak{g}$ is Ad–invariant, $\mathrm{Ad}_{\mathbf{h}}$ commutes with the covariant derivatives of the connection A. Choose the equivalent Sobolev norm constructed with this connection; for real orders, we may use powers of $I + \nabla_A^* \nabla_A$. The parallel endomorphism commutes with this operator and its powers. It is therefore an isometry of $H^{s+1}(M, \mathrm{ad}\,\mathbf{P})$. In particular, it preserves both K_A and its orthogonal complement X. Thus

$$H^{s+1}(M, \mathrm{ad}\,\mathbf{P}) = \mathfrak{h} \oplus X$$

is an Ad_H–invariant decomposition.

We now construct the required tube. By left translation, the subbundle complementary to TH in the re-

striction of the gauge group tangent bundle to H is

$$N_{\mathbf{h}}H := (dL_{\mathbf{h}})_e X, \qquad NH \cong H \times X, \qquad (\mathbf{h}, \xi) \longmapsto (dL_{\mathbf{h}})_e \xi.$$

Invariance of X makes this identification compatible also with right translations by elements of H. Consider

$$\Theta \colon H \times X \longrightarrow \mathcal{G}^{s+1}(\mathbf{P}), \qquad \Theta(\mathbf{h}, \xi) := \mathbf{h}\exp(\xi).$$

This map is smooth by the Lie group structure already constructed. In the left trivialization at $(\mathbf{h}, 0)$, its differential is

$$(dL_{\mathbf{h}^{-1}})_{\mathbf{h}} D\Theta_{(\mathbf{h},0)}\big((dL_{\mathbf{h}})_e \eta, \xi\big) = \eta + \xi, \qquad (\eta, \xi) \in \mathfrak{h} \oplus X.$$

It is an isomorphism. The inverse function theorem gives, around each $(\mathbf{h}, 0)$, an open product $W_{\mathbf{h}} \times B_X(0, r_{\mathbf{h}})$ on which Θ is a diffeomorphism onto its image, with $\mathbf{h} \in W_{\mathbf{h}} \subseteq H$ and $r_{\mathbf{h}} > 0$. The open sets $W_{\mathbf{h}}$ cover H. Choose a subcover $W_{\mathbf{h}_1}, \dots, W_{\mathbf{h}_N}$ and set

$$\varepsilon_0 := \min_{1 \le i \le N} r_{\mathbf{h}_i} > 0.$$

If $\mathbf{h} \in H$ and $\|\xi\|_{H^{s+1}(M, \mathrm{ad}\,\mathbf{P})} < \varepsilon_0$, some $W_{\mathbf{h}_i}$ contains $\mathbf{h}$ and $(\mathbf{h}, \xi) \in W_{\mathbf{h}_i} \times B_X(0, r_{\mathbf{h}_i})$. Thus Θ is a local diffeomorphism on all of $H \times B_X(0, \varepsilon_0)$. Here and below, B_X denotes a ball for the norm $H^{s+1}(M, \mathrm{ad}\,\mathbf{P})$ restricted to X.

Injectivity can be made uniform. If there were no $0 < \varepsilon \le \varepsilon_0$ for which Θ was injective, there would be sequences

$$\mathbf{h}_j, \mathbf{k}_j \in H, \qquad \xi_j, \eta_j \in X, \qquad \|\xi_j\|_{H^{s+1}(M, \mathrm{ad}\,\mathbf{P})}, \|\eta_j\|_{H^{s+1}(M, \mathrm{ad}\,\mathbf{P})} \longrightarrow 0,$$

with $(\mathbf{h}_j, \xi_j) \neq (\mathbf{k}_j, \eta_j)$ and $\Theta(\mathbf{h}_j, \xi_j) = \Theta(\mathbf{k}_j, \eta_j)$. After passing to subsequences, compactness of H gives $\mathbf{h}_j \to \mathbf{h}$ and $\mathbf{k}_j \to \mathbf{k}$. Passing to the limit gives $\mathbf{h} = \mathbf{k}$. For large j, the two pairs then belong to a common domain of a local inverse of Θ around $(\mathbf{h}, 0)$, forcing $(\mathbf{h}_j, \xi_j) = (\mathbf{k}_j, \eta_j)$, a contradiction. Consequently, for some $\varepsilon > 0$,

$$\Theta \colon H \times B_X(0, \varepsilon) \xrightarrow{\cong} \mathcal{N}_\varepsilon := \Theta\big(H \times B_X(0, \varepsilon)\big) \tag{27.33}$$

is a diffeomorphism. Its image is open because Θ is a local diffeomorphism and contains H. Thus (27.33) is indeed a tubular neighborhood of H, obtained from the complementary normal bundle NH, rather than merely a chart at the identity. The terminology agrees with Definition 2.12.2: as in Fermi coordinates, a neighborhood of the zero section of a normal bundle is identified with a neighborhood of the submanifold; here the diffeomorphism is Θ rather than a Riemannian exponential map on the Hilbert manifold.

The ball $B_X(0, \varepsilon)$ is H–invariant for the preceding norm. The tube is equivariant under the right action

$$(\mathbf{h}, \xi) \cdot \mathbf{k} = (\mathbf{h}\mathbf{k}, \mathrm{Ad}_{\mathbf{k}^{-1}} \xi), \qquad \Theta((\mathbf{h}, \xi) \cdot \mathbf{k}) = \Theta(\mathbf{h}, \xi)\mathbf{k},$$

and also under left translations. This is precisely the compatibility required by the associated quotient.

To conclude, choose an open H–invariant neighborhood

$$\mathcal{S}_0 \subset \mathcal{S}_A^s, \qquad A \in \mathcal{S}_0,$$

and shrink $\mathcal{S}_0$ and ε simultaneously so that the local diffeomorphism Ψ obtained above is injective on

$(\mathcal{S}_0 - A) \times B_X(0,\varepsilon)$. Let q be the projection onto the associated quotient and set

$$\mathcal{W}_A := q(\mathcal{S}_0 \times \mathcal{N}_\varepsilon).$$

We may take $\mathcal{S}_0$ to be a ball for an H–invariant norm obtained by averaging any equivalent norm over the compact group. The action of H on $\mathcal{S}_A^s \times \mathcal{G}^{s+1}(\mathbf{P})$ is free because of its second factor and proper because H is compact; in particular, the projection q is open and $\mathcal{W}_A$ is an open neighborhood of $[A,e]$. If $\mathbf{u} = \mathbf{h}\operatorname{Exp}(\xi)$ belongs to $\mathcal{N}_\varepsilon$, then, in the associated quotient,

$$[B, \mathbf{h}\operatorname{Exp}(\xi)] = [B \triangleleft \mathbf{h}, \operatorname{Exp}(\xi)],$$

, with $B \triangleleft \mathbf{h} \in \mathcal{S}_0$ after shrinking $\mathcal{S}_0$ invariantly. This representative is unique. Indeed, if

$$[B_1, \operatorname{Exp}(\xi_1)] = [B_2, \operatorname{Exp}(\xi_2)],$$

, there exists $\mathbf{k} \in H$ such that $B_2 = B_1 \triangleleft \mathbf{k}$ and $\operatorname{Exp}(\xi_2) = \mathbf{k}^{-1}\operatorname{Exp}(\xi_1)$. Hence

$$\Theta(e, \xi_1) = \Theta(\mathbf{k}, \xi_2),$$

, and injectivity of the tube implies $\mathbf{k} = e$, $\xi_1 = \xi_2$, and $B_1 = B_2$. Thus

$$\mathcal{S}_0 \times B_X(0,\varepsilon) \longrightarrow \mathcal{W}_A, \qquad (B,\xi) \longmapsto [B, \operatorname{Exp}(\xi)]$$

is a smooth bijective chart with smooth inverse induced by (27.33). In this chart, the map (27.31) agrees with

$$(B,\xi) \longmapsto B \triangleleft \operatorname{Exp}(\xi),$$

, that is, the parametrization Ψ translated by A. Its image $\mathcal{U}_A$ is open, and the restriction is a diffeomorphism. This proves the local parametrization. To obtain a slice for the full group, we must also control gauge transformations that have not been chosen in advance in $\mathcal{N}_\varepsilon$.

Fix a faithful unitary representation of G with associated vector bundle $\mathbf{E}$. Gauge transformations are represented as unitary endomorphisms of $\mathbf{E}$, and $d_A\mathbf{u}$ here denotes their covariant derivative before multiplication by $\mathbf{u}^{-1}$. The elliptic estimate for the fixed connection A gives

$$\|\mathbf{u}\|_{H^{s+1}(M,\operatorname{End}\mathbf{E})} \le C_A\big(\|d_A\mathbf{u}\|_{H^s(M,T^*M\otimes\operatorname{End}\mathbf{E})} + \|\mathbf{u}\|_{L^2(M,\operatorname{End}\mathbf{E})}\big).$$

This estimate applies to arbitrary endomorphisms, not just group elements. If $(A + \mathbf{b}_1) \triangleleft \mathbf{u} = A + \mathbf{b}_2$, the action formula is equivalent to

$$d_A\mathbf{u} = \mathbf{u}\mathbf{b}_2 - \mathbf{b}_1\mathbf{u}.$$

Sobolev product estimates imply

$$\|d_A\mathbf{u}\|_{H^s(M,T^*M\otimes\operatorname{End}\mathbf{E})} \le C\big(\|\mathbf{b}_1\|_{H^s(M,T^*M\otimes\operatorname{End}\mathbf{E})} + \|\mathbf{b}_2\|_{H^s(M,T^*M\otimes\operatorname{End}\mathbf{E})}\big)\|\mathbf{u}\|_{H^{s+1}(M,\operatorname{End}\mathbf{E})}.$$

Moreover, $\|\mathbf{u}\|_{L^2(M,\operatorname{End}\mathbf{E})}$ has a common bound because $\mathbf{u}$ is unitary and M has finite volume. If the norms of $\mathbf{b}_1, \mathbf{b}_2$ are sufficiently small, the first estimate absorbs the term containing $\|\mathbf{u}\|_{H^{s+1}(M,\operatorname{End}\mathbf{E})}$ and gives a uniform bound on this norm.

Suppose there exist $\mathbf{b}_{1,j}, \mathbf{b}_{2,j} \to 0$ in H^s and transformations $\mathbf{u}_j$ relating the two connections but remaining outside $\mathcal{N}_\varepsilon$. The preceding bound and Rellich's theorem allow extraction of a subsequence converging in H^s and, by embedding, in C^0, to a group-valued section $\mathbf{u}$. The differential identity shows that $d_A \mathbf{u}_j \to 0$ in H^s, so $d_A \mathbf{u} = 0$ in distributions. The stabilizer regularity argument proves that $\mathbf{u} \in H = \mathrm{Stab}(A)$. Applying the elliptic estimate to $\mathbf{u}_j - \mathbf{u}$ gives

$$\|\mathbf{u}_j - \mathbf{u}\|_{H^{s+1}(M,\mathrm{End}\,\mathbf{E})} \le C_A \big(\|d_A \mathbf{u}_j\|_{H^s(M,T^*M\otimes \mathrm{End}\,\mathbf{E})} + \|\mathbf{u}_j - \mathbf{u}\|_{L^2(M,\mathrm{End}\,\mathbf{E})} \big) \longrightarrow 0.$$

This contradicts the fact that $\mathcal{N}_\varepsilon$ is an open neighborhood of H. Consequently, after shrinking $\mathcal{S}_0$, every transformation relating two points of $\mathcal{S}_0$ belongs to $\mathcal{N}_\varepsilon$.

Write this transformation as $\mathbf{u} = \mathbf{h}\,\mathrm{Exp}\,\xi$, with $\mathbf{h} \in H$ and $\xi \in X$. If $B_1 \triangleleft \mathbf{u} = B_2$, with $B_1, B_2 \in \mathcal{S}_0$, invariance under H keeps $B_1 \triangleleft \mathbf{h}$ in $\mathcal{S}_0$. Injectivity of the parametrization Ψ compares the pairs $(B_1 \triangleleft \mathbf{h}, \xi)$ and $(B_2, 0)$ and gives $\xi = 0$, $B_2 = B_1 \triangleleft \mathbf{h}$. This proves uniqueness with respect to any group element.

Finally, the differential of the parametrization remains invertible at (B, e) for every B in a sufficiently small neighborhood of A, by continuity and openness of the set of isomorphisms. Translation by the action transfers this property to $(B, \mathbf{u})$ for any $\mathbf{u}$. The map from the associated quotient is thus a local diffeomorphism at all its points, and the preceding argument proves its injectivity. Its image is open and invariant and contains the orbit of A; being an open injective map with smooth local inverses, it is a diffeomorphism onto that image. This completes the slice construction. □

The gain of one derivative in the gauge element is visible both in $\mathbf{u}^{-1} d\mathbf{u}$ and in the elliptic isomorphism used in the Coulomb argument.

On a compact base, $d_A^* d_A$ has compact resolvent: its spectrum is discrete, each eigenspace is finite-dimensional, and there is no essential spectrum. The elliptic estimate on $(\ker d_A)^\perp$ replaces, in this case, the additional gap assumption arising on a noncompact base.

On a complete noncompact base without boundary, we say that a smooth connection B satisfies the connection condition (B_k) if there exist constants $D_0, \dots, D_k > 0$ such that

$$\|(\nabla^B)^i \mathbf{F}_B\|_\infty \le D_i, \qquad 0 \le i \le k. \tag{27.34}$$

For fixed A_0, define its affine Sobolev component by

$$\mathcal{A}^r_{A_0}(\mathbf{P}) := A_0 + H^r(M, T^*M \otimes \mathrm{ad}\,\mathbf{P}).$$

On a noncompact base, a gauge transformation is likewise not required to be integrable as a function with values in G. Fix a faithful unitary representation of G and use the connection induced by A_0. Consider sections $\mathbf{u}$ of $\mathrm{Ad}(\mathbf{P})$ of class H^{r+1}_{loc} for which

$$\mathbf{u}^{-1} d_{A_0} \mathbf{u} := A_0 \triangleleft \mathbf{u} - A_0 \in H^r(M, T^*M \otimes \mathrm{ad}\,\mathbf{P}).$$

This set is $\mathcal{G}^{r+1}(A_0)$. Its topology is described by the charts $\xi \mapsto \mathbf{u}\,\mathrm{Exp}\,\xi$, with $\xi \in H^{r+1}(M, \mathrm{ad}\,\mathbf{P})$ of small uniform norm. The norms are always based on A_0 and $\mathbf{g}$.

The definition is compatible with multiplication. If $\mathbf{b}_{\mathbf{u}} = \mathbf{u}^{-1} d_{A_0} \mathbf{u}$, the action law gives

$$\mathbf{b}_{\mathbf{uv}} = \mathrm{Ad}_{\mathbf{v}^{-1}} \mathbf{b}_{\mathbf{u}} + \mathbf{b}_{\mathbf{v}}, \qquad \mathbf{b}_{\mathbf{u}^{-1}} = -\mathrm{Ad}_{\mathbf{u}}\, \mathbf{b}_{\mathbf{u}}.$$

The coefficients $\mathbf{u}$ are bounded because G is compact. Estimates for their derivatives follow from $d_{A_0}\mathbf{u} = \mathbf{u}\mathbf{b}_{\mathbf{u}}$: in the step from order j to $j+1$, Leibniz's rule differentiates one of the factors $\mathbf{b}_{\mathbf{u}}$ or adds a new factor by differentiating $\mathbf{u}$. For $j \in \{0,\dots,r\}$, Sobolev products, with $r > m/2$, control all terms. In particular, $\mathrm{Ad}_{\mathbf{u}}$ and its inverse are multipliers in H^r. The preceding two identities preserve the membership condition, and the charts construct the Hilbert Lie group described in [55, §3]. Its action on the affine component is written as

$$(A_0 + \mathbf{a}) \triangleleft \mathbf{u} = A_0 + \mathbf{b}_{\mathbf{u}} + \mathrm{Ad}_{\mathbf{u}^{-1}}\,\mathbf{a}.$$

Let $\mathcal{G}_e^{r+1}(A_0)$ be the identity component of this group. A central constant section $c \in Z(G)$ has $d_{A_0}c = 0$, so it belongs to the full group even if it does not belong to that component. If $Z(G)$ is countable, set

$$\mathcal{G}_\bullet^{r+1}(A_0) := \bigcup_{c \in Z(G)} c\,\mathcal{G}_e^{r+1}(A_0).$$

If the center is uncountable, set $\mathcal{G}_\bullet^{r+1}(A_0) = \mathcal{G}_e^{r+1}(A_0)$. The selected components form a subgroup. Since the Hilbert model is separable, the identity component is second countable; a countable union of its translates preserves this property. This is the restriction used in the slice theorem.

Definition 27.4.8. (Essential spectrum and spectral gap) Let L be a densely defined nonnegative self-adjoint operator on a Hilbert space. Its *essential spectrum* $\sigma_{\mathrm{e}}(L)$ is the set of $\lambda \in \mathbb{R}$ for which $L - \lambda I \colon \mathcal{D}(L) \longrightarrow H$ is not Fredholm, where $\mathcal{D}(L)$ carries the graph norm. We say there is a *spectral gap above the kernel* if there exists $\gamma > 0$ such that

$$\langle Lu, u\rangle \geq \gamma \|u\|^2, \qquad u \in \mathcal{D}(L) \cap (\ker L)^{\perp}.$$

If $\inf \sigma_{\mathrm{e}}(L|_{(\ker L)^{\perp}}) > 0$, this gap also follows, with the convention $\inf \varnothing = +\infty$. Indeed, below the essential spectrum there can be only isolated eigenvalues of finite multiplicity. A sequence of positive eigenvalues tending to zero would place zero in the essential spectrum. Nor can zero be an eigenvalue of the restriction to $(\ker L)^{\perp}$. Its spectrum is therefore bounded away from zero. The spectral theorem gives the inequality, and the inverse on the complement of the kernel is bounded; it follows that the range of L is closed.

Theorem 27.4.9. (Eichhorn–Heber: gauge slice on a complete noncompact manifold) Let $(M^m, \mathbf{g})$ be a smooth complete noncompact Riemannian manifold without boundary and of bounded geometry: it has positive injectivity radius and curvature bounds (B_k). Let $\mathbf{P} \longrightarrow M$ be a principal bundle with compact group, let A_0 be a connection satisfying (27.34) and

$$\mathrm{YM}(A_0) = \frac{1}{2}\int_M |\mathbf{F}_{A_0}|^2_{\mathbf{g},h_{\mathrm{ad}}}\, d\lambda_{\mathbf{g}} < \infty,$$

, and suppose

$$k - 1 \geq r > \frac{m}{2} + 2.$$

For $A \in \mathcal{A}^r_{A_0}(\mathbf{P})$, assume the spectral gap

$$\inf \sigma_{\mathrm{e}}\left(\Delta_A^{(0)} \restriction_{(\ker \Delta_A^{(0)})^{\perp}}\right) > 0.$$

Then $d_A : H^{r+1}(M, \mathrm{ad}\,\mathbf{P}) \to H^r(M, T^*M \otimes \mathrm{ad}\,\mathbf{P})$ has closed range in H^r and admits the kernel of $d_A^* : H^r \to$

H^{r-1} as a complement. The sum is orthogonal for the L^2 inner product, and the orbit of A under $\mathcal{G}_\bullet^{r+1}(A_0)$ has an equivariant tube and a slice. If, in addition, the same gap holds for the reference connection,

$$\inf \sigma_{\mathrm{e}} \left(\Delta_{A_0}^{(0)} \restriction_{(\ker \Delta_{A_0}^{(0)})^\perp} \right) > 0,$$

, the quotient of the component by the subgroup $\mathcal{G}_\bullet^{r+1}(A_0)$ corresponding to A_0 has a regular quasistratification determined by conjugacy classes of stabilizers.

The Hodge decomposition used here is Proposition 4.12, p. 282, and the slice is Theorem 4.17, pp. 283–284, of [55], both under the gap corresponding to A. The quasistratification is their Theorem 5.13, pp. 285–286, and requires the gap at A_0. These conditions make the range of d_A a closed subspace and allow orbit directions to be separated from Coulomb directions. The full proof requires elliptic theory with Sobolev coefficients on a noncompact manifold and does not reduce to the local implicit function theorem.

There is a parallel result for the action of diffeomorphisms on metrics. For a metric $\mathbf{g}$, denote by $\Delta_{\mathbf{g}}^{(0)} = d_{\mathbf{g}}^* d$ the nonnegative self-adjoint realization of the Beltrami Laplacian on $L^2(M, d\lambda_{\mathbf{g}})$.

Theorem 27.4.10. (Eichhorn: slice for metrics of negative curvature) Let $(M^m, \mathbf{g}_0)$ be a smooth complete noncompact Riemannian manifold without boundary, with positive injectivity radius and bounded curvature and curvature derivatives, and let $r > \frac{m}{2} + 2$. Suppose $K_{\mathbf{g}_0} \le -c < 0$. Let $\mathbf{g}$ be a metric in the Sobolev component of order r of $\mathbf{g}_0$, with strictly negative sectional curvature, positive injectivity radius, and uniformly bounded $\mathrm{Rm}_{\mathbf{g}}, \nabla \mathrm{Rm}_{\mathbf{g}}$. Require, in addition, the positive equality of gaps

$$\inf \sigma_{\mathrm{e}}(\Delta_{\mathbf{g}_0}^{(0)}) = \inf \sigma_{\mathrm{e}}(\Delta_{\mathbf{g}}^{(0)}) > 0.$$

Then the identity component of the diffeomorphism group of order $r+1$ acts properly on this admissible set, and the orbit of $\mathbf{g}$ admits a topological slice. The action is regarded as continuous at the indicated Sobolev levels; differentiating it requires the level changes associated with composition and pullback.

This result is Theorem 5.8 of [52, p. 115]. The conclusion uses negative curvature, the uniform conditions (I) and (B_1), membership in the component, and equality of spectral gaps together. Its proof constructs the equivariant tube and establishes properness of the action using uniform elliptic theory.

27.5 Diffeomorphism groups, Hilbert scales, and ILH

27.5.1 The Sobolev group at fixed regularity

Let M^m be a smooth compact manifold with or without boundary and let $s > \frac{m}{2} + 1$. If $\partial M = \varnothing$, the set

$$\mathrm{Diff}^s(M) := \{ \eta \in H^s(M, M) \mid \eta \text{ is bijective and } \eta^{-1} \in H^s(M, M) \}$$

is open in $H^s(M, M)$ and is therefore a Hilbert manifold. If $\partial M \neq \varnothing$, introduce the double DM, which is a finite-dimensional manifold without boundary. In this case, $\mathrm{Diff}^s(M)$ consists of the C^1 diffeomorphisms of M whose coordinate representations and those of their inverses are H^s; in boundary charts, use the restriction spaces on the half-space. Work near one such diffeomorphism $\eta \in \mathrm{Diff}^s(M)$ within $H^s(M, DM)$. Choose on DM a product metric in a collar of ∂M; thus ∂M is totally geodesic. In the exponential chart centered at η, the condition of mapping

boundary to boundary is equivalent to

$$\operatorname{Tr}(\mathbf{X}) \in H^{s-\frac{1}{2}}(\partial M, (\eta|_{\partial M})^* T\partial M).$$

Indeed, a sufficiently short geodesic with both endpoints on ∂M is the geodesic for the induced metric on that hypersurface; its initial vector is tangent. The reverse implication follows because the hypersurface is totally geodesic.

The operator taking the normal component of the trace,

$$H^s(M, \eta^* TDM) \longrightarrow H^{s-\frac{1}{2}}(\partial M, (\eta|_{\partial M})^* N\partial M),$$

, is continuous and surjective. The trace extension operator in the collar, followed by inclusion of the normal bundle, provides a continuous right inverse. Its kernel is therefore a closed complemented subspace. Sobolev trivializations of the pullback bundle are justified using $H^{s-1/2}(\partial M)$, which is an algebra in this range.

It remains to check that maps in this chart take values in M and are diffeomorphisms. In collar coordinates with inward coordinate $t \geq 0$, the normal component of η vanishes at $t = 0$, and its normal derivative is strictly positive there. Compactness of the boundary gives a positive lower bound on a smaller collar. A sufficiently small perturbation in C^1 preserves this bound and, by integration from $t = 0$, maps the interior collar into the interior. Outside the collar, the image under η lies at positive distance from the boundary, a condition preserved by C^0 closeness.

The differential remains invertible, and the boundary restriction is a local diffeomorphism. For global injectivity, cover M by finitely many charts in which small perturbations of η are injective, using the inverse function estimate. There then exists $\delta > 0$ such that two points at distance less than δ belong to one of these charts. Pairs of points at distance at least δ form a compact set, and their images under η are separated by a positive distance. A small perturbation in C^0 preserves this separation. Thus no identification of points can arise. The image is open, including in boundary charts, and closed by compactness; it meets every component met by η, so it is all of M. The inverse is H^s by Sobolev inversion estimates.

The embedding $H^s \hookrightarrow C^1$ makes this argument applicable in a Sobolev neighborhood of η. We obtain a chart of $\operatorname{Diff}^s(M)$ on the kernel of the normal trace. Its tangent space at η consists of sections of $\eta^* TM$ whose trace is tangent to the boundary. This construction is Lemma 6.6 of [46]; it uses a Hilbert manifold without boundary modeled on that kernel.

Localization near diffeomorphisms is part of the argument. The set of all maps of pairs $M \to M$ may have additional constraints imposed by positivity of the normal coordinate. For example, at the constant zero map from $[0,1]$ to itself, every differentiable variation with a parameter of both signs has zero velocity at every point, since the value zero is a minimum. The preceding linear model is not obtained there.

Theorem 27.5.1. (Ebin–Marsden) Let M be a smooth compact manifold with or without boundary. If $s > \frac{m}{2} + 1$, the preceding space is a topological group. For $\eta \in \operatorname{Diff}^s(M)$, right translation $R_\eta(\varphi) = \varphi \circ \eta$ is smooth. Left translation and inversion, however, are not generally smooth at the same level. More precisely, for $j \in \mathbb{N}_0$,

$$L_\eta \colon \operatorname{Diff}^s(M) \longrightarrow \operatorname{Diff}^s(M) \quad \text{is } C^j \text{ if } \eta \in \operatorname{Diff}^{s+j}(M),$$

, and inversion is C^j as a map $\operatorname{Diff}^{s+j}(M) \longrightarrow \operatorname{Diff}^s(M)$. Thus $\operatorname{Diff}^s(M)$ is not a Hilbert Lie group in the usual sense.

Continuity and the regularity assertions follow from the composition lemmas α and ω in Section 2 of [46]; restriction to the boundary-preserving subspaces is established in its Section 6. The loss is already visible on differentiation:

$$DL_\eta(\varphi)\mathbf{X} = (d\eta \circ \varphi)\mathbf{X},$$

, which contains one derivative of η. The derivative of $\eta \mapsto \eta^{-1}$ follows from $\eta \circ \eta^{-1} = \mathrm{id}$ and likewise contains $d\eta^{-1}$.

Lemma 27.5.2. (Composition at lower levels and differentiation of curves) Let M be a smooth compact manifold of dimension m, with or without boundary, and let $s > m/2 + 1$. For $0 \le r \le s$, composition defines a continuous map

$$H^r(M,\mathbb{R}^d) \times \mathrm{Diff}^s(M) \longrightarrow H^r(M,\mathbb{R}^d), \qquad (F,\eta) \longmapsto F \circ \eta.$$

For each η_0, there exist a neighborhood $\mathcal{U}$ and a constant $C_{r,\mathcal{U}}$ with

$$\|F \circ \eta\|_{H^r(M,\mathbb{R}^d)} \le C_{r,\mathcal{U}} \|F\|_{H^r(M,\mathbb{R}^d)}, \qquad \eta \in \mathcal{U}. \tag{27.35}$$

If $F \in C^1(I, H^s(M,\mathbb{R}^d))$ and $\eta \in C^1(I, \mathrm{Diff}^s(M))$, then $z = F \circ \eta^{-1}$ belongs to $C(I, H^s(M,\mathbb{R}^d)) \cap C^1(I, H^{s-1}(M,\mathbb{R}^d))$ and

$$\partial_t z = (\partial_t F) \circ \eta^{-1} - dz(\mathbf{v}), \qquad \mathbf{v} = \dot\eta \circ \eta^{-1}. \tag{27.36}$$

In local frames, the same conclusions hold for sections along η; using covariant derivatives, the formula is $\partial_t \mathbf{z} = (\nabla_t \mathbf{F}) \circ \eta^{-1} - \nabla_{\mathbf{v}} \mathbf{z}$.

Proof. For $r = s$, use continuous composition from Proposition 27.3.5. Its continuity at $(0, \eta_0)$ and linearity in F give a uniform bound on the norm of the operator $R_\eta : F \mapsto F \circ \eta$ when η lies in a neighborhood of η_0: simply apply continuity on a ball of radius δ and then scale F. For $r = 0$, change of variables gives

$$\|F \circ \eta\|^2_{L^2(M,\mathbb{R}^d)} = \int_M |F(y)|^2 J_{\eta^{-1}}(y)\, d\lambda_{\mathbf{g}}(y) \le \|J_{\eta^{-1}}\|_{L^\infty(M)} \|F\|^2_{L^2(M,\mathbb{R}^d)}.$$

The Jacobian is uniformly bounded near η_0 because inversion is continuous and $H^s(M,TM) \hookrightarrow C^1(M,TM)$. Interpolate these two operators using Lemma 27.2.19 to obtain (27.35) for every $r \in [0,s]$.

To check joint continuity, let $F_j \to F$ in $H^r(M,\mathbb{R}^d)$ and $\eta_j \to \eta$ in $\mathrm{Diff}^s(M)$. Choose $G \in C^\infty(M,\mathbb{R}^d)$ with $\|F - G\|_{H^r(M,\mathbb{R}^d)} < \varepsilon$. For large j, all composition operators under consideration have a common bound, and

$$\begin{aligned}\|F_j \circ \eta_j - F \circ \eta\|_{H^r(M,\mathbb{R}^d)} \le C\|F_j - F\|_{H^r(M,\mathbb{R}^d)} + 2C\varepsilon \\ + \|G \circ \eta_j - G \circ \eta\|_{H^r(M,\mathbb{R}^d)}.\end{aligned}$$

The last term tends to zero even in $H^s(M,\mathbb{R}^d)$, by smooth superposition with G. First let $j \to \infty$ and then $\varepsilon \to 0$.

For curves, continuity already proved gives $z \in C(I, H^s(M,\mathbb{R}^d))$. Evaluation and embedding into C^1 allow pointwise differentiation of the identity $F(t,x) = z(t, \eta(t,x))$, giving (27.36) pointwise. Its right-hand side is a continuous curve in $H^{s-1}(M,\mathbb{R}^d)$: the first term is continuous by composition, and the second by the product and differentiation estimate in Lemma 27.2.19. Denote this side by $b(t)$. The integral $z(t_*) + \int_{t_*}^t b(\tau)\, d\tau$ exists in $H^{s-1}(M,\mathbb{R}^d)$. Point evaluation is continuous in this space because $s - 1 > m/2$; evaluating gives

the same integral identity satisfied by $z(t,x)$. The two functions agree, and by the fundamental theorem of calculus for the Bochner integral, z is of class C^1 in $H^{s-1}(M,\mathbb{R}^d)$ with derivative b. For sections, perform the calculation in a finite cover of frames. The connection coefficients add the smooth contractions of the covariant derivative and satisfy the same product estimates; the formulas agree on overlaps by the transformation rule for a connection. □

Theorem 27.5.3. (Sobolev diffeomorphisms of a complete noncompact manifold) Let $(M^m,\mathbf{g})$ be a smooth oriented complete noncompact Riemannian manifold without boundary and of bounded geometry of order k. For $1<p<\infty$ and $k>r>\frac{m}{p}+1$, let

$$\mathcal{D}^{p,r}(M):=\left\{\eta\in\Omega^{p,r}(M,M)\;\middle|\;\begin{array}{l}\eta \text{ is a } C^1 \text{ orientation-preserving diffeomorphism,}\\ \inf\limits_{x\in M}\lambda_{\min}(d\eta_x)>0\end{array}\right\},$$

, where $\lambda_{\min}(d\eta_x):=\inf\limits_{\substack{v\in T_xM\\ |v|_{\mathbf{g},x}=1}}|d\eta_x v|_{\mathbf{g},\eta(x)}$. Then $\mathcal{D}^{p,r}(M)$ is open in $\Omega^{p,r}(M,M)$, and each component is a Banach manifold of class C^{k+1-r}, a Hilbert manifold for $p=2$. The identity component $\mathcal{D}_0^{p,r}(M)$ is a metrizable topological group under composition and inversion.

Openness can be seen in the constructed charts. If η belongs to the preceding set and h is sufficiently close in a chart, C^1 closeness preserves a positive lower bound for dh. The uniform bound on $d\eta^{-1}$ also implies that $F=\eta^{-1}\circ h$ has small uniform displacement from the identity. A map with bounded displacement on a complete finite-dimensional manifold is proper: the preimage of a compact set lies in a closed bounded metric neighborhood of that compact set, which is compact by Hopf–Rinow. Since F is a local diffeomorphism, it is a proper covering. If the displacement is less than the injectivity radius, the homotopy $F_t(x)=\exp_x(t\log_x F(x))$ joins it to the identity. On each component, F_* therefore induces an isomorphism of fundamental groups, and the covering has one sheet. This gives injectivity and surjectivity of F and hence of h. The covering and continuation arguments are those in the chapter on infinite-dimensional calculus.

Sobolev composition estimates apply in uniform charts: the lower bound on $d\eta$ controls the change-of-variables Jacobian, and bounds on derivatives of the center control the coefficients. In a fixed neighborhood, products and inverses of elements close to the identity again belong to the Sobolev charts at the identity and depend continuously on them. For continuity, first approximate the outer factor by a smooth map, apply the uniform estimate to the error, and then use continuity for that fixed map. In a connected component, every element is a product of finitely many elements of any symmetric neighborhood of the identity: the union of these products is an open subgroup and is also closed in the component. Local estimates transfer to every finite product. This gives the topological group $\mathcal{D}_0^{p,r}(M)$ with a countable neighborhood base at the identity. Pairs (a,b) with $a^{-1}b$ in one of these neighborhoods form a base for its left uniformity. Continuity of multiplication allows symmetric neighborhoods to be chosen whose cubes lie in the preceding neighborhood; Proposition 27.2.12 gives a compatible metric. These are the properties of Theorems 6.4 and 6.5 of [49, §6] used here.

The topology retains global control in the Sobolev norms of the charts. At fixed regularity, one obtains a topological group; the differentiable properties recovered by moving to higher levels motivate the ILH tower.

27.5.2 Hilbert scales and ILH towers

The preceding loss of derivatives naturally leads to working with a scale of spaces instead of fixing a single regularity.

Definition 27.5.4. (Hilbert scale) Let $s_0 \in \mathbb{Z}$. A *Hilbert scale* is a family $(H^s)_{s\in\mathbb{Z},\, s\geq s_0}$ with continuous dense inclusions $H^{s+1} \hookrightarrow H^s$. Its smooth core is $H^\infty := \bigcap_{s\in\mathbb{Z},\, s\geq s_0} H^s$, equipped with the initial topology of the inclusions $H^\infty \longrightarrow H^s$; equivalently, $H^\infty = \varprojlim_{s\in\mathbb{Z},\, s\geq s_0} H^s$.

Definition 27.5.5. (Differentiable compatibility with loss) Fix $\ell \in \mathbb{N}_0$ and $s \in \mathbb{Z}$ with $s \geq s_0$. A family of maps $F^s \colon \mathcal{U}^{s+\ell} \longrightarrow \mathcal{N}^s$ is an *extension between levels of class* ℓ of F^∞ if its restrictions are compatible with the inclusions, each F^s is of class C^ℓ, and, for $0 \leq j \leq \ell$, its differentials, expressed in compatible charts, satisfy on neighborhoods with common control data an estimate

$$\|D^j F^s(x)(v_1,\dots,v_j)\|_{H^s} \leq C\,\mathcal{P}(\|x\|_{H^{s+\ell}}) \prod_{i=1}^{j} \|v_i\|_{H^{s+\ell}},$$

, where $\mathcal{P}$ is a polynomial independent of the smooth approximation. The constant may depend on the charts and their control data. For diffeomorphisms, in addition to Sobolev bounds, a common bound on $\|(d\eta)^{-1}\|_\infty$ is fixed; boundedness of the $H^s(\Omega,\mathbb{R}^m)$ norms of the coordinate expressions of η on the domains Ω of the fixed charts alone does not prevent the differential from approaching a singular matrix. We say that F^∞ is *smooth in the ILH tower* if it admits these extensions for every ℓ. This definition uses Banach calculus at each level and explicitly records the derivatives that must be recovered by ascending the scale.

Definition 27.5.6. (Compatible ILH tower) An *ILH tower* modeled on (H^s) is a family of Hilbert manifolds $(\mathcal{M}^s)_{s\in\mathbb{Z},\, s\geq s_0}$ with smooth dense inclusions $\mathcal{M}^{s+1} \hookrightarrow \mathcal{M}^s$ whose charts restrict compatibly and whose core is $\mathcal{M}^\infty := \bigcap_{s\in\mathbb{Z},\, s\geq s_0} \mathcal{M}^s$. An ILH group tower also has a group operation on G^∞ and extensions of multiplication and inversion between levels. The regularities of these extensions and the loss of derivatives are specified in Definition 27.5.5; the mere equality $G^\infty = \bigcap_{s\in\mathbb{Z},\, s\geq s_0} G^s$ does not suffice.

Proposition 27.5.7. If each H^{s+1} is dense in H^s, then H^∞, with the norms $\|\cdot\|_{H^s}$, is a Fréchet space. A sequence converges in H^∞ if and only if it converges at every level H^s.

Proof. The metric

$$d(u,v) := \sum_{j=0}^{\infty} 2^{-j} \frac{\|u-v\|_{H^{s_0+j}}}{1+\|u-v\|_{H^{s_0+j}}}$$

generates the projective topology. If (u_n) is Cauchy, it converges in each H^s to an element u_s. Continuity of the inclusions shows that these limits are compatible and represent a unique $u \in \bigcap_{s\in\mathbb{Z},\, s\geq s_0} H^s$; then $u_n \to u$ in all norms. □

Proposition 27.5.8. (Smooth core of the Sobolev scale) If M is a smooth compact manifold with or without boundary and $\mathbf{E} \longrightarrow M$ is a smooth vector bundle, then $\Gamma(\mathbf{E}) = \bigcap_{s\in\mathbb{Z},\ s\geq s_0} H^s(M,\mathbf{E})$ as locally convex spaces: the projective topology of the Sobolev norms agrees with the usual topology of uniform convergence of all derivatives. If M is noncompact, we always have $\bigcap_{s\in\mathbb{Z},\ s\geq s_0} H^s(M,\mathbf{E}) \subseteq \Gamma(\mathbf{E})$, but the inclusion may be strict because a smooth section need not be integrable at infinity.

Proof. First suppose M is compact. For fixed s, choose an integer $k \geq \max\{s,0\}$. Inclusion in the scale and equivalence between the H^k norm and the covariant norm of order k give constants $A_{s,k}, B_k > 0$ such that, for $\mathbf{u} \in \Gamma(\mathbf{E})$,

$$\|\mathbf{u}\|_{H^s(M,\mathbf{E})} \leq A_{s,k}\|\mathbf{u}\|_{H^k(M,\mathbf{E})} \leq B_k \lambda_{\mathbf{g}}(M)^{1/2} \sum_{\ell=0}^{k} \|\nabla^\ell \mathbf{u}\|_{C^0(M,T^{(0,\ell)}(TM)\otimes\mathbf{E};\mathbf{g},\mathbf{h}_\mathbf{E})}.$$

Thus each inclusion $\Gamma(\mathbf{E}) \longrightarrow H^s(M,\mathbf{E})$ is continuous. In the opposite direction, given j, choose $s > j + m/2$. Sobolev embedding gives $\|\mathbf{u}\|_{C^j(M,\mathbf{E})} \leq C_{s,j}\|\mathbf{u}\|_{H^s(M,\mathbf{E})}$. Thus the scale norms and the C^j seminorms generate the same topology. On a noncompact base, even a nonzero parallel section may have infinite L^2 norm, proving the last assertion. □

Definition 27.5.9. (The term *strong ILH*) We reserve the term *strong ILH Lie group* for Omori's notion [110, Chapter I, §1.1]. It requires a Hilbert chain, a compatible chart at the identity, and conditions $(N,1)$–$(N,7)$ for extensions of multiplication, translations, their iterated differentials, inversion, and conjugation by smooth elements. A compatible ILH tower in the sense of the preceding definitions will not be regarded as *strong ILH* until these axioms have been verified.

Remark 27.5.10. (Three forms of uniform control) The notions used in this chapter act on different objects. Amann's uniform regularity is a coordinate property of the atlas and the base metric; bounded geometry is its intrinsic formulation through injectivity radius, curvature, and, when there is boundary, collar data. An Eichhorn uniformity is imposed on a configuration space and serves to define global closeness, components, and completions. An ILH tower, finally, organizes a family of Hilbert completions and losses of regularity between them.

Theorems 13.2.5 and 14.4.8 relate the first two notions, without and with boundary. Neither determines by itself a uniformity on configurations, and a uniformity does not provide the charts and estimates between levels required by an ILH tower.

Proposition 27.5.11. (Operations on the diffeomorphism core) Let M be a smooth compact manifold with or without boundary and let $s_0 \in \mathbb{Z}$ with $s_0 > \frac{m}{2} + 1$. Then

$$\mathrm{Diff}^\infty(M) = \bigcap_{s\in\mathbb{Z},\ s\geq s_0} \mathrm{Diff}^s(M)$$

, and composition and inversion are smooth in the sense of Definition 27.5.5. More precisely, for each $\ell \geq 0$,

$$\mathrm{Diff}^{s+\ell}(M) \times \mathrm{Diff}^s(M) \longrightarrow \mathrm{Diff}^s(M), \qquad (\eta,\varphi) \longmapsto \eta \circ \varphi,$$

and

$$\mathrm{Diff}^{s+\ell}(M) \longrightarrow \mathrm{Diff}^{s}(M), \qquad \eta \longmapsto \eta^{-1},$$

are of class C^{ℓ}.

Proof. The set-theoretic equality follows from Proposition 27.5.8 applied in charts and the same assertion for the inverse. The estimates follow by differentiating composition. Differentiation with respect to the inner argument φ uses spatial derivatives of the outer factor η. In coordinates, for $j \in \{1,\dots,\ell\}$, its leading term is

$$D^{j}_{\varphi}(\eta\circ\varphi)[\mathbf{X}_1,\dots,\mathbf{X}_j] = (D^{j}\eta\circ\varphi)[\mathbf{X}_1,\dots,\mathbf{X}_j].$$

Dependence on the outer factor is linear in these coordinates; mixed derivatives are obtained by replacing η by its variation in this formula. Chart changes add smooth superpositions and products of the same order. The space H^s, with $s > m/2+1$, is an algebra, and composition estimates control each term in terms of the $H^{s+\ell}(\Omega,\mathbb{R}^m)$ norms of the coordinate expressions of η on the domains Ω of the fixed charts, and the common data of the neighborhood of φ. For inversion, differentiate $\eta\circ\eta^{-1} = \mathrm{id}$; each derivative of order ℓ is a finite sum of products of spatial differentials of the outer factor and factors $(d\eta\circ\eta^{-1})^{-1}$. The first step is $D(\eta^{-1})[\mathbf{X}] = -(d\eta\circ\eta^{-1})^{-1}(\mathbf{X}\circ\eta^{-1})$. In passing from order j to $j+1$, Leibniz's rule differentiates one of these factors; the rule $D(B^{-1})[C] = -B^{-1}CB^{-1}$ handles the inverse factors, and the chain rule handles the compositions. At most one additional spatial derivative of η is needed at each step, through order ℓ. The lower bound on $d\eta$ in a neighborhood of a diffeomorphism controls the matrix inverses. This proves the extensions and their bounds at each level. □

This definition does not assert that each G^s is a Hilbert Lie group. In the diffeomorphism example, G^s is a topological group with smooth right translations; the smooth operation reappears in the limit because any finite loss can be compensated by ascending finitely many levels.

Scales do not remove derivative loss; they record it. An argument at fixed regularity must close in a single H^s. An ILH argument may temporarily ascend to H^{s+j} and then descend, provided the estimates are uniform and compatible. This distinction will be decisive when interpreting the geometric differential operators of the next chapter as fields on scales of function spaces.

Remark 27.5.12. (Hierarchy of structures) A Hilbert manifold at a fixed regularity level, a compatible tower, and a *strong ILH* Lie group are successively stronger structures. The identity $G^{\infty} = \bigcap_{s\in\mathbb{Z},\ s\geq s_0} G^s$ alone provides neither compatible charts nor estimates for derivative loss, and these charts do not automatically imply Omori's axioms either. In what follows, constructions at fixed regularity are treated using Banach calculus, while operations with derivative loss are organized by means of Definition 27.5.5.

28

Geometric applications in infinite dimensions

The constructions of the preceding chapter take on their clearest meaning when an equation can be recognized as a geometric condition on a configuration space. In this chapter we apply this viewpoint to harmonic maps, the Yang–Mills equations, and the Euler equation for an incompressible fluid. Although the problems differ, in each case the unknown is no longer viewed as a collection of components, but as a point of an infinite-dimensional manifold.

The procedure will be the same in each application. First we identify the configuration space and its tangent space; we then introduce the natural functional or metric and compute its variation in an arbitrary direction. Integration by parts then reveals the corresponding differential equation. Symmetries are also part of the problem: invariance under reparametrizations or gauge transformations produces degenerate directions and requires us to distinguish the geometric equation from a particular choice of coordinates or gauge.

The L^2 metrics used in these applications are generally weak with respect to the chosen Sobolev topologies. Thus expressions such as "gradient of the energy" will initially be understood in the formal L^2 sense: the resulting operator usually loses derivatives and does not by itself define a vector field on the configuration space at that regularity. When an evolution equation or a smooth spray is needed, we shall specify the regularity scale or elliptic mechanism that recovers the required derivatives. The geometric interpretation of these equations therefore depends on estimates controlling the loss and recovery of derivatives.

Three problems, three geometries

The theory of harmonic maps developed by extending the Dirichlet energy to maps between manifolds; Yang–Mills theory made the curvature of a connection a central functional of gauge theory; Arnold and, in a precise analytic framework, Ebin and Marsden interpreted the Euler equations as geodesics on a diffeomorphism group. These three examples show that the geometry of the configuration space is not merely decorative: it determines the variables, the symmetries, and the regularity at which the equation is well posed [46].

28.1 Harmonic maps

The first example extends the Dirichlet functional from the calculus of variations to maps between manifolds. Let $(M^m, \mathbf{g})$ be a compact Riemannian manifold with or without boundary and $(N, \mathbf{h})$ a finite-dimensional Riemannian manifold without boundary. For a smooth map $f : M \longrightarrow N$, the differential is a section of $T^*M \otimes f^*TN$, and its *Dirichlet energy* is

$$\mathcal{E}(f) := \frac{1}{2}\int_M |df|^2_{\mathbf{g},\mathbf{h}}\, d\lambda_{\mathbf{g}}. \tag{28.1}$$

The Levi–Civita connection of $\mathbf{h}$ induces a connection, still denoted by ∇, on f^*TN and on $T^*M \otimes f^*TN$. The *tension field* of f is

$$\boldsymbol{\tau}(f) := \operatorname{tr}_{\mathbf{g}}(\nabla df) = \sum_{i=1}^{m} \big(\nabla_{\mathbf{e}_i} df(\mathbf{e}_i) - df(\nabla^M_{\mathbf{e}_i}\mathbf{e}_i)\big), \tag{28.2}$$

where $(\mathbf{e}_i)_{i=1}^m$ is any local orthonormal frame. This expression is tensorial and therefore independent of the chosen frame.

Proposition 28.1.1. (First variation of the energy) Let $(M^m, \mathbf{g})$ be a compact Riemannian manifold, with or without boundary, and $(N, \mathbf{h})$ a Riemannian manifold without boundary. Let f_t be a smooth variation of $f = f_0$, and let

$$\mathbf{V} := \partial_t f_t|_{t=0} \in \Gamma(f^*TN).$$

Then

$$\frac{d}{dt}\Big|_{t=0} \mathcal{E}(f_t) = -\int_M \langle \boldsymbol{\tau}(f), \mathbf{V}\rangle_{\mathbf{h}}\, d\lambda_{\mathbf{g}} + \int_{\partial M} \langle df(\boldsymbol{\nu}), \mathbf{V}\rangle_{\mathbf{h}}\, d\sigma_{\mathbf{g}}, \tag{28.3}$$

where $\boldsymbol{\nu}$ is the outward unit normal when $\partial M \neq \varnothing$.

Proof. Consider the map

$$F : (-\varepsilon, \varepsilon) \times M \longrightarrow N, \qquad F(t, x) := f_t(x).$$

Since the Levi–Civita connection of N is torsion-free and the vector fields ∂_t and $\mathbf{e}_i$ commute,

$$\nabla_{\partial_t} df_t(\mathbf{e}_i) = \nabla_{\mathbf{e}_i} \partial_t f_t.$$

Evaluating at $t = 0$ gives

$$\frac{d}{dt}\Big|_{t=0} \frac{1}{2}|df_t|^2_{\mathbf{g},\mathbf{h}} = \sum_{i=1}^{m} \langle \nabla_{\mathbf{e}_i}\mathbf{V}, df(\mathbf{e}_i)\rangle_{\mathbf{h}}.$$

Define the 1-form

$$\boldsymbol{\alpha}(\mathbf{X}) := \langle \mathbf{V}, df(\mathbf{X})\rangle_{\mathbf{h}}.$$

The Leibniz rule and the definition of the tension field give

$$\operatorname{div}_{\mathbf{g}} \boldsymbol{\alpha}^\sharp = \sum_{i=1}^{m} \langle \nabla_{\mathbf{e}_i}\mathbf{V}, df(\mathbf{e}_i)\rangle_{\mathbf{h}} + \langle \mathbf{V}, \boldsymbol{\tau}(f)\rangle_{\mathbf{h}}.$$

Consequently,

$$\frac{d}{dt}\Big|_{t=0} \mathcal{E}(f_t) = \int_M \operatorname{div}_{\mathbf{g}} \boldsymbol{\alpha}^\sharp\, d\lambda_{\mathbf{g}} - \int_M \langle \mathbf{V}, \boldsymbol{\tau}(f)\rangle_{\mathbf{h}}\, d\lambda_{\mathbf{g}}.$$

Stokes' theorem transforms the first term into

$$\int_{\partial M} \boldsymbol{\alpha}(\boldsymbol{\nu})\, d\sigma_{\mathbf{g}} = \int_{\partial M} \langle \mathbf{V}, df(\boldsymbol{\nu})\rangle_{\mathbf{h}}\, d\sigma_{\mathbf{g}}.$$

□

If $\partial M = \varnothing$, or if the trace of f is fixed and only variations with $\operatorname{Tr}\mathbf{V} = 0$ are allowed, the boundary term vanishes. In this variational problem, the formal L^2 representative of the differential is

$$\operatorname{grad}_{L^2} \mathcal{E}(f) = -\boldsymbol{\tau}(f). \tag{28.4}$$

Consequently, for these variations the critical points are exactly the maps satisfying $\boldsymbol{\tau}(f) = 0$, called *harmonic maps*. Variations compactly supported in the interior establish the necessity of the equation, and the first variation establishes its sufficiency. If the trace is allowed to vary freely, one must also impose $df(\boldsymbol{\nu}) = 0$ on the boundary: once the tension field vanishes, extending any smooth vector field from the boundary makes the trace of $\mathbf{V}$ arbitrary in the remaining term. Thus, for free variations, the boundary term cannot be discarded or generally represented by an interior L^2 gradient. This variational formulation goes back to [85]; the preceding calculation also fixes the sign convention we shall use.

Proposition 28.1.2. (Linearization of the tension field and second variation) Let $(M^m, \mathbf{g})$ be a compact Riemannian manifold without boundary, $(N, \mathbf{h})$ a Riemannian manifold without boundary, and $f : M \longrightarrow N$ a smooth map. Define

$$\nabla^*\nabla := -\operatorname{tr}_{\mathbf{g}}(\nabla^2)$$

on sections of f^*TN. The derivative of the tension field is understood covariantly: transport $\boldsymbol{\tau}(f_t)$ to f^*TN along the variation and differentiate at $t = 0$. We denote this derivative by $D\boldsymbol{\tau}(f)[\mathbf{V}]$. For every variation with variational vector field $\mathbf{V}$,

$$D\boldsymbol{\tau}(f)[\mathbf{V}] = -\nabla^*\nabla\mathbf{V} + \sum_{i=1}^{m} \operatorname{Rm}_{\mathbf{h}}\big(\mathbf{V}, df(\mathbf{e}_i)\big)\, df(\mathbf{e}_i). \tag{28.5}$$

If f is harmonic, the linearization of $-\boldsymbol{\tau}$ is the Jacobi operator

$$J_f\mathbf{V} = \nabla^*\nabla\mathbf{V} - \sum_{i=1}^{m} \operatorname{Rm}_{\mathbf{h}}\big(\mathbf{V}, df(\mathbf{e}_i)\big)\, df(\mathbf{e}_i). \tag{28.6}$$

The Hessian of the energy is given by

$$D^2\mathcal{E}(f)[\mathbf{V},\mathbf{W}] = \int_M \left(\langle \nabla\mathbf{V}, \nabla\mathbf{W}\rangle_{\mathbf{g}, f^*\mathbf{h}} - \sum_{i=1}^{m} \big\langle \operatorname{Rm}_{\mathbf{h}}\big(\mathbf{V}, df(\mathbf{e}_i)\big)\, df(\mathbf{e}_i), \mathbf{W}\big\rangle_{f^*\mathbf{h}} \right) d\lambda_{\mathbf{g}}. \tag{28.7}$$

In particular,

$$D^2\mathcal{E}(f)[\mathbf{V},\mathbf{V}] = \int_M \left(|\nabla\mathbf{V}|^2_{\mathbf{g}, f^*\mathbf{h}} - \sum_{i=1}^{m} \big\langle \operatorname{Rm}_{\mathbf{h}}\big(\mathbf{V}, df(\mathbf{e}_i)\big)\, df(\mathbf{e}_i), \mathbf{V}\big\rangle_{f^*\mathbf{h}} \right) d\lambda_{\mathbf{g}}. \tag{28.8}$$

Proof. Let $F(t,x) = f_t(x)$, and extend the frame $(\mathbf{e}_i)$ locally without dependence on t. The absence of torsion implies

$$\nabla_{\partial_t} df_t(\mathbf{e}_i) = \nabla_{\mathbf{e}_i} \mathbf{V}.$$

Commuting the covariant derivatives once more gives

$$(\nabla_{\partial_t}\nabla_{\mathbf{e}_i} - \nabla_{\mathbf{e}_i}\nabla_{\partial_t}) df_t(\mathbf{e}_i) = \mathrm{Rm}_{\mathbf{h}}\big(dF(\partial_t), dF(\mathbf{e}_i)\big) df_t(\mathbf{e}_i),$$

so that, at $t = 0$,

$$\nabla_{\partial_t}\nabla_{\mathbf{e}_i} df_t(\mathbf{e}_i) = \nabla_{\mathbf{e}_i}\nabla_{\mathbf{e}_i}\mathbf{V} + \mathrm{Rm}_{\mathbf{h}}\big(\mathbf{V}, df(\mathbf{e}_i)\big) df(\mathbf{e}_i).$$

At a given point, choose the frame so that $\nabla^M_{\mathbf{e}_i}\mathbf{e}_i = 0$. Taking the trace gives (28.5); since both sides are tensorial, the identity holds at every point and for any frame.

Now suppose that $\boldsymbol{\tau}(f) = 0$. Differentiating the first variation in a second direction produces a term from the variation of the second vector field; this term is multiplied by $\boldsymbol{\tau}(f)$ and vanishes. Thus

$$D^2\mathcal{E}(f)[\mathbf{V},\mathbf{W}] = \int_M \langle J_f \mathbf{V}, \mathbf{W}\rangle_{f^*\mathbf{h}}\, d\lambda_{\mathbf{g}}.$$

Integrating $\nabla^*\nabla$ by parts gives (28.7). The symmetries of the curvature tensor show that this form is symmetric. Finally, the principal symbol of J_f is

$$\sigma_2(J_f)(x,\xi) = -|\xi|^2_{\mathbf{g}}\,\mathrm{id}_{T_{f(x)}N}, \qquad x \in M, \quad \xi \in T^*_xM \setminus \{0\},$$

with the symbol convention from the chapter on differential operators, which replaces ∂_j by ξ_j without introducing the factor i. The sign comes from the principal term $-g^{ij}\partial_i\partial_j$. Thus J_f is elliptic; integration by parts and the curvature symmetries separately establish its formal self-adjointness. □

We turn to the formulation in Sobolev spaces. Fix an integer

$$s > \frac{m}{2} + 1.$$

Exponential charts make $H^s(M,N)$ into a Hilbert manifold. More precisely, Theorem 27.3.4 constructs the isomorphism

$$\mathcal{I}_f : H^s(M, f^*TN) \longrightarrow T_f H^s(M,N), \qquad \mathcal{I}_f(\mathbf{V}) := \left.\frac{d}{dt}\right|_{t=0} \mathrm{Exp}_f(t\mathbf{V}).$$

In the chart Exp_f, this map and its inverse are represented by the identity on the model space. In particular,

$$T_f H^s(M,N) \cong H^s(M, f^*TN).$$

The tension field contains two derivatives of f, so its natural codomain has two fewer orders of regularity. To describe it, consider

$$\boldsymbol{\mathcal{T}}^{s-2} := \coprod_{\widetilde{f} \in H^s(M,N)} \Big(\{\widetilde{f}\} \times H^{s-2}(M, \widetilde{f}^*TN)\Big), \qquad \pi_{\boldsymbol{\mathcal{T}}^{s-2}}(\widetilde{f}, \mathbf{V}) := \widetilde{f}.$$

Let $\mathcal{U}_f$ be the domain of an exponential chart centered at f. If $\widetilde{f} = \operatorname{Exp}_f(u) \in \mathcal{U}_f$, parallel transport along

$$t \longmapsto \exp^N_{f(x)}(tu(x))$$

defines a bundle isometry

$$P_{f,\widetilde{f}} \colon \widetilde{f}^* TN \longrightarrow f^* TN.$$

The corresponding trivialization is

$$\Theta_f \colon \pi^{-1}_{\boldsymbol{\mathcal{T}}^{s-2}}(\mathcal{U}_f) \longrightarrow \mathcal{U}_f \times H^{s-2}(M, f^*TN), \qquad \Theta_f(\widetilde{f}, \mathbf{V}) := \big(\widetilde{f}, P_{f,\widetilde{f}}\mathbf{V}\big).$$

These trivializations equip $\boldsymbol{\mathcal{T}}^{s-2}$ with the structure of a smooth Banach bundle. The analytic point is continuity of multiplication between the coefficients of the transition maps and the sections. After multiplying by fixed cutoff functions for a trivialization and extending to $\mathbb{R}^m$, write

$$a \colon \mathbb{R}^m \to \operatorname{End}(\mathbb{R}^n), \qquad W \colon \mathbb{R}^m \to \mathbb{R}^n.$$

In these representations, we have

$$\|aW\|_{H^{s-2}(\mathbb{R}^m,\mathbb{R}^n)} \le C_s \|a\|_{H^s(\mathbb{R}^m,\operatorname{End}(\mathbb{R}^n))} \|W\|_{H^{s-2}(\mathbb{R}^m,\mathbb{R}^n)}, \tag{28.9}$$

where a is matrix-valued and W locally represents a section. The constant depends on M, s, and the trivializations, but not on a or W.

To verify the estimate, apply the Leibniz rule to each derivative of order at most $s-2$. If $\alpha, \beta \in \mathbb{N}_0^m$, $|\alpha| \le s-2$ and $\beta_i \le \alpha_i$ for $i \in \{1, \dots, m\}$, the regularities of the two factors satisfy

$$(s - |\beta|) + (s - 2 - |\alpha - \beta|) = 2s - 2 - |\alpha| \ge s > \frac{m}{2}.$$

Set $a_1 = s - |\beta|$ and $a_2 = s - 2 - |\alpha - \beta|$. Both are nonnegative and $a_1 + a_2 > m/2$. We may choose $p_1, p_2 \in [2, \infty]$ with $1/p_1 + 1/p_2 = 1/2$ so that the embeddings $H^{a_i}(\mathbb{R}^m) \hookrightarrow L^{p_i}(\mathbb{R}^m)$ are continuous. If one of the a_i is zero, take $p_i = 2$ and the other exponent to be infinity, which is allowed because the other order exceeds $m/2$. If both are positive, the strict inequality allows the exponents to be chosen away from any critical endpoint that would require L^∞. Hölder's inequality then estimates each product in L^2. Summing over the multi-indices and the finitely many charts yields (28.9).

On an overlap of charts centered at f_0 and f_1,

$$\Theta_{f_1} \circ \Theta_{f_0}^{-1}(\widetilde{f}, W) = \Big(\widetilde{f}, P_{f_1,\widetilde{f}} P^{-1}_{f_0,\widetilde{f}} W\Big).$$

The coefficient

$$\widetilde{f} \longmapsto P_{f_1,\widetilde{f}} P^{-1}_{f_0,\widetilde{f}}$$

depends smoothly on $\widetilde{f}$, with values in $H^s(M, \operatorname{Hom}(f_0^*TN, f_1^*TN))$, by Lemma 27.3.2. Estimate (28.9) proves smoothness of the transition map and its inverse.

To see which terms must be estimated, in coordinates on M and N the tension field has components

$$\tau^{\alpha}(f)=\sum_{i,j=1}^{m} g^{ij}\left(\partial_i\partial_j f^{\alpha}-\sum_{a=1}^{m}\Gamma_{ij}^{a}\partial_a f^{\alpha}+\sum_{\beta,\gamma=1}^{\dim N}\Gamma_{\beta\gamma}^{\alpha}(f)\partial_i f^{\beta}\partial_j f^{\gamma}\right),\qquad \alpha\in\{1,\dots,\dim N\}.$$

On each fixed coordinate domain $\Omega\subseteq\mathbb{R}^m$, the first term belongs to $H^{s-2}(\Omega)$; the coefficients on the base are smooth. The first derivatives of the components of f belong to $H^{s-1}(\Omega)$, which is an algebra, and $\Gamma_{\beta\gamma}^{\alpha}(f)$ depends smoothly on the components of f with values in $H^{s}(\Omega)$. Estimate (28.9) controls multiplication at the lower level. Each differentiation with respect to f replaces one factor by its variation or differentiates a superposition; it does not add a spatial derivative to the variation vectors. This proves smoothness with values in the fibers $H^{s-2}(M,f^{*}TN)$. For the energy, the same products are applied to $|df|^2$, followed by the continuous integral on L^1. Hence

$$\mathcal{E}\colon H^{s}(M,N)\longrightarrow\mathbb{R}$$

is smooth. Similarly, the tension field defines the smooth section

$$\boldsymbol{\tau}\colon H^{s}(M,N)\longrightarrow\boldsymbol{\mathcal{T}}^{s-2},\qquad f\longmapsto(f,\boldsymbol{\tau}(f)),\qquad \pi_{\boldsymbol{\mathcal{T}}^{s-2}}\circ\boldsymbol{\tau}=\mathrm{id}_{H^{s}(M,N)}.\tag{28.10}$$

To compute its vertical derivative at f, we use the trivialization by parallel transport centered precisely at f. This gives the continuous linear operator

$$D\boldsymbol{\tau}(f)\colon H^{s}(M,f^{*}TN)\longrightarrow H^{s-2}(M,f^{*}TN),$$

whose expression on smooth maps is (28.5). If f is harmonic, $J_f=-D\boldsymbol{\tau}(f)$ has the same domain and codomain. In another trivialization, differentiating the change of frame produces a term multiplied by $\boldsymbol{\tau}(f)$; this is why the linearization at a zero is independent of that choice. For nonharmonic maps, the intrinsic expression above is the covariant derivative, not the ordinary derivative of all representations simultaneously.

Thus $-\boldsymbol{\tau}(f)$ does not generally belong to the tangent space $T_fH^{s}(M,N)$, but to the fiber of lower regularity $H^{s-2}(M,f^{*}TN)$. An alternative is to use a strong metric on the mapping space. The representative of the differential with respect to such a metric is obtained by formally regularizing through

$$(1+\nabla^{*}\nabla)^{-s}(-\boldsymbol{\tau}(f)).$$

Its construction requires studying how the elliptic operators involved depend on f.

Finiteness of the energy requires only that df be square integrable, whereas the manifold structure and pointwise evaluation require regularity greater than $\frac{m}{2}$. This difference between the energy level and the geometric level also appears in compactness questions. In dimension two, for example, a sequence with bounded energy may concentrate energy and produce bubbles; on a noncompact base, it may also lose energy at infinity.

28.2 Yang–Mills theory and gauge reduction

The second application has an additional symmetry. A connection is not an isolated object: the gauge group transforms distinct connections describing the same geometry. This invariance makes the Hessian of the Yang–Mills functional degenerate in directions tangent to the gauge orbits and leads naturally to the Coulomb condition.

Let $(M^m,\mathbf{g})$ be a compact Riemannian manifold with or without boundary, and let $\mathbf{P}\longrightarrow M$ be a principal

bundle with compact structure group G. Denote its adjoint bundle by

$$\operatorname{ad}\mathbf{P} := \mathbf{P} \times_{\mathrm{Ad}} \mathfrak{g}$$

and fix an Ad-invariant inner product on $\mathfrak{g}$. We denote the induced metric on $\operatorname{ad}\mathbf{P}$ by $\mathbf{h}_{\mathrm{ad}}$.

The curvature of a connection $\mathbf{A}$ is an adjoint-bundle-valued 2-form:

$$\mathbf{F}_{\mathbf{A}} \in \Omega^2(M, \operatorname{ad}\mathbf{P}) := \Gamma\left(\Lambda^2(T^*M) \otimes \operatorname{ad}\mathbf{P}\right).$$

The superscript 2 indicates the degree of the form: for each $x \in M$, $\mathbf{F}_{\mathbf{A}}(x)$ takes two vectors in T_xM, depends alternatingly on them, and takes values in $(\operatorname{ad}\mathbf{P})_x$.

The space of connections is affine, modeled on $\Omega^1(M, \operatorname{ad}\mathbf{P})$. If $\mathbf{a}$ is an $\operatorname{ad}\mathbf{P}$-valued 1-form, the curvature of $\mathbf{A}+\mathbf{a}$ satisfies

$$\mathbf{F}_{\mathbf{A}+\mathbf{a}} = \mathbf{F}_{\mathbf{A}} + d_{\mathbf{A}}\mathbf{a} + \frac{1}{2}[\mathbf{a} \wedge \mathbf{a}]. \tag{28.11}$$

The Yang–Mills functional is

$$\mathrm{YM}(\mathbf{A}) := \frac{1}{2}\int_M |\mathbf{F}_{\mathbf{A}}|^2_{\mathbf{g},\mathbf{h}_{\mathrm{ad}}}\, d\lambda_{\mathbf{g}}. \tag{28.12}$$

Proposition 28.2.1. (First variation of Yang–Mills) Let $(M, \mathbf{g})$ be a compact Riemannian manifold with or without boundary, let $\mathbf{P} \to M$ be a principal bundle with compact structure group, and let $\mathbf{A}$ be a smooth connection. For $\mathbf{a} \in \Omega^1(M, \operatorname{ad}\mathbf{P})$,

$$D\,\mathrm{YM}(\mathbf{A})[\mathbf{a}] = \int_M \langle d^*_{\mathbf{A}}\mathbf{F}_{\mathbf{A}}, \mathbf{a}\rangle_{\mathbf{g},\mathbf{h}_{\mathrm{ad}}}\, d\lambda_{\mathbf{g}} + \int_{\partial M} \langle \iota_{\boldsymbol{\nu}}\mathbf{F}_{\mathbf{A}}, \mathbf{a}\rangle_{\mathbf{g},\mathbf{h}_{\mathrm{ad}}}\, d\sigma_{\mathbf{g}}. \tag{28.13}$$

Here $\boldsymbol{\nu}$ is the outward unit normal and

$$d^*_{\mathbf{A}}\mathbf{F} = -\operatorname{tr}_{\mathbf{g}}(\nabla^{\mathbf{A}}\mathbf{F})$$

on $\operatorname{ad}\mathbf{P}$-valued 2-forms. Contraction is performed between the derivative index and the first index of the form: for $\mathbf{X} \in T_xM$,

$$(d^*_{\mathbf{A}}\mathbf{F})(\mathbf{X}) = -\sum_{i=1}^{m} (\nabla^{\mathbf{A}}_{\mathbf{e}_i}\mathbf{F})(\mathbf{e}_i, \mathbf{X}).$$

Proof. Substituting $t\mathbf{a}$ into (28.11), the part linear in t is $d_{\mathbf{A}}\mathbf{a}$. Consequently,

$$\left.\frac{d}{dt}\right|_{t=0} \mathrm{YM}(\mathbf{A} + t\mathbf{a}) = \int_M \langle \mathbf{F}_{\mathbf{A}}, d_{\mathbf{A}}\mathbf{a}\rangle_{\mathbf{g},\mathbf{h}_{\mathrm{ad}}}\, d\lambda_{\mathbf{g}}.$$

The Green form from Chapter 9 gives the adjoint and the boundary term. To make the contraction explicit, define

$$\alpha(\mathbf{X}) := \sum_{j=1}^{m} \langle \mathbf{F}_{\mathbf{A}}(\mathbf{X}, \mathbf{e}_j), \mathbf{a}(\mathbf{e}_j)\rangle_{\mathbf{h}_{\mathrm{ad}}}.$$

In an orthonormal frame normal at the point of calculation, the Leibniz rule and antisymmetry of $\mathbf{F}_{\mathbf{A}}$ give $\operatorname{div}\alpha^\sharp = \langle \mathbf{F}_{\mathbf{A}}, d_{\mathbf{A}}\mathbf{a}\rangle - \langle d^*_{\mathbf{A}}\mathbf{F}_{\mathbf{A}}, \mathbf{a}\rangle$. Using the norm of 2-forms means that we sum once over $i < j$, rather than twice over ordered pairs. Upon integration, $\alpha(\boldsymbol{\nu}) = \langle \iota_{\boldsymbol{\nu}}\mathbf{F}_{\mathbf{A}}, \mathbf{a}\rangle$ yields exactly (28.13). □

If M has no boundary, or if the induced tangential connection on ∂M is fixed, the admissible variations make

the boundary term vanish. In the second case, we require $\iota^*\mathbf{a} = 0$, where $\iota : \partial M \hookrightarrow M$ is the inclusion; the normal component of $\mathbf{a}$ does not contribute because $(\iota_{\boldsymbol{\nu}}\mathbf{F}_{\mathbf{A}})(\boldsymbol{\nu}) = 0$. The formal L^2 representative of the differential and the interior Euler–Lagrange equation are then

$$\operatorname{grad}_{L^2} \mathrm{YM}(\mathbf{A}) = d_{\mathbf{A}}^{*}\mathbf{F}_{\mathbf{A}}, \qquad d_{\mathbf{A}}^{*}\mathbf{F}_{\mathbf{A}} = 0. \tag{28.14}$$

If the connection on the boundary may also vary freely, the critical point condition additionally includes $\iota_{\boldsymbol{\nu}}\mathbf{F}_{\mathbf{A}} = 0$ on ∂M. Interior variations first determine the Yang–Mills equation; arbitrariness of the tangential trace then determines this natural boundary condition.

To write the Hessian, we first specify the algebraic term containing the curvature. Define pointwise the endomorphism

$$\boldsymbol{\mathcal{R}}_{\mathbf{A}} \colon T^*M \otimes \operatorname{ad}\mathbf{P} \longrightarrow T^*M \otimes \operatorname{ad}\mathbf{P}$$

by

$$\langle \boldsymbol{\mathcal{R}}_{\mathbf{A}}\eta, \zeta\rangle_{\mathbf{g},\mathbf{h}_{\mathrm{ad}};x} := \langle \mathbf{F}_{\mathbf{A}}, [\eta \wedge \zeta]\rangle_{\mathbf{g},\mathbf{h}_{\mathrm{ad}};x}, \qquad \eta, \zeta \in T_x^*M \otimes (\operatorname{ad}\mathbf{P})_x.$$

The Riesz representation theorem in each fiber determines a unique $\boldsymbol{\mathcal{R}}_{\mathbf{A}}\eta$. Its coefficients are algebraic contractions of $\mathbf{F}_{\mathbf{A}}$ with the bracket on $\mathfrak{g}$, so $\boldsymbol{\mathcal{R}}_{\mathbf{A}}$ is a smooth endomorphism of order zero. For $1 \le i, j \le m$, $[\eta \wedge \zeta](\mathbf{e}_i, \mathbf{e}_j) = [\eta(\mathbf{e}_i), \zeta(\mathbf{e}_j)] - [\eta(\mathbf{e}_j), \zeta(\mathbf{e}_i)]$. Antisymmetry of the bracket implies $[\eta \wedge \zeta] = [\zeta \wedge \eta]$; thus the endomorphism $\boldsymbol{\mathcal{R}}_{\mathbf{A}}$ is symmetric in each fiber, as required for the Hessian.

Proposition 28.2.2. (Hessian and gauge-fixed operator) Let $(M, \mathbf{g})$ be a compact Riemannian manifold with or without boundary, let $\mathbf{P} \to M$ be a principal bundle with compact structure group, and let $\mathbf{A}$ be a smooth connection. For $\mathbf{a}, \mathbf{b} \in \Omega^1(M, \operatorname{ad}\mathbf{P})$,

$$D^2 \mathrm{YM}(\mathbf{A})[\mathbf{a}, \mathbf{b}] = \int_M \left(\langle d_{\mathbf{A}}\mathbf{a}, d_{\mathbf{A}}\mathbf{b}\rangle_{\mathbf{g},\mathbf{h}_{\mathrm{ad}}} + \langle \mathbf{F}_{\mathbf{A}}, [\mathbf{a} \wedge \mathbf{b}]\rangle_{\mathbf{g},\mathbf{h}_{\mathrm{ad}}} \right) d\lambda_{\mathbf{g}}. \tag{28.15}$$

If M is compact without boundary and $\mathbf{A}$ is a Yang–Mills connection, the Hessian is represented by

$$H_{\mathbf{A}}\mathbf{a} = d_{\mathbf{A}}^{*} d_{\mathbf{A}}\mathbf{a} + \boldsymbol{\mathcal{R}}_{\mathbf{A}}\mathbf{a}. \tag{28.16}$$

Moreover,

$$H_{\mathbf{A}}(d_{\mathbf{A}}\xi) = 0 \qquad \text{for every } \xi \in \Omega^0(M, \operatorname{ad}\mathbf{P}).$$

The gauge-fixed operator

$$L_{\mathbf{A}}\mathbf{a} = (d_{\mathbf{A}}^{*} d_{\mathbf{A}} + d_{\mathbf{A}} d_{\mathbf{A}}^{*})\mathbf{a} + \boldsymbol{\mathcal{R}}_{\mathbf{A}}\mathbf{a} \tag{28.17}$$

has principal symbol

$$\sigma_2(L_{\mathbf{A}})(x, \zeta) = -|\zeta|_{\mathbf{g}}^2 \, \mathrm{id}_{T_x^*M \otimes (\operatorname{ad}\mathbf{P})_x}, \qquad \zeta \in T_x^*M \setminus \{0\}. \tag{28.18}$$

Proof. Substitute $\mathbf{A} + t\mathbf{a} + s\mathbf{b}$ into (28.11). The coefficient of ts in

$$\frac{1}{2} \| \mathbf{F}_{\mathbf{A}+t\mathbf{a}+s\mathbf{b}} \|^2_{L^2(M, \Lambda^2(T^*M) \otimes \operatorname{ad}\mathbf{P})}$$

is

$$\int_M \langle d_{\mathbf{A}}\mathbf{a}, d_{\mathbf{A}}\mathbf{b}\rangle_{\mathbf{g},\mathbf{h}_{\mathrm{ad}}} \, d\lambda_{\mathbf{g}} + \int_M \langle \mathbf{F}_{\mathbf{A}}, [\mathbf{a} \wedge \mathbf{b}]\rangle_{\mathbf{g},\mathbf{h}_{\mathrm{ad}}} \, d\lambda_{\mathbf{g}},$$

which proves (28.15). When M is compact without boundary, integration by parts in the first term gives (28.16).

Let $\xi \in \Omega^0(M, \operatorname{ad}\mathbf{P})$. Gauge invariance implies, for every connection $\mathbf{B}$,

$$D\,\mathrm{YM}(\mathbf{B})[d_{\mathbf{B}}\xi] = 0.$$

Differentiate this identity at $\mathbf{B} = \mathbf{A}$ in the direction $\mathbf{b}$. The term arising from the variation of $d_{\mathbf{B}}\xi$ is multiplied by $D\,\mathrm{YM}(\mathbf{A})$ and vanishes because $\mathbf{A}$ is critical. Thus

$$D^2\,\mathrm{YM}(\mathbf{A})[\mathbf{b}, d_{\mathbf{A}}\xi] = 0$$

for every $\mathbf{b}$. Symmetry of the Hessian gives

$$H_{\mathbf{A}}(d_{\mathbf{A}}\xi) = 0.$$

Finally, for $\zeta \in T_x^*M \setminus \{0\}$,

$$\sigma_2(d_{\mathbf{A}}^* d_{\mathbf{A}})(x,\zeta) = -\iota_{\zeta^\sharp}(\zeta \wedge \cdot),$$

whereas

$$\sigma_2(d_{\mathbf{A}} d_{\mathbf{A}}^*)(x,\zeta) = -\zeta \wedge \iota_{\zeta^\sharp}(\cdot).$$

The identity

$$\iota_{\zeta^\sharp}(\zeta \wedge a) + \zeta \wedge \iota_{\zeta^\sharp} a = |\zeta|_{\mathbf{g}}^2 a$$

shows that the sum of the two symbols is $-|\zeta|_{\mathbf{g}}^2 \mathrm{id}$. Since $\boldsymbol{\mathcal{R}}_{\mathbf{A}}$ has order zero, we obtain (28.18). □

On the compact manifold without boundary, the Coulomb condition

$$d_{\mathbf{A}}^* \mathbf{a} = 0$$

selects the L^2-orthogonal complement of the infinitesimal directions $d_{\mathbf{A}}\xi$. On this subspace, the term $d_{\mathbf{A}} d_{\mathbf{A}}^* \mathbf{a}$ vanishes, so $L_{\mathbf{A}}$ agrees with the Hessian. On the full space of 1-forms, this term completes the symbol and yields an elliptic operator.

On a compact base without boundary, projection onto the Coulomb complement is obtained by solving an elliptic equation on adjoint-bundle-valued 0-forms.

Proposition 28.2.3. (Coulomb decomposition in the compact case) Let $(M, \mathbf{g})$ be a compact Riemannian manifold without boundary, let $\mathbf{P} \to M$ be a principal bundle with compact structure group, let $\mathbf{A}$ be a smooth connection, and let $s \geq 1$. Then

$$H^s(M, T^*M \otimes \operatorname{ad}\mathbf{P}) = \ker d_{\mathbf{A}}^* \oplus d_{\mathbf{A}}\left(H^{s+1}(M, \operatorname{ad}\mathbf{P}) \cap (\ker d_{\mathbf{A}})^\perp\right).$$

The two projections associated with this direct sum are continuous.

Proof. The operator

$$\Delta_{\mathbf{A}}^{(0)} := d_{\mathbf{A}}^* d_{\mathbf{A}}$$

is elliptic, nonnegative, and self-adjoint. Its resolvent maps $L^2(M,\operatorname{ad}\mathbf{P})$ continuously into $H^2(M,\operatorname{ad}\mathbf{P})$ by Corollary 11.4.4. The inclusion

$$H^2(M,\operatorname{ad}\mathbf{P}) \hookrightarrow L^2(M,\operatorname{ad}\mathbf{P})$$

is compact by Theorem 9.2.2. The spectral theorem for operators with compact resolvent provides a constant $c_{\mathbf{A}} > 0$ such that

$$\langle \Delta_{\mathbf{A}}^{(0)}\xi,\xi\rangle_{L^2(M,\operatorname{ad}\mathbf{P})} \geq c_{\mathbf{A}}\|\xi\|^2_{L^2(M,\operatorname{ad}\mathbf{P})}, \qquad \xi \in H^2(M,\operatorname{ad}\mathbf{P}) \cap (\ker d_{\mathbf{A}})^{\perp_{L^2}}.$$

Let us make the construction of the inverse precise. Let (ξ_j) be an orthonormal basis of eigensections, with $\Delta_{\mathbf{A}}^{(0)}\xi_j = \lambda_j\xi_j$. The kernel is $\ker d_{\mathbf{A}}$, since $\langle \Delta_{\mathbf{A}}^{(0)}\xi,\xi\rangle_{L^2(M,\operatorname{ad}\mathbf{P})} = \|d_{\mathbf{A}}\xi\|^2_{L^2(M,T^*M\otimes\operatorname{ad}\mathbf{P})}$. For $\mathbf{f} \in H^{s-1}(M,\operatorname{ad}\mathbf{P})$ orthogonal to this kernel, the series

$$\xi = \sum_{\lambda_j>0} \lambda_j^{-1}\langle \mathbf{f},\xi_j\rangle_{L^2(M,\operatorname{ad}\mathbf{P})}\xi_j$$

converges in $L^2(M,\operatorname{ad}\mathbf{P})$, because $\lambda_j \geq c_{\mathbf{A}} > 0$ in the sum. Moreover, $\displaystyle\sum_{j=1}^{\infty} \lambda_j^2|\langle \xi,\xi_j\rangle|^2 = \|\mathbf{f}\|^2_{L^2(M,\operatorname{ad}\mathbf{P})}$; the spectral characterization of the domain gives $\Delta_{\mathbf{A}}^{(0)}\xi = \mathbf{f}$ and $\|\xi\|_{L^2(M,\operatorname{ad}\mathbf{P})} \leq c_{\mathbf{A}}^{-1}\|\mathbf{f}\|_{L^2(M,\operatorname{ad}\mathbf{P})}$. A parametrix of order -2 and Corollary 15.6.6 give, for every real $s \geq 1$,

$$\|\xi\|_{H^{s+1}(M,\operatorname{ad}\mathbf{P})} \leq C_s\big(\|\mathbf{f}\|_{H^{s-1}(M,\operatorname{ad}\mathbf{P})} + \|\xi\|_{L^2(M,\operatorname{ad}\mathbf{P})}\big) \leq C_s'\|\mathbf{f}\|_{H^{s-1}(M,\operatorname{ad}\mathbf{P})}.$$

The same energy identity proves injectivity on the complement of the kernel. Thus

$$\Delta_{\mathbf{A}}^{(0)}\colon H^{s+1}(M,\operatorname{ad}\mathbf{P}) \cap (\ker d_{\mathbf{A}})^{\perp} \longrightarrow H^{s-1}(M,\operatorname{ad}\mathbf{P}) \cap (\ker d_{\mathbf{A}})^{\perp}$$

is a topological isomorphism. If

$$\mathbf{a} \in H^s(M, T^*M \otimes \operatorname{ad}\mathbf{P}),$$

then, for every $\eta \in \ker d_{\mathbf{A}}$,

$$\langle d_{\mathbf{A}}^*\mathbf{a},\eta\rangle_{L^2(M,\operatorname{ad}\mathbf{P})} = \langle \mathbf{a}, d_{\mathbf{A}}\eta\rangle_{L^2(M,T^*M\otimes\operatorname{ad}\mathbf{P})} = 0.$$

Therefore $d_{\mathbf{A}}^*\mathbf{a}$ belongs to the codomain of the preceding restriction. There exists a unique

$$\xi \in H^{s+1}(M,\operatorname{ad}\mathbf{P}) \cap (\ker d_{\mathbf{A}})^{\perp}$$

such that

$$\Delta_{\mathbf{A}}^{(0)}\xi = d_{\mathbf{A}}^*\mathbf{a}.$$

Set

$$\mathbf{b} := \mathbf{a} - d_{\mathbf{A}}\xi.$$

Then $d_{\mathbf{A}}^*\mathbf{b} = 0$, so $\mathbf{a} = \mathbf{b} + d_{\mathbf{A}}\xi$.
If $d_{\mathbf{A}}\xi \in \ker d_{\mathbf{A}}^*$, then

$$\|d_{\mathbf{A}}\xi\|^2_{L^2(M,T^*M\otimes\operatorname{ad}\mathbf{P})} = \langle \Delta_{\mathbf{A}}^{(0)}\xi,\xi\rangle_{L^2(M,\operatorname{ad}\mathbf{P})} = 0,$$

and hence $d_{\mathbf{A}}\xi = 0$. The sum is direct. Finally, the estimate for the inverse of $\Delta_{\mathbf{A}}^{(0)}$ proves continuity of the two projections. □

Now fix

$$s > \frac{m}{2} + 1$$

and a smooth connection $\mathbf{A}_0$. The Sobolev completion of the space of connections is the affine space

$$\mathcal{A}^s(\mathbf{P}) := \mathbf{A}_0 + H^s(M, T^*M \otimes \operatorname{ad}\mathbf{P}),$$

and

$$T_{\mathbf{A}}\mathcal{A}^s(\mathbf{P}) = H^s(M, T^*M \otimes \operatorname{ad}\mathbf{P}).$$

Identity (28.11) shows that the curvature map loses one derivative:

$$\mathcal{F}\colon \mathcal{A}^s(\mathbf{P}) \longrightarrow H^{s-1}\left(M, \Lambda^2(T^*M) \otimes \operatorname{ad}\mathbf{P}\right), \qquad \mathcal{F}(\mathbf{A}) := \mathbf{F}_{\mathbf{A}}.$$

The functional

$$\mathrm{YM}\colon \mathcal{A}^s(\mathbf{P}) \longrightarrow \mathbb{R}, \qquad \mathrm{YM}(\mathbf{A}) = \frac{1}{2}\int_M |\mathbf{F}_{\mathbf{A}}|^2_{\mathbf{g},\mathbf{h}_{\mathrm{ad}}}\, d\lambda_{\mathbf{g}},$$

is also smooth. Indeed, the linear part of $\mathcal{F}$ is a first-order differential operator, and the remaining part is quadratic. The Sobolev product estimates control $[\mathbf{a} \wedge \mathbf{a}]$, while the inclusion

$$H^{s-1}\left(M, \Lambda^2(T^*M) \otimes \operatorname{ad}\mathbf{P}\right) \hookrightarrow L^2\left(M, \Lambda^2(T^*M) \otimes \operatorname{ad}\mathbf{P}\right)$$

allows us to integrate the squared norm of the curvature.

The gauge group $\mathcal{G}^{s+1}(\mathbf{P}) = H^{s+1}(M, \mathrm{Ad}(\mathbf{P}))$ acts smoothly on $\mathcal{A}^s(\mathbf{P})$. For each smooth connection $\mathbf{A}$, the Hessian and Coulomb operators induce continuous linear maps

$$H_{\mathbf{A}}, L_{\mathbf{A}}\colon H^s(M, T^*M \otimes \operatorname{ad}\mathbf{P}) \longrightarrow H^{s-2}(M, T^*M \otimes \operatorname{ad}\mathbf{P}).$$

The Yang–Mills gradient loses two derivatives; more precisely,

$$\mathcal{Y}\colon \mathcal{A}^s(\mathbf{P}) \longrightarrow H^{s-2}(M, T^*M \otimes \operatorname{ad}\mathbf{P}), \qquad \mathcal{Y}(\mathbf{A}) := d_{\mathbf{A}}^*\mathbf{F}_{\mathbf{A}}, \tag{28.19}$$

is smooth.

Remark 28.2.4. (The noncompact case) On a complete, noncompact manifold without boundary and of bounded geometry, the compactness of the resolvent used in the preceding decomposition is no longer available. Theorem 27.4.9 assumes that G is compact, that the reference connection $\mathbf{A}_0$ has bounded geometry and finite Yang–Mills energy, and that

$$k - 1 \geq r > \frac{m}{2} + 2.$$

It also requires that the connection $\mathbf{A}$ belong to the Sobolev component under consideration and that

$$\inf \sigma_{\mathrm{e}} \left(\Delta_{\mathbf{A}}^{(0)} \restriction_{(\ker \Delta_{\mathbf{A}}^{(0)})^{\perp}} \right) > 0.$$

Under these hypotheses, one obtains a Hodge decomposition and a local slice for the action of the reduced subgroup $\mathcal{G}_{\bullet}^{r+1}(\mathbf{A}_0)$.

The range in question is that of $d_{\mathbf{A}} : H^{r+1}(M, \operatorname{ad} \mathbf{P}) \to H^r(M, T^*M \otimes \operatorname{ad} \mathbf{P})$; the complement is the kernel of $d_{\mathbf{A}}^* : H^r(M, T^*M \otimes \operatorname{ad} \mathbf{P}) \to H^{r-1}(M, \operatorname{ad} \mathbf{P})$. Orthogonality is measured in $L^2(M, T^*M \otimes \operatorname{ad} \mathbf{P})$, whereas the sum and its projections are continuous in $H^r(M, T^*M \otimes \operatorname{ad} \mathbf{P})$. The reduced subgroup is the one defined using the components of the full group in the preceding chapter. The spectral gap ensures that the range of $d_{\mathbf{A}}$ is closed and replaces the compact resolvent argument used on the compact base.

28.3 Incompressible fluids as geodesics

The third application uses a diffeomorphism group as its configuration space. Incompressibility requires these diffeomorphisms to preserve volume, and the kinetic energy defines a weak right-invariant metric on this group. The corresponding geodesic equation is the Euler equation.

Let $(M^m, \mathbf{g})$ be a compact, connected, oriented Riemannian manifold, with or without boundary, and let

$$s > \frac{m}{2} + 1.$$

Denote by $\operatorname{Diff}_{\mu}^s(M)$ the identity component of the group $\operatorname{Diff}^s(M)$ of diffeomorphisms preserving $d\lambda_{\mathbf{g}}$ and ∂M. When the boundary is empty, conditions referring to it are omitted. In this section, $\Delta_{\mathbf{g}} = \operatorname{div}_{\mathbf{g}} \nabla$ has the sign of the Laplacian on functions from the chapter on Riemannian geometry; the Hodge Laplacian $d\delta + \delta d$ used at the end is nonnegative. Define

$$\mathfrak{X}_{\mu}^s(M) := \left\{ \mathbf{u} \in H^s(M, TM) \,\middle|\, \operatorname{div}_{\mathbf{g}} \mathbf{u} = 0, \quad (\mathbf{u} \cdot \boldsymbol{\nu}) \restriction_{\partial M} = 0 \right\}. \tag{28.20}$$

The same notation $\mathfrak{X}_{\mu}^t(M)$ will be used for any $t > 1/2$, interpreting the divergence distributionally and the normal condition by means of the trace. In particular, it is defined for $t = s - 1$.

Lemma 28.3.1. (Global estimate for the Neumann problem) Let $(M, \mathbf{g})$ be a smooth compact connected Riemannian manifold, with or without boundary. For $a \geq 0$, let $f \in H^a(M)$ and, when $\partial M \neq \varnothing$, $h \in H^{a+1/2}(\partial M)$, with

$$\int_M f \, d\lambda_{\mathbf{g}} = \int_{\partial M} h \, d\sigma_{\mathbf{g}}.$$

There exists a unique mean-zero solution $q \in H^{a+2}(M)$ of $\Delta_{\mathbf{g}} q = f$, $\partial_{\boldsymbol{\nu}} q = h$, and

$$\|q\|_{H^{a+2}(M)} \leq C_a \left(\|f\|_{H^a(M)} + \|h\|_{H^{a+1/2}(\partial M)} \right). \tag{28.21}$$

When the boundary is empty, h and its norm are omitted.

Proof. Begin with $h = 0$ and mean-zero $f \in L^2(M)$. Corollary 9.6.4 makes the form $\int_M \langle \nabla v, \nabla \varphi \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}}$ coercive on the mean-zero subspace of $H^1(M)$. Theorem B.3.14, applied to the functional $\varphi \mapsto -\int_M f \varphi \, d\lambda_{\mathbf{g}}$, gives a

weak solution $v \in H^1(M)$ and

$$\|v\|_{H^1(M)} \le C\|f\|_{L^2(M)}. \tag{28.22}$$

Since f has mean zero, the weak identity holds for every $\varphi \in H^1(M)$, without any restriction on its mean or trace.

We now establish regularity up to the boundary. In an interior chart or a chart straightening the boundary, write $\omega = \sqrt{\det(\mathbf{g})}$ and $A^{ij} = \omega g^{ij}$. In a coordinate region Q, which is a ball or a half-ball, the weak identity is

$$\sum_{i,j=1}^{m} \int_Q A^{ij} \partial_j v \, \partial_i \varphi \, dx = -\int_Q \omega f \varphi \, dx. \tag{28.23}$$

Test functions need not vanish on the flat face of the half-ball; their supports remain away from the other faces. In a smaller chart, the matrix A is uniformly positive: $A^{ij}\xi_i\xi_j \ge \lambda|\xi|^2$ for some $\lambda > 0$.

Let χ be a cutoff supported away from those other faces, with $\chi = 1$ on a smaller region. For a coordinate direction α, tangential if there is a boundary, set

$$D_h^\alpha z(x) = \frac{z(x + he_\alpha) - z(x)}{h}, \qquad \varphi = -D_{-h}^\alpha(\chi^2 D_h^\alpha v).$$

For small $|h|$, this test function belongs to $H^1(Q)$ and is admissible. Changing variables in the differences gives $\int z D_{-h}^\alpha w = -\int (D_h^\alpha z) w$, while

$$D_h^\alpha(A\nabla v) = A(\cdot + he_\alpha)\nabla D_h^\alpha v + (D_h^\alpha A)\nabla v.$$

The principal term in (28.23) is therefore $\int_Q \chi^2 A^{ij}(x + he_\alpha)\partial_j D_h^\alpha v \, \partial_i D_h^\alpha v \, dx$. The remaining terms contain $\nabla\chi$, $D_h^\alpha A$, or f. We use

$$\|D_h^\alpha v\|_{L^2(\operatorname{supp}\chi)} \le \|\partial_\alpha v\|_{L^2(Q)}, \qquad \|D_h^\alpha A\|_{L^\infty(\operatorname{supp}\chi)} \le \|\partial_\alpha A\|_{L^\infty(Q)}.$$

For the term involving f, retain the difference on the test function:

$$\left| \int_Q \omega f D_{-h}^\alpha(\chi^2 D_h^\alpha v)\, dx \right| \le C\|f\|_{L^2(Q)} \big(\|\chi \nabla D_h^\alpha v\|_{L^2(Q,\mathbb{R}^m)} + \|v\|_{H^1(Q)} \big).$$

These inequalities follow from the integral formula for translations and Cauchy–Schwarz; for functions in $H^1(Q)$, they follow by the smooth approximation in Lemma 27.2.19(c), using a cutoff in a larger chart. Applying Young's inequality to each product and absorbing half the principal term yields

$$\|\chi \nabla D_h^\alpha v\|^2_{L^2(Q,\mathbb{R}^m)} \le C\big(\|f\|^2_{L^2(Q)} + \|v\|^2_{H^1(Q)} \big), \tag{28.24}$$

with C independent of h. When tested against compactly supported smooth functions, a weakly convergent subsequence of these differences has limit $\partial_\alpha \nabla v$. This gives in L^2 all second-order derivatives except, in a boundary chart, the double normal derivative.

The interior equation determines the remaining derivative:

$$A^{mm}\partial_m^2 v = \omega f - \sum_{\substack{1\le i,j\le m\\ (i,j)\neq(m,m)}} A^{ij}\partial_i\partial_j v - \sum_{i,j=1}^{m}(\partial_i A^{ij})\partial_j v. \tag{28.25}$$

All terms on the right belong to L^2, and $A^{mm}\ge\lambda$. This distributional equality proves that $\partial_m^2 v\in L^2$ on the smaller region. In an interior chart, all difference directions are allowed from the outset. A finite cover and the chosen cutoffs give $v\in H^2(M)$ and $\|v\|_{H^2(M)}\le C(\|f\|_{L^2(M)}+\|v\|_{H^1(M)})$.

For higher orders, we proceed by induction. Suppose that $f\in H^j(M)$ and that $v\in H^{j+1}(M)$ has already been obtained, with $j\ge 1$. If β is a tangential multi-index of length j, differentiate (28.23) tangentially in the distributional sense. The field $w=\partial^\beta v\in H^1(Q)$ satisfies

$$\int_Q A\nabla w\cdot\nabla\varphi\,dx = -\int_Q \partial^\beta(\omega f)\varphi\,dx + \int_Q \mathbf{G}_\beta\cdot\nabla\varphi\,dx,$$

where

$$\mathbf{G}_\beta = -\sum_{0<\gamma\le\beta}\binom{\beta}{\gamma}(\partial^\gamma A)\nabla\partial^{\beta-\gamma}v.$$

Here $\partial^\beta(\omega f)\in L^2(Q)$ and $\mathbf{G}_\beta\in H^1(Q,\mathbb{R}^m)$: each derivative of v in $\mathbf{G}_\beta$ has order at most j. The same difference quotient proof applies to w. The additional term becomes $\int_Q D_h^\alpha\mathbf{G}_\beta\cdot\nabla(\chi^2 D_h^\alpha w)\,dx$ and is estimated by

$$C\|\mathbf{G}_\beta\|_{H^1(Q,\mathbb{R}^m)}\big(\|\chi\nabla D_h^\alpha w\|_{L^2(Q,\mathbb{R}^m)}+\|w\|_{H^1(Q)}\big).$$

This gives all derivatives of order $j+2$ with at most one normal index. For the others, differentiate (28.25) j times. A derivative with $b\ge 2$ normal indices is expressed through derivatives of the same order with at most $b-1$ normal indices, derivatives of v of order at most $j+1$, and derivatives of f of order at most j. Induction on b determines them all. Combining the finitely many charts, induction on j gives

$$\|v\|_{H^{j+2}(M)}\le C_j\big(\|f\|_{H^j(M)}+\|v\|_{H^1(M)}\big),\qquad j\in\mathbb{N}_0.$$

The preceding tangential differentiations are also justified by successive differences; their distributional limits are the derivatives written above, and the bounds use only orders already obtained in the induction. For arbitrary $f\in L^2(M)$, let Tf be the mean-zero weak solution with datum $f-\overline{f}$, where $\overline{f}=\lambda_{\mathbf{g}}(M)^{-1}\int_M f\,d\lambda_{\mathbf{g}}$. We have proved that the same operator T is continuous from $H^j(M)$ to $H^{j+2}(M)$ for each integer $j\ge 0$. The interpolation in Lemma 27.2.19, applied between consecutive integers, gives $T:H^a(M)\to H^{a+2}(M)$ for every $a\ge 0$. Its weak identity remains the one defining it in $L^2(M)$.

We now treat $h\neq 0$. Theorem 14.4.18, with $p=2$ and a first-order jet, provides $b\in H^{a+2}(M)$ with

$$b|_{\partial M}=0,\qquad \partial_{\boldsymbol{\nu}} b=h,\qquad \|b\|_{H^{a+2}(M)}\le C_a\|h\|_{H^{a+1/2}(\partial M)}.$$

The theorem is formulated using the inward collar coordinate: to obtain the outward normal, prescribe the jet $(0,-h)$. The divergence identity for $b\in H^2(M)$ follows by approximation in $H^2(M)$ by smooth functions; the Laplacian converges in $L^2(M)$ and the normal derivative in $H^{1/2}(\partial M)$. Thus $\int_M(f-\Delta_{\mathbf{g}}b)\,d\lambda_{\mathbf{g}}=0$. The

function

$$q = b + T(f - \Delta_{\mathbf{g}} b) - \overline{b}$$

has the required mean, equation, and normal condition. The bounds for T, b, and $\Delta_{\mathbf{g}} : H^{a+2}(M) \to H^a(M)$ prove (28.21). If two solutions have the same data, their difference z satisfies $\int_M |\nabla z|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}} = 0$ upon using z as a weak test function. Connectedness and the zero mean imply $z = 0$. □

Proposition 28.3.2. (Neumann problem and Hodge–Leray projection) Let $(M^m, \mathbf{g})$ be a smooth compact connected oriented Riemannian manifold, with or without boundary. For $r \geq 0$ there exists a continuous linear operator

$$Q : H^r(M, TM) \longrightarrow \left\{ q \in H^{r+1}(M) \;\middle|\; \int_M q \, d\lambda_{\mathbf{g}} = 0 \right\}$$

characterized by

$$\int_M \langle \nabla Q\mathbf{X}, \nabla \varphi \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} = \int_M \langle \mathbf{X}, \nabla \varphi \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}}, \qquad \varphi \in H^1(M). \tag{28.26}$$

Set

$$\mathfrak{X}^0_\mu(M) := \left\{ \mathbf{Y} \in L^2(M, TM) \;\middle|\; \int_M \langle \mathbf{Y}, \nabla \varphi \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} = 0 \quad \forall \varphi \in H^1(M) \right\}.$$

The operator $\mathbb{P}\mathbf{X} := \mathbf{X} - \nabla Q\mathbf{X}$ is the orthogonal projection of $L^2(M, TM)$ onto $\mathfrak{X}^0_\mu(M)$, and

$$\|Q\mathbf{X}\|_{H^{r+1}(M)} + \|\mathbb{P}\mathbf{X}\|_{H^r(M,TM)} \leq C_r \|\mathbf{X}\|_{H^r(M,TM)}. \tag{28.27}$$

If $r > 1/2$, its range in $H^r(M, TM)$ is $\mathfrak{X}^r_\mu(M)$, with the definition of divergence and trace given above. In particular, for $s > m/2 + 1$ and $\mathbf{X} \in H^{s-1}(M, TM)$, $q = Q\mathbf{X} \in H^s(M)$ solves

$$\Delta_{\mathbf{g}} q = \operatorname{div}_{\mathbf{g}} \mathbf{X}, \qquad \partial_{\boldsymbol{\nu}} q = \langle \operatorname{Tr} \mathbf{X}, \boldsymbol{\nu} \rangle_{\mathbf{g}}. \tag{28.28}$$

The first equality is distributional, and the second is an equality of traces. We have the direct sum, orthogonal in $L^2(M, TM)$,

$$H^{s-1}(M, TM) = \mathfrak{X}^{s-1}_\mu(M) \oplus \nabla\big(H^s(M)/\mathbb{R}\big).$$

Moreover, Q and $\mathbb{P}$ map smooth data to data smooth up to the boundary.

Proof. For $\mathbf{X} \in L^2(M, TM)$, Poincaré and Lax–Milgram, used as in the preceding lemma, apply to the functional $\varphi \mapsto \int_M \langle \mathbf{X}, \nabla \varphi \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}}$. Its norm does not exceed $\|\mathbf{X}\|_{L^2(M,TM)}$. This yields a unique mean-zero $Q\mathbf{X}$ with $\|Q\mathbf{X}\|_{H^1(M)} \leq C\|\mathbf{X}\|_{L^2(M,TM)}$. The weak identity directly proves that $\mathbb{P}\mathbf{X} \in \mathfrak{X}^0_\mu(M)$ and that $\mathbf{X} - \mathbb{P}\mathbf{X}$ is orthogonal to this subspace. If $\mathbf{X} \in \mathfrak{X}^0_\mu(M)$, uniqueness gives $Q\mathbf{X} = 0$; thus $\mathbb{P}^2 = \mathbb{P}$ and $\mathbb{P}$ is the asserted orthogonal projection.

If $\mathbf{X} \in H^k(M, TM)$, with integer $k \geq 1$, the data $f = \operatorname{div}_{\mathbf{g}} \mathbf{X}$ and $h = \langle \operatorname{Tr} \mathbf{X}, \boldsymbol{\nu} \rangle_{\mathbf{g}}$ belong to $H^{k-1}(M)$ and $H^{k-1/2}(\partial M)$, respectively. To justify their compatibility, take $\mathbf{X}_j \in \Gamma(TM)$ with $\mathbf{X}_j \to \mathbf{X}$ in $H^1(M, TM)$, by Lemma 27.2.19. Theorem 2.14.21 holds for each $\mathbf{X}_j$. Differentiation and the trace are continuous from $H^1(M, TM)$ to $L^2(M)$ and $H^{1/2}(\partial M, TM|_{\partial M})$, respectively. Moreover,

$$\left| \int_M \operatorname{div}_{\mathbf{g}}(\mathbf{X}_j - \mathbf{X}) \, d\lambda_{\mathbf{g}} \right| \leq \lambda_{\mathbf{g}}(M)^{1/2} \| \operatorname{div}_{\mathbf{g}}(\mathbf{X}_j - \mathbf{X}) \|_{L^2(M)},$$

and the boundary integral satisfies the corresponding bound by Cauchy–Schwarz on ∂M. Both errors tend to zero. This proves the divergence formula for every vector field in $H^1(M, TM)$ and, in particular, compatibility of the specified data. The preceding lemma with $a = k - 1$ provides $q \in H^{k+1}(M)$ with $\|q\|_{H^{k+1}(M)} \le C_k \|\mathbf{X}\|_{H^k(M,TM)}$. Integration by parts gives (28.26), so $q = Q\mathbf{X}$ by uniqueness. Interpolate this same operator between $k = 0, 1, 2, \ldots$; Lemma 27.2.19 gives the bounds in Q for every $r \ge 0$. Continuity of the gradient proves those for $\mathbb{P}$.

Let us make the normal condition precise. If $r > 1/2$ and $\mathbf{Y} \in H^r(M, TM)$ has zero distributional divergence, then

$$\int_M \langle \mathbf{Y}, \nabla\varphi \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} = \int_{\partial M} \varphi \langle \operatorname{Tr} \mathbf{Y}, \boldsymbol{\nu} \rangle_{\mathbf{g}} \, d\sigma_{\mathbf{g}}, \qquad \varphi \in C^\infty(M). \tag{28.29}$$

For $r \ge 1$, this is Green's formula obtained by smooth approximation. For $1/2 < r < 1$, the construction of the trace on the half-space implies that restrictions to the collar hypersurfaces at distance t converge in $L^2(\partial M, TM|_{\partial M})$ to the trace as $t \downarrow 0$, identifying the fibers by means of the collar. In the Euclidean proof, this convergence follows by Fourier analysis in the tangential variables and Cauchy–Schwarz in the normal variable; the integral $\int_{\mathbb{R}} (1 + \xi_m^2)^{-r} \, d\xi_m$ is finite. Take a cutoff ζ_ε that is zero near the boundary, one outside the collar of width ε, and in the collar equals $\zeta(t/\varepsilon)$, with $\zeta(0) = 0$, $\zeta(1) = 1$. Applying the zero-divergence condition to $\varphi\zeta_\varepsilon$ gives

$$0 = \int_M \zeta_\varepsilon \langle \mathbf{Y}, \nabla\varphi \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} + \int_M \varphi \langle \mathbf{Y}, \nabla\zeta_\varepsilon \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}}.$$

The first term converges to the interior integral in (28.29). Convergence of the collar restrictions and $\int_0^1 \zeta'(t)\, dt = 1$ make the second term converge to the negative of the boundary integral, since the collar coordinate increases inward. This proves the remaining identity.

If $\mathbf{Y} \in \mathfrak{X}^0_\mu(M) \cap H^r(M, TM)$, test functions supported in the interior give $\operatorname{div}_{\mathbf{g}} \mathbf{Y} = 0$. The preceding identity and the extension of every smooth boundary function give $\langle \operatorname{Tr} \mathbf{Y}, \boldsymbol{\nu} \rangle_{\mathbf{g}} = 0$. Conversely, these two conditions make the right-hand side of (28.29) vanish; density of $C^\infty(M)$ in $H^1(M)$ extends the identity to all test functions in that space. This identifies the range. Applied to $\mathbf{Y} = \mathbf{X} - \nabla Q\mathbf{X}$, the same argument also gives (28.28). Finally, if $\mathbf{X}$ is smooth, the bounds at each integer order give $Q\mathbf{X} \in H^{k+1}(M)$ for every k. The Sobolev embeddings at each order prove that $Q\mathbf{X}$ and $\mathbb{P}\mathbf{X}$ are smooth up to the boundary. □

Corollary 28.3.3. (Approximation preserving incompressibility) For $r \ge 0$, smooth divergence-free vector fields tangent to ∂M are dense in $\mathfrak{X}^0_\mu(M) \cap H^r(M, TM)$. In particular, they are dense in $\mathfrak{X}^{s-1}_\mu(M)$ for $s > m/2 + 1$ and in $\mathfrak{X}^0_\mu(M)$ with the $L^2(M, TM)$ norm.

Proof. Let $\mathbf{Z}$ be an element of the indicated space. Lemma 27.2.19 provides $\mathbf{V}_j \in \Gamma(TM)$ with $\|\mathbf{V}_j - \mathbf{Z}\|_{H^r(M,TM)} \to 0$. Using the mean-zero operator from the preceding proposition, define

$$q_j = Q\mathbf{V}_j, \qquad \mathbf{Z}_j = \mathbf{V}_j - \nabla q_j = \mathbb{P}\mathbf{V}_j.$$

Each q_j and each $\mathbf{Z}_j$ is smooth up to the boundary. The Neumann equations give $\operatorname{div}_{\mathbf{g}} \mathbf{Z}_j = 0$ and $\langle \mathbf{Z}_j, \boldsymbol{\nu} \rangle_{\mathbf{g}} = 0$. Since $\mathbb{P}\mathbf{Z} = \mathbf{Z}$, the explicit estimate is

$$\|\mathbf{Z}_j - \mathbf{Z}\|_{H^r(M,TM)} = \|\mathbb{P}(\mathbf{V}_j - \mathbf{Z})\|_{H^r(M,TM)} \le C_r \|\mathbf{V}_j - \mathbf{Z}\|_{H^r(M,TM)} \longrightarrow 0.$$

□

Theorem 28.3.4. (Ebin–Marsden: the volume-preserving group) Let $(M^m, \mathbf{g})$ be a compact connected oriented Riemannian manifold, with or without boundary. If

$$s > \frac{m}{2} + 1,$$

then $\mathrm{Diff}^s_\mu(M)$ is a closed *split* Hilbert submanifold of $\mathrm{Diff}^s(M)$. For each $\eta \in \mathrm{Diff}^s_\mu(M)$, the map

$$\mathcal{I}_\eta : \mathfrak{X}^s_\mu(M) \longrightarrow T_\eta \,\mathrm{Diff}^s_\mu(M), \qquad \mathcal{I}_\eta(\mathbf{u}) := \mathbf{u} \circ \eta,$$

is a topological linear isomorphism, with inverse

$$\mathbf{U} \longmapsto \mathbf{U} \circ \eta^{-1}.$$

In particular,

$$T_{\mathrm{id}} \,\mathrm{Diff}^s_\mu(M) = \mathfrak{X}^s_\mu(M).$$

The submanifold structure is proved in Theorems 4.2 and 8.1 of [46, pp. 114 and 123]. The identification of the tangent space follows from right translation and the Sobolev composition theorem for a fixed diffeomorphism.

The weak right-invariant kinetic metric is

$$\mathbf{G}_\eta(\mathbf{U}, \mathbf{V}) = \int_M \left\langle \mathbf{U} \circ \eta^{-1}, \mathbf{V} \circ \eta^{-1} \right\rangle_{\mathbf{g}} d\lambda_{\mathbf{g}}. \tag{28.30}$$

Since η preserves volume, a change of variables transforms this formula into

$$\mathbf{G}_\eta(\mathbf{U}, \mathbf{V}) = \int_M \mathbf{g}_{\eta(x)}(\mathbf{U}(x), \mathbf{V}(x))\, d\lambda_{\mathbf{g}}(x).$$

Smooth dependence of this metric is verified in the latter expression by superposition and products, without assuming smoothness of inversion on $\mathrm{Diff}^s(M)$. For a curve $\eta(t)$, define its Eulerian velocity by

$$\mathbf{u}(t) := \dot\eta(t) \circ \eta(t)^{-1}.$$

The kinetic action is

$$\mathcal{A}(\eta) := \frac{1}{2} \int_{t_0}^{t_1} \int_M |\mathbf{u}(t,x)|^2_{\mathbf{g}}\, d\lambda_{\mathbf{g}}\, dt. \tag{28.31}$$

Proposition 28.3.5. (Euler as a geodesic equation) Let $(M^m, \mathbf{g})$ be a smooth compact connected oriented Riemannian manifold, with or without boundary, and let $s > m/2 + 1$. A curve $\eta \in C^2([t_0, t_1], \mathrm{Diff}^s_\mu(M))$, with fixed endpoints, is critical for (28.31) if and only if its Eulerian velocity satisfies

$$\partial_t \mathbf{u} + \nabla_{\mathbf{u}} \mathbf{u} = -\nabla p, \qquad \mathrm{div}_{\mathbf{g}}\, \mathbf{u} = 0, \qquad \langle \mathrm{Tr}\, \mathbf{u}, \boldsymbol{\nu} \rangle_{\mathbf{g}} = 0 \quad \text{on } \partial M. \tag{28.32}$$

Here

$$\mathbf{u} \in C([t_0, t_1], H^s(M, TM)) \cap C^1([t_0, t_1], H^{s-1}(M, TM)), \qquad p \in C([t_0, t_1], H^s(M)),$$

and the first equation is interpreted in $H^{s-1}(M, TM)$. The pressure is determined at each time up to a spatial constant; the normalization $\int_M p(t,x)\, d\lambda_{\mathbf{g}}(x) = 0$ makes it unique. The boundary condition is omitted when

$\partial M = \varnothing$.

Proof. Write $I = [t_0, t_1]$. We use variations of class C^2 in (ε, t) with values in $\mathrm{Diff}^s_\mu(M)$ and fixed endpoints. Continuous composition from Lemma 27.5.2 and continuous inversion from Theorem 27.5.1 give $\mathbf{u} = \dot\eta \circ \eta^{-1} \in C(I, H^s(M, TM))$. The embedding $H^s(M, TM) \hookrightarrow C^1(M, TM)$ allows us to differentiate the identity $\dot\eta = \mathbf{u} \circ \eta$ pointwise. This gives

$$\partial_t \mathbf{u} = (\nabla_t \dot\eta) \circ \eta^{-1} - \nabla_{\mathbf{u}} \mathbf{u}. \tag{28.33}$$

The covariant acceleration $\nabla_t \dot\eta$ is continuous in the space of sections $H^s(M, \eta(t)^* TM)$ along η: in coordinates, its components are $\ddot\eta^a + \sum_{b,c=1}^{m} \Gamma^a_{bc}(\eta)\dot\eta^b \dot\eta^c$. Superposition and the product estimate in Lemma 27.2.19 control each term. By (27.9), the right-hand side of (28.33) is continuous in $H^{s-1}(M, TM)$. The last part of Lemma 27.5.2, or its proof using the Bochner integral of this right-hand side, gives $\mathbf{u} \in C^1(I, H^{s-1}(M, TM))$. Thus this regularity follows from the given curve, before imposing the Euler equation.

Let η_ε be an admissible variation, and set

$$\mathbf{W}(t) = \partial_\varepsilon \eta_\varepsilon(t)\big|_0, \qquad \mathbf{w} = \mathbf{W} \circ \eta^{-1}.$$

The tangent-space identification in Theorem 28.3.4 implies $\mathbf{w}(t) \in \mathfrak{X}^s_\mu(M)$ and $\mathbf{w}(t_0) = \mathbf{w}(t_1) = 0$. The same argument applied to $\mathbf{W}$ shows that

$$\mathbf{w} \in C(I, H^s(M, TM)) \cap C^1(I, H^{s-1}(M, TM)), \quad \partial_t \mathbf{w} = (\nabla_t \mathbf{W}) \circ \eta^{-1} - \nabla_{\mathbf{u}} \mathbf{w}.$$

Conversely, let $\mathbf{w}$ be smooth in $I \times M$, divergence-free, tangent to the boundary, and zero at the temporal endpoints. For each t, take the flow φ^t_ε of the spatial vector field $\mathbf{w}(t, \cdot)$. Theorem 1.8.15 and the dependence of ODEs on parameters give a common interval in ε and smooth dependence on (ε, t, x); a common choice is possible because $I \times M$ is compact. Tangency makes the boundary invariant by uniqueness of the flow, and Lie's formula for the volume form gives

$$\frac{d}{d\varepsilon} (\varphi^t_\varepsilon)^* d\lambda_{\mathbf{g}} = (\varphi^t_\varepsilon)^* ((\mathrm{div}_{\mathbf{g}} \mathbf{w}(t)) d\lambda_{\mathbf{g}}) = 0.$$

Moreover, $\mathbf{w}(t_i) = 0$ implies $\varphi^{t_i}_\varepsilon = \mathrm{id}$ for $i = 0, 1$. By smooth superposition,

$$\eta_\varepsilon(t) = \varphi^t_\varepsilon \circ \eta(t)$$

is an admissible variation of class C^2 with Eulerian vector field $\mathbf{w}$. The path in ε starting at $\eta(t)$ ensures that it remains in the identity component.

We now differentiate the velocity of a general variation. The version of the preceding calculation with parameter ε proves the existence of $\delta\mathbf{u} = \partial_\varepsilon \mathbf{u}_\varepsilon|_0$ in $C(I, H^{s-1}(M, TM))$. Differentiate $\dot\eta_\varepsilon = \mathbf{u}_\varepsilon \circ \eta_\varepsilon$ and $\mathbf{W} = \mathbf{w} \circ \eta$ covariantly. This gives

$$\nabla_\varepsilon \dot\eta_\varepsilon\big|_0 = (\delta\mathbf{u} + \nabla_{\mathbf{w}} \mathbf{u}) \circ \eta, \qquad \nabla_t \mathbf{W} = (\partial_t \mathbf{w} + \nabla_{\mathbf{u}} \mathbf{w}) \circ \eta.$$

The Levi–Civita connection is torsion-free, and the mixed derivatives of η_ε commute. The two left-hand

sides are equal, and we obtain Lin's identity

$$\delta\mathbf{u} = \partial_t \mathbf{w} + [\mathbf{u},\mathbf{w}] = \partial_t \mathbf{w} + \nabla_{\mathbf{u}}\mathbf{w} - \nabla_{\mathbf{w}}\mathbf{u} \quad \text{in } C(I, H^{s-1}(M,TM)). \tag{28.34}$$

All contractions belong to this space by (27.9).
The functional $\mathbf{v} \mapsto \frac{1}{2}\|\mathbf{v}\|^2_{L^2(M,TM)}$ is differentiable, and $H^{s-1}(M,TM) \hookrightarrow L^2(M,TM)$. The preceding differentiation, uniform on the compact interval I, allows differentiation under the time integral:

$$\delta\mathcal{A} = \int_I \int_M \langle \mathbf{u}, \delta\mathbf{u}\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}}\, dt.$$

Since $\mathbf{u}$ and $\mathbf{w}$ are curves of class C^1 in $L^2(M,TM)$, the product rule in that space gives

$$\int_I \int_M \langle \mathbf{u}, \partial_t \mathbf{w}\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}}\, dt = -\int_I \int_M \langle \partial_t \mathbf{u}, \mathbf{w}\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}}\, dt.$$

The endpoint term is zero because $\mathbf{w}(t_i) = 0$. For spatial integration, we directly use $\mathbf{u}(t), \mathbf{w}(t) \in C^1(M,TM)$, metric compatibility, and the divergence formula in $H^1(M,TM)$ justified in Proposition 28.3.2. The vector fields to which it is applied even belong to $H^s(M,TM)$ by the product estimate. Indeed,

$$\begin{aligned} \operatorname{div}_{\mathbf{g}}(\langle \mathbf{u},\mathbf{w}\rangle_{\mathbf{g}}\mathbf{u}) &= \langle \nabla_{\mathbf{u}}\mathbf{u}, \mathbf{w}\rangle_{\mathbf{g}} + \langle \mathbf{u}, \nabla_{\mathbf{u}}\mathbf{w}\rangle_{\mathbf{g}}, \\ \operatorname{div}_{\mathbf{g}}(\tfrac{1}{2}|\mathbf{u}|^2_{\mathbf{g}}\mathbf{w}) &= \langle \mathbf{u}, \nabla_{\mathbf{w}}\mathbf{u}\rangle_{\mathbf{g}}. \end{aligned}$$

We have used $\operatorname{div}_{\mathbf{g}}\mathbf{u} = \operatorname{div}_{\mathbf{g}}\mathbf{w} = 0$. The normal fluxes of both displayed vector fields are zero. Consequently,

$$\begin{aligned} \int_M \langle \mathbf{u}, \nabla_{\mathbf{u}}\mathbf{w}\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}} &= -\int_M \langle \nabla_{\mathbf{u}}\mathbf{u}, \mathbf{w}\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}}, \\ -\int_M \langle \mathbf{u}, \nabla_{\mathbf{w}}\mathbf{u}\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}} &= -\tfrac{1}{2}\int_M \mathbf{w}(|\mathbf{u}|^2_{\mathbf{g}})\, d\lambda_{\mathbf{g}} = 0. \end{aligned}$$

Thus

$$\delta\mathcal{A} = -\int_I \int_M \langle \mathbf{F}(t), \mathbf{w}(t)\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}}\, dt, \qquad \mathbf{F} = \partial_t \mathbf{u} + \nabla_{\mathbf{u}}\mathbf{u} \in C(I, H^{s-1}(M,TM)). \tag{28.35}$$

Suppose that η is critical. For a smooth vector field $\mathbf{Z} \in \mathfrak{X}^s_\mu(M)$ and $\chi \in C^\infty_c((t_0,t_1))$, the vector field $\mathbf{w}(t,x) = \chi(t)\mathbf{Z}(x)$ arises from the variation constructed above. By (28.35),

$$\int_{t_0}^{t_1} \chi(t)\langle \mathbf{F}(t), \mathbf{Z}\rangle_{L^2(M,TM)}\, dt = 0.$$

The scalar function obtained by pairing is continuous. The fundamental lemma of the calculus of variations makes it vanish on (t_0,t_1), and continuity makes it vanish at the endpoints as well. Fix $t \in I$. By Corollary 28.3.3, there exist smooth vector fields $\mathbf{Z}_j \in \mathfrak{X}^s_\mu(M)$ with

$$\mathbf{Z}_j \longrightarrow \mathbb{P}\mathbf{F}(t) \quad \text{in } H^{s-1}(M,TM).$$

By Cauchy–Schwarz and orthogonality of $\mathbb{P}$,

$$0 = \lim_{j\to\infty} \langle \mathbf{F}(t), \mathbf{Z}_j\rangle_{L^2(M,TM)} = \langle \mathbf{F}(t), \mathbb{P}\mathbf{F}(t)\rangle_{L^2(M,TM)} = \|\mathbb{P}\mathbf{F}(t)\|^2_{L^2(M,TM)}.$$

Thus $\mathbf{F}(t) = \nabla Q\mathbf{F}(t)$. Define $p(t) = -Q\mathbf{F}(t)$. Proposition 28.3.2 gives the equation, the zero mean, and, for $t,\tau \in I$,

$$\|p(t) - p(\tau)\|_{H^s(M)} \le C_{s-1}\|\mathbf{F}(t) - \mathbf{F}(\tau)\|_{H^{s-1}(M,TM)}.$$

This proves continuity of the pressure in time. If two pressures produce the same equation, their difference has zero gradient; by connectedness it is constant, and its zero mean makes it vanish.
Conversely, suppose that (28.32). For every admissible variation, $\mathbf{w}(t) \in \mathfrak{X}^0_\mu(M)$ and $p(t) \in H^s(M) \subseteq H^1(M)$. The definition of $\mathfrak{X}^0_\mu(M)$ implies $\int_M \langle \nabla p(t), \mathbf{w}(t)\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}} = 0$. Substituting $\mathbf{F} = -\nabla p$ into (28.35) gives $\delta\mathcal{A} = 0$. □

The subspace $\mathfrak{X}^0_\mu(M)$ is closed in $L^2(M,TM)$, since it is the intersection of the kernels of the continuous functionals $\mathbf{v} \mapsto \langle \mathbf{v}, \nabla\varphi\rangle_{L^2(M,TM)}$, with $\varphi \in H^1(M)$. Since $\mathbf{u}(t)$ belongs to this subspace, so do its difference quotients. Their convergence to $\partial_t\mathbf{u}(t)$ in $H^{s-1}(M,TM)$, and hence in $L^2(M,TM)$, gives $\partial_t\mathbf{u}(t) \in \mathfrak{X}^{s-1}_\mu(M)$. Thus $\mathbb{P}\partial_t\mathbf{u} = \partial_t\mathbf{u}$ and $Q\partial_t\mathbf{u} = 0$. Applying $\mathbb{P}$ to (28.32) eliminates the pressure gradient and gives the reduced equation

$$\partial_t\mathbf{u} = -\mathbb{P}(\nabla_{\mathbf{u}}\mathbf{u}). \tag{28.36}$$

For $\mathbf{X} = \nabla_{\mathbf{u}}\mathbf{u}$, let q be the function from Proposition 28.3.2. The identity

$$\nabla_{\mathbf{u}}\mathbf{u} = \mathbb{P}(\nabla_{\mathbf{u}}\mathbf{u}) + \nabla q,$$

, substituted into (28.36), shows that $p = -q$ and that

$$\Delta_{\mathbf{g}} p = -\operatorname{div}_{\mathbf{g}}(\nabla_{\mathbf{u}}\mathbf{u}), \qquad \partial_\nu p = -\langle \nabla_{\mathbf{u}}\mathbf{u}, \nu\rangle_{\mathbf{g}}.$$

In Eulerian coordinates, for the fixed metric $\mathbf{g}$ and the boundary conditions incorporated in $\mathbb{P}_{\mathbf{g}}$, the right-hand side defines the smooth quadratic map

$$\mathscr{E}_{\mathbf{g}} \colon \mathfrak{X}^s_\mu(M) \longrightarrow \mathfrak{X}^{s-1}_\mu(M), \qquad \mathscr{E}_{\mathbf{g}}(\mathbf{u}) := -\mathbb{P}_{\mathbf{g}}(\nabla_{\mathbf{u}}\mathbf{u}).$$

Since

$$s - 1 > \frac{m}{2},$$

the Sobolev product estimate gives

$$\|\nabla_{\mathbf{u}}\mathbf{u}\|_{H^{s-1}(M,TM)} \le C_{M,\mathbf{g},s}\|\mathbf{u}\|^2_{H^s(M,TM)}.$$

Proposition 28.3.2 proves continuity of $\mathbb{P}_{\mathbf{g}}$ on $H^{s-1}(M,TM)$. Thus the Eulerian formulation loses one derivative. Its linearization along a solution is

$$\partial_t\mathbf{v} + \nabla_{\mathbf{u}}\mathbf{v} + \nabla_{\mathbf{v}}\mathbf{u} = -\nabla q, \qquad \operatorname{div}_{\mathbf{g}}\mathbf{v} = 0, \qquad (\mathbf{v}\cdot\nu)\restriction_{\partial M} = 0. \tag{28.37}$$

Proposition 28.3.6. (Regularity of the pressure) Under the hypotheses of Proposition 28.3.5, for each $\mathbf{u} \in \mathfrak{X}^s_\mu(M)$ the mean-zero function

$$p(\mathbf{u}) = -Q(\nabla_{\mathbf{u}}\mathbf{u})$$

belongs to $H^{s+1}(M)$. If $\mathrm{II}_{\mathrm{ext}}(\mathbf{V},\mathbf{W}) = \langle \nabla_{\mathbf{V}}\boldsymbol{\nu}, \mathbf{W}\rangle_{\mathbf{g}}$ for vectors tangent to the boundary, then

$$\Delta_{\mathbf{g}} p(\mathbf{u}) = -\sum_{i,j=1}^{m} (\nabla_i u^j)(\nabla_j u^i) - \mathrm{Ric}_{\mathbf{g}}(\mathbf{u},\mathbf{u}), \tag{28.38}$$

$$\partial_{\boldsymbol{\nu}} p(\mathbf{u}) = \mathrm{II}_{\mathrm{ext}}(\mathrm{Tr}\,\mathbf{u}, \mathrm{Tr}\,\mathbf{u}). \tag{28.39}$$

The interior datum belongs to $H^{s-1}(M)$ and the boundary datum to $H^{s-1/2}(\partial M)$. There exist constants C_s, C_s' such that

$$\|p(\mathbf{u})\|_{H^{s+1}(M)} + \|\nabla p(\mathbf{u})\|_{H^s(M,TM)} \le C_s \|\mathbf{u}\|^2_{H^s(M,TM)}, \tag{28.40}$$

$$\|p(\mathbf{u}) - p(\mathbf{v})\|_{H^{s+1}(M)} \le C_s'\big(\|\mathbf{u}\|_{H^s(M,TM)} + \|\mathbf{v}\|_{H^s(M,TM)}\big)\|\mathbf{u}-\mathbf{v}\|_{H^s(M,TM)}. \tag{28.41}$$

In particular, the normalized pressure of an Euler solution belongs to $C(I, H^{s+1}(M))$.

Proof. Begin with a smooth divergence-free vector field tangent to the boundary. In an orthonormal frame normal at the point of calculation, write $\nabla_i u^j = \langle \nabla_{\mathbf{e}_i}\mathbf{u}, \mathbf{e}_j\rangle_{\mathbf{g}}$. The Leibniz rule gives

$$\mathrm{div}_{\mathbf{g}}(\nabla_{\mathbf{u}}\mathbf{u}) = \sum_{i,j=1}^{m} (\nabla_i u^j)(\nabla_j u^i) + \sum_{i,j=1}^{m} u^j \nabla_i \nabla_j u^i.$$

The definition of curvature as a commutator implies

$$\sum_{i=1}^{m} \nabla_i \nabla_j u^i = \nabla_j \left(\sum_{i=1}^{m} \nabla_i u^i \right) + \sum_{k=1}^{m} \mathrm{Ric}_{kj}\, u^k.$$

Multiplying by u^j and summing, the first part vanishes because $\mathrm{div}_{\mathbf{g}}\,\mathbf{u} = 0$. We obtain

$$\mathrm{div}_{\mathbf{g}}(\nabla_{\mathbf{u}}\mathbf{u}) = \sum_{i,j=1}^{m} (\nabla_i u^j)(\nabla_j u^i) + \mathrm{Ric}_{\mathbf{g}}(\mathbf{u},\mathbf{u}).$$

On the boundary, differentiate $\langle \mathbf{u}, \boldsymbol{\nu}\rangle_{\mathbf{g}} = 0$ tangentially in the direction $\mathbf{u}$ and use metric compatibility:

$$0 = \langle \nabla_{\mathbf{u}}\mathbf{u}, \boldsymbol{\nu}\rangle_{\mathbf{g}} + \langle \mathbf{u}, \nabla_{\mathbf{u}}\boldsymbol{\nu}\rangle_{\mathbf{g}}.$$

This gives both pressure data in the smooth case.

For a vector field $\mathbf{u} \in \mathfrak{X}^s_\mu(M)$, Corollary 28.3.3 gives smooth vector fields $\mathbf{u}_j \in \mathfrak{X}^s_\mu(M)$ converging in $H^s(M,TM)$. Let $f(\mathbf{u})$ and $h(\mathbf{u})$ be the right-hand sides of (28.38) and (28.39). The contraction defining f is independent of the frame, as the smooth identity shows. Lemma 27.2.19, with $s-1 > m/2$, gives

$$\|f(\mathbf{u})\|_{H^{s-1}(M)} \le C_s \|\mathbf{u}\|^2_{H^s(M,TM)},$$

$$\|f(\mathbf{u}_j)-f(\mathbf{u})\|_{H^{s-1}(M)} \le C_s\big(\|\mathbf{u}_j\|_{H^s(M,TM)}+\|\mathbf{u}\|_{H^s(M,TM)}\big)\|\mathbf{u}_j-\mathbf{u}\|_{H^s(M,TM)}.$$

To verify the second bound, simply decompose each difference of products as $(A_j-A)B_j+A(B_j-B)$ and use the first product estimate. On the other hand, $\nabla_{\mathbf{u}_j}\mathbf{u}_j \to \nabla_{\mathbf{u}}\mathbf{u}$ in $H^{s-1}(M,TM)$, so their divergences converge in $H^{s-2}(M)$. The smooth identity and the stronger convergence of the $f(\mathbf{u}_j)$ identify, in the distributional sense, $-\operatorname{div}_{\mathbf{g}}(\nabla_{\mathbf{u}}\mathbf{u}) = f(\mathbf{u})$.
The continuous trace from Theorem 14.5.9 gives

$$\operatorname{Tr}\mathbf{u}_j \to \operatorname{Tr}\mathbf{u} \quad \text{in } H^{s-1/2}(\partial M, TM|_{\partial M}).$$

Since $s-1/2 > (m-1)/2$, the same product lemma, now on ∂M, yields

$$\|h(\mathbf{u})\|_{H^{s-1/2}(\partial M)} \le C_s\|\mathbf{u}\|^2_{H^s(M,TM)},$$
$$\|h(\mathbf{u}_j)-h(\mathbf{u})\|_{H^{s-1/2}(\partial M)} \le C_s\big(\|\mathbf{u}_j\|_{H^s(M,TM)}+\|\mathbf{u}\|_{H^s(M,TM)}\big)\|\mathbf{u}_j-\mathbf{u}\|_{H^s(M,TM)}.$$

The trace of $\nabla_{\mathbf{u}_j}\mathbf{u}_j$ converges in $H^{s-3/2}(\partial M, TM|_{\partial M})$, since $s-1>1/2$. Taking limits in the smooth boundary identity gives $-\langle \operatorname{Tr}(\nabla_{\mathbf{u}}\mathbf{u}), \boldsymbol{\nu}\rangle_{\mathbf{g}} = h(\mathbf{u})$, with the higher regularity just proved. If $m=1$, the boundary is finite and its spaces of sections are finite-dimensional; the same conclusion is immediate.
For each j, the divergence formula gives $\int_M f(\mathbf{u}_j)\,d\lambda_{\mathbf{g}} = \int_{\partial M} h(\mathbf{u}_j)\,d\sigma_{\mathbf{g}}$. The preceding convergences allow us to take limits in both integrals. Thus the data $f(\mathbf{u}), h(\mathbf{u})$ satisfy Neumann compatibility. Lemma 28.3.1, with $a=s-1$, gives a mean-zero solution in $H^{s+1}(M)$ and the bound (28.40). By weak uniqueness, it agrees with $-Q(\nabla_{\mathbf{u}}\mathbf{u})$. Applying the same Neumann estimate to differences of the data, with the product bounds already written, proves (28.41). This last inequality, applied to $\mathbf{u}(t)$ and $\mathbf{u}(\tau)$, proves continuity in time in $H^{s+1}(M)$. Finally, $\nabla_t\dot\eta = -(\nabla p)\circ\eta$ by (28.33), and the Lagrangian acceleration takes values at the $H^s(M,\eta^*TM)$ level of sections. □

In Lagrangian coordinates, this loss disappears from the geodesic vector field. The spray is a smooth map

$$\mathbf{S}\colon T\operatorname{Diff}^s_\mu(M) \longrightarrow T\big(T\operatorname{Diff}^s_\mu(M)\big), \qquad T\pi\circ\mathbf{S} = \mathrm{id}_{T\operatorname{Diff}^s_\mu(M)}.$$

Besides the preceding gain, differentiable dependence on η is needed. An estimate at a single point does not suffice for this. Precisely, the Ebin–Marsden result constructs the projection on the tangent bundles by means of the Neumann problem conjugated by Lagrangian charts, and proves that this projection depends smoothly on the chart. Differentiation is performed on operators between fixed spaces; for their inverses, one uses $D(B^{-1})[H] = -B^{-1}HB^{-1}$. The highest-order terms arising when differentiating composition combine with those from the projection. The cancellation expressed by the preceding divergence and boundary identities allows the acceleration to be estimated in $H^s(M,\eta^*TM)$. The precise result, including the boundary, is that of [46, Theorems 10.2 and 11.1, pp. 134–135]; it provides the smooth connection and the displayed spray, not merely a formal operator with a loss of derivatives.

In a tangent bundle chart, the spray has the form $\mathbf{S}(x,v) = (v, \mathcal{Q}(x,v))$, with $\mathcal{Q}$ smooth and quadratic in v. In a neighborhood of each initial datum, its differential is bounded, by continuity at that datum; the mean value formula makes it locally Lipschitz. The ODE theorem from the chapter on Banach flows therefore provides an interval $(-T,T)$ and a unique Lagrangian solution with the prescribed initial datum. Its Eulerian velocity belongs to $C((-T,T),\mathfrak{X}^s_\mu(M)) \cap C^1((-T,T),\mathfrak{X}^{s-1}_\mu(M))$. That theorem is not applied directly to the right-hand side of (28.36),

whose codomain has one fewer order of regularity. Theorem 12.1 of [46, p. 137] treats propagation of additional regularity separately.

The pressure is recovered by taking the divergence in (28.32). The resulting equation is a Neumann problem, whose boundary condition comes from the normal component of Euler's equation. This elliptic problem is local in time, but local existence does not imply completeness of the kinetic metric or global control of solutions. In dimension three, global continuation of a smooth solution is a question distinct from the geodesic interpretation.

On the complete manifold without boundary, let $\Delta_1 = d\delta + \delta d$ be the nonnegative Hodge Laplacian on $L^2(M, T^*M)$, with its self-adjoint realization. Here δ is the formal adjoint of d, and the complement of $\ker \Delta_1$ is taken in $L^2(M, T^*M)$.

Theorem 28.3.7. (Eichhorn–Schmid: Euler on a noncompact base) Let $(M^m, \mathbf{g})$ be smooth, oriented, complete, connected, noncompact, and without boundary, with bounded geometry of order k. Suppose that

$$\inf \sigma_{\mathrm{e}} \left(\Delta_1 \restriction_{(\ker \Delta_1)^\perp} \right) > 0, \qquad k > r > \frac{m}{2} + 1, \qquad k, r \in \mathbb{N}.$$

The identity component $\mathcal{D}^{2,r}_{\mu,0}(M)$ of the group of volume-preserving Sobolev diffeomorphisms is a split submanifold of class C^{k+1-r} of $\mathcal{D}^{2,r}_0(M)$. Each datum $\mathbf{u}_0 \in H^r(M, TM)$ with $\operatorname{div}_{\mathbf{g}} \mathbf{u}_0 = 0$ determines a unique local Euler solution, with

$$\mathbf{u} \in C((-T, T), H^r(M, TM)) \cap C^1((-T, T), H^{r-1}(M, TM)), \qquad \mathbf{u}(0) = \mathbf{u}_0,$$

for some $T > 0$. The pressure is chosen in $H^{r+1}(M)$; its differential therefore belongs to the closed range of $d : H^1(M) \to L^2(M, T^*M)$. This condition is part of the class of solutions in which uniqueness is asserted. No mean normalization is imposed on the base of infinite volume. If the geometry is bounded to all orders, the kinetic metric has a smooth connection and spray on this submanifold. In that case, its Lagrangian flow is the flow of a smooth ODE on the Hilbert tangent bundle.

Proof. The hypothesis $k > r$ allows us to use the diffeomorphism manifold from Theorem 27.5.3; in particular, $k + 1 - r \geq 2$. The submanifold result for the volume form is [56, Theorem 3.3], applied to the identity component. The spectral condition provides closed range for the Hodge operators and a complement to the directions changing volume. The norms and topology are those of the Sobolev charts at the identity; there is no need to extend to all maps a uniformity with radii independent of their bounds.

Let $\gamma > 0$ be a gap constant for Δ_1 on $(\ker \Delta_1)^\perp$, and let $\Delta_0 = \delta d = -\Delta_{\mathbf{g}}$ in $L^2(M)$. If $v \in C^\infty_c(M)$, the form dv is orthogonal to the kernel of Δ_1, and commutation of d with the Hodge Laplacians gives

$$\|\Delta_0 v\|^2_{L^2(M)} = \langle \Delta_1 dv, dv \rangle_{L^2(M, T^*M)} \geq \gamma \|dv\|^2_{L^2(M, T^*M)} = \gamma \langle \Delta_0 v, v \rangle_{L^2(M)}.$$

Theorem 12.1.10 states that $C^\infty_c(M)$ is a core for Δ_0. Thus, for $v \in \mathcal{D}(\Delta_0)$, choose $v_j \in C^\infty_c(M)$ with $v_j \to v$ and $\Delta_0 v_j \to \Delta_0 v$ in $L^2(M)$. The squared norms and inner product in the preceding inequality converge, so it holds for $v \in \mathcal{D}(\Delta_0)$. If E_0 is the spectral resolution of Δ_0, this inequality is

$$\int_{[0,\infty)} \lambda(\lambda - \gamma)\, d\langle E_0(\lambda) v, v \rangle_{L^2(M)} \geq 0.$$

A nonzero spectral projection on a compact interval $[a, b] \subset (0, \gamma)$ would give a nonzero vector in $\mathcal{D}(\Delta_0)$ for

which the integral is strictly negative. All such projections therefore vanish, and $\sigma(\Delta_0) \subseteq \{0\} \cup [\gamma, \infty)$. The volume of a connected noncompact manifold of bounded geometry is infinite: one can choose infinitely many disjoint balls of a common radius with volumes bounded below. A function in $L^2(M)$ in the kernel of Δ_0 has zero gradient and is constant, hence zero. Since an isolated point in the spectrum of a self-adjoint operator is an eigenvalue, zero does not belong to its spectrum either. Thus Δ_0^{-1} is bounded on $L^2(M)$.
The Hodge decomposition and uniform elliptic estimates give

$$\mathbb{P}\mathbf{X} = \mathbf{X} - \big(d\Delta_0^{-1}\delta(\mathbf{X}^\flat)\big)^\sharp.$$

This projection is continuous on $H^{r-1}(M, TM)$ and $H^r(M, TM)$. For $\mathbf{X} = \nabla_{\mathbf{u}}\mathbf{u}$, take

$$p = -\Delta_0^{-1}\delta\big((\nabla_{\mathbf{u}}\mathbf{u})^\flat\big).$$

The divergence cancellation computed above places the argument of Δ_0^{-1} in $H^{r-1}(M)$; the elliptic estimate gives $p \in H^{r+1}(M)$. The local bounds are summed over a uniform cover of finite multiplicity, and the gap controls the norm of the inverse on $L^2(M)$. This choice preserves orthogonality between the pressure and divergence-free vector fields. Allowing the gradient of an arbitrary harmonic potential, without requiring it to come from a function in $L^2(M)$, would change the class of solutions and is not the pressure condition used in this theorem.
Existence and uniqueness for geometry of finite order is the analytic result of [56, Corollary 4.6], in the strict range adopted here. Continuity in $H^r(M, TM)$ is part of that solution; the projected equation and continuity of the product $H^r(M, TM) \times H^r(M, TM) \to H^{r-1}(M, TM)$ give the continuous time derivative in $H^{r-1}(M, TM)$. This assertion does not presuppose that an atlas of finite regularity is a smooth atlas.
With geometric bounds at all orders, the charts, the pointwise connection operator, and the conjugated Hodge projection have continuous derivatives of all orders in the Sobolev charts. The construction in [56, §4] then gives a smooth connection and spray on $T\mathcal{D}^{2,r}_{\mu,0}(M)$. The ODE argument already explained applies on the tangent bundle modeled on $H^r(M, TM)$: the spray is, in particular, C^1 and locally Lipschitz. Its projection is a Lagrangian curve η of class C^2, with $\eta(0) = \mathrm{id}$ and $\dot\eta(0) = \mathbf{u}_0$. The equality $\mathbf{u} = \dot\eta \circ \eta^{-1}$ recovers the preceding solution, and uniqueness of the ODE implies Lagrangian uniqueness. The result with finite geometric bounds and the interpretation through a smooth spray are thus formulated with their respective hypotheses. □

Loss of regularity and choice of variables

The three examples show that a variational formulation does not by itself determine the appropriate function space. In the harmonic map problem, the tension field contains two derivatives of the map. In Yang–Mills theory, the curvature loses one derivative and the gradient $d^*_{\mathbf{A}}\mathbf{F}_{\mathbf{A}}$ loses two. In Euler's equation, the Eulerian expression loses one derivative, whereas Lagrangian variables produce a smooth spray in the compact case and in the noncompact version with geometric bounds of all orders specified above.

Symmetries also determine the form of the analysis. Gauge invariance requires separating the directions $d_{\mathbf{A}}\xi$; invariance under reparametrizations leads to working on a diffeomorphism group; and ellipticity controls local regularity, but does not by itself provide global compactness. On a noncompact manifold, uniform conditions and often spectral hypotheses enter the picture.

A strong metric may change the representative of a differential within the chosen tangent space, but it does not eliminate the loss of regularity of the original geometric operator. This distinction between the energy level, the geometric level, and the level at which the equation lives will be essential in the variational applications of the following chapters.

Part VII

Variational methods on Riemannian manifolds

Introduction to Part VII

Many nonlinear equations can be written as the condition that an energy remain unchanged to first order under perturbations of the unknown. In this case, solving the equation amounts to finding critical points of a functional defined on a space of functions or sections. Computing the first variation identifies the equation; the difficulty lies in proving that these critical points exist and in understanding the mechanisms that prevent the sequences used to find them from escaping.

The direct method studies minima. A minimizing sequence is controlled through coercivity, a subsequence is extracted by reflexivity, and the minimum is recovered through lower semicontinuity. Superlinear problems require a different geometry: the desired critical point may be a saddle point rather than a minimum. Palais–Smale conditions, pseudogradients, and deformation lemmas then allow minimax arguments to be constructed, including the mountain pass theorem.

The Nehari manifold introduces a third perspective. When the functional has a suitable radial geometry, each positive ray may intersect a natural constraint at a unique point. The problem is thus reduced to a more controlled geometry without artificially imposing an external condition. These chapters bring together the tools developed throughout the book: Sobolev spaces specify the domain of the functional, embeddings control the nonlinearities, integration by parts identifies the weak equation, and Banach geometry makes it possible to formulate constraints, tangent spaces, and deformation flows. Variational theory therefore emerges as a natural continuation of the analysis developed in the preceding parts.

From Euler and Lagrange to Palais and Smale

The calculus of variations began with problems about curves and surfaces in which a geometric or physical quantity had to be minimized. Euler and Lagrange developed the differential language that makes it possible to pass from an energy to an equation. With functional analysis, the unknown could be understood as a point of an infinite-dimensional space. The direct method organized existence arguments for minima through compactness and semicontinuity; Morse theory and minimax methods extended the search to critical points that are not minima; and Palais and Smale introduced a compactness condition adapted to these problems. The Nehari constraint, in turn, made a radial identity into a particularly effective tool for nonlinear equations.

29

Variational formulation of elliptic problems

Variational calculus allows partial differential equations to be studied through functionals defined on spaces of functions or sections. This perspective applies both on Euclidean domains and on Riemannian manifolds and, more generally, on smooth vector bundles. The common idea is first to formulate a notion of weak solution, obtained by multiplying the equation by test functions or sections and integrating by parts, and then to construct an energy functional whose Fréchet derivative reproduces that weak identity exactly. In this way, weak solutions arise as critical points of the functional.

The Green and integration-by-parts formulas developed in the preceding chapters provide the link between a differential operator and its weak formulation. In this part we will use them to identify the test spaces and recognize the Fréchet derivative of the associated energy functional.

For Poisson's equation, the quadratic functional

$$u \longmapsto \frac{1}{2}\int_M |du|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}} - \int_M f\,u \, d\lambda_{\mathbf{g}}$$

produces the weak equation $-\Delta_{\mathbf{g}} u = f$. Replacing the quadratic term by $\frac{1}{p}\int_M |du|_{\mathbf{g}}^p \, d\lambda_{\mathbf{g}}$ gives the p-Laplacian, and the natural space changes from $W^{1,2}$ to $W^{1,p}$. Zeroth-order nonlinearities will be treated using Nemytski operators: the Carathéodory conditions and growth bounds will determine when the map $u \mapsto f(\cdot, u)$ acts continuously between the required Lebesgue spaces.

From an equation to an energy

The calculus of variations arose from the study of curves that extremize lengths, times, or actions. In modern elliptic equations, the same principle is formulated on function spaces: the first variation of an energy produces a weak identity, and critical points represent solutions. This translation is powerful because it replaces a pointwise equation by global properties of the functional, but it works only when integrability, differentiability, and boundary terms are justified in the chosen space.

29.1 Carathéodory functions and superposition operators

In variational problems, the spatial variable and the dependent variable play different roles. Often, the coefficients of the equation depend only measurably on the base point, whereas the dependence on the unknown must retain enough continuity for compositions to be measurable and integral functionals to be well defined. The Carathéodory conditions formalize precisely this situation.

Definition 29.1.1. (Carathéodory function) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let V and W be finite-dimensional real vector spaces. A function $f : M\times V \longrightarrow W$ is a **Carathéodory function** if, for each $\xi \in V$, the function $x \longmapsto f(x,\xi)$ is $\lambda_{\mathbf{g}}$-measurable and, for almost every $x \in M$, the function $\xi \longmapsto f(x,\xi)$ is continuous.

Proposition 29.1.2. (Measurability of compositions) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, let $f : M \times V \longrightarrow W$ be a Carathéodory function, and let $u : M \longrightarrow V$ be a measurable function. Then the function $x \longmapsto f(x,u(x))$ is $\lambda_{\mathbf{g}}$-measurable.

Proof. Since V is finite-dimensional, there exists a sequence $(u_j)_{j\in\mathbb{N}}$ of measurable simple functions such that $u_j(x) \to u(x)$ for almost every $x \in M$. For each $j \in \mathbb{N}$, we can write

$$u_j = \sum_{i=1}^{N_j} \xi_{i,j}\mathbf{1}_{E_{i,j}},$$

where the sets $E_{1,j},\dots,E_{N_j,j}$ are measurable and pairwise disjoint. Adding the set $M \setminus \bigcup_{i=1}^{N_j} E_{i,j}$ with value $0 \in V$ if necessary, we may assume that $M = \bigcup_{i=1}^{N_j} E_{i,j}$. Therefore,

$$f(x,u_j(x)) = \sum_{i=1}^{N_j} f(x,\xi_{i,j})\mathbf{1}_{E_{i,j}}(x).$$

Since $x \longmapsto f(x,\xi_{i,j})$ is measurable for each i, the function $x \longmapsto f(x,u_j(x))$ is measurable.
There is a measurable set $N \subseteq M$, with $\lambda_{\mathbf{g}}(N) = 0$, such that $f(x,\cdot)$ is continuous and $u_j(x) \to u(x)$ for every $x \in M \setminus N$. Consequently, $f(x,u_j(x)) \to f(x,u(x))$ for every $x \in M \setminus N$. Since $\lambda_{\mathbf{g}}$ is complete, an almost everywhere pointwise limit of measurable functions with values in a finite-dimensional space is measurable. Therefore, $x \longmapsto f(x,u(x))$ is measurable. □

The preceding formulation extends naturally to nonlinearities acting on sections of vector bundles. In this case, both the unknown and its image belong to fibers that depend on the base point. The next definition expresses the Carathéodory condition without choosing trivializations.

Definition 29.1.3. (Fiberwise Carathéodory map) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{F} \to M$ and $\mathbf{G} \to M$ be smooth real vector bundles of finite rank. A fiber-preserving map $\mathscr{G} : \mathbf{F} \longrightarrow \mathbf{G}$ is called a **fiberwise Carathéodory map** if the following conditions hold:

(a) there exists a measurable set $M_0 \subseteq M$, with $\lambda_{\mathbf{g}}(M \setminus M_0) = 0$, such that $\mathscr{G}_x \colon \mathbf{F}_x \longrightarrow \mathbf{G}_x$ is continuous for every $x \in M_0$;

(b) for every open set $U \subseteq M$ and every measurable section $\mathbf{u} \colon U \longrightarrow \mathbf{F} \restriction_U$, the section $x \longmapsto \mathscr{G}_x(\mathbf{u}(x))$ is measurable on $\mathbf{G} \restriction_U$.

The second condition in the preceding definition can be checked using trivializations. The next result shows that the intrinsic definition agrees with the usual Carathéodory condition for the local representations.

Proposition 29.1.4. (Local characterization of Carathéodory maps) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{F} \to M$ and $\mathbf{G} \to M$ be smooth real vector bundles of finite rank, and let $\mathscr{G} \colon \mathbf{F} \longrightarrow \mathbf{G}$ be a fiber-preserving map. Then $\mathscr{G}$ is a fiberwise Carathéodory map if and only if, for every open set $U \subseteq M$ over which $\mathbf{F}$ and $\mathbf{G}$ admit smooth trivializations

$$\Phi_{\mathbf{F}} \colon \mathbf{F} \restriction_U \longrightarrow U \times \mathbb{R}^r, \qquad \Phi_{\mathbf{G}} \colon \mathbf{G} \restriction_U \longrightarrow U \times \mathbb{R}^s,$$

the local representation $\mathscr{G}_U \colon U \times \mathbb{R}^r \longrightarrow \mathbb{R}^s$, determined by

$$\Phi_{\mathbf{G}} \circ \mathscr{G} \circ \Phi_{\mathbf{F}}^{-1}(x, \xi) = \big(x, \mathscr{G}_U(x, \xi)\big),$$

is a Carathéodory function.

Proof. Suppose first that $\mathscr{G}$ is a fiberwise Carathéodory map. Fix $\xi \in \mathbb{R}^r$ and consider the smooth section $\mathbf{u}_\xi \colon U \longrightarrow \mathbf{F} \restriction_U$ defined by $\mathbf{u}_\xi(x) := \Phi_{\mathbf{F}}^{-1}(x, \xi)$. By the second condition in Definition 29.1.3, the section $x \longmapsto \mathscr{G}_x(\mathbf{u}_\xi(x))$ is measurable on $\mathbf{G} \restriction_U$. Its local representation with respect to $\Phi_{\mathbf{G}}$ is the function $x \longmapsto \mathscr{G}_U(x, \xi)$, which is therefore measurable.

On the other hand, there is a measurable set $M_0 \subseteq M$, with $\lambda_{\mathbf{g}}(M \setminus M_0) = 0$, such that $\mathscr{G}_x \colon \mathbf{F}_x \longrightarrow \mathbf{G}_x$ is continuous for every $x \in M_0$. Since the restrictions of $\Phi_{\mathbf{F}}$ and $\Phi_{\mathbf{G}}$ to the fibers are linear isomorphisms, the function $\xi \longmapsto \mathscr{G}_U(x, \xi)$ is continuous for every $x \in U \cap M_0$. Therefore, $\mathscr{G}_U$ is a Carathéodory function.

Conversely, suppose that the local representations of $\mathscr{G}$ are Carathéodory functions. Since M is second countable, we can choose a countable cover $(U_k)_{k \in \mathbb{N}}$ by common trivialization domains for $\mathbf{F}$ and $\mathbf{G}$. For each $k \in \mathbb{N}$, there exists a measurable set $N_k \subseteq U_k$, with $\lambda_{\mathbf{g}}(N_k) = 0$, such that the local representation $\mathscr{G}_{U_k}(x, \cdot)$ is continuous for every $x \in U_k \setminus N_k$. If $N := \bigcup_{k \in \mathbb{N}} N_k$, then $\lambda_{\mathbf{g}}(N) = 0$ and $\mathscr{G}_x \colon \mathbf{F}_x \longrightarrow \mathbf{G}_x$ is continuous for every $x \in M \setminus N$.

Now let $U \subseteq M$ be an open set, and let $\mathbf{u} \colon U \longrightarrow \mathbf{F} \restriction_U$ be a measurable section. For each $k \in \mathbb{N}$, let $u_k \colon U \cap U_k \longrightarrow \mathbb{R}^r$ be the local representation of $\mathbf{u}$. Since $\mathscr{G}_{U_k}$ is a Carathéodory function, Proposition 29.1.2 shows that the function

$$x \longmapsto \mathscr{G}_{U_k}(x, u_k(x))$$

is measurable on $U \cap U_k$. This function is the local representation of the section $x \longmapsto \mathscr{G}_x(\mathbf{u}(x))$. Since the sets $U \cap U_k$ form a countable cover of U, it follows that $x \longmapsto \mathscr{G}_x(\mathbf{u}(x))$ is a measurable section of $\mathbf{G} \restriction_U$. Therefore, $\mathscr{G}$ is a fiberwise Carathéodory map. □

Remark 29.1.5. To verify that a fiber-preserving map is fiberwise Carathéodory, it suffices to check that its local representations are Carathéodory functions with respect to a countable trivializing cover. Proposition 29.1.4 also shows that this property does not depend on the chosen trivializations.
In particular, every continuous fiber-preserving map $\mathscr{G}\colon \mathbf{F} \longrightarrow \mathbf{G}$ is a fiberwise Carathéodory map. If $\mathbf{F} = M \times V$ and $\mathbf{G} = M \times W$ are trivial bundles, the definition reduces to the usual Carathéodory condition for a function $f : M \times V \longrightarrow W$.

Definition 29.1.6. (Nemytski operator between bundles) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{F} \to M$ and $\mathbf{G} \to M$ be smooth real vector bundles of finite rank, and let $\mathscr{G}\colon \mathbf{F} \longrightarrow \mathbf{G}$ be a fiberwise Carathéodory map. The operator defined pointwise by $\mathcal{N}_{\mathscr{G}}(\mathbf{u})(x) := \mathscr{G}_x(\mathbf{u}(x))$, whenever the resulting section belongs to the target space under consideration, is called the **Nemytski operator**, **superposition operator**, or **substitution operator** associated with $\mathscr{G}$.

The next result gives a growth condition ensuring that the superposition operator acts continuously between Lebesgue spaces of sections. The independent term belonging to $L^q(M)$ allows manifolds of infinite volume to be included.

Theorem 29.1.7. (Continuity of superposition operators between bundles) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary, let $\mathbf{F} \to M$ and $\mathbf{G} \to M$ be smooth real vector bundles of finite rank equipped with bundle metrics $\mathbf{h}_{\mathbf{F}}$ and $\mathbf{h}_{\mathbf{G}}$, and let $\mathscr{G}\colon \mathbf{F} \longrightarrow \mathbf{G}$ be a fiberwise Carathéodory map. Let $1 \le p, q < \infty$ and suppose that there exist a measurable function $a\colon M \longrightarrow [0, \infty)$, with $a \in L^q(M)$, and a constant $C \ge 0$ such that

$$|\mathscr{G}_x(\xi)|_{\mathbf{h}_{\mathbf{G}}} \le a(x) + C|\xi|_{\mathbf{h}_{\mathbf{F}}}^{\frac{p}{q}}$$

for almost every $x \in M$ and every $\xi \in \mathbf{F}_x$. Then the operator

$$\mathcal{N}_{\mathscr{G}}\colon L^p(M, \mathbf{F}) \longrightarrow L^q(M, \mathbf{G}), \qquad \mathcal{N}_{\mathscr{G}}(\mathbf{u})(x) := \mathscr{G}_x(\mathbf{u}(x)),$$

is well defined, is continuous, and maps bounded sets to bounded sets.

Proof. Let $\mathbf{u} \in L^p(M, \mathbf{F})$. Definition 29.1.3 ensures that $\mathcal{N}_{\mathscr{G}}(\mathbf{u})$ is a measurable section of $\mathbf{G}$. Moreover, by the growth hypothesis and the inequality $(\alpha + \beta)^q \le 2^{q-1}(\alpha^q + \beta^q)$, we have

$$|\mathscr{G}_x(\mathbf{u}(x))|_{\mathbf{h}_{\mathbf{G}}}^q \le 2^{q-1} a(x)^q + 2^{q-1} C^q |\mathbf{u}(x)|_{\mathbf{h}_{\mathbf{F}}}^p$$

for almost every $x \in M$. Therefore,

$$\|\mathcal{N}_{\mathscr{G}}(\mathbf{u})\|_{L^q(M,\mathbf{G})}^q \le 2^{q-1} \|a\|_{L^q(M)}^q + 2^{q-1} C^q \|\mathbf{u}\|_{L^p(M,\mathbf{F})}^p.$$

In particular, $\mathcal{N}_{\mathscr{G}}(\mathbf{u}) \in L^q(M, \mathbf{G})$. Furthermore, if two sections agree almost everywhere, their images under $\mathcal{N}_{\mathscr{G}}$ also agree almost everywhere, so the operator is well defined on the equivalence classes of $L^p(M, \mathbf{F})$.
The preceding estimate also shows that $\mathcal{N}_{\mathscr{G}}$ maps bounded sets to bounded sets. If $B \subseteq L^p(M, \mathbf{F})$ is bounded, there exists $R > 0$ such that $\|\mathbf{u}\|_{L^p(M,\mathbf{F})} \le R$ for every $\mathbf{u} \in B$, and then

$$\|\mathcal{N}_{\mathscr{G}}(\mathbf{u})\|_{L^q(M,\mathbf{G})}^q \le 2^{q-1} \|a\|_{L^q(M)}^q + 2^{q-1} C^q R^p$$

for every $\mathbf{u} \in B$.

We prove continuity. Let $(\mathbf{u}_j)_{j\in\mathbb{N}} \subseteq L^p(M,\mathbf{F})$ be such that $\mathbf{u}_j \to \mathbf{u}$ in $L^p(M,\mathbf{F})$. Consider an arbitrary subsequence $(\mathbf{u}_{j_\ell})_{\ell\in\mathbb{N}}$. Passing to a further subsequence, denoted by $(\mathbf{v}_\ell)_{\ell\in\mathbb{N}}$, we may assume that $\|\mathbf{v}_\ell - \mathbf{u}\|_{L^p(M,\mathbf{F})} \le 2^{-\ell}$ for every $\ell \in \mathbb{N}$.

Define

$$H(x) := \sum_{\ell=1}^{\infty} |\mathbf{v}_\ell(x) - \mathbf{u}(x)|_{\mathbf{h}_\mathbf{F}}.$$

Minkowski's inequality (Theorem B.7.3) implies

$$\|H\|_{L^p(M)} \le \sum_{\ell=1}^{\infty} \|\mathbf{v}_\ell - \mathbf{u}\|_{L^p(M,\mathbf{F})} \le \sum_{\ell=1}^{\infty} 2^{-\ell} < \infty.$$

Consequently, $H(x) < \infty$ for almost every $x \in M$. At each point of this set of full measure, we have $\mathbf{v}_\ell(x) \to \mathbf{u}(x)$ in $\mathbf{F}_x$ and

$$|\mathbf{v}_\ell(x)|_{\mathbf{h}_\mathbf{F}} \le |\mathbf{u}(x)|_{\mathbf{h}_\mathbf{F}} + H(x).$$

Continuity of $\mathscr{G}_x$ for almost every $x \in M$ gives

$$\mathscr{G}_x(\mathbf{v}_\ell(x)) \longrightarrow \mathscr{G}_x(\mathbf{u}(x))$$

for almost every $x \in M$.

On the other hand, the triangle inequality and the growth hypothesis imply the existence of a constant $C_0 > 0$, independent of ℓ, such that

$$|\mathscr{G}_x(\mathbf{v}_\ell(x)) - \mathscr{G}_x(\mathbf{u}(x))|^q_{\mathbf{h}_\mathbf{G}} \le C_0\left(a(x)^q + |\mathbf{v}_\ell(x)|^p_{\mathbf{h}_\mathbf{F}} + |\mathbf{u}(x)|^p_{\mathbf{h}_\mathbf{F}}\right)$$

for almost every $x \in M$. Since

$$|\mathbf{v}_\ell(x)|^p_{\mathbf{h}_\mathbf{F}} \le 2^{p-1}\left(|\mathbf{u}(x)|^p_{\mathbf{h}_\mathbf{F}} + H(x)^p\right),$$

there is a constant $C_1 > 0$, independent of ℓ, such that

$$|\mathscr{G}_x(\mathbf{v}_\ell(x)) - \mathscr{G}_x(\mathbf{u}(x))|^q_{\mathbf{h}_\mathbf{G}} \le C_1\left(a(x)^q + |\mathbf{u}(x)|^p_{\mathbf{h}_\mathbf{F}} + H(x)^p\right)$$

for almost every $x \in M$. The right-hand side belongs to $L^1(M)$. Theorem B.6.14 gives

$$\|\mathcal{N}_\mathscr{G}(\mathbf{v}_\ell) - \mathcal{N}_\mathscr{G}(\mathbf{u})\|^q_{L^q(M,\mathbf{G})} \longrightarrow 0.$$

We have shown that every subsequence of $(\mathbf{u}_j)_{j\in\mathbb{N}}$ has a subsequence whose image converges to $\mathcal{N}_\mathscr{G}(\mathbf{u})$ in $L^q(M,\mathbf{G})$. By the subsequence criterion, $\mathcal{N}_\mathscr{G}(\mathbf{u}_j) \to \mathcal{N}_\mathscr{G}(\mathbf{u})$ in $L^q(M,\mathbf{G})$. Therefore, $\mathcal{N}_\mathscr{G}$ is continuous. □

The case of trivial bundles yields the usual result for vector-valued Carathéodory functions.

Corollary 29.1.8. (Nemytski operator between Lebesgue spaces) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, let $1 \le p, q < \infty$, and let $f : M \times \mathbb{R}^N \longrightarrow \mathbb{R}^L$ be a Carathéodory function. Suppose that

there exist a measurable function $a\colon M \longrightarrow [0,\infty)$, with $a \in L^q(M)$, and a constant $C \geq 0$ such that

$$\|f(x,\xi)\| \leq a(x) + C\|\xi\|^{\frac{p}{q}}$$

for almost every $x \in M$ and every $\xi \in \mathbb{R}^N$. Then the operator

$$\mathcal{N}_f\colon L^p(M,\mathbb{R}^N) \longrightarrow L^q(M,\mathbb{R}^L), \qquad \mathcal{N}_f(u)(x) := f(x,u(x)),$$

is well defined, is continuous, and maps bounded sets to bounded sets.

Proof. Simply apply Theorem 29.1.7 to the trivial bundles $\mathbf{F} = M\times\mathbb{R}^N$ and $\mathbf{G} = M\times\mathbb{R}^L$, equipped with their Euclidean bundle metrics. □

Corollary 29.1.9. (The case of conjugate exponents) Let $(M,\mathbf{g})$ be a compact Riemannian manifold with or without boundary, let $\mathbf{F} \to M$ and $\mathbf{G} \to M$ be smooth real vector bundles of finite rank equipped with bundle metrics $\mathbf{h_F}$ and $\mathbf{h_G}$, and let $\mathscr{G}\colon \mathbf{F} \longrightarrow \mathbf{G}$ be a continuous fiber-preserving map. Suppose that $m > 1$ and that there exists a constant $C > 0$ such that

$$|\mathscr{G}_x(\xi)|_{\mathbf{h_G}} \leq C\big(1 + |\xi|_{\mathbf{h_F}}^{m-1}\big)$$

for every $x \in M$ and every $\xi \in \mathbf{F}_x$. If $m' := \dfrac{m}{m-1}$, then the operator $\mathcal{N}_{\mathscr{G}}\colon L^m(M,\mathbf{F}) \longrightarrow L^{m'}(M,\mathbf{G})$ is well defined, is continuous, and maps bounded sets to bounded sets.

Proof. Since $\mathscr{G}$ is continuous and preserves fibers, it is a fiberwise Carathéodory map. Moreover, $\dfrac{m}{m'} = m-1$. Since M is compact, the constant function $a(x) := C$ belongs to $L^{m'}(M)$. The result follows from Theorem 29.1.7 by taking $p = m$ and $q = m'$. □

Remark 29.1.10. (The compact case) If M is compact, then $\lambda_{\mathbf{g}}(M) < \infty$ and every constant function belongs to $L^q(M)$. Consequently, in Theorem 29.1.7 the growth hypothesis can be replaced by

$$|\mathscr{G}_x(\xi)|_{\mathbf{h_G}} \leq C\big(1 + |\xi|_{\mathbf{h_F}}^{\frac{p}{q}}\big).$$

Similarly, in Corollary 29.1.8 it suffices to assume that $\|f(x,\xi)\| \leq C(1 + \|\xi\|^{\frac{p}{q}})$ for almost every $x \in M$ and every $\xi \in \mathbb{R}^N$.

Corollary 29.1.11. (Differentiability of powers of the norm) Let $(M,\mathbf{g})$ be a Riemannian manifold with or without boundary, and let $\mathbf{E} \to M$ be a smooth real vector bundle of finite rank, equipped with a bundle metric $\mathbf{h_E}$. For $1 < \ell < \infty$, the functional

$$Q_\ell(\mathbf{u}) := \frac{1}{\ell}\|\mathbf{u}\|_{L^\ell(M,\mathbf{E})}^\ell$$

is of class C^1 on $L^\ell(M,\mathbf{E})$ and

$$DQ_\ell(\mathbf{u})(\mathbf{v}) = \int_M |\mathbf{u}|_{\mathbf{h_E}}^{\ell-2}\langle \mathbf{u},\mathbf{v}\rangle_{\mathbf{h_E}}\, d\lambda_{\mathbf{g}}.$$

The integrand is interpreted as zero where $\mathbf{u} = 0$.

Proof. In each fiber, the map $\xi \mapsto |\xi|^\ell/\ell$ is of class C^1 and its differential is represented by $b_\ell(\xi) := |\xi|^{\ell-2}\xi$, with $b_\ell(0) = 0$. At zero, differentiability follows from $|\xi|^\ell/|\xi| \to 0$, since $\ell > 1$; away from zero, apply the chain rule. Theorem 29.1.7, with exponents ℓ and $\ell' := \ell/(\ell-1)$ and zero independent term, shows that b_ℓ is continuous from $L^\ell(M,\mathbf{E})$ to $L^{\ell'}(M,\mathbf{E})$.
By Hölder, the proposed formula defines a continuous linear functional of norm at most $\|\mathbf{u}\|^{\ell-1}_{L^\ell(M,\mathbf{E})}$. The fundamental theorem of calculus in each fiber and Fubini give

$$Q_\ell(\mathbf{u}+\mathbf{h}) - Q_\ell(\mathbf{u}) = \int_0^1 \int_M \langle b_\ell(\mathbf{u}+t\mathbf{h}), \mathbf{h}\rangle_{\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \, dt.$$

Indeed, the integral of the absolute value is at most $(\|\mathbf{u}\|_{L^\ell(M,\mathbf{E})} + \|\mathbf{h}\|_{L^\ell(M,\mathbf{E})})^{\ell-1}\|\mathbf{h}\|_{L^\ell(M,\mathbf{E})}$, by Hölder. Subtracting the proposed functional, we obtain

$$\begin{aligned}\left| Q_\ell(\mathbf{u}+\mathbf{h}) - Q_\ell(\mathbf{u}) - \int_M \langle b_\ell(\mathbf{u}), \mathbf{h}\rangle_{\mathbf{h}_\mathbf{E}} \, d\lambda_\mathbf{g} \right| \\ \le \|\mathbf{h}\|_{L^\ell(M,\mathbf{E})} \sup_{t\in[0,1]} \|b_\ell(\mathbf{u}+t\mathbf{h}) - b_\ell(\mathbf{u})\|_{L^{\ell'}(M,\mathbf{E})}.\end{aligned}$$

Continuity of b_ℓ at $\mathbf{u}$ makes the supremum tend to zero as $\mathbf{h} \to 0$: all the points $\mathbf{u}+t\mathbf{h}$ lie at distance at most $\|\mathbf{h}\|_{L^\ell(M,\mathbf{E})}$ from $\mathbf{u}$. This proves Fréchet differentiability. Finally, Hölder gives

$$\|DQ_\ell(\mathbf{u}) - DQ_\ell(\mathbf{w})\|_{(L^\ell)'} \le \|b_\ell(\mathbf{u}) - b_\ell(\mathbf{w})\|_{L^{\ell'}(M,\mathbf{E})},$$

so the differential is continuous. □

29.2 Classical, strong, and weak solutions

First consider the scalar problem

$$\begin{cases} -\Delta_\mathbf{g} u = f(x,u) & \text{in } M, \\ u = 0 & \text{on } \partial M, \end{cases} \tag{29.1}$$

where $(M,\mathbf{g})$ is a compact Riemannian manifold of dimension n with nonempty smooth boundary and $f : M\times\mathbb{R} \longrightarrow \mathbb{R}$ is a Carathéodory function. This equation will serve as a model for introducing the basic notions. We adopt the convention

$$2^* := \begin{cases} \dfrac{2n}{n-2}, & n \ge 3, \\ +\infty, & n \in \{1,2\}. \end{cases}$$

When $|f(x,t)|$ grows like $|t|^{r-1}$, the growth is said to be sublinear if $1 < r < 2$ and superlinear subcritical if $2 < r < 2^*$. If $n \ge 3$, the case $r = 2^*$ is called critical and the case $r > 2^*$ supercritical. For $n \in \{1,2\}$, no finite critical exponent occurs in the first-order embeddings. These terms depend on the function space under consideration: 2^* is the limiting exponent for the embedding of $W^{1,2}_0(M)$.

Definition 29.2.1. (Classical solution) Let $(M,\mathbf{g})$ be a compact Riemannian manifold with nonempty boundary, and let $f\colon M\times\mathbb{R}\to\mathbb{R}$ be a Carathéodory function. A classical solution of (29.1) is a function $u\in C^2(M)$ satisfying the equation at every point of M and whose restriction to ∂M is zero.

Definition 29.2.2. (Strong solution) Let $(M,\mathbf{g})$ be a compact Riemannian manifold with nonempty boundary, and let $f\colon M\times\mathbb{R}\to\mathbb{R}$ be a Carathéodory function. A strong solution of (29.1) is a function $u\in W^{2,2}(M)\cap W_0^{1,2}(M)$ such that $-\Delta_{\mathbf{g}}u=f(x,u)$ almost everywhere on M.

Green's formula, obtained earlier from Theorem 2.14.21, shows that every sufficiently regular solution satisfies

$$\int_M \langle\nabla u,\nabla v\rangle_{\mathbf{g}}\,d\lambda_{\mathbf{g}}=\int_M f(x,u)v\,d\lambda_{\mathbf{g}}.$$

This leads to the notion natural in Sobolev spaces.

Definition 29.2.3. (Weak solution) Let $(M,\mathbf{g})$ be a compact Riemannian manifold with nonempty boundary, and let $f\colon M\times\mathbb{R}\to\mathbb{R}$ be a Carathéodory function. A weak solution of (29.1) is a function $u\in W_0^{1,2}(M)$ such that

$$\int_M \langle\nabla u,\nabla v\rangle_{\mathbf{g}}\,d\lambda_{\mathbf{g}}=\int_M f(x,u)v\,d\lambda_{\mathbf{g}}$$

for every $v\in W_0^{1,2}(M)$, provided that the right-hand side is well defined.

Every classical solution is both strong and weak. Passing from a weak solution to a strong or classical solution requires elliptic regularity results and depends on the geometry of M, the regularity of the boundary, and the hypotheses on the nonlinearity.

The same procedure applies to sections. Let $\mathbf{E}\to M$ be a smooth real vector bundle of finite rank, equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a connection $\nabla^{\mathbf{E}}$ compatible with $\mathbf{h}_{\mathbf{E}}$. An equation in $\mathbf{E}$ is tested against sections $\varphi\in W_0^{1,q}(M,\mathbf{E})$, and integration by parts is performed using the induced connection and its formal adjoint. The boundary condition is incorporated through the characterization of $W_0^{1,q}(M,\mathbf{E})$ as the kernel of the trace operator.

29.3 Energy functionals and critical points

Let X be a real Banach space, and let $I\colon X\longrightarrow\mathbb{R}$. We use the notation $DI(u)\in X'$ for the Fréchet derivative. A point $u\in X$ is critical if $DI(u)=0$.

Proposition 29.3.1. (Scalar energy functional) Let $(M,\mathbf{g})$ be a compact Riemannian manifold of dimension n with nonempty boundary. Suppose that $f\colon M\times\mathbb{R}\longrightarrow\mathbb{R}$ is a Carathéodory function and that there exist $C>0$ and $r\in(1,2^*)$ such that $|f(x,t)|\le C(1+|t|^{r-1})$. Define $F(x,t):=\displaystyle\int_0^t f(x,s)\,ds$ and

$$I(u):=\frac{1}{2}\int_M|\nabla u|_{\mathbf{g}}^2\,d\lambda_{\mathbf{g}}-\int_M F(x,u)\,d\lambda_{\mathbf{g}}$$

on $X = W_0^{1,2}(M)$. Then $I \in C^1(X, \mathbb{R})$ and

$$DI(u)(v) = \int_M \langle \nabla u, \nabla v \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} - \int_M f(x,u) v \, d\lambda_{\mathbf{g}}$$

for all $u, v \in X$. In particular, the critical points of I are exactly the weak solutions of (29.1).

Proof. Write $I = Q - P$, where

$$Q(u) := \frac{1}{2} \int_M |\nabla u|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}}, \qquad P(u) := \int_M F(x,u) \, d\lambda_{\mathbf{g}}.$$

The functional Q is of class C^1 and

$$DQ(u)(v) = \int_M \langle \nabla u, \nabla v \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}}.$$

The growth hypothesis implies

$$|F(x,t)| \le C|t| + \frac{C}{r}|t|^r.$$

Since $X \hookrightarrow L^1(M) \cap L^r(M)$ continuously, P is well defined. Likewise, Corollary 29.1.8, applied with $p = r$ and $q = r' := \dfrac{r}{r-1}$, shows that

$$u \longmapsto f(\cdot, u)$$

is continuous from $L^r(M)$ to $L^{r'}(M)$.
For $u \in X$, define $K_u \in X'$ by

$$K_u(v) := \int_M f(x,u) v \, d\lambda_{\mathbf{g}}.$$

If $C_S > 0$ is a constant for the embedding $X \hookrightarrow L^r(M)$, then

$$|K_u(v)| \le \|f(\cdot,u)\|_{L^{r'}(M)} \|v\|_{L^r(M)} \le C_S \|f(\cdot,u)\|_{L^{r'}(M)} \|v\|_X,$$

so K_u is linear and continuous.
Let $h \in X$. For almost every $x \in M$, Theorem B.6.5, applied to $s \longmapsto F(x, u(x) + sh(x))$, gives

$$F(x,u+h) - F(x,u) = \int_0^1 f(x, u+sh) h \, ds.$$

Hölder's inequality (Proposition B.7.9) and the growth bound justify applying Fubini's theorem for Bochner integrals B.6.26, in its scalar case, to $(M, \lambda_{\mathbf{g}}) \times ([0,1], ds)$. Consequently,

$$P(u+h) - P(u) - K_u(h) = \int_0^1 \int_M \big(f(x,u+sh) - f(x,u) \big) h \, d\lambda_{\mathbf{g}} \, ds$$

and

$$|P(u+h) - P(u) - K_u(h)| \le C_S \|h\|_X \int_0^1 \|f(\cdot, u+sh) - f(\cdot,u)\|_{L^{r'}(M)} \, ds.$$

Let $(h_j)_{j \in \mathbb{N}} \subseteq X$ be such that $h_j \to 0$ in X. For each $s \in [0,1]$, we have $u + sh_j \to u$ in $L^r(M)$, and continuity of

the Nemytski operator implies

$$\|f(\cdot, u+sh_j) - f(\cdot, u)\|_{L^{r'}(M)} \longrightarrow 0.$$

Moreover, there exists $R > 0$ such that $\|u+sh_j\|_{L^r(M)} \le R$ for every j and every $s \in [0,1]$. The estimate obtained in the first part of the proof of Corollary 29.1.8 provides a constant $C_R > 0$ such that

$$\|f(\cdot, u+sh_j) - f(\cdot, u)\|_{L^{r'}(M)} \le C_R$$

for every j and every $s \in [0,1]$. Theorem B.6.14, applied in the variable s, gives

$$\int_0^1 \|f(\cdot, u+sh_j) - f(\cdot, u)\|_{L^{r'}(M)}\, ds \longrightarrow 0.$$

Therefore,

$$\lim_{h\to 0} \frac{|P(u+h) - P(u) - K_u(h)|}{\|h\|_X} = 0,$$

so P is Fréchet differentiable and $DP(u) = K_u$.
Finally, if $u_j \to u$ in X, then $u_j \to u$ in $L^r(M)$ and

$$\|DP(u_j) - DP(u)\|_{X'} \le C_S \|f(\cdot, u_j) - f(\cdot, u)\|_{L^{r'}(M)} \longrightarrow 0.$$

Thus, $P \in C^1(X, \mathbb{R})$, $I = Q - P \in C^1(X, \mathbb{R})$, and the asserted formula for DI holds. Comparing it with Definition 29.2.3, we conclude that $DI(u) = 0$ if and only if u is a weak solution of (29.1). □

Proposition 29.3.2. (Second derivative of the potential functional) Let $(M, \mathbf{g})$ be a compact Riemannian manifold of dimension n with nonempty boundary, and let f be the nonlinearity in Proposition 29.3.1. Suppose in addition that $f(x,\cdot)$ is of class C^1 for almost every x, that f_t is a Carathéodory function, and that there exist $C > 0$ and $r \in (2, 2^*)$ such that

$$|f_t(x,t)| \le C\left(1 + |t|^{r-2}\right)$$

for almost every $x \in M$ and every $t \in \mathbb{R}$. Then $I \in C^2(X, \mathbb{R})$ and

$$D^2 I(u)(v,w) = \int_M \langle \nabla v, \nabla w \rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}} - \int_M f_t(x,u) v w\, d\lambda_{\mathbf{g}}.$$

Proof. Let $P(u) := \displaystyle\int_M F(x,u)\, d\lambda_{\mathbf{g}}$. By the preceding proposition,

$$DP(u)(v) = \int_M f(x,u) v\, d\lambda_{\mathbf{g}}.$$

Define $s := \dfrac{r}{r-2}$. Then $\frac{1}{s} + \frac{2}{r} = 1$. Corollary 29.1.8, applied with source exponent r and target exponent s, shows that

$$u \longmapsto f_t(\cdot, u)$$

is continuous from $L^r(M)$ to $L^s(M)$, since $\frac{r}{s} = r - 2$.

For $u \in X$, define the bilinear form

$$B_u(h,v) := \int_M f_t(x,u)hv \, d\lambda_{\mathbf{g}}.$$

By Hölder's inequality (Proposition B.7.9) and the embedding $X \hookrightarrow L^r(M)$,

$$|B_u(h,v)| \le \|f_t(\cdot,u)\|_{L^s(M)}\|h\|_{L^r(M)}\|v\|_{L^r(M)} \le C_S^2\|f_t(\cdot,u)\|_{L^s(M)}\|h\|_X\|v\|_X.$$

Therefore, $B_u \in \mathcal{L}^2(X;\mathbb{R})$.
For $h, v \in X$, Theorem B.6.5, applied in the second variable, gives

$$f(x,u+h) - f(x,u) = \int_0^1 f_t(x,u+\tau h)h \, d\tau$$

for almost every $x \in M$. Thus,

$$\big(DP(u+h) - DP(u) - B_u(h,\cdot)\big)(v) = \int_0^1 \int_M \big(f_t(x,u+\tau h) - f_t(x,u)\big)hv \, d\lambda_{\mathbf{g}} \, d\tau.$$

Taking the supremum over $\|v\|_X \le 1$ and applying Hölder, we obtain

$$\|DP(u+h) - DP(u) - B_u(h,\cdot)\|_{X'} \le C_S^2\|h\|_X \int_0^1 \|f_t(\cdot,u+\tau h) - f_t(\cdot,u)\|_{L^s(M)} \, d\tau.$$

If $h_j \to 0$ in X, then $u + \tau h_j \to u$ in $L^r(M)$ for each $\tau \in [0,1]$. Continuity of the Nemytski operator associated with f_t implies that the integrand converges to zero. Moreover, the family $(u+\tau h_j)_{j,\tau}$ is bounded in $L^r(M)$, and the boundedness estimate of Corollary 29.1.8 provides a constant independent of j and τ that dominates the integrand. By Theorem B.6.14, applied in $[0,1]$,

$$\int_0^1 \|f_t(\cdot,u+\tau h_j) - f_t(\cdot,u)\|_{L^s(M)} \, d\tau \longrightarrow 0.$$

Consequently,

$$\lim_{h\to 0} \frac{\|DP(u+h) - DP(u) - B_u(h,\cdot)\|_{X'}}{\|h\|_X} = 0.$$

This proves that DP is Fréchet differentiable and that $D^2P(u) = B_u$.
If $u_j \to u$ in X, then $u_j \to u$ in $L^r(M)$ and

$$\|D^2P(u_j) - D^2P(u)\|_{\mathcal{L}^2(X;\mathbb{R})} \le C_S^2\|f_t(\cdot,u_j) - f_t(\cdot,u)\|_{L^s(M)} \longrightarrow 0.$$

Therefore, $P \in C^2(X,\mathbb{R})$. Since the second derivative of the quadratic term is the form $(v,w) \mapsto \int_M \langle \nabla v, \nabla w\rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}}$, the formula for D^2I follows from $I = Q - P$. □

In the subcritical regime, the compact embedding of $W_0^{1,2}(M)$ into $L^r(M)$ makes the potential term stable under the weak convergences that occur in the direct method and in the Nehari method.

30

The direct method in the calculus of variations

The direct method turns a minimization problem into a combination of three properties: coercivity, compactness, and lower semicontinuity. Coercivity keeps minimizing sequences in bounded sets; weak compactness allows a convergent subsequence to be extracted; and lower semicontinuity ensures that the limit does not increase the energy. In reflexive spaces, this scheme gives a general criterion for the existence of minimizers.

The distinction between weak compactness and weak convergence of sequences allows two versions of the method to be formulated. After establishing them, we will apply them to a sublinear elliptic problem. In that example, the Dirichlet condition controls the quadratic part of the energy, whereas compactness of a Sobolev embedding allows passage to the limit in the nonlinear term.

The direct method and the power of weak convergence

The direct method does not attempt to solve the Euler–Lagrange equation explicitly. It starts from a sequence whose energy approaches the infimum and seeks enough compactness to obtain a limit. Weak convergence is decisive because every bounded sequence in a reflexive Banach space admits a weakly convergent subsequence; lower semicontinuity prevents the energy from jumping upward at the limit. This combination, developed in the modern calculus of variations, turns structural properties of the space and the functional into an existence theorem.

30.1 Lower semicontinuity

A minimizing sequence often converges only weakly. For its limit to remain a minimizer, the energy must not increase on passing to the limit; this is precisely the role of lower semicontinuity.

Definition 30.1.1. Let X be a topological space. A function $\varphi\colon X \longrightarrow \mathbb{R}$ is said to be lower semicontinuous if, for every $a \in \mathbb{R}$, the set $\{x \in X \mid \varphi(x) > a\}$ is open in X.

Example 30.1.2. Every continuous function $\varphi\colon X \longrightarrow \mathbb{R}$ is lower semicontinuous, since the preimage of any open set is an open set in X.

Example 30.1.3. Consider the function $\varphi\colon \mathbb{R} \longrightarrow \mathbb{R}$ defined by

$$\varphi(x) = \begin{cases} 0, & \text{if } x \leq 0, \\ 1, & \text{if } x > 0. \end{cases}$$

Then the function φ is lower semicontinuous. Indeed, if $a < 0$, the set $\{x \in \mathbb{R} \mid \varphi(x) > a\}$ is $\mathbb{R}$; if $0 \leq a < 1$, it is $(0, +\infty)$; and if $a \geq 1$, it is empty. All three sets are open. The discontinuity at 0 is compatible with lower semicontinuity because the value at that point agrees with the smaller of the two one-sided values.

Lemma 30.1.4. Let X be a first-countable topological space, and let $\psi\colon X \longrightarrow \mathbb{R}$ be a functional. Then ψ is lower semicontinuous if and only if

$$\psi(x) \leq \liminf_{n\to\infty} \psi(x_n),$$

for every sequence $(x_n)_{n\in\mathbb{N}} \subset X$ such that $x_n \to x$ in X.

Proof. Suppose first that ψ is lower semicontinuous. We wish to prove that $\psi(x) \leq \liminf_{n\to\infty} \psi(x_n)$ for every sequence $(x_n)_{n\in\mathbb{N}} \subset X$ such that $x_n \to x$. Let $\varepsilon > 0$. Consider the set

$$V_\varepsilon := \{y \in X \mid \psi(y) > \psi(x) - \varepsilon\} = \psi^{-1}\big((\psi(x) - \varepsilon, +\infty)\big).$$

Since ψ is lower semicontinuous, the set V_ε is open. Since $x_n \to x$, there exists $n_0 \in \mathbb{N}$ such that $x_n \in V_\varepsilon$ for every $n \geq n_0$. Therefore,

$$\psi(x_n) > \psi(x) - \varepsilon, \quad \text{for every } n \geq n_0,$$

which implies $\liminf_{n\to\infty} \psi(x_n) \geq \psi(x) - \varepsilon$.
Since $\varepsilon > 0$ is arbitrary, it follows that $\psi(x) \leq \liminf_{n\to\infty} \psi(x_n)$.
Conversely, suppose that $\psi(x) \leq \liminf_{n\to\infty} \psi(x_n)$ for every sequence $(x_n)_{n\in\mathbb{N}} \subset X$ such that $x_n \to x$. We show that ψ is lower semicontinuous. Let $a \in \mathbb{R}$ and consider the set $F := \{x \in X \mid \psi(x) \leq a\}$. We claim that F is closed. Suppose, for a contradiction, that it is not. Then there exists $x_0 \in \overline{F} \setminus F$; that is, x_0 is a point of the closure of F but $\psi(x_0) > a$. Since X is first countable, x_0 has a countable base of open neighborhoods $(U_n)_{n\in\mathbb{N}}$. For each $n \in \mathbb{N}$, set $V_n := \bigcap_{j=1}^{n} U_j$. Since $x_0 \in \overline{F}$, we can choose $x_n \in F \cap V_n$. If U is a neighborhood of x_0, there exists $j \in \mathbb{N}$ such that $U_j \subseteq U$; for every $n \geq j$, we have $x_n \in V_n \subseteq U_j \subseteq U$. Therefore, $x_n \to x_0$. By hypothesis, $\psi(x_0) \leq \liminf_{n\to\infty} \psi(x_n)$.
Since $x_n \in F$, we have $\psi(x_n) \leq a$ for every $n \in \mathbb{N}$, and hence $\liminf_{n\to\infty} \psi(x_n) \leq a$. Consequently, $\psi(x_0) \leq a$, contradicting $\psi(x_0) > a$. Therefore, F is closed for every $a \in \mathbb{R}$, which implies that ψ is lower semicontinuous. □

Theorem 30.1.5. Let X be a nonempty compact topological space, and let $\varphi\colon X \longrightarrow \mathbb{R}$ be a lower semicontinuous functional. Then φ is bounded below and attains its infimum; that is, there exists $u_0 \in X$ such

that

$$\varphi(u_0) = \inf_{x \in X} \varphi(x).$$

Proof. Observe that $X = \bigcup_{n=1}^{\infty} \varphi^{-1}((-n, +\infty))$.
Since φ is lower semicontinuous, each set $\varphi^{-1}((-n, +\infty))$ is open in X.
Since X is compact, the preceding cover admits a finite subcover. If $n_0 \in \mathbb{N}$ is the largest of its indices, then $X = \bigcup_{n=1}^{n_0} \varphi^{-1}((-n, +\infty))$.
Therefore, for every $x \in X$ we have $\varphi(x) > -n_0$, which implies that φ is bounded below.
Since $X \neq \varnothing$, the set $\varphi(X)$ is nonempty and bounded below. Completeness of $\mathbb{R}$ then provides a real number $c = \inf_{x \in X} \varphi(x)$.
Suppose, for a contradiction, that $\varphi(x) > c$ for every $x \in X$. Then $X = \bigcup_{n=1}^{\infty} \varphi^{-1}\left(\left(c + \frac{1}{n}, +\infty\right)\right)$.
Again, compactness provides a finite subcover. Taking $k \in \mathbb{N}$ to be the largest index of that subcover, we obtain $X = \bigcup_{n=1}^{k} \varphi^{-1}\left(\left(c + \frac{1}{n}, +\infty\right)\right)$.
It follows that $\varphi(x) > c + \frac{1}{k}$ for every $x \in X$, which implies that $c + \frac{1}{k}$ is a lower bound for $\varphi(X)$. This contradicts the definition of the infimum, since it would imply $c \geq c + \frac{1}{k}$. Therefore, there exists $u_0 \in X$ such that $\varphi(u_0) = \inf_{x \in X} \varphi(x)$.

□

Definition 30.1.6. Let X be a normed space. A function $\varphi \colon X \longrightarrow \mathbb{R}$ is said to be weakly lower semicontinuous if it is lower semicontinuous with respect to the weak topology $\sigma(X, X')$. In particular, if a sequence $(x_n)_{n \in \mathbb{N}} \subseteq X$ satisfies $x_n \rightharpoonup x$ in X, then

$$\varphi(x) \leq \liminf_{n \to \infty} \varphi(x_n).$$

The implication from lower semicontinuity to the inequality for sequences does not require first countability: the first part of the proof of Lemma 30.1.4 suffices. The converse does require additional justification when working with the weak topology.

Definition 30.1.7. Let X be a normed space. A functional $\varphi \colon X \longrightarrow \mathbb{R}$ is sequentially weakly lower semicontinuous if, for every sequence $(x_n)_{n \in \mathbb{N}} \subseteq X$ and every $x \in X$ such that $x_n \rightharpoonup x$, we have

$$\varphi(x) \leq \liminf_{n \to \infty} \varphi(x_n).$$

The weak topology of an infinite-dimensional Banach space need not be first countable. We therefore keep the two notions distinct. In the applications, it will suffice to check the sequential condition and use a version of the direct method formulated for it.

Theorem 30.1.8. (Direct method in the calculus of variations) Let E be a reflexive Banach space, and let $\varphi \colon E \longrightarrow \mathbb{R}$ be a functional satisfying:

(i) φ is weakly lower semicontinuous;

(ii) φ is coercive, that is, $\varphi(u) \to +\infty$ as $\|u\| \to +\infty$: for every $a \in \mathbb{R}$ there exists $R_a > 0$ such that $\varphi(u) > a$ for every $u \in E$ with $\|u\| \geq R_a$.

Then φ is bounded below and attains its infimum; that is, there exists $u_0 \in E$ such that

$$\varphi(u_0) = \inf_{u \in E} \varphi(u).$$

Proof. Let $R > 0$ be such that

$$\varphi(u) \geq \varphi(0), \quad \text{for every } u \in E \text{ with } \|u\| \geq R.$$

Since E is a reflexive Banach space, Theorem B.11.38 implies that the closed ball $\overline{B}_{d_E}(0,R) = \{u \in E \mid \|u\| \leq R\}$, where d_E is the metric induced by the norm, is weakly compact.
Moreover, the restriction of φ to $\overline{B}_{d_E}(0,R)$ is weakly lower semicontinuous. Therefore, applying Theorem 30.1.5 shows that φ is bounded below on $\overline{B}_{d_E}(0,R)$ and that there exists $u_0 \in \overline{B}_{d_E}(0,R)$ such that $\varphi(u_0) = \inf_{u \in \overline{B}_{d_E}(0,R)} \varphi(u)$.
By the choice of R, for every $u \in E$ with $\|u\| \geq R$ we have $\varphi(u) \geq \varphi(0) \geq \varphi(u_0)$, which implies that $\varphi(u_0) = \inf_{u \in E} \varphi(u)$.

□

Coercivity is equivalent to boundedness of every sublevel set $\{u \in E \mid \varphi(u) \leq a\}$, with $a \in \mathbb{R}$. Indeed, the radius R_a in the definition encloses that sublevel set in a ball. Conversely, if the sublevel set is contained in a ball of radius r_a, any $R_a > r_a$ satisfies the coercivity condition. This observation allows us to work directly with minimizing sequences.

Theorem 30.1.9. (Sequential form of the direct method) Let E be a reflexive Banach space, and let $\varphi\colon E \longrightarrow \mathbb{R}$ be a coercive, sequentially weakly lower semicontinuous functional. Then φ is bounded below and there exists $u_0 \in E$ such that

$$\varphi(u_0) = \inf_{u \in E} \varphi(u).$$

Proof. First we rule out the possibility that the infimum is $-\infty$. If it were, for each $n \in \mathbb{N}$ we could choose $u_n \in E$ with $\varphi(u_n) \leq -n$. The entire sequence would lie in the sublevel set $\{u \in E \mid \varphi(u) \leq -1\}$, which is bounded by coercivity. Corollary B.11.39 gives a subsequence $(u_{n_j})_{j \in \mathbb{N}}$ and a point $u \in E$ such that $u_{n_j} \rightharpoonup u$. Sequential semicontinuity would give

$$\varphi(u) \leq \liminf_{j \to \infty} \varphi(u_{n_j}) = -\infty,$$

which is impossible because φ takes real values. Consequently, $c := \inf_{u \in E} \varphi(u)$ is finite; moreover, $c \leq \varphi(0) < +\infty$.
By the definition of the infimum, we can now choose, for each $n \in \mathbb{N}$, a point $v_n \in E$ such that

$$c \leq \varphi(v_n) < c + \frac{1}{n}.$$

This sequence lies in the sublevel set at height $c+1$ and is therefore bounded. Applying the cited corollary

again, we obtain $u_0 \in E$ and a subsequence $(v_{n_j})_{j\in\mathbb{N}}$ such that $v_{n_j} \rightharpoonup u_0$. Then

$$c \le \varphi(u_0) \le \liminf_{j\to\infty} \varphi(v_{n_j}) = c.$$

The two inequalities force $\varphi(u_0) = c$. □

The extraction of weakly convergent subsequences rests on Eberlein–Šmulian and reflexivity, through the cited corollary in Appendix B. This is also the formulation of the direct method used in [138, chap. I, §1, Theorem 1.2].

Under the hypotheses of the last theorem, topological lower semicontinuity can also be recovered. Fix $a \in \mathbb{R}$ and set $K_a := \{u \in E \mid \varphi(u) \le a\}$. If K_a is nonempty, every sequence in K_a is bounded and admits a weakly convergent subsequence in E. Sequential semicontinuity ensures that its limit remains in K_a. Thus, K_a is sequentially weakly compact and, by Theorem B.11.36, weakly compact. Since the weak topology is Hausdorff, K_a is weakly closed. The empty sublevel set is also closed, so all sublevel sets are closed. Proposition B.11.15 then implies that φ is weakly lower semicontinuous. This argument uses both coercivity and reflexivity; it has not assumed that the two notions of semicontinuity agree in an arbitrary weak topology.

We turn to an application in which the energy is not convex. Its quadratic part will be weakly lower semicontinuous, and a compact embedding will allow us to handle the remaining part.

30.2 Solving a sublinear problem

Let $(M, \mathbf{g})$ be a nonempty compact Riemannian manifold of dimension $n \ge 1$, with smooth boundary, and suppose that every connected component of M has nonempty boundary. We will work with real functions. The condition on the components allows the norm of a function with zero trace to be controlled by its gradient.

We will use the Poincaré inequality of Theorem 9.6.8, applied to the trivial real bundle with $p = 2$. Its hypothesis on each component is precisely the one just imposed, and its range $1 \le p < \infty$ includes this exponent in every dimension $n \ge 1$. The constant depends on M and $\mathbf{g}$.

Consider the sublinear problem

$$\begin{cases} -\Delta_{\mathbf{g}} u = |u|^{q-2}u & \text{in } M, \\ u = 0 & \text{on } \partial M, \end{cases} \tag{30.1}$$

where $1 < q < 2$. We use the sign $\Delta_{\mathbf{g}} = \operatorname{div}_{\mathbf{g}} \nabla$, so that $-\Delta_{\mathbf{g}}$ is nonnegative under the Dirichlet condition. The expression $|t|^{q-2}t$ is defined to be zero when $t = 0$; with this convention it is continuous on all of $\mathbb{R}$. The condition $u = 0$ on ∂M is understood in the trace sense.

The aim is to find $u \in W_0^{1,2}(M)$ such that

$$\int_M \langle \nabla u, \nabla v \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} = \int_M |u|^{q-2} u \, v \, d\lambda_{\mathbf{g}}$$

for every $v \in W_0^{1,2}(M)$. The associated energy functional is

$$I(u) = \frac{1}{2} \int_M |\nabla u|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}} - \frac{1}{q} \int_M |u|^q \, d\lambda_{\mathbf{g}}.$$

Proposition 30.2.1. (Application to the sublinear problem) Suppose that every connected component of the compact manifold M has nonempty smooth boundary. If $1 < q < 2$, the functional I attains its global minimum on $W_0^{1,2}(M)$, and every minimizer is a nontrivial weak solution of problem (30.1).

Proof. The nonlinearity $f(x,t) = |t|^{q-2}t$ satisfies the hypotheses of Proposition 29.3.1 with exponent $r = q$: it is continuous and its growth is $|t|^{q-1}$, with $1 < q < 2 \le 2^*$. Hence, $I \in C^1(W_0^{1,2}(M), \mathbb{R})$ and its critical points are precisely the weak solutions. More explicitly,

$$DI(u)(v) = \int_M \langle \nabla u, \nabla v \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} - \int_M |u|^{q-2} u \, v \, d\lambda_{\mathbf{g}}$$

for all $u, v \in W_0^{1,2}(M)$. The second term is finite by Hölder, since $|u|^{q-2}u \in L^{q/(q-1)}(M)$ and $v \in L^q(M)$.
Let C_P be the Poincaré constant from Theorem 9.6.8. Since M has finite volume, Hölder and Poincaré give

$$\|u\|_{L^q(M)} \le \lambda_{\mathbf{g}}(M)^{\frac{1}{q}-\frac{1}{2}} \|u\|_{L^2(M)}, \qquad \|u\|^2_{W^{1,2}(M)} \le (1 + C_P^2) \|\nabla u\|^2_{L^2(M,TM)}.$$

Consequently, we can take $C_1 := \dfrac{1}{2(1+C_P^2)}$ and $C_2 := \dfrac{1}{q} \lambda_{\mathbf{g}}(M)^{1-q/2}$ to obtain

$$I(u) \ge C_1 \|u\|^2_{W^{1,2}(M)} - C_2 \|u\|^q_{W^{1,2}(M)}.$$

If $t := \|u\|_{W^{1,2}(M)} > 0$, the right-hand side of this estimate is $t^2(C_1 - C_2 t^{q-2})$. Since $q - 2 < 0$, there exists $R > 0$ such that $C_2 t^{q-2} \le C_1/2$ for every $t \ge R$. Thus, $I(u) \ge C_1 \|u\|^2_{W^{1,2}(M)}/2$ as $\|u\|_{W^{1,2}(M)} \ge R$, proving coercivity.
To study passage to the limit, let $(u_j)_{j\in\mathbb{N}} \subseteq W_0^{1,2}(M)$ be a sequence such that $u_j \rightharpoonup u$ in that space. By Proposition B.11.20, there exists $R_0 > 0$ such that $\|u_j\|_{W^{1,2}(M)} \le R_0$ for every $j \in \mathbb{N}$. The preceding estimate implies $I(u_j) \ge -C_2 R_0^q$, whereas the definition of I gives $I(u_j) \le R_0^2/2$. Hence, $\ell := \liminf_{j\to\infty} I(u_j)$ is a real number. Choose a subsequence $(u_{j_k})_{k\in\mathbb{N}}$ such that $I(u_{j_k}) \to \ell$. Corollary 9.4.29, applied to the trivial real bundle with $m = 1$ and $p = 2$, gives compactness of $W^{1,2}(M) \hookrightarrow L^2(M)$. Since $\lambda_{\mathbf{g}}(M) < \infty$, Hölder gives the continuous embedding

$$\|w\|_{L^q(M)} \le \lambda_{\mathbf{g}}(M)^{\frac{1}{q}-\frac{1}{2}} \|w\|_{L^2(M)} \qquad (1 < q < 2).$$

By composition, $W^{1,2}(M) \hookrightarrow L^q(M)$ is compact. Passing to a subsequence of $(u_{j_k})_{k\in\mathbb{N}}$, which we continue to denote in the same way, we obtain strong convergence in $L^q(M)$. Its limit is u: the continuous embedding into $L^q(M)$ carries weak convergence in u_{j_k} to weak convergence in $L^q(M)$, and every strong limit is also a weak limit. Uniqueness of the weak limit identifies the two limits. In particular, $\|u_{j_k}\|_{L^q(M)} \to \|u\|_{L^q(M)}$, and hence

$$\int_M |u_{j_k}|^q \, d\lambda_{\mathbf{g}} \longrightarrow \int_M |u|^q \, d\lambda_{\mathbf{g}}.$$

The operator $u \mapsto \nabla u$ is linear and continuous from $W_0^{1,2}(M)$ to $L^2(M, TM)$, so $\nabla u_{j_k} \rightharpoonup \nabla u$. Weak lower semicontinuity of the norm, Proposition B.11.20, and convergence of the nonlinear term give

$$I(u) \le \liminf_{k\to\infty} \left(\frac{1}{2} \|\nabla u_{j_k}\|^2_{L^2(M,TM)} - \frac{1}{q} \|u_{j_k}\|^q_{L^q(M)} \right) = \ell.$$

Thus, I is sequentially weakly lower semicontinuous. The space $W_0^{1,2}(M)$ is Hilbert, being a closed subspace

of $W^{1,2}(M)$, and in particular is reflexive. Theorem 30.1.9 then provides $u_0 \in W_0^{1,2}(M)$ such that $I(u_0) = \inf_{u \in W_0^{1,2}(M)} I(u)$.

It remains to prove that $u_0 \neq 0$. Take $v \in C_c^\infty(\mathrm{Int}(M)) \setminus \{0\}$. For $t > 0$,

$$I(tv) = \frac{t^2}{2} \int_M |\nabla v|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}} - \frac{t^q}{q} \int_M |v|^q \, d\lambda_{\mathbf{g}}.$$

Write $A := \displaystyle\int_M |\nabla v|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}}$ and $B := \displaystyle\int_M |v|^q \, d\lambda_{\mathbf{g}}$. We have $B > 0$, since $v \neq 0$, and $A > 0$ by Poincaré. The preceding equality becomes $I(tv) = t^q(At^{2-q}/2 - B/q)$. Since $2 - q > 0$, any

$$0 < t_0 < \left(\frac{2B}{qA}\right)^{\frac{1}{2-q}}$$

satisfies $I(t_0 v) < 0 = I(0)$. Consequently, $I(u_0) \leq I(t_0 v) < 0$ and $u_0 \neq 0$. For each $v \in W_0^{1,2}(M)$, the real map $t \mapsto I(u_0 + tv)$ has a minimum at $t = 0$, so its derivative there is zero. Thus, $DI(u_0)(v) = 0$ for every $v \in W_0^{1,2}(M)$, which is the asserted weak solution identity. □

If only $\partial M \neq \varnothing$ were assumed, there could be a closed component M_0. For the function u_t equal to t on M_0 and zero on the other components, we would have

$$I(u_t) = -\frac{\lambda_{\mathbf{g}}(M_0)}{q} |t|^q \longrightarrow -\infty \qquad \text{as } |t| \to \infty.$$

In that case the energy has no global minimum on $W_0^{1,2}(M)$. Nevertheless, a nontrivial weak solution can still be obtained if there is some component with boundary: apply the proposition on that component and extend the solution by zero to the remaining ones. The weak identity on M reduces to the identity on the chosen component, since both the function and its gradient vanish on the others. This extension does not assert that the solution minimizes the energy on all of M.

30.3 Exercises

Exercise 30.3.1. Let E be a reflexive Banach space, and let $C \subset E$ be a nonempty closed convex set. Prove that if $\psi \colon E \longrightarrow \mathbb{R}$ is a weakly lower semicontinuous and coercive functional, then ψ attains its infimum on C; that is, there exists $x_0 \in C$ such that

$$\psi(x_0) = \inf_{x \in C} \psi(x).$$

Hint. Theorem B.11.16 implies that C is weakly closed. Repeat the sequential proof of the direct method with sequences contained in C; their weak limits will also belong to C. To bound the infimum above, use the value of ψ at a fixed point of C, which exists because $C \neq \varnothing$.

Exercise 30.3.2. Let E be a real Hilbert space, and let $a \colon E \times E \longrightarrow \mathbb{R}$ be a continuous bilinear form satisfying the coercivity condition

$$a(u,u) \geq \alpha \|u\|^2, \quad \text{for every } u \in E,$$

for some $\alpha > 0$. Let also $f : E \longrightarrow \mathbb{R}$ be a continuous linear functional.
Given a nonempty closed convex set $C \subset E$, prove that there exists a unique $u_0 \in C$ such that

$$\psi(u_0) = \inf_{u \in C} \psi(u),$$

where the functional $\psi \colon E \longrightarrow \mathbb{R}$ is defined by

$$\psi(u) = \frac{1}{2} a(u,u) - f(u).$$

Hint. It is not necessary to assume that a is symmetric. Define $a_s(u,v) := (a(u,v)+a(v,u))/2$ and observe that $a(u,u) = a_s(u,u)$. The quadratic part is continuous and strictly convex; by Corollary B.11.17, it is weakly lower semicontinuous. To make uniqueness precise, check that

$$\psi((1-t)u + tv) = (1-t)\psi(u) + t\psi(v) - \frac{t(1-t)}{2} a(v-u, v-u)$$

for all $u, v \in E$ and every $t \in (0,1)$. Also characterize the minimum by $a_s(u_0, v-u_0) \geq f(v-u_0)$ for every $v \in C$.

Exercise 30.3.3. Consider the problem

$$\begin{cases} -\Delta u = u^2 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{30.2}$$

where $\Omega \subset \mathbb{R}^3$ is a bounded domain. Work in $W_0^{1,2}(\Omega)$, and interpret the Dirichlet condition through the definition of this space as the closure of $C_c^\infty(\Omega)$ in $W^{1,2}(\Omega)$. This formulation does not require assigning a pointwise trace to an arbitrary boundary.

(a) Define an energy functional associated with problem (30.2) such that, if this functional is of class C^1, its critical points are weak solutions of (30.2).

(b) Prove that this functional is of class C^1.

Hint. Use $F(t) = t^3/3$, whose derivative is t^2. The potential $|t|^3/3$ would have a different derivative. The embedding $W_0^{1,2}(\Omega) \hookrightarrow L^3(\Omega)$ allows the integral of the potential and its derivative to be controlled. Also check that this energy tends to $-\infty$ along tv as $t \to +\infty$, when $v \in C_c^\infty(\Omega) \setminus \{0\}$ is nonnegative. This distinguishes the variational formulation from the hypotheses needed to obtain a global minimum.

Exercise 30.3.4. Let $(M, \mathbf{g})$ be a nonempty compact Riemannian manifold of dimension $n \geq 1$, with smooth boundary, and suppose that every connected component has nonempty boundary. Let $1 < q < 2$. Suppose that the elliptic estimate

$$\|u\|_{H^2(M)} \leq C \|\Delta_{\mathbf{g}} u\|_{L^2(M)}$$

holds on $H_0^2(M)$. Here $H_0^2(M) = W_0^{2,2}(M)$, and ν is the outward unit normal. The conditions $u = 0$ and $\partial_\nu u = 0$ are interpreted in the trace sense: Theorem 9.4.23 requires vanishing of the traces up to order one,

and tangential derivatives of the zero trace of u also vanish. Consider the problem with clamped boundary conditions

$$\begin{cases} \Delta_{\mathbf{g}}^2 u = |u|^{q-2}u & \text{in } M, \\ u = 0, \quad \partial_\nu u = 0 & \text{on } \partial M. \end{cases} \tag{30.3}$$

(a) Rigorously formulate the notion of a weak solution in $H_0^2(M)$.

(b) Prove that the functional

$$I(u) := \frac{1}{2}\int_M |\Delta_{\mathbf{g}} u|^2 \, d\lambda_{\mathbf{g}} - \frac{1}{q}\int_M |u|^q \, d\lambda_{\mathbf{g}}$$

is well defined and belongs to $C^1(H_0^2(M), \mathbb{R})$, and compute $DI(u)$.

(c) Prove that I is coercive and sequentially weakly lower semicontinuous, and deduce that it attains its global minimum.

(d) Prove that the minimizer is nonzero and is a weak solution of (30.3).

Hint. Use the elliptic estimate to work with the norm $\|\Delta_{\mathbf{g}} u\|_{L^2(M)}$, the compact embedding of $H_0^2(M)$ into $L^q(M)$, and the fact that $q < 2$. To prove that the minimizer is nonzero, evaluate $I(tv)$ with $v \in C_c^\infty(\mathrm{Int}(M)) \setminus \{0\}$ and small $t > 0$.

Exercise 30.3.5. Let $(M, \mathbf{g})$ be a nonempty compact Riemannian manifold of dimension $n \geq 1$, with smooth boundary, such that every connected component has nonempty boundary. Let $-\Delta_{\mathbf{g},D}$ be the nonnegative self-adjoint Dirichlet realization of the Laplacian. Let $0 < s < 1$ and $1 < q < 2$, and define $H_{0,D}^s(M) := \mathcal{D}((-\Delta_{\mathbf{g},D})^{s/2})$. Suppose it is a Hilbert space under the norm

$$\|u\|_{H_{0,D}^s(M)} := \|(-\Delta_{\mathbf{g},D})^{\frac{s}{2}} u\|_{L^2(M)}$$

and that the inclusion $H_{0,D}^s(M) \hookrightarrow L^q(M)$ is compact. Consider

$$(-\Delta_{\mathbf{g},D})^s u = |u|^{q-2}u \quad \text{in } M. \tag{30.4}$$

Formulate the corresponding weak identity and prove, using the direct method, that there exists a nontrivial weak solution.

Hint. Study the functional

$$I(u) := \frac{1}{2}\int_M |(-\Delta_{\mathbf{g},D})^{\frac{s}{2}} u|^2 \, d\lambda_{\mathbf{g}} - \frac{1}{q}\int_M |u|^q \, d\lambda_{\mathbf{g}}.$$

Prove separately that it is well defined, that it is of class C^1, that it is coercive, and that it is sequentially weakly lower semicontinuous. The assumed compactness gives strong convergence in $L^q(M)$ along a subsequence of any weakly convergent sequence in $H_{0,D}^s(M)$. Apply Theorem 30.1.9. The space $H_{0,D}^s(M)$ is defined through the spectral Dirichlet realization: no pointwise trace condition is added for every $s \in (0,1)$, nor is it identified, without another result, with the closure of $C_c^\infty(\mathrm{Int}(M))$ in a different fractional norm. In the weak formulation, the powers of order $s/2$ act on u and on the test function; it is not initially required that u belong to $\mathcal{D}((-\Delta_{\mathbf{g},D})^s)$.

Exercise 30.3.6. Let $(M,\mathbf{g})$ be a nonempty compact Riemannian manifold of dimension $n \geq 1$, with smooth boundary, such that every connected component has nonempty boundary. Let $1 < q < 2$, and let $\mathscr{M}\colon [0,+\infty) \longrightarrow (0,+\infty)$ be continuous and nondecreasing. Suppose that there exists $m_0 > 0$ such that $\mathscr{M}(t) \geq m_0$ for every $t \geq 0$, and define

$$\widehat{\mathscr{M}}(t) := \int_0^t \mathscr{M}(s)\,ds.$$

Consider the problem

$$\begin{cases} -\mathscr{M}\Big(\displaystyle\int_M |\nabla u|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}}\Big)\,\Delta_{\mathbf{g}} u = |u|^{q-2}u & \text{in } M, \\ u = 0 & \text{on } \partial M. \end{cases} \tag{30.5}$$

Prove that the functional

$$I(u) := \frac{1}{2}\widehat{\mathscr{M}}\Big(\int_M |\nabla u|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}}\Big) - \frac{1}{q}\int_M |u|^q \, d\lambda_{\mathbf{g}}, \qquad u \in W_0^{1,2}(M),$$

is of class C^1, compute its derivative, and prove that it has a nonzero global minimizer, which is a weak solution of (30.5).

Hint. Monotonicity of $\mathscr{M}$ implies that $\widehat{\mathscr{M}}$ is convex, whereas $\mathscr{M} \geq m_0$ gives $\widehat{\mathscr{M}}(t) \geq m_0 t$. Moreover, $\widehat{\mathscr{M}}$ is increasing because $\mathscr{M} > 0$. Combine this property with lower semicontinuity of $\|\nabla u\|^2_{L^2(M,TM)}$, and use the compact embedding $W_0^{1,2}(M) \hookrightarrow L^q(M)$ for the nonlinear term. Apply the chain rule to compute DI. To obtain a negative energy value, fix $v \neq 0$ and observe that, by continuity of $\mathscr{M}$ at 0, there exists $C_0 > 0$ such that $\widehat{\mathscr{M}}(t^2\|\nabla v\|^2_{L^2(M,TM)}) \leq C_0 t^2 \|\nabla v\|^2_{L^2(M,TM)}$ for every sufficiently small $t > 0$. Then compare t^2 with t^q.

Exercise 30.3.7. Let $(M,\mathbf{g})$ be a nonempty compact Riemannian manifold of positive dimension, with or without smooth boundary, and let $K\colon M \times M \longrightarrow (0,+\infty)$ be a measurable symmetric kernel. Suppose that

$$\|u\|_{X_K}^2 := \int_M \int_M |u(x) - u(y)|^2 K(x,y)\, d\lambda_{\mathbf{g}}(x)\, d\lambda_{\mathbf{g}}(y)$$

defines a norm on a nonzero real Hilbert space $X_K(M)$ of measurable functions, identified when they agree almost everywhere, and that, for some $1 < q < 2$, the inclusion $X_K(M) \hookrightarrow L^q(M)$ is continuous, injective, and compact. The requirement that this be a norm excludes nonzero constants from $X_K(M)$, because their difference $u(x) - u(y)$ would be zero. We do not work with classes of functions modulo constants: the term $\displaystyle\int_M |u|^q \, d\lambda_{\mathbf{g}}$ would not be well defined on that quotient. Consider the bilinear form

$$\mathcal{B}_K(u,v) := \int_M \int_M (u(x) - u(y))(v(x) - v(y)) K(x,y)\, d\lambda_{\mathbf{g}}(x)\, d\lambda_{\mathbf{g}}(y).$$

(a) Define $\mathcal{L}_K\colon X_K(M) \longrightarrow X_K(M)'$ by $\langle \mathcal{L}_K u, v\rangle := \mathcal{B}_K(u,v)$ for all $u, v \in X_K(M)$, and formulate the weak equation $\mathcal{L}_K u = |u|^{q-2}u$ as an equality in $X_K(M)'$. On the right-hand side, a function in $L^{q/(q-1)}(M)$ acts on $v \in X_K(M)$ by integration.

(b) Prove that

$$I(u) := \frac{1}{2}\mathcal{B}_K(u,u) - \frac{1}{q}\int_M |u|^q \, d\lambda_{\mathbf{g}}$$

belongs to $C^1(X_K(M),\mathbb{R})$ and that its critical points are precisely the weak solutions.

(c) Apply the direct method to prove the existence of a nontrivial weak solution.

Hint. Cauchy–Schwarz on the measure space $K(x,y)\,d\lambda_{\mathbf{g}}(x)\,d\lambda_{\mathbf{g}}(y)$ gives $|\mathcal{B}_K(u,v)| \le \|u\|_{X_K}\|v\|_{X_K}$. The quadratic part is convex and weakly lower semicontinuous. For the nonlinear part, use the assumed compact embedding and differentiability of the functional $u \mapsto \|u\|_{L^q(M)}^q/q$. Nontriviality follows by comparing $I(tv)$ with $I(0)$ for a fixed element $v \in X_K(M)\setminus\{0\}$ and sufficiently small $t > 0$. The equation is asserted only against test functions in $X_K(M)$; if this space incorporates a constraint, an identity against all smooth test functions does not follow without further argument.

Exercise 30.3.8. Let $(M,\mathbf{g})$ be a nonempty compact Riemannian manifold of dimension $n \ge 1$ with smooth boundary, and suppose that every connected component has nonempty boundary. Let $1 < p < \infty$ and $1 < q < p$, and consider

$$\begin{cases} -\Delta_{p,\mathbf{g}} u = |u|^{q-2}u & \text{in } M,\\ u = 0 & \text{on } \partial M, \end{cases} \qquad \Delta_{p,\mathbf{g}} u := \operatorname{div}_{\mathbf{g}}\big(|\nabla u|_{\mathbf{g}}^{p-2}\nabla u\big).$$

Formulate the weak problem in $W_0^{1,p}(M)$ and prove that it has a nontrivial weak solution by minimizing

$$I(u) := \frac{1}{p}\int_M |\nabla u|_{\mathbf{g}}^p \, d\lambda_{\mathbf{g}} - \frac{1}{q}\int_M |u|^q \, d\lambda_{\mathbf{g}}.$$

Hint. Corollary 29.1.11 and the chain rule give differentiability of both terms. Use Theorem 9.6.8 for the trivial real bundle. Corollary 9.4.29, with $m = 1$, gives compactness $W^{1,p}(M) \hookrightarrow L^p(M)$ for every $1 \le p < \infty$. Since $q < p$ and the volume is finite, its composition with $L^p(M) \hookrightarrow L^q(M)$ gives the required compact embedding. Convexity of the principal term provides its weak lower semicontinuity; $1 < p < \infty$ ensures reflexivity of $W_0^{1,p}(M)$. Apply Theorem 30.1.9 and compare t^p with t^q to prove nontriviality. In the expression for the p-Laplacian, define $|\xi|^{p-2}\xi = 0$ when $\xi = 0$, and all derivatives in the weak problem are understood in the sense of distributions.

31

Palais–Smale, pseudogradients, and deformations

The direct method produces critical points by minimization. Minimax methods require a different mechanism: the sublevel sets of a functional must be deformed within bands containing no critical points. On a Hilbert space this deformation can be constructed, under sufficient regularity, using the negative gradient flow. On a general Banach space there is no canonical identification with the dual, so the gradient is replaced by a descent field retaining only the indispensable estimates.

We will construct these fields and prove the deformation lemma first on Banach spaces and then on complete Banach–Finsler manifolds. The Palais–Smale condition will appear exactly where it is necessary to prevent an almost critical sequence from escaping without converging. The exposition follows Struwe [138, chap. II, §3, pp. 81–87]: the linear case corresponds to Lemma II.3.2 and Theorem II.3.4, pp. 81–84; the intrinsic version to §§II.3.7–II.3.10 and Theorem II.3.11, pp. 85–87.

Palais and Smale: compactness in the search for saddle points

Finite-dimensional Morse theory uses gradient flow to deform sublevel sets without crossing critical points. Palais and Smale identified a compactness condition that preserves this strategy in infinite-dimensional spaces. A sequence with controlled energy and small derivative must have a convergent subsequence. When this holds, topological changes in the sublevel sets are tied to actual critical points, and minimax arguments acquire analytic content [113, 112].

31.1 Sublevel sets, critical points, and the Palais–Smale condition

Let X be a real Banach space, and let $I \in C^1(X, \mathbb{R})$. We denote by X' the continuous dual of X and by $\|DI(u)\|_{X'}$ the dual norm of the derivative of I at u.

Definition 31.1.1. (Critical sets and sublevel sets) The critical set of I, the critical set at level $\beta \in \mathbb{R}$, and

the open sublevel set at height $a \in \mathbb{R}$ are, respectively,

$$\operatorname{Crit}(I) := \{u \in X \mid DI(u) = 0\}, \qquad K_\beta := \{u \in X \mid I(u) = \beta,\ DI(u) = 0\},$$

and

$$I^{<a} := \{u \in X \mid I(u) < a\}.$$

The closed sublevel set is denoted by $I^{\le a} := \{u \in X \mid I(u) \le a\}$.

Definition 31.1.2. (Palais–Smale condition) A sequence $(u_j) \subset X$ is a *Palais–Smale sequence* for I if $(I(u_j))$ is bounded and

$$\|DI(u_j)\|_{X'} \longrightarrow 0.$$

The functional I satisfies the Palais–Smale condition, abbreviated *(PS)*, if every Palais–Smale sequence has a norm-convergent subsequence.
For $\beta \in \mathbb{R}$, we say that I satisfies $(PS)_\beta$ if every sequence (u_j) such that

$$I(u_j) \longrightarrow \beta, \qquad \|DI(u_j)\|_{X'} \longrightarrow 0$$

has a convergent subsequence in X.

The global condition (PS) implies $(PS)_\beta$ for every β. The levelwise version is exactly the compactness involved in a deformation around a fixed height. These formulations and their relation to the original condition of Palais and Smale are discussed in [138, chap. II, §2, pp. 77–80].

For $\delta, \rho > 0$ set

$$N_{\beta,\delta} := \{u \in X \,\big|\, |I(u) - \beta| < \delta,\ \|DI(u)\|_{X'} < \delta\},$$
$$U_{\beta,\rho} := \left\{u \in X \,\middle|\, \operatorname{dist}(u, K_\beta) < \rho\right\}.$$

If $K_\beta = \varnothing$, adopt the convention $U_{\beta,\rho} = \varnothing$.

Lemma 31.1.3. (Local consequence of Palais–Smale) Suppose that I satisfies $(PS)_\beta$. Then:

(a) K_β is compact;

(b) $(U_{\beta,\rho})_{\rho>0}$ is a neighborhood base of K_β;

(c) $(N_{\beta,\delta})_{\delta>0}$ is a neighborhood base of K_β.

In particular, if N is an open neighborhood of K_β, there exist $\delta, \rho \in (0, 1]$ such that

$$N \supseteq U_{\beta,2\rho} \supseteq U_{\beta,\rho} \supseteq N_{\beta,\delta}. \tag{31.1}$$

Proof. Every sequence in K_β is a $(PS)_\beta$ sequence. By hypothesis it has a convergent subsequence, and continuity of I and DI shows that its limit belongs to K_β. Since X is metrizable, K_β is compact.
Let N be an open neighborhood of K_β. If no $U_{\beta,\rho}$ were contained in N, there would exist $\rho_j \to 0^+$ and $u_j \in U_{\beta,\rho_j} \setminus N$. For each j we could choose $v_j \in K_\beta$ with $\|u_j - v_j\| < 2\rho_j$. Compactness of K_β would allow us to

assume that $v_j \to v \in K_\beta$; then also $u_j \to v$, contradicting openness of N.
If no $N_{\beta,\delta}$ were contained in N, we could choose $u_j \in N_{\beta,\frac{1}{j}} \setminus N$. This would be a $(PS)_\beta$ sequence. A subsequence would converge to a point of $K_\beta \subset N$, a contradiction. This proves the three assertions. Finally, choose first $\rho \in (0,1]$ so that $U_{\beta,2\rho} \subseteq N$ and then $\delta \in (0,1]$ so that $N_{\beta,\delta} \subseteq U_{\beta,\rho}$. □

Corollary 31.1.4. (Uniform separation of the derivative from zero) If the hypotheses of the preceding lemma hold and N is an open neighborhood of K_β, there exists $\delta > 0$ such that

$$|I(u) - \beta| < \delta, \quad u \notin N \quad \Longrightarrow \quad \|DI(u)\|_{X'} \geq \delta.$$

Proof. Take δ so that $N_{\beta,\delta} \subseteq N$. If the first two conditions hold and $\|DI(u)\|_{X'} < \delta$, then $u \in N_{\beta,\delta} \subseteq N$, a contradiction. □

31.2 Construction of pseudogradients on Banach spaces

Write

$$\widetilde{X} := X \setminus \mathrm{Crit}(I).$$

This set is open because DI is continuous.

Definition 31.2.1. (Pseudogradient vector field) A field $v\colon \widetilde{X} \longrightarrow X$ is a *pseudogradient* for I if it is locally Lipschitz and, for every $u \in \widetilde{X}$, satisfies

$$\|v(u)\| < 2\min\{\|DI(u)\|_{X'}, 1\}, \tag{31.2}$$

$$DI(u)[v(u)] > \min\{\|DI(u)\|_{X'}, 1\}\|DI(u)\|_{X'}. \tag{31.3}$$

The second inequality expresses that $-v$ is a descent direction. The first simultaneously provides control near critical points and a global speed bound. Replacing the gradient by a controlled descent direction is the functional-analytic mechanism used in [112].

Theorem 31.2.2. (Existence of pseudogradients) Every functional $I \in C^1(X,\mathbb{R})$ admits a pseudogradient vector field on $\widetilde{X}$.

Proof. Fix $u \in \widetilde{X}$ and write

$$q_u := \|DI(u)\|_{X'} > 0, \qquad m_u := \min\{q_u, 1\}.$$

By the definition of the dual norm, there exists $z_u \in X$, with $\|z_u\| = 1$, such that, after changing its sign if necessary,

$$DI(u)[z_u] > \frac{3}{4} q_u.$$

Define $w_u := \frac{3}{2} m_u z_u$. Then

$$\|w_u\| = \frac{3}{2} m_u < 2m_u, \qquad DI(u)[w_u] > \frac{9}{8} m_u q_u > m_u q_u.$$

Since DI is continuous and the inequalities are strict, there exists an open neighborhood $W_u \subseteq \widetilde{X}$ of u such

that, for every $y \in W_u$,

$$\|w_u\| < 2\min\{\|DI(y)\|_{X'}, 1\}, \tag{31.4}$$

$$DI(y)[w_u] > \min\{\|DI(y)\|_{X'}, 1\}\,\|DI(y)\|_{X'}. \tag{31.5}$$

The metric space $\widetilde{X}$ is paracompact by Theorem 24.8.8. Choose a locally finite open refinement $(A_i)_{i\in J}$ of the cover $(W_u)_{u\in\widetilde{X}}$ and, for each i, a point u_i such that $A_i \subseteq W_{u_i}$. Applying the locally finite shrinking in Lemma 24.8.7 gives an open cover $(B_i)_{i\in J}$ of $\widetilde{X}$ such that

$$\overline{B_i}^{\widetilde{X}} \subseteq A_i \qquad (i \in J).$$

This shrinking is essential: the distance functions used below have support contained in the closure of B_i, not necessarily in B_i.

For $y \in \widetilde{X}$ set

$$r_i(y) := \operatorname{dist}\bigl(y, \widetilde{X} \setminus B_i\bigr).$$

If $B_i = \widetilde{X}$, interpret $r_i \equiv 1$. Each r_i is Lipschitz, is positive precisely on B_i, and

$$\operatorname{supp}(r_i) \subseteq \overline{B_i}^{\widetilde{X}} \subseteq A_i.$$

The sum $r := \displaystyle\sum_{i\in J} r_i$ is locally finite and strictly positive. Therefore,

$$\varphi_i := \frac{r_i}{r}$$

defines a locally Lipschitz partition of unity on $\widetilde{X}$, with $\operatorname{supp}(\varphi_i) \subseteq A_i$.

Define

$$v(y) := \sum_{i\in J} \varphi_i(y)\, w_{u_i}.$$

The sum is locally finite, so v is locally Lipschitz. If $\varphi_i(y) > 0$, then $y \in A_i \subseteq W_{u_i}$ and the inequalities (31.4) and (31.5) hold for w_{u_i} at y. Taking the convex combination gives (31.2) and (31.3). This proves the theorem. □

31.3 The deformation lemma on a Banach space

Two formulations appear in the literature and should be distinguished. The first starts from a uniform derivative bound throughout an energy band and requires no compactness hypothesis. The second, due to Struwe, uses Palais–Smale to obtain this bound outside a neighborhood of the critical set. We will state and prove both, then make their logical relationship precise. The first form is customary in quantitative treatments of minimax; see, for example, [152].

31.3.1 A quantitative lemma without Palais–Smale

Theorem 31.3.1. (Quantitative deformation lemma) Let X be a real Banach space, let $I \in C^1(X,\mathbb{R})$, and fix $\beta \in \mathbb{R}$, $a > 0$, and $\sigma > 0$. Suppose that

$$|I(u) - \beta| \le 2a \quad \Longrightarrow \quad \|DI(u)\|_{X'} \ge \sigma. \tag{31.6}$$

Then, for each $\varepsilon \in (0, a)$, there exists a continuous map

$$H : [0,1] \times X \longrightarrow X, \qquad H_t(u) := H(t,u),$$

satisfying:

(i) $H_0 = \mathrm{id}_X$ and each H_t is a homeomorphism of X;

(ii) if $|I(u) - \beta| \ge 2a$, then $H_t(u) = u$ for every $t \in [0,1]$;

(iii) $t \mapsto I(H_t(u))$ is nonincreasing for every $u \in X$;

(iv)
$$H_1\big(I^{\le \beta+\varepsilon}\big) \subseteq I^{\le \beta-\varepsilon};$$

(v) if $\mu := \min\{\sigma, 1\}\sigma$, then
$$\|H_t(u) - u\| \le \frac{4\varepsilon}{\mu} \qquad (t \in [0,1],\ u \in X).$$

In particular, the conclusion is quantitative both in the decrease of energy and in the displacement of points.

Proof. Let v be the pseudogradient from Theorem 31.2.2. Choose a Lipschitz function $\chi : \mathbb{R} \to [0,1]$ such that

$$\chi(s) = 1 \quad \text{if } |s - \beta| \le a, \qquad \chi(s) = 0 \quad \text{if } |s - \beta| \ge 2a.$$

For example, one can interpolate linearly on each of the two intermediate intervals. Define

$$e(u) := \begin{cases} -\chi(I(u))\, v(u), & u \notin \mathrm{Crit}(I), \\ 0, & u \in \mathrm{Crit}(I). \end{cases} \tag{31.7}$$

We carefully verify that e is locally Lipschitz on all of X. This property is immediate outside $\mathrm{Crit}(I)$, since I is locally Lipschitz, χ is Lipschitz, and v is locally Lipschitz. By (31.6) there are no critical points in the closed band $|I - \beta| \le 2a$. Hence, if u is critical, then $|I(u) - \beta| > 2a$; continuity of I shows that $\chi \circ I$ vanishes in a neighborhood of u, and there $e \equiv 0$. Moreover, by (31.2),

$$\|e(u)\| \le 2 \qquad (u \in X). \tag{31.8}$$

Theorem 25.4.5 provides a global flow $\Phi : X \times \mathbb{R} \to X$ for e. Uniqueness of solutions implies that each Φ_s is a homeomorphism with inverse Φ_{-s}, and also that a point where e vanishes remains fixed. By the chain

rule,

$$\frac{d}{ds} I(\Phi_s(u)) = -\chi(I(\Phi_s(u)))DI(\Phi_s(u))[v(\Phi_s(u))] \le 0. \tag{31.9}$$

At critical points, the right-hand side of (31.9) is interpreted as zero. In particular, energy does not increase. Set

$$\mu := \min\{\sigma, 1\}\sigma > 0, \qquad T := \frac{2\varepsilon}{\mu}, \qquad H_t(u) := \Phi_{tT}(u).$$

Properties (i)–(iii) follow from the preceding argument. The speed bound (31.8) gives

$$\|H_t(u) - u\| \le \int_0^{tT} \|e(\Phi_s(u))\|\, ds \le 2tT \le \frac{4\varepsilon}{\mu},$$

which is (v).

Only (iv) remains to be proved. Let $u \in I^{\le \beta+\varepsilon}$. If $I(u) \le \beta - \varepsilon$, monotonicity suffices. Suppose, otherwise, that $I(u) > \beta - \varepsilon$ and $I(\Phi_T(u)) > \beta - \varepsilon$. Then, for every $s \in [0, T]$,

$$\beta - \varepsilon < I(\Phi_s(u)) \le I(u) \le \beta + \varepsilon.$$

Since $\varepsilon < a$, along the entire trajectory we have $\chi(I(\Phi_s(u))) = 1$ and, by (31.6), $\|DI(\Phi_s(u))\|_{X'} \ge \sigma$. The descent property of the pseudogradient then implies

$$\frac{d}{ds} I(\Phi_s(u)) \le -\mu.$$

Integrating between 0 and T gives

$$I(\Phi_T(u)) \le I(u) - \mu T \le \beta + \varepsilon - 2\varepsilon = \beta - \varepsilon,$$

a contradiction. Consequently, $H_1(u) = \Phi_T(u) \in I^{\le \beta-\varepsilon}$. □

Hypothesis (31.6) says that the entire band is regular, with the derivative uniformly bounded away from zero. It does not assert compactness of sequences with bounded energy. This is why the preceding lemma applies even when (PS) fails, provided that the slope bound can be verified by another argument.

31.3.2 Struwe's general lemma

The following is the quantitative form of Theorem II.3.4 in [138, pp. 83–84]. The proof uses continuation of the flow in both time directions and estimates how long a trajectory remains in the region of uniform descent, with the constants in the statement.

Theorem 31.3.2. (Struwe's deformation lemma) Let X be a real Banach space, and let $I \in C^1(X, \mathbb{R})$ be a functional satisfying (PS). Fix $\beta \in \mathbb{R}$, $\varepsilon_0 > 0$, and an open neighborhood N of K_β. Then there exist $\varepsilon \in (0, \varepsilon_0)$ and a continuous flow

$$\Phi\colon X \times \mathbb{R} \longrightarrow X, \qquad \Phi_t(u) := \Phi(u, t),$$

with the following properties:

(i) $\Phi_0 = \mathrm{id}_X$ and each Φ_t is a homeomorphism, with $\Phi_t^{-1} = \Phi_{-t}$;

(ii) $\Phi_{t+s} = \Phi_t \circ \Phi_s$ for every $s, t \in \mathbb{R}$;

(iii) if $u \in \mathrm{Crit}(I)$ or $|I(u) - \beta| \geq \varepsilon_0$, then $\Phi_t(u) = u$ for every $t \in \mathbb{R}$;

(iv) $t \mapsto I(\Phi_t(u))$ is nonincreasing for every $u \in X$;

(v)
$$\Phi_1\left(I^{<\beta+\varepsilon} \setminus N\right) \subseteq I^{<\beta-\varepsilon}, \qquad \Phi_1\left(I^{<\beta+\varepsilon}\right) \subseteq I^{<\beta-\varepsilon} \cup N.$$

In particular, the restriction of $(\Phi_t)_{t\in\mathbb{R}}$ to $t \geq 0$ is the sublevel deformation semiflow.

Proof. By Lemma 31.1.3 we can choose $\delta, \rho \in (0, 1]$ such that

$$N \supseteq U_{\beta,2\rho} \supseteq U_{\beta,\rho} \supseteq N_{\beta,\delta}. \tag{31.10}$$

Let $\eta\colon X \longrightarrow [0, 1]$ be a locally Lipschitz function such that

$$\eta = 0 \quad \text{in } N_{\beta,\frac{\delta}{2}}, \qquad \eta = 1 \quad \text{in } X \setminus N_{\beta,\delta}. \tag{31.11}$$

It can be constructed without any additional regularity of the functional. Indeed,

$$C_{\beta,\frac{\delta}{2}} := \left\{ u \in X \,\middle|\, |I(u) - \beta| \leq \frac{\delta}{2}, \quad \|DI(u)\|_{X'} \leq \frac{\delta}{2} \right\}, \qquad A := C_{\beta,\frac{\delta}{2}}, \qquad B := X \setminus N_{\beta,\delta}$$

are closed by continuity of I and $u \mapsto \|DI(u)\|_{X'}$. Moreover,

$$A \cap B = \varnothing, \qquad N_{\beta,\frac{\delta}{2}} \subseteq A \subseteq N_{\beta,\delta}.$$

When A and B are nonempty, define

$$\eta(u) := \frac{d_A(u)}{q(u)}, \qquad d_A(u) := \mathrm{dist}(u, A), \quad d_B(u) := \mathrm{dist}(u, B), \quad q(u) := d_A(u) + d_B(u).$$

The functions d_A and d_B are 1-Lipschitz. Since A and B are closed and disjoint, $q(u) > 0$ for every u: equality $q(u) = 0$ would imply $u \in A \cap B$. Fixing $u_0 \in X$ and writing $q_0 := q(u_0) > 0$, if $\|u - u_0\| < \frac{q_0}{4}$, then

$$q(u) \geq q_0 - |d_A(u) - d_A(u_0)| - |d_B(u) - d_B(u_0)| > \frac{q_0}{2}.$$

Therefore, the denominator is locally bounded away from zero. For u and $\widetilde{u}$ in that ball, write $a = d_A(u)$, $\widetilde{a} = d_A(\widetilde{u})$, $q = q(u)$, and $\widetilde{q} = q(\widetilde{u})$. Then

$$\left| \frac{a}{q} - \frac{\widetilde{a}}{\widetilde{q}} \right| \leq \frac{|a - \widetilde{a}|}{q} + \frac{\widetilde{a}\,|q - \widetilde{q}|}{q\widetilde{q}}.$$

Here $\widetilde{a}$ is locally bounded, whereas d_A, d_B, and q are Lipschitz. Thus, η is locally Lipschitz. On A we have $d_A = 0$, and on B we have $d_B = 0$; disjointness and closedness show, respectively, that the other summand is positive. Consequently, $\eta = 0$ on A and $\eta = 1$ on B, proving (31.11).
If $A = \varnothing \neq B$, take $\eta \equiv 1$. If $B = \varnothing$, take $\eta \equiv 0$, including the case where both are empty. Since $N_{\beta,\frac{\delta}{2}} \subseteq A$, these conventions preserve the two required values in (31.11).

Set

$$a := \min\{\varepsilon_0, \frac{\delta}{4}\}$$

and define the Lipschitz cutoff $\chi : \mathbb{R} \longrightarrow [0,1]$ by

$$\chi(s) := \begin{cases} 1, & |s-\beta| \le \frac{a}{2}, \\ 2 - \dfrac{2|s-\beta|}{a}, & \frac{a}{2} < |s-\beta| < a, \\ 0, & |s-\beta| \ge a. \end{cases}$$

Let v be a pseudogradient provided by Theorem 31.2.2. Define the truncated field

$$e(u) := \begin{cases} -\eta(u)\chi(I(u))v(u), & u \notin \mathrm{Crit}(I), \\ 0, & u \in \mathrm{Crit}(I). \end{cases} \tag{31.12}$$

The field e is locally Lipschitz. On $\widetilde{X}$, the pseudogradient v is so by construction, η is locally Lipschitz, and $\chi \circ I$ is as well, since χ is Lipschitz and I is of class C^1 and therefore locally Lipschitz. On a ball where all three factors are bounded and have finite Lipschitz constants, the estimate

$$\|abc - a'b'c'\| \le |a-a'||b||c\| + |a'||b-b'||c\| + |a'||b'||c-c'\|$$

for $a, a', b, b' \in \mathbb{R}$ and $c, c' \in X$, applied to $a = \eta(u)$, $b = \chi(I(u))$, and $c = v(u)$, proves that their product is locally Lipschitz. If u is critical and $|I(u)-\beta| < \frac{\delta}{2}$, the cutoff η vanishes in a neighborhood of u. If $|I(u)-\beta| \ge \frac{\delta}{2}$, then $|I(u)-\beta| > a$ and $\chi \circ I$ vanishes in a neighborhood of u. Consequently, e is identically zero near every critical point; its regularity is not being deduced through a pointwise extension of v. Moreover,

$$\|e(u)\| \le 2 \qquad (u \in X). \tag{31.13}$$

Applying Theorem 25.4.5 to the autonomous problem

$$\frac{d}{dt}\Phi_t(u) = e(\Phi_t(u)), \qquad \Phi_0(u) = u, \tag{31.14}$$

gives a solution defined for all $t \in \mathbb{R}$, continuous with respect to (u,t). Uniqueness gives

$$\Phi_{t+s} = \Phi_t \circ \Phi_s, \qquad \Phi_t \circ \Phi_{-t} = \Phi_0 = \mathrm{id}_X .$$

Thus, $\Phi_t^{-1} = \Phi_{-t}$ and each Φ_t is a homeomorphism. Existence only for $t \ge 0$ would have produced a semiflow but would not suffice to conclude surjectivity of Φ_t.

If u is critical or $|I(u)-\beta| \ge \varepsilon_0$, then $e(u) = 0$; uniqueness implies that the solution starting at u is constant. By the chain rule and the pseudogradient properties,

$$\begin{aligned} \frac{d}{dt} I(\Phi_t(u)) &= DI(\Phi_t(u)) \left[\frac{d}{dt}\Phi_t(u)\right] \\ &= -\eta(\Phi_t(u))\chi(I(\Phi_t(u)))DI(\Phi_t(u))[v(\Phi_t(u))] \le 0. \end{aligned} \tag{31.15}$$

At a critical point the right-hand side is interpreted as zero. This proves the first four properties.
Now choose

$$0 < \varepsilon < \min\left\{\frac{a}{2}, \frac{\rho\delta^2}{4}\right\}. \tag{31.16}$$

Let $u \in I^{<\beta+\varepsilon}$ and suppose that $I(\Phi_1(u)) \geq \beta - \varepsilon$. Monotonicity implies, for $0 \leq t \leq 1$,

$$\beta - \varepsilon \leq I(\Phi_t(u)) < \beta + \varepsilon.$$

Hence $\chi(I(\Phi_t(u))) = 1$. Define

$$A_u := \{t \in [0,1] \mid \Phi_t(u) \notin N_{\beta,\delta}\}.$$

If $t \in A_u$, then $|I(\Phi_t(u)) - \beta| < \varepsilon < \delta$, so exclusion from $N_{\beta,\delta}$ forces $\|DI(\Phi_t(u))\|_{X'} \geq \delta$. Since $\delta \leq 1$ and $\eta = 1$ outside $N_{\beta,\delta}$, from (31.15) we obtain

$$\frac{d}{dt} I(\Phi_t(u)) \leq -\delta^2 \qquad (t \in A_u).$$

Integrating,

$$I(\Phi_1(u)) < \beta + \varepsilon - \delta^2 |A_u|, \tag{31.17}$$

where $|A_u|$ denotes Lebesgue measure.
Suppose that $u \notin N$ or $\Phi_1(u) \notin N$. Then

$$|A_u| \geq \frac{\rho}{2}. \tag{31.18}$$

Indeed, if $K_\beta = \varnothing$, δ can be chosen with $N_{\beta,\delta} = \varnothing$, and the assertion is immediate because $\rho \leq 1$. Suppose $K_\beta \neq \varnothing$. By (31.10), an endpoint outside N is outside $U_{\beta,2\rho}$, whereas $N_{\beta,\delta} \subseteq U_{\beta,\rho}$. The function $x \mapsto \operatorname{dist}(x, K_\beta)$ is 1-Lipschitz, and (31.13) gives

$$\|\Phi_t(u) - \Phi_s(u)\| \leq \int_s^t \|e(\Phi_\tau(u))\|\, d\tau \leq 2|t-s|.$$

Thus, passing from the exterior of $U_{\beta,2\rho}$ to $N_{\beta,\delta} \subseteq U_{\beta,\rho}$, or making the reverse journey, requires at least $\frac{\rho}{2}$ units of time. Before the first entry, or after the last exit, respectively, the trajectory remains outside $N_{\beta,\delta}$. If it never enters, $A_u = [0,1]$. This proves (31.18).
Estimates (31.17), (31.18), and (31.16) yield

$$I(\Phi_1(u)) < \beta + \varepsilon - \frac{\rho\delta^2}{2} < \beta - \varepsilon,$$

contradicting the preceding assumption. If $u \in I^{<\beta+\varepsilon} \setminus N$, apply the argument to the initial endpoint and obtain the first inclusion in (v). For an arbitrary $u \in I^{<\beta+\varepsilon}$, either $\Phi_1(u) \in N$ or the same argument applied to the final endpoint gives $\Phi_1(u) \in I^{<\beta-\varepsilon}$. This proves the second inclusion. □

Remark 31.3.3. (Levelwise hypotheses) Condition (PS) was used only in Lemma 31.1.3. Therefore, in the preceding theorem it suffices to assume $(PS)_\beta$. If $K_\beta = \varnothing$, there exists $\delta > 0$ such that $N_{\beta,\delta} = \varnothing$; in this case we may take $N = \varnothing$ and obtain a uniform decrease in energy in a band around β.

31.3.3 Relationship between the two deformation lemmas

The difference between the two statements lies in the source of the lower bound for $\|DI\|$. The quantitative lemma assumes it; Struwe's lemma deduces it from $(PS)_\beta$ outside a neighborhood of K_β. The next result formalizes this relationship and specifies exactly which part of Palais–Smale is used.

Proposition 31.3.4. (From compactness to a slope bounded away from zero) Let $I \in C^1(X,\mathbb{R})$ and let $\beta \in \mathbb{R}$.

(a) If I satisfies $(PS)_\beta$ and $K_\beta = \varnothing$, there exist $a, \sigma > 0$ such that

$$|I(u) - \beta| \le 2a \quad \Longrightarrow \quad \|DI(u)\|_{X'} \ge \sigma.$$

Therefore, Lemma 31.3.1 uniformly deforms the sublevel set just above β into one just below it.

(b) If I satisfies $(PS)_\beta$ and N is an open neighborhood of K_β, there exist $a, \sigma > 0$ such that

$$|I(u) - \beta| \le 2a, \qquad u \notin N \quad \Longrightarrow \quad \|DI(u)\|_{X'} \ge \sigma.$$

Struwe's lemma is the relative version of the same mechanism: an additional cutoff stops the flow near K_β and preserves uniform decrease outside N.

Proof. For (a), suppose there are no such a and σ. For each $j \in \mathbb{N}$ we could choose $u_j \in X$ with

$$|I(u_j) - \beta| \le \frac{2}{j}, \qquad \|DI(u_j)\|_{X'} < \frac{1}{j}.$$

The sequence (u_j) would be a $(PS)_\beta$ sequence. A subsequence would converge to some $u \in X$, and continuity of I and DI would give $I(u) = \beta$ and $DI(u) = 0$, contradicting $K_\beta = \varnothing$.
For (b), Corollary 31.1.4 provides $\delta > 0$ such that

$$|I(u) - \beta| < \delta, \qquad u \notin N \quad \Longrightarrow \quad \|DI(u)\|_{X'} \ge \delta.$$

It suffices to take, for example, $a = \delta/4$ and $\sigma = \delta$. The proof of Theorem 31.3.2 then shows why it does not suffice to turn off the field inside N: the nested neighborhoods $U_{\beta,\rho} \subset U_{\beta,2\rho}$ are used to control also the trajectories entering or leaving N. □

Thus, the statements are not equivalent without additional hypotheses. If $K_\beta \neq \varnothing$, the global hypothesis of the quantitative lemma is impossible, because DI vanishes on K_β. If $K_\beta = \varnothing$, however, $(PS)_\beta$ turns the quantitative lemma into the case of Struwe's lemma needed for minimax contradiction arguments.

31.4 The intrinsic Banach–Finsler formulation

Now consider a reversible Banach–Finsler manifold without boundary M with the regularity and local compatibility of norms from Section 26.3 in Chapter 26. Denote by $\|\xi\|_p$ the norm of $\xi \in T_pM$, by d the length distance, and by $\|\alpha\|_{p,*}$ the dual norm of $\alpha \in T_p'M$ defined in Definition 26.3.3. In particular,

$$\|\alpha\|_{p,*} = \sup\left\{ |\alpha(\xi)| \,\middle|\, \xi \in T_pM,\ \|\xi\|_p \le 1 \right\}.$$

Reversibility is the property of the structure F specified in Definition 26.3.1. When class $C^{1,1}$ is required, we will use the atlas of Definition 24.1.5, in accordance with Definition 26.3.7. Locally Lipschitz fields and their flows are understood as in Remark 25.4.3. Since all arguments apply componentwise, we assume below that M is connected.

Definition 31.4.1. (Intrinsic Palais–Smale condition) Let M be a reversible Banach–Finsler manifold without boundary, and let $I \in C^1(M,\mathbb{R})$. A sequence $(p_j) \subset M$ is a Palais–Smale sequence if $(I(p_j))$ is bounded and

$$\|dI_{p_j}\|_{p_j,*} \longrightarrow 0.$$

The functional satisfies (PS) if every Palais–Smale sequence has a convergent subsequence in M. It satisfies $(PS)_\beta$ if the same conclusion holds for every sequence such that

$$I(p_j) \longrightarrow \beta, \qquad \|dI_{p_j}\|_{p_j,*} \longrightarrow 0.$$

Define intrinsically

$$\begin{aligned} K_\beta &:= \{p \in M \mid I(p) = \beta,\ dI_p = 0\},\\ N_{\beta,\delta} &:= \{p \in M \mid |I(p)-\beta| < \delta,\ \|dI_p\|_{p,*} < \delta\},\\ U_{\beta,\rho} &:= \{p \in M \mid d(p,K_\beta) < \rho\}. \end{aligned}$$

We also retain the notation $I^{<a} := \{p \in M \mid I(p) < a\}$ for open sublevel sets and $I^{\le a} := \{p \in M \mid I(p) \le a\}$ for closed ones. Local compatibility of the Finsler structure implies that d induces the topology of M and that $p \mapsto \|dI_p\|_{p,*}$ is continuous. Hence the argument of Lemma 31.1.3, which uses only metrizability, continuity, and the definition of $(PS)_\beta$, gives the following result.

Lemma 31.4.2. (Neighborhoods of the critical set on a Finsler manifold) Let M be a reversible Banach–Finsler manifold without boundary, and let $I \in C^1(M,\mathbb{R})$. If I satisfies $(PS)_\beta$, then K_β is compact and the families $(U_{\beta,\rho})_{\rho>0}$ and $(N_{\beta,\delta})_{\delta>0}$ are neighborhood bases of K_β. In particular, for every open neighborhood N of K_β, there exist $\delta,\rho \in (0,1]$ such that

$$N \supseteq U_{\beta,2\rho} \supseteq U_{\beta,\rho} \supseteq N_{\beta,\delta}.$$

Proof. A sequence in K_β is a $(PS)_\beta$ sequence, and by continuity every subsequential limit remains in K_β; therefore, K_β is compact. If a neighborhood N contained no $N_{\beta,\delta}$, a choice $p_j \in N_{\beta,\frac{1}{j}} \setminus N$ would give a $(PS)_\beta$ sequence whose convergent subsequence would have a limit in $K_\beta \subset N$, a contradiction. The assertion for $U_{\beta,\rho}$ follows from compactness of K_β and the same metric argument: for points at decreasing distance from K_β, choose nearby points in K_β and extract a convergent subsequence. The final chain is obtained by choosing first ρ and then δ. □

Definition 31.4.3. (Finsler pseudogradient) Let M be a reversible Banach–Finsler manifold without boundary, and let $I \in C^1(M,\mathbb{R})$. Let

$$\widetilde{M} := \{p \in M \mid dI_p \neq 0\}.$$

A locally Lipschitz vector field $\mathbf{v}\colon \widetilde{M} \longrightarrow TM$ is a *Finsler pseudogradient* of I if $\mathbf{v}(p) \in T_pM$ and

$$\|\mathbf{v}(p)\|_p < 2\min\{\|dI_p\|_{p,*}, 1\},$$
$$dI_p[\mathbf{v}(p)] > \min\{\|dI_p\|_{p,*}, 1\}\,\|dI_p\|_{p,*}$$

for every $p \in \widetilde{M}$.

Theorem 31.4.4. (Existence of a Finsler pseudogradient) Let M be a paracompact Banach–Finsler manifold of class $C^{1,1}$. Then every $I \in C^1(M,\mathbb{R})$ admits a Finsler pseudogradient on $\widetilde{M}$.

Proof. Fix $p \in \widetilde{M}$ and write $q_p := \|dI_p\|_{p,*}$ and $m_p := \min\{q_p, 1\}$. By the definition of the dual norm, there exists $\xi_p \in T_pM$, $\|\xi_p\|_p = 1$, such that

$$dI_p[\xi_p] > \frac{3}{4}q_p.$$

Therefore,

$$\left\|\frac{3}{2}m_p\xi_p\right\|_p = \frac{3}{2}m_p < 2m_p, \qquad dI_p\left[\frac{3}{2}m_p\xi_p\right] > \frac{9}{8}m_pq_p > m_pq_p.$$

Choose a chart (U,φ) of the $C^{1,1}$ atlas about p, with $U \subseteq \widetilde{M}$, and the tangent trivialization $\tau_q := d\varphi_q\colon T_qM \longrightarrow X$. Define

$$\mathbf{w}_p(q) := \tau_q^{-1}\tau_p\left(\frac{3}{2}m_p\xi_p\right), \qquad q \in U.$$

Its components in the chart φ are constant, and $\mathbf{w}_p(p) = \frac{3}{2}m_p\xi_p$. By admissibility of the Finsler structure, Definition 26.3.1, and comparison (26.14), after shrinking U there exist constants $c_p, C_p > 0$ such that

$$c_p\|\tau_q(z)\|_X \le \|z\|_q \le C_p\|\tau_q(z)\|_X$$

for every point q in the domain and every $z \in T_qM$. The functions $q \mapsto \|\mathbf{w}_p(q)\|_q$ and $q \mapsto dI_q[\mathbf{w}_p(q)]$ are continuous by continuity of F, dI, and the local field in this trivialization. Moreover, $q \mapsto \|dI_q\|_{q,*}$ is continuous by Proposition 26.3.4, as is its minimum with 1. Since both inequalities at p are strict, we can shrink the domain again to a neighborhood W_p on which $\mathbf{w}_p$ satisfies

$$\|\mathbf{w}_p(q)\|_q < 2\min\{\|dI_q\|_{q,*}, 1\},$$
$$dI_q[\mathbf{w}_p(q)] > \min\{\|dI_q\|_{q,*}, 1\}\,\|dI_q\|_{q,*}.$$

In the chart φ, the field has constant components and is locally Lipschitz. Remark 25.4.3 shows that this property is preserved in all charts of the $C^{1,1}$ atlas.

The open set $\widetilde{M}$, with the restricted Finsler distance, is metrizable by Theorem 26.3.5 and paracompact by Theorem 24.8.8. Choose a locally finite open refinement $(A_i)_{i\in J}$ of $(W_p)_{p\in\widetilde{M}}$ and, by Lemma 24.8.7, a shrinking $(B_i)_{i\in J}$ with $\overline{B_i}^{\widetilde{M}} \subseteq A_i$. Define

$$r_i(q) := d\big(q, \widetilde{M}\setminus B_i\big), \qquad r(q) := \sum_{i\in J} r_i(q), \qquad \varphi_i(q) := \frac{r_i(q)}{r(q)}.$$

If $B_i = \widetilde{M}$, take $r_i \equiv 1$. Each r_i is Lipschitz with respect to d and positive precisely on B_i. The sum is locally

finite and positive because $(B_i)_{i\in J}$ covers $\widetilde{M}$. Near each point, r is bounded away from zero; hence the quotients φ_i are locally d-Lipschitz. Theorem 26.3.5 transfers this regularity to the charts. Moreover,

$$\sum_{i\in J}\varphi_i = 1, \qquad \operatorname{supp}(\varphi_i) \subseteq \overline{B_i}^{\widetilde{M}} \subseteq A_i.$$

For each i choose p_i with $A_i \subseteq W_{p_i}$ and set

$$\mathbf{v}(q) := \sum_{i\in J}\varphi_i(q)\mathbf{w}_{p_i}(q).$$

In this formula, each product $\varphi_i\mathbf{w}_{p_i}$ is extended by zero outside W_{p_i}. This extension is locally Lipschitz on $\widetilde{M}$: inside W_{p_i} it is a product of locally Lipschitz functions and fields, which are locally bounded in coordinates; outside W_{p_i} it is identically zero on a neighborhood, since $\operatorname{supp}(\varphi_i) \subseteq A_i \subseteq W_{p_i}$ and the support is closed in $\widetilde{M}$. Each sum is finite on a neighborhood of the point under consideration. Therefore, $\mathbf{v}$ is locally Lipschitz; since it is a convex combination of directions satisfying the two inequalities on the corresponding support, it is a Finsler pseudogradient. □

Completeness enters at a single point: it turns uniform speed control into continuation of integral curves.

Proposition 31.4.5. (Bounded fields on complete Finsler manifolds) Let (M, d) be a reversible complete Banach–Finsler manifold without boundary of class $C^{1,1}$, and let $\mathbf{e}$ be a vector field locally Lipschitz in charts. If there exists $C > 0$ such that

$$\|\mathbf{e}(p)\|_p \le C \qquad (p \in M),$$

then all its maximal integral curves are defined on $\mathbb{R}$. The flow $\Phi\colon M\times\mathbb{R} \longrightarrow M$ is continuous, satisfies

$$\Phi_{t+s} = \Phi_t \circ \Phi_s, \qquad \Phi_t^{-1} = \Phi_{-t},$$

and each Φ_t is a homeomorphism.

Proof. Remark 25.4.3 provides local existence, uniqueness, and continuous dependence in the chosen atlas. Let $\gamma\colon (a,b) \longrightarrow M$ be a maximal integral curve. For $a < s < t < b$, the definition of the length distance gives

$$d(\gamma(s),\gamma(t)) \le L(\gamma\restriction_{[s,t]}) = \int_s^t \|\mathbf{e}(\gamma(\tau))\|_{\gamma(\tau)}\,d\tau \le C|t-s|. \tag{31.19}$$

If $b < +\infty$, the estimate shows that $\gamma(t)$ is a Cauchy family as $t \to b^-$. Completeness provides $p_b \in M$ such that $\gamma(t) \to p_b$. Since the Finsler distance induces the manifold topology, we can work in a chart about p_b. Local existence for differential equations in Banach spaces produces an integral curve starting at p_b at time b. Continuity of $\mathbf{e}$ and the integral equation allow it to be concatenated with γ, and local uniqueness shows that this concatenation extends the original curve. This contradicts maximality. Thus, $b = +\infty$. Applying the same argument as $t \to a^+$ gives $a = -\infty$.

Continuous dependence on the initial value produces a continuous flow. Uniqueness of integral curves gives the group law and, taking $s = -t$, the identity $\Phi_t^{-1} = \Phi_{-t}$. Hence each Φ_t is a homeomorphism. Observe that the argument uses metric completeness at (31.19), not compactness of a closed ball. □

Theorem 31.4.6. (Banach–Finsler deformation lemma) Let M be a reversible, complete, paracompact Banach–Finsler manifold without boundary, of class $C^{1,1}$, satisfying the hypotheses of Theorem 31.4.4. Let $I \in C^1(M,\mathbb{R})$ be a functional satisfying (PS). Given $\beta \in \mathbb{R}$, $\varepsilon_0 > 0$, and an open neighborhood N of K_β, there exist $\varepsilon \in (0,\varepsilon_0)$ and a continuous flow $\Phi\colon M \times \mathbb{R} \longrightarrow M$ such that:

(i) each Φ_t is a homeomorphism, $\Phi_t^{-1} = \Phi_{-t}$, and $\Phi_{t+s} = \Phi_t \circ \Phi_s$;

(ii) $\Phi_t(p) = p$ if $dI_p = 0$ or $|I(p) - \beta| \geq \varepsilon_0$;

(iii) $I(\Phi_t(p))$ is nonincreasing in t;

(iv)
$$\Phi_1\left(I^{<\beta+\varepsilon} \setminus N\right) \subseteq I^{<\beta-\varepsilon}, \qquad \Phi_1\left(I^{<\beta+\varepsilon}\right) \subseteq I^{<\beta-\varepsilon} \cup N.$$

Here too it suffices to assume $(PS)_\beta$.

Proof. Lemma 31.4.2 provides $\delta, \rho \in (0,1]$ such that

$$N \supseteq U_{\beta,2\rho} \supseteq U_{\beta,\rho} \supseteq N_{\beta,\delta}.$$

Take
$$a := \min\{\varepsilon_0, \frac{\delta}{4}\}$$
and construct the spatial cutoff entirely from the Finsler distance. Let

$$C^M_{\beta,\frac{\delta}{2}} := \left\{ p \in M \,\middle|\, |I(p) - \beta| \leq \frac{\delta}{2}, \quad \|dI_p\|_{p,*} \leq \frac{\delta}{2} \right\}, \qquad A_M := C^M_{\beta,\frac{\delta}{2}}, \qquad B_M := M \setminus N_{\beta,\delta}.$$

Continuity of I and $p \mapsto \|dI_p\|_{p,*}$ shows that A_M and B_M are closed. Moreover,

$$A_M \cap B_M = \varnothing, \qquad N_{\beta,\frac{\delta}{2}} \subseteq A_M \subseteq N_{\beta,\delta}.$$

If both sets are nonempty, set

$$\eta(p) := \frac{d^M_A(p)}{q_M(p)}, \quad d^M_A(p) := d(p, A_M), \quad d^M_B(p) := d(p, B_M), \quad q_M(p) := d^M_A(p) + d^M_B(p). \tag{31.20}$$

The functions d^M_A and d^M_B are 1-Lipschitz with respect to d. Closedness and disjointness imply $q_M(p) > 0$ for every p. Fixing $p_0 \in M$ and writing $q_0 := q_M(p_0) > 0$, if $d(p,p_0) < \frac{q_0}{4}$, then

$$q_M(p) \geq q_0 - |d^M_A(p) - d^M_A(p_0)| - |d^M_B(p) - d^M_B(p_0)| > \frac{q_0}{2}.$$

Thus the denominator is locally bounded away from zero. For p and $\widetilde{p}$ in that ball, with $a = d^M_A(p)$, $\widetilde{a} = d^M_A(\widetilde{p})$, $q = q_M(p)$, and $\widetilde{q} = q_M(\widetilde{p})$, we have

$$\left| \frac{a}{q} - \frac{\widetilde{a}}{\widetilde{q}} \right| \leq \frac{|a - \widetilde{a}|}{q} + \frac{\widetilde{a}\,|q - \widetilde{q}|}{q\widetilde{q}}.$$

The factor $\widetilde{a}$ is locally bounded, so η is locally d-Lipschitz. Local equivalence between d and the norm of a Finsler chart gives the required local regularity in charts. Since $d^M_A = 0$ on A_M and $d^M_B = 0$ on B_M, while the

other summand is positive, we obtain $\eta = 0$ on A_M and $\eta = 1$ on B_M.
If $A_M = \varnothing \neq B_M$, take $\eta \equiv 1$. If $B_M = \varnothing$, take $\eta \equiv 0$, including the case where both are empty. In every case, η equals zero on $N_{\beta,\frac{\delta}{2}}$ and one outside $N_{\beta,\delta}$.
Let $\chi\colon \mathbb{R} \longrightarrow [0,1]$ be the Lipschitz function already defined in the Banach proof: it equals one on $[\beta - \frac{a}{2}, \beta + \frac{a}{2}]$ and zero outside $(\beta - a, \beta + a)$.
Let $\mathbf{v}$ be the pseudogradient from Theorem 31.4.4 and define

$$\mathbf{e}(p) := \begin{cases} -\eta(p)\chi(I(p))\mathbf{v}(p), & dI_p \neq 0, \\ 0, & dI_p = 0. \end{cases}$$

On the open set $\widetilde{M}$, the three factors η, $\chi \circ I$, and $\mathbf{v}$ are locally Lipschitz in charts and locally bounded; the product inequality used in the Banach proof shows that $\mathbf{e}$ is locally Lipschitz there. Critical points remain to be checked. If $dI_p = 0$ and $|I(p) - \beta| < \frac{\delta}{2}$, then p belongs to the open set $N_{\beta,\frac{\delta}{2}}$, where $\eta = 0$. If $dI_p = 0$ and $|I(p) - \beta| \geq \frac{\delta}{2}$, then $|I(p) - \beta| \geq \frac{\delta}{2} > a$; by continuity, $\chi \circ I$ vanishes on a neighborhood of p. In both cases $\mathbf{e}$ is identically zero on a neighborhood of the critical point. Therefore, the definition by cases is not a mere pointwise extension of the pseudogradient, and $\mathbf{e}$ is locally Lipschitz on all of M. Moreover,

$$\|\mathbf{e}(p)\|_p \leq 2. \tag{31.21}$$

Proposition 31.4.5 gives a global flow of homeomorphisms defined in both time directions. In particular, completeness is used explicitly in the estimate

$$d(\Phi_s(p), \Phi_t(p)) \leq \int_s^t \|\mathbf{e}(\Phi_\tau(p))\|_{\Phi_\tau(p)}\, d\tau \leq 2|t - s|. \tag{31.22}$$

The intrinsic chain rule gives

$$\begin{aligned} \frac{d}{dt} I(\Phi_t(p)) &= dI_{\Phi_t(p)}\big[\partial_t \Phi_t(p)\big] \\ &= -\eta(\Phi_t(p))\chi(I(\Phi_t(p)))dI_{\Phi_t(p)}[\mathbf{v}(\Phi_t(p))] \leq 0. \end{aligned}$$

Choose

$$0 < \varepsilon < \min\left\{\frac{a}{2}, \frac{\rho\delta^2}{4}\right\}.$$

If $p \in I^{<\beta+\varepsilon}$ and $I(\Phi_1(p)) \geq \beta - \varepsilon$, the entire trajectory between times zero and one remains in the band $|I - \beta| \leq \varepsilon < a/2$, where $\chi = 1$. For

$$A_p := \{t \in [0,1] \mid \Phi_t(p) \notin N_{\beta,\delta}\}$$

we have, using $\delta \leq 1$,

$$\frac{d}{dt} I(\Phi_t(p)) \leq -\delta^2 \quad (t \in A_p), \qquad I(\Phi_1(p)) < \beta + \varepsilon - \delta^2 |A_p|.$$

If $p \notin N$ or $\Phi_1(p) \notin N$, then $|A_p| \geq \frac{\rho}{2}$. Indeed, an endpoint outside N is outside $U_{\beta,2\rho}$, whereas $N_{\beta,\delta} \subseteq U_{\beta,\rho}$. Distance to K_β is 1-Lipschitz, and (31.22) shows that crossing the strip between the two neighborhoods requires at least $\frac{\rho}{2}$ units of time. During that interval the trajectory lies outside $N_{\beta,\delta}$. If $K_\beta = \varnothing$, choose δ

with $N_{\beta,\delta} = \varnothing$, and the conclusion is immediate. Therefore,

$$I(\Phi_1(p)) < \beta + \varepsilon - \frac{\rho\delta^2}{2} < \beta - \varepsilon.$$

Applying this contradiction first when $p \notin N$ and then when $\Phi_1(p) \notin N$ gives the two inclusions. The fixed-point properties follow from uniqueness of the flow at zeros of $\mathbf{e}$. □

This theorem is the version of Theorem II.3.11 in [138, p. 87]. The preceding proof displays its three global ingredients separately: Palais–Smale sequential compactness, the locally finite partition producing the pseudogradient, and Finsler completeness, which prevents trajectories from escaping in finite time.

31.5 Motivation and the mountain pass theorem

The direct method seeks the bottom of the energy. In many superlinear problems, however, the functional is not bounded below: along certain rays the potential part eventually dominates and the energy tends to $-\infty$. At the same time, the origin may be a strict local minimum. To travel from this local valley to a region of negative energy, every path must climb over a barrier. The mountain pass selects, among all such paths, the smallest possible maximum height. It does not minimize I over X; it minimizes the maximum of I along each path.

Ambrosetti and Rabinowitz: a critical point by minimax

The mountain pass theorem, introduced by Ambrosetti and Rabinowitz, turned this geometric picture into an existence principle in infinite dimensions [8]. Topology forces paths to cross a barrier; the deformation lemma shows that the lowest crossing height cannot be regular; and Palais–Smale prevents almost critical sequences from escaping. The three ingredients are distinct, and each plays a precise role.

31.5.1 Paths, barriers, and the minimax level

Definition 31.5.1. (Path minimax level) Let $u_0, u_1 \in X$. The class of paths with fixed endpoints is

$$\Gamma(u_0,u_1) := \{\gamma \in C([0,1],X) \mid \gamma(0) = u_0,\ \gamma(1) = u_1\}.$$

For $I \in C^1(X,\mathbb{R})$, its minimax level is

$$c(u_0,u_1) := \inf_{\gamma\in\Gamma(u_0,u_1)} \max_{t\in[0,1]} I(\gamma(t)). \tag{31.23}$$

The class is nonempty because it contains the segment $t \mapsto (1-t)u_0 + tu_1$. For each path, the maximum of $I \circ \gamma$ exists: it is the maximum of a continuous function on the compact set $[0,1]$. Moreover, all these maxima are at least $\max\{I(u_0), I(u_1)\}$, and the segment between the endpoints provides a finite upper bound for their infimum. Thus the number in (31.23) is real.

Lemma 31.5.2. (Forced crossing of the barrier) Let $u_0, u_1 \in X$ and $r > 0$, with $\|u_1 - u_0\| > r$. Every $\gamma \in \Gamma(u_0,u_1)$ intersects the sphere

$$S_r(u_0) := \{u \in X \mid \|u - u_0\| = r\}.$$

Consequently, if

$$b := \inf_{u \in S_r(u_0)} I(u),$$

then $c(u_0, u_1) \geq b$.

Proof. The function $h(t) := \|\gamma(t) - u_0\|$ is continuous, $h(0) = 0$, and $h(1) = \|u_1 - u_0\| > r$. The intermediate value theorem gives $t_r \in (0,1)$ with $h(t_r) = r$. Hence,

$$\max_{t \in [0,1]} I(\gamma(t)) \geq I(\gamma(t_r)) \geq b.$$

Taking the infimum over γ proves the last assertion. □

31.5.2 The abstract theorem and its proof

Theorem 31.5.3. (Mountain pass theorem) Let X be a real Banach space, and let $I \in C^1(X, \mathbb{R})$. Suppose there exist $u_0, u_1 \in X$ and $r > 0$ such that

$$\|u_1 - u_0\| > r$$

and

$$\max\{I(u_0), I(u_1)\} < b := \inf_{\|u - u_0\| = r} I(u). \tag{31.24}$$

Let

$$c := c(u_0, u_1) = \inf_{\gamma \in \Gamma(u_0, u_1)} \max_{t \in [0,1]} I(\gamma(t)).$$

Then $c \geq b$ and, if I satisfies $(PS)_c$, there exists $u_c \in X$ such that

$$I(u_c) = c, \qquad DI(u_c) = 0.$$

Proof. Lemma 31.5.2 gives $c \geq b$. On the other hand, the path class contains the segment between the endpoints, on which the energy has a finite maximum. Therefore, $c \in \mathbb{R}$. Moreover,

$$d := c - \max\{I(u_0), I(u_1)\} > 0. \tag{31.25}$$

Suppose, for a contradiction, that $K_c = \varnothing$. Since I satisfies $(PS)_c$, Proposition 31.3.4 provides $a_0, \sigma > 0$ such that

$$|I(u) - c| \leq 2a_0 \quad \Longrightarrow \quad \|DI(u)\|_{X'} \geq \sigma.$$

Shrinking a_0 preserves this property. Take

$$0 < a < \min\left\{a_0, \frac{d}{2}\right\} \qquad \text{and} \qquad 0 < \varepsilon < a.$$

Lemma 31.3.1, applied with $\beta = c$, produces a deformation H. By (31.25),

$$|I(u_i) - c| = c - I(u_i) \geq d > 2a \qquad (i = 0, 1),$$

so H_1 fixes both endpoints.

The definition of the infimum ensures that there exists $\gamma_\varepsilon \in \Gamma(u_0,u_1)$ such that

$$\max_{t\in[0,1]} I(\gamma_\varepsilon(t)) < c+\varepsilon. \tag{31.26}$$

Define

$$\widetilde{\gamma}_\varepsilon(t) := H_1(\gamma_\varepsilon(t)).$$

Continuity of H_1 and the fact that the endpoints are fixed show that $\widetilde{\gamma}_\varepsilon \in \Gamma(u_0,u_1)$. Moreover, (31.26) and the conclusion of the quantitative lemma give

$$I(\widetilde{\gamma}_\varepsilon(t)) \le c-\varepsilon \qquad (0\le t\le 1).$$

Consequently,

$$c \le \max_{t\in[0,1]} I(\widetilde{\gamma}_\varepsilon(t)) \le c-\varepsilon,$$

which is impossible. Therefore, $K_c \neq \varnothing$ and any of its elements is the desired point u_c. □

The proof displays the role of each hypothesis. The topological barrier puts c above the endpoint energies; $(PS)_c$ turns the absence of critical points into a uniform slope bound; and the deformation lemma lowers an almost optimal path without moving its endpoints, contradicting the definition of c. One may also directly apply Struwe's lemma 31.3.2 with $N=\varnothing$; Proposition 31.3.4 explains why both arguments use the same mechanism in this case.

Corollary 31.5.4. (Usual form with the origin and negative energy) Let $I \in C^1(X,\mathbb{R})$ and suppose that:

(i) $I(0)=0$;

(ii) there exist $\rho,\alpha>0$ such that $I(u)\ge\alpha$ when $\|u\|=\rho$;

(iii) there exists $e\in X$ such that $\|e\|>\rho$ and $I(e)<0$.

If

$$c_e := \inf_{\gamma\in\Gamma(0,e)} \max_{t\in[0,1]} I(\gamma(t))$$

and I satisfies $(PS)_{c_e}$, then $c_e\ge\alpha$ and there exists $u\in X\setminus\{0\}$ with

$$DI(u)=0, \qquad I(u)=c_e.$$

Proof. Apply the theorem with $u_0=0$, $u_1=e$, $r=\rho$, and $b\ge\alpha$. Since $c_e\ge\alpha>0=I(0)$, the resulting critical point cannot be the origin. □

31.5.3 Model: the Beltrami p-Laplacian with a pure power

Let $(M,\mathbf{g})$ be a nonempty compact Riemannian manifold of dimension n, with smooth boundary, such that every connected component has nonempty boundary. Suppose

$$1<p<n, \qquad p<r<p^* := \frac{np}{n-p},$$

and equip

$$X := W_0^{1,p}(M)$$

with the equivalent norm

$$\|u\| := \left(\int_M |\nabla u|_{\mathbf{g}}^p \, d\lambda_{\mathbf{g}} \right)^{1/p}.$$

Equivalence with the Sobolev norm follows from the Poincaré inequality, Theorem 9.6.8. The condition $p < n$ is retained here to define the finite critical exponent p^*; coercivity does not require that restriction. Consider

$$I(u) := \frac{1}{p}\|u\|^p - \frac{1}{r}\|u\|_{L^r(M)}^r. \tag{31.27}$$

Corollary 29.1.11, applied to TM with exponent p and to the trivial real bundle with exponent r, together with the continuous linear operators $u \mapsto \nabla u$ and $X \hookrightarrow L^r(M)$, allows the chain rule to be applied. Thus, the functional belongs to $C^1(X, \mathbb{R})$ and

$$DI(u)[v] = \int_M |\nabla u|_{\mathbf{g}}^{p-2} \langle \nabla u, \nabla v \rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} - \int_M |u|^{r-2} u v \, d\lambda_{\mathbf{g}}. \tag{31.28}$$

Its critical points are therefore exactly the weak solutions of

$$\begin{cases} -\operatorname{div}_{\mathbf{g}}\left(|\nabla u|_{\mathbf{g}}^{p-2} \nabla u \right) = |u|^{r-2} u & \text{in } M, \\ u = 0 & \text{on } \partial M. \end{cases} \tag{31.29}$$

Proposition 31.5.5. (Mountain pass geometry) The functional in (31.27) satisfies the geometric hypotheses of Corollary 31.5.4.

Proof. The continuous embedding $X \hookrightarrow L^r(M)$ provides $C_S > 0$ such that $\|u\|_{L^r(M)} \le C_S \|u\|$. Therefore,

$$I(u) \ge \frac{1}{p}\|u\|^p - \frac{C_S^r}{r}\|u\|^r. \tag{31.30}$$

Since $r > p$, we can choose $\rho > 0$ so that

$$\frac{C_S^r}{r}\rho^{r-p} \le \frac{1}{2p}.$$

If $\|u\| = \rho$, the preceding estimate gives

$$I(u) \ge \frac{\rho^p}{2p} =: \alpha > 0.$$

On the other hand, fix $w \in X \setminus \{0\}$. For $t > 0$,

$$I(tw) = \frac{t^p}{p}\|w\|^p - \frac{t^r}{r}\|w\|_{L^r(M)}^r.$$

The second coefficient is positive and $r > p$; dividing by t^r shows that $I(tw)/t^r \to -\|w\|_{L^r(M)}^r/r$. Consequently, $I(tw) \to -\infty$. For sufficiently large t, $e := tw$ satisfies $\|e\| > \rho$ and $I(e) < 0$. □

The strong convergence required by the Palais–Smale condition will follow from the next monotonicity property.

Lemma 31.5.6. (Property of type (S_+)) Define $\mathcal{A}_p\colon X \to X'$ by

$$\mathcal{A}_p(u)[v] := \int_M |\nabla u|_{\mathbf{g}}^{p-2}\langle \nabla u, \nabla v\rangle_{\mathbf{g}}\, d\lambda_{\mathbf{g}}.$$

If $u_j \rightharpoonup u$ in X and

$$\limsup_{j\to\infty} \mathcal{A}_p(u_j)[u_j - u] \le 0,$$

then $u_j \to u$ in X.

Proof. Let $F(v) := \|v\|^p/p$. This functional is convex, is of class C^1, and $DF(v) = \mathcal{A}_p(v)$. The supporting inequality for a differentiable convex functional, applied at u_j, gives

$$F(u) \ge F(u_j) + DF(u_j)[u - u_j].$$

Therefore,

$$\limsup_{j\to\infty} F(u_j) \le F(u).$$

Weak lower semicontinuity of the norm gives the opposite inequality for the lower limit. It follows that $\|u_j\| \to \|u\|$.

With the chosen norm, X is identified isometrically through $u \mapsto \nabla u$ with a closed subspace of $L^p(M, TM)$. The latter is uniformly convex for $1 < p < \infty$, and uniform convexity passes to subspaces. Recall why, in a uniformly convex space, weak convergence together with convergence of norms implies strong convergence. If $u = 0$, the assertion is immediate. If $u \neq 0$, normalize $y_j := u_j/\|u_j\|$ and $y := u/\|u\|$. If a subsequence satisfied $\|y_j - y\| \ge \eta > 0$, uniform convexity would give $\|(y_j + y)/2\| \le 1 - \delta$ for some $\delta > 0$. By Hahn–Banach there exists $\ell \in X'$ with $\|\ell\| = 1$ and $\ell(y) = 1$; since $y_j \rightharpoonup y$,

$$\left\|\frac{y_j + y}{2}\right\| \ge \ell\left(\frac{y_j + y}{2}\right) \longrightarrow 1,$$

a contradiction. Thus, $y_j \to y$ and, using $\|u_j\| \to \|u\|$, we obtain $u_j \to u$. □

Proposition 31.5.7. (Palais–Smale for the subcritical power) The functional in (31.27) satisfies condition (PS).

Proof. Let $(u_j) \subset X$ be a Palais–Smale sequence. There exist $C > 0$ and a sequence $d_j \to 0^+$ such that

$$|I(u_j)| \le C, \qquad \|DI(u_j)\|_{X'} \le d_j.$$

The exact identity

$$I(u_j) - \frac{1}{r} DI(u_j)[u_j] = \left(\frac{1}{p} - \frac{1}{r}\right)\|u_j\|^p \tag{31.31}$$

implies

$$\left(\frac{1}{p} - \frac{1}{r}\right)\|u_j\|^p \le C + \frac{d_j}{r}\|u_j\|.$$

The sequence is bounded. Indeed, if a subsequence had norm tending to infinity, dividing the last inequality by $\|u_j\|^p$ would leave the left-hand side positive while the right-hand side tended to zero, since $p > 1$.

Since X is reflexive, after passing to a subsequence there exists $u \in X$ such that $u_j \rightharpoonup u$. Corollary 9.4.31 gives the compact embedding because $r < p^*$; therefore,

$$u_j \longrightarrow u \quad \text{in } L^r(M).$$

From (31.28) we obtain

$$\mathcal{A}_p(u_j)[u_j - u] = DI(u_j)[u_j - u] + \int_M |u_j|^{r-2} u_j (u_j - u)\, d\lambda_{\mathbf{g}}.$$

The first term tends to zero because $(u_j - u)$ is bounded in X and $\|DI(u_j)\|_{X'} \to 0$. For the second, Hölder gives

$$\left| \int_M |u_j|^{r-2} u_j (u_j - u)\, d\lambda_{\mathbf{g}} \right| \le \|u_j\|_{L^r(M)}^{r-1} \|u_j - u\|_{L^r(M)} \longrightarrow 0.$$

Lemma 31.5.6 implies $u_j \to u$ in X. Every Palais–Smale sequence therefore has a convergent subsequence. □

Corollary 31.5.8. (Nontrivial solution of the power problem) Problem (31.29) has a nontrivial weak solution $u \in W_0^{1,p}(M)$.

Proof. Propositions 31.5.5 and 31.5.7 allow Corollary 31.5.4 to be applied. The resulting critical point has energy at least $\alpha > 0$, so it is not the origin, and (31.28) is precisely the weak formulation of (31.29). □

This example clarifies when the mountain pass contributes something that Nehari reduction does not automatically provide. The minimax argument uses only a barrier, a low-energy direction, and compactness at the selected level; it does not require every radial function $t \mapsto I(tu)$ to have a unique maximum or $\{u \neq 0 \mid DI(u)[u] = 0\}$ to be a submanifold. In the next chapter we will compare the two methods and prove that, for the pure power, their levels agree exactly.

The same abstract argument works on a complete Banach–Finsler manifold whenever the minimax class is preserved by composition of its elements with the deformation in Theorem 31.4.6. This is the starting point for more general geometric minimax principles.

32

Variational constraints and the Nehari method

Many energy functionals cannot be minimized directly on the entire ambient space: the origin may be a trivial minimum, the functional may lack coercivity, or the relevant geometry may be concentrated on a constraint set. In such situations it is useful to study critical points of the functional on a suitable submanifold.

The structure of regular level sets and the description of their tangent spaces were established in Chapter 24. Corollary 23.4.2, obtained from Theorem 23.3.8, provides the Lagrange multiplier principle in Banach spaces. Here we apply that framework to variational constraints and, in particular, to the Nehari manifold.

In the Nehari method, the constraint is obtained by setting the derivative of the functional in the radial direction u equal to zero. This condition eliminates the direction in which the energy may lose coercivity or lead to the trivial critical point, while retaining the tangential variations relevant to locating nonzero solutions.

Zeev Nehari and natural constraints

The method associated with Nehari uses the radial derivative of the energy to select a set where an unproductive direction disappears [108]. Under suitable hypotheses, this constraint is natural: a critical point of the restricted functional is also critical on the whole space. The advantage is not merely technical. The radial identity reflects the balance between terms of different homogeneities and turns the search for nontrivial solutions into a geometric problem on a submanifold of the function space.

32.1 The Nehari method

The Nehari manifold turns a necessary variational condition into a useful geometric constraint. Let $I\colon X \longrightarrow \mathbb{R}$ be an energy functional on a Banach space suitable for seeking weak solutions. Every critical point u satisfies $DI(u) = 0$ in X' and, in particular, $DI(u)(u) = 0$.

This motivates considering the set

$$\mathcal{N} := \{u \in X \setminus \{0\} \mid DI(u)(u) = 0\},$$

called the *Nehari manifold associated with I*. The idea of the method is to study first the functional I restricted to $\mathcal{N}$ and then to show that, under suitable hypotheses, critical points of $I\restriction_{\mathcal{N}}$ are in fact critical points of I on all of X.

The results of Section 24.7 provide a geometric description of this constraint. If $V = \{u \in \Omega \mid J(u) = c\}$ is a regular level set in an open set $\Omega \subseteq X$, then $T_u V = \ker(DJ(u))$ and

$$d(\varphi\restriction_V)_u = D\varphi(u)\restriction_{T_u V}.$$

For this reason, define

$$\|D\varphi(u)\|_{*,V} := \|D\varphi(u)\restriction_{T_u V}\|_{\mathcal{L}(T_u V,\mathbb{R})}.$$

If $T_u V \neq \{0\}$, this norm can also be written as

$$\|D\varphi(u)\|_{*,V} = \sup_{\substack{v\in T_u V\\ \|v\|=1}} |D\varphi(u)(v)|.$$

The norm on $T_u V$ is induced by its identification with the subspace $\ker(DJ(u)) \subseteq X$ and measures the slope of φ only in admissible directions.

Lemma 32.1.1. Let X be a real vector space, and let $f, g\colon X \longrightarrow \mathbb{R}$ be linear functionals, with $g \neq 0$. If $\ker(g) \subset \ker(f)$, then there exists a unique $\lambda \in \mathbb{R}$ such that $f = \lambda g$.

Proof. Since $g \neq 0$, there exists $x_0 \in X$ such that $g(x_0) \neq 0$. Define $\lambda := \dfrac{f(x_0)}{g(x_0)}$. We show that $f(x) = \lambda g(x)$ for every $x \in X$. Let $x \in X$ and consider $y := x - \dfrac{g(x)}{g(x_0)}x_0$. Then $g(y) = g(x) - \dfrac{g(x)}{g(x_0)}g(x_0) = 0$, so $y \in \ker(g)$. By hypothesis, $y \in \ker(f)$, and then $0 = f(y) = f(x) - \dfrac{g(x)}{g(x_0)}f(x_0)$. Therefore, $f(x) = \dfrac{f(x_0)}{g(x_0)}g(x) = \lambda g(x)$. Since this holds for every $x \in X$, it follows that $f = \lambda g$. Uniqueness is immediate: if $\lambda_1 g = \lambda_2 g$, then $(\lambda_1 - \lambda_2)g = 0$, and since $g \neq 0$, it follows that $\lambda_1 = \lambda_2$. □

Lemma 32.1.2. (Duality lemma) Let X be a real Banach space, and let $f, g \in X'$, with $g \neq 0$. Then

$$\|f\restriction_{\ker(g)}\|_{(\ker(g))'} = \min_{\lambda\in\mathbb{R}} \|f - \lambda g\|_{X'}.$$

If $\ker(g) \neq \{0\}$, the left-hand side agrees with $\sup\limits_{\substack{y\in\ker(g)\\ \|y\|=1}} |f(y)|$.

Proof. Let $\lambda \in \mathbb{R}$. Since $(f - \lambda g)\restriction_{\ker(g)} = f\restriction_{\ker(g)}$, we have

$$\|f\restriction_{\ker(g)}\|_{(\ker(g))'} \leq \|f - \lambda g\|_{X'}.$$

Taking the infimum over λ, we obtain

$$\|f\restriction_{\ker(g)}\|_{(\ker(g))'} \leq \inf_{\lambda\in\mathbb{R}} \|f - \lambda g\|_{X'}.$$

By Corollary B.2.29, there exists $\widetilde{f} \in X'$ extending $f \restriction_{\ker(g)}$ and satisfying

$$\|\widetilde{f}\|_{X'} = \|f \restriction_{\ker(g)}\|_{(\ker(g))'}.$$

Since $f - \widetilde{f}$ vanishes on $\ker(g)$, Lemma 32.1.1 provides $\lambda_0 \in \mathbb{R}$ such that $f - \widetilde{f} = \lambda_0 g$. Therefore,

$$\inf_{\lambda \in \mathbb{R}} \|f - \lambda g\|_{X'} \leq \|f - \lambda_0 g\|_{X'} = \|\widetilde{f}\|_{X'} = \|f \restriction_{\ker(g)}\|_{(\ker(g))'}.$$

The two inequalities prove equality and also show that the infimum is attained at λ_0. The last assertion is the usual characterization of the norm of a continuous linear functional on a nontrivial normed space. □

Proposition 32.1.3. (Characterization of constrained critical points) Let X be a real Banach space, let $\Omega \subset X$ be an open set, and let $J \in C^1(\Omega, \mathbb{R})$ and $c \in \mathbb{R}$. Suppose that $V := \{u \in \Omega \mid J(u) = c\}$ is a regular level set, that is, $DJ(u) \neq 0$ for every $u \in V$. If $\varphi \in C^1(\Omega, \mathbb{R})$ and $u \in V$, then

$$\|D\varphi(u)\|_{*,V} = \min_{\lambda \in \mathbb{R}} \|D\varphi(u) - \lambda DJ(u)\|_{X'}.$$

Moreover, u is a critical point of the restriction $\varphi \restriction_V$ if and only if there exists $\lambda \in \mathbb{R}$ such that

$$D\varphi(u) = \lambda DJ(u).$$

Proof. Since V is a regular level set of J in the open set Ω, Theorem 24.7.2 implies that $T_u V = \ker(DJ(u))$. Moreover, by Lemma 24.7.3,

$$d(\varphi \restriction_V)_u = D\varphi(u) \restriction_{T_u V}.$$

Therefore,

$$\|D\varphi(u)\|_{*,V} = \|D\varphi(u) \restriction_{\ker(DJ(u))}\|_{(\ker(DJ(u)))'}.$$

Applying Lemma 32.1.2 with $f = D\varphi(u)$ and $g = DJ(u)$ gives

$$\|D\varphi(u)\|_{*,V} = \min_{\lambda \in \mathbb{R}} \|D\varphi(u) - \lambda DJ(u)\|_{X'}.$$

We now prove the characterization of critical points. By definition, u is a critical point of $\varphi \restriction_V$ if and only if $d(\varphi \restriction_V)_u = 0$. By Lemma 24.7.3, this is equivalent to $D\varphi(u)(v) = 0$ for every $v \in T_u V$. Since $T_u V = \ker(DJ(u))$, this is equivalent to $\ker(DJ(u)) \subset \ker(D\varphi(u))$. Since $DJ(u) \neq 0$, Lemma 32.1.1 gives $\lambda \in \mathbb{R}$ such that $D\varphi(u) = \lambda DJ(u)$.
Conversely, if there exists $\lambda \in \mathbb{R}$ such that $D\varphi(u) = \lambda DJ(u)$, then for every $v \in T_u V = \ker(DJ(u))$ we have $D\varphi(u)(v) = \lambda DJ(u)(v) = 0$. Therefore, $d(\varphi \restriction_V)_u = 0$ and u is a critical point of $\varphi \restriction_V$. This proves the equivalence. □

In particular, for the Nehari manifold take $\Omega := X \setminus \{0\}$, which is open in X, and define $J \colon \Omega \longrightarrow \mathbb{R}$ by $J(u) := DI(u)(u)$. Then

$$\mathcal{N} = \{u \in \Omega \mid J(u) = 0\} = \{u \in X \setminus \{0\} \mid DI(u)(u) = 0\}.$$

Therefore, if $J \in C^1(\Omega, \mathbb{R})$ and $DJ(u) \neq 0$ for every $u \in \mathcal{N}$, Theorem 24.7.2 implies that $\mathcal{N}$ is an embedded

Banach submanifold of class C^1 and codimension 1. Furthermore, for each $u \in \mathcal{N}$ we have

$$T_u\mathcal{N} = \ker(DJ(u)).$$

If I is also of class C^2 on Ω, then J is of class C^1 and, for every $v \in X$,

$$DJ(u)(v) = D^2I(u)(v,u) + DI(u)(v).$$

In the next section we will apply this framework to the superlinear subcritical problem on a compact Riemannian manifold.

32.2 The Nehari manifold in a model case

Let $(M,\mathbf{g})$ be a nonempty compact Riemannian manifold with smooth boundary. Consider $X = W_0^{1,2}(M)$ and

$$I(u) := \frac{1}{2}\int_M |\nabla u|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}} - \frac{1}{r}\int_M |u|^r \, d\lambda_{\mathbf{g}}, \qquad 2 < r < 2^*.$$

Then

$$J(u) := DI(u)(u) = \int_M |\nabla u|_{\mathbf{g}}^2 \, d\lambda_{\mathbf{g}} - \int_M |u|^r \, d\lambda_{\mathbf{g}},$$

and the Nehari manifold is $\mathcal{N} = J^{-1}(0) \setminus \{0\}$.

Proposition 32.2.1. (The Nehari manifold as a hypersurface) Let $(M,\mathbf{g})$ be a compact Riemannian manifold with nonempty boundary, and let X, I, J, and $\mathcal{N}$ be the objects defined at the beginning of this section. The set $\mathcal{N}$ is an embedded Banach submanifold of class C^1 and codimension 1 in $X \setminus \{0\}$. Moreover, for each $u \in \mathcal{N}$,

$$T_u\mathcal{N} = \ker DJ(u).$$

Proof. By Proposition 29.3.2, $I \in C^2(X,\mathbb{R})$ and $J \in C^1(X \setminus \{0\},\mathbb{R})$. For $u, v \in X$,

$$DJ(u)(v) = 2\int_M \langle \nabla u, \nabla v\rangle_{\mathbf{g}} \, d\lambda_{\mathbf{g}} - r\int_M |u|^{r-2}uv \, d\lambda_{\mathbf{g}}.$$

If $u \in \mathcal{N}$, then

$$DJ(u)(u) = (2-r)\int_M |u|^r \, d\lambda_{\mathbf{g}} < 0.$$

Therefore, $DJ(u) \neq 0$ for every $u \in \mathcal{N}$. Theorem 24.7.2 implies that $\mathcal{N}$ is an embedded submanifold of codimension 1 and that $T_u\mathcal{N} = \ker DJ(u)$. □

This example explains why the term Nehari manifold is used when the functional is of class C^2. In quasilinear problems, however, the functional may be only of class C^1; in that situation it is not legitimate to assume that $u \mapsto DI(u)(u)$ is differentiable. The radial method of Szulkin and Weth works directly with the topological structure of the constraint.

32.3 The radial reduction of Szulkin and Weth

The Nehari method can be developed without assuming that the constraint set is a differentiable submanifold. The idea is to select on each positive ray the unique point where the functional attains its maximum and to transfer the variational problem to the unit sphere. We present the abstract framework of Szulkin and Weth [139, §3.1, Propositions 8–9 and Corollary 10] in the notation adopted in this book.

Let X be a uniformly convex real Banach space, let $I \in C^1(X,\mathbb{R})$, and suppose that $I(0) = 0$. Denote the unit sphere by

$$S_X := \{u \in X \mid \|u\|_X = 1\}$$

A function $\varphi\colon [0,+\infty) \longrightarrow [0,+\infty)$ is called a **normalization function** if it is continuous, $\varphi(0) = 0$, it is strictly increasing, and $\varphi(t) \to +\infty$ as $t \to +\infty$. We consider the following hypotheses:

(A1) There exists a normalization function φ such that the functional

$$\psi(u) := \int_0^{\|u\|_X} \varphi(t)\,dt, \qquad u \in X,$$

belongs to $C^1(X \setminus \{0\},\mathbb{R})$, the duality map $\mathcal{J} := D\psi\colon X \setminus \{0\} \longrightarrow X'$ maps bounded sets to bounded sets, and

$$\mathcal{J}(w)(w) = 1$$

for every $w \in S_X$.

(A2) For each $w \in X \setminus \{0\}$ there exists $s_w > 0$ such that, if $\alpha_w\colon (0,+\infty) \longrightarrow \mathbb{R}$ is given by $\alpha_w(s) := I(sw)$, then

$$\alpha_w'(s) > 0 \quad \text{if } 0 < s < s_w, \qquad \alpha_w'(s) < 0 \quad \text{if } s > s_w.$$

(A3) There exists $\delta > 0$ such that $s_w \geq \delta$ for every $w \in S_X$ and, for each compact set $K \subseteq S_X$, there exists $C_K > 0$ such that $s_w \leq C_K$ for every $w \in K$.

Hypothesis (A2) implies that s_w is the unique global maximum of α_w and that $s_w w$ is the unique point of the positive ray generated by w belonging to the Nehari set

$$\mathcal{N} := \{u \in X \setminus \{0\} \mid DI(u)(u) = 0\}.$$

Theorem 32.3.1. (Radial reduction principle) Suppose hypotheses (A1)–(A3) hold. Define

$$\widehat{m}\colon X \setminus \{0\} \longrightarrow \mathcal{N}, \qquad \widehat{m}(w) := s_w w,$$

and let $m := \widehat{m}\restriction_{S_X}$. Then the following assertions hold:

(a) the map $\widehat{m}$ is continuous;

(b) $m\colon S_X \longrightarrow \mathcal{N}$ is a homeomorphism and

$$m^{-1}(u) = \frac{u}{\|u\|_X}$$

for every $u \in \mathcal{N}$;

(c) the functional $\widehat{\Psi} := I \circ \widehat{m}$ belongs to $C^1(X \setminus \{0\}, \mathbb{R})$ and

$$D\widehat{\Psi}(w)(z) = \frac{\|\widehat{m}(w)\|_X}{\|w\|_X} DI(\widehat{m}(w))(z) \tag{32.1}$$

for all $w \in X \setminus \{0\}$ and $z \in X$;

(d) the sphere S_X is an embedded Banach submanifold of class C^1, the functional $\Psi := I \circ m$ belongs to $C^1(S_X, \mathbb{R})$, and

$$D\Psi(w)(z) = \|m(w)\|_X DI(m(w))(z) \tag{32.2}$$

for all $w \in S_X$ and $z \in T_w S_X$;

(e) a point $w \in S_X$ is critical for Ψ if and only if $m(w)$ is a nontrivial critical point of I;

(f) the minimax characterization

$$\inf_{u \in \mathcal{N}} I(u) = \inf_{w \in S_X} \Psi(w) = \inf_{w \in X \setminus \{0\}} \max_{s > 0} I(sw).$$

holds.

Proof. Begin with a scaling property. If $w \in X \setminus \{0\}$ and $t > 0$, then $\alpha_{tw}(s) = I(stw) = \alpha_w(st)$. Uniqueness of the maximum given by (A2) implies

$$s_{tw} = \frac{s_w}{t} \tag{32.3}$$

and hence $\widehat{m}(tw) = \widehat{m}(w)$.

The first part of (A3) shows that $\mathcal{N}$ is bounded away from the origin. If $u \in \mathcal{N}$ and $w := \frac{u}{\|u\|_X} \in S_X$, then $u = s_w w$ and $\|u\|_X = s_w \geq \delta$. Moreover, $\mathcal{N}$ is closed in X. If $u_j \in \mathcal{N}$ and $u_j \to u$ in X, separation from the origin implies $u \neq 0$, whereas continuity of $DI \colon X \longrightarrow X'$ gives

$$DI(u)(u) = \lim_{j \to \infty} DI(u_j)(u_j) = 0.$$

Consequently, $u \in \mathcal{N}$.

We prove continuity of $\widehat{m}$. Let $w_j \to w \neq 0$. By (32.3), we may replace each w_j and w by their normalizations and assume that $w_j, w \in S_X$. The set $K := \{w\} \cup \{w_j \mid j \in \mathbb{N}\}$ is compact. By (A3), the sequence (s_{w_j}) is bounded and bounded away from zero. Every subsequence therefore has a further subsequence, denoted in the same way, such that $s_{w_j} \to s > 0$. Hence,

$$\widehat{m}(w_j) = s_{w_j} w_j \longrightarrow sw.$$

Since $\mathcal{N}$ is closed, $sw \in \mathcal{N}$. Uniqueness of the intersection of the positive ray generated by w with $\mathcal{N}$ implies $s = s_w$, and therefore $\widehat{m}(w_j) \to \widehat{m}(w)$. The subsequence criterion proves continuity of $\widehat{m}$.

Continuity of m is immediate. If $u \in \mathcal{N}$ and $w := \frac{u}{\|u\|_X}$, then $w \in S_X$ and, by radial uniqueness, $s_w = \|u\|_X$; thus, $m(w) = u$. This proves that m is bijective and that its inverse is given by $m^{-1}(u) = \frac{u}{\|u\|_X}$. Since normalization is continuous on $X \setminus \{0\}$, m^{-1} is continuous and m is a homeomorphism.

We now study regularity of $\widehat{\Psi}$. Fix $w \in X \setminus \{0\}$ and $z \in X$. For sufficiently small $t \neq 0$, write $s_t := s_{w+tz}$. Since

$s_w w$ maximizes $s \mapsto I(sw)$ and $s_t(w+tz)$ maximizes $s \mapsto I(s(w+tz))$, we have

$$I(s_w(w+tz)) - I(s_w w) \le \widehat{\Psi}(w+tz) - \widehat{\Psi}(w) \le I(s_t(w+tz)) - I(s_t w).$$

Applying the mean value theorem to the real functions obtained by restricting I to the corresponding segments gives $\eta_t, \tau_t \in (0,1)$ such that

$$I(s_w(w+tz)) - I(s_w w) = t s_w DI\big(s_w(w+\eta_t tz)\big)(z)$$

and

$$I(s_t(w+tz)) - I(s_t w) = t s_t DI\big(s_t(w+\tau_t tz)\big)(z).$$

Continuity of $w \mapsto s_w$ and DI implies that both quotients, after division by t, converge to $s_w DI(s_w w)(z)$ as $t \to 0$. For $t > 0$ the result follows directly by squeezing, and for $t < 0$ the inequalities reverse on division by t and produce the same limit. Therefore, the directional derivative exists and

$$D_z \widehat{\Psi}(w) = s_w DI(s_w w)(z).$$

Since $s_w = \frac{\|\widehat{m}(w)\|_X}{\|w\|_X}$, we obtain (32.1). The right-hand side is linear and continuous in z, and depends continuously on w in the norm of X'. By Corollary 23.1.17, $\widehat{\Psi} \in C^1(X \setminus \{0\}, \mathbb{R})$.

Let $c_\varphi := \displaystyle\int_0^1 \varphi(t)\,dt$. Since φ is strictly increasing, $S_X = \psi^{-1}(c_\varphi)$. Moreover, (A1) gives $D\psi(w)(w) = \mathcal{J}(w)(w) = 1$ for every $w \in S_X$. The value c_φ is regular, and Theorem 24.7.2 implies that S_X is an embedded submanifold of class C^1 and

$$T_w S_X = \ker \mathcal{J}(w).$$

Identity (32.2) follows by restricting (32.1) to S_X, since $\|w\|_X = 1$.

If $DI(m(w)) = 0$, then (32.2) shows that $D\Psi(w) = 0$. Conversely, suppose that $D\Psi(w) = 0$. Given $v \in X$, define

$$\alpha := \mathcal{J}(w)(v), \qquad z := v - \alpha w.$$

Since $\mathcal{J}(w)(w) = 1$, we have $\mathcal{J}(w)(z) = 0$, so $z \in T_w S_X$. The Nehari identity gives $DI(m(w))(m(w)) = 0$ and, since $m(w) = \|m(w)\|_X w$, also $DI(m(w))(w) = 0$. On the other hand, (32.2) and $D\Psi(w) = 0$ imply $DI(m(w))(z) = 0$. Consequently,

$$DI(m(w))(v) = DI(m(w))(z) + \alpha DI(m(w))(w) = 0.$$

Since v was arbitrary, $DI(m(w)) = 0$.

Finally, bijectivity of m gives

$$\inf_{u \in \mathcal{N}} I(u) = \inf_{w \in S_X} \Psi(w).$$

By (A2), $I(s_w w) = \max_{s>0} I(sw)$, and this quantity depends only on the positive ray generated by w. Normalizing each nonzero vector then yields

$$\inf_{w \in S_X} \Psi(w) = \inf_{w \in X \setminus \{0\}} \max_{s>0} I(sw).$$

□

Radial reduction allows minimization on $\mathcal{N}$, which need not be a differentiable submanifold, to be replaced by a problem of class C^1 on the unit sphere.

32.4 Mountain pass and Nehari in the power model

Return to the power problem of Chapter 31. Let $(M,\mathbf{g})$ be a nonempty compact Riemannian manifold of dimension n, with smooth boundary, such that every connected component has nonempty boundary, and suppose

$$1 < p < n, \qquad p < r < p^* := \frac{np}{n-p}.$$

On

$$X := W_0^{1,p}(M), \qquad \|u\| := \|\nabla u\|_{L^p(M)},$$

consider

$$I(u) := \frac{1}{p}\|u\|^p - \frac{1}{r}\|u\|_{L^r(M)}^r. \tag{32.4}$$

Its derivative was calculated in (31.28). Introduce

$$G(u) := DI(u)[u] = \|u\|^p - \|u\|_{L^r(M)}^r$$

and

$$\mathcal{N} := \{u \in X \setminus \{0\} \mid G(u) = 0\}.$$

The scaling argument allows each positive ray to be projected onto $\mathcal{N}$ and relates this projection to energy minimization.

Theorem 32.4.1. (Radial projection, minimizer, and ground state) For the functional in (32.4), the following assertions hold.

(a) For each $u \in X \setminus \{0\}$ there exists a unique $t_u > 0$ such that $t_u u \in \mathcal{N}$, given by

$$t_u = \left(\frac{\|u\|^p}{\|u\|_{L^r(M)}^r} \right)^{1/(r-p)}. \tag{32.5}$$

Moreover,

$$I(t_u u) = \max_{t>0} I(tu).$$

(b) The Nehari level

$$m := \inf_{u \in \mathcal{N}} I(u)$$

is positive and is attained at some $u_0 \in \mathcal{N}$.

(c) The minimizer u_0 is a nontrivial critical point of I and is a ground state:

$$I(u_0) = m = \inf\{I(v) \mid v \neq 0,\ DI(v) = 0\}.$$

(d) The radial characterization

$$m = \inf_{u \in X \setminus \{0\}} \max_{t>0} I(tu). \tag{32.6}$$

holds.

Proof. Fix $u \neq 0$ and define $\varphi_u(t) := I(tu)$ for $t > 0$. Then

$$\varphi_u(t) = \frac{t^p}{p}\|u\|^p - \frac{t^r}{r}\|u\|_{L^r(M)}^r,$$
$$\varphi_u'(t) = t^{p-1}\left(\|u\|^p - t^{r-p}\|u\|_{L^r(M)}^r\right).$$

Both coefficients are positive. Since $t \mapsto t^{r-p}$ is strictly increasing, φ_u' vanishes exactly once, precisely at the value in (32.5); it is positive before and negative afterward. This point is therefore the unique global maximum of φ_u. Moreover,

$$G(tu) = t\varphi_u'(t),$$

which proves (a).
If $u \in \mathcal{N}$, the Nehari identity gives

$$\|u\|^p = \|u\|_{L^r(M)}^r, \qquad I(u) = \left(\frac{1}{p} - \frac{1}{r}\right)\|u\|^p. \tag{32.7}$$

Let $C_S > 0$ be a constant for the embedding $X \hookrightarrow L^r(M)$. Then

$$\|u\|^p = \|u\|_{L^r(M)}^r \leq C_S^r\|u\|^r.$$

Since $u \neq 0$, it follows that

$$\|u\| \geq C_S^{-r/(r-p)} =: \delta > 0.$$

Together with (32.7), this shows that

$$m \geq \left(\frac{1}{p} - \frac{1}{r}\right)\delta^p > 0. \tag{32.8}$$

Now let $(u_j) \subset \mathcal{N}$ be a minimizing sequence. By (32.7), (u_j) is bounded in X. After passing to a subsequence,

$$u_j \rightharpoonup u \quad \text{in } X, \qquad u_j \to u \quad \text{in } L^r(M),$$

where the second convergence follows from the subcritical compact embedding. If $\kappa := 1/p - 1/r > 0$, then

$$m = \lim_{j\to\infty} I(u_j) = \kappa \lim_{j\to\infty} \|u_j\|^p = \kappa \lim_{j\to\infty} \|u_j\|_{L^r(M)}^r = \kappa\|u\|_{L^r(M)}^r. \tag{32.9}$$

Positivity of m implies $u \neq 0$. Weak lower semicontinuity gives

$$\|u\|^p \leq \liminf_{j\to\infty} \|u_j\|^p = \|u\|_{L^r(M)}^r. \tag{32.10}$$

If the inequality were strict, formula (32.5) would give $0 < t_u < 1$ and $t_u u \in \mathcal{N}$. Using (32.7) and (32.9) again, we would obtain

$$m \leq I(t_u u) = \kappa t_u^p \|u\|^p < \kappa\|u\|_{L^r(M)}^r = m,$$

a contradiction. Thus equality holds in (32.10); consequently, $u \in \mathcal{N}$ and $I(u) = m$. We have proved (b), with $u_0 := u$.

We now prove that the constraint is natural. The functional G belongs to $C^1(X, \mathbb{R})$ and, for $v \in \mathcal{N}$,

$$DG(v)[v] = p\|v\|^p - r\|v\|^r_{L^r(M)} = (p-r)\|v\|^p < 0.$$

In particular, $DG(v) \neq 0$ on $\mathcal{N}$, so $\mathcal{N}$ is a hypersurface of class C^1. Since u_0 minimizes I on this hypersurface, the Lagrange multiplier principle provides $\lambda \in \mathbb{R}$ such that

$$DI(u_0) = \lambda DG(u_0).$$

Evaluating at u_0 gives

$$0 = DI(u_0)[u_0] = \lambda(p-r)\|u_0\|^p,$$

and hence $\lambda = 0$ and $DI(u_0) = 0$. Every nontrivial critical point v of I satisfies $G(v) = DI(v)[v] = 0$, and therefore belongs to $\mathcal{N}$ with $I(v) \geq m = I(u_0)$. This proves (c).

Finally, by (a), each positive ray meets $\mathcal{N}$ exactly once and attains its maximum there. Taking all nonzero directions gives

$$\inf_{u \neq 0} \max_{t>0} I(tu) = \inf_{v \in \mathcal{N}} I(v) = m,$$

which is (d). □

32.4.1 Conceptual comparison

The two methods organize the same energy in different ways. The following table compares their hypotheses, constructions, and conclusions.

Table 32.1: The mountain pass and Nehari methods.

	Mountain pass	**Nehari method**
Main idea	Minimax over paths	Minimization on a natural constraint
Main object	The class $\Gamma(0, e)$	The manifold $\mathcal{N}$
Variational level	$c_e = \inf_{\gamma \in \Gamma(0,e)} \max_t I(\gamma(t))$	$m = \inf_{u \in \mathcal{N}} I(u)$
Geometry	Mountain pass barrier	Radial geometry
Construction	Paths from the origin to a point of negative energy	Points satisfying $DI(u)[u] = 0$
Compactness	Usually $(PS)_{c_e}$	Compactness of minimizing sequences
Typical result	A nontrivial critical point	Often a ground state
Main strength	Flexible minimax principle; does not require radial uniqueness	Precise description of least-energy solutions
Main difficulty	Verifying Palais–Smale at the minimax level	Proving naturalness, radial projection, and attainment of the minimum

The decisive difference arises when the radial function $t \mapsto I(tu)$ may have several critical points or none. The mountain pass method may still work if the global barrier and the Palais–Smale condition remain in place. Nehari reduction, on the other hand, requires hypotheses controlling the intersection of each ray with $\mathcal{N}$. When this intersection is unique, Nehari's method can be viewed as a radial minimax; the mountain pass method allows

competition among all paths, not only rays.

32.4.2 Exact equality of the levels

For each direction u, one can construct a radial path ending at a large multiple of u. If the class $\Gamma(0,e)$ has a fixed endpoint e, this multiple must be connected to e. The region of negative energy allows this connection to be made without increasing the maximum height of the path.

Theorem 32.4.2. (Equality of the mountain pass and Nehari levels) Let $e \in X$ satisfy $I(e) < 0$, and define

$$c_e := \inf_{\gamma \in \Gamma(0,e)} \max_{t \in [0,1]} I(\gamma(t)).$$

Then

$$c_e = m = \inf_{u \in \mathcal{N}} I(u) = \inf_{u \neq 0} \max_{t>0} I(tu).$$

In particular, the level does not depend on the choice of the endpoint with negative energy.

Proof. We divide the proof into the two inequalities.
First inequality: $m \le c_e$. Let C_S be a constant for the embedding $X \hookrightarrow L^r(M)$. For $v \in X$,

$$G(v) = \|v\|^p - \|v\|_{L^r(M)}^r \ge \|v\|^p - C_S^r \|v\|^r.$$

Choose $\eta > 0$ so small that $C_S^r \eta^{r-p} < 1$. Then

$$0 < \|v\| \le \eta \quad \Longrightarrow \quad G(v) > 0. \tag{32.11}$$

On the other hand, $I(e) < 0$ implies

$$\frac{1}{p}\|e\|^p < \frac{1}{r}\|e\|_{L^r(M)}^r,$$

and, since $r/p > 1$,

$$G(e) = \|e\|^p - \|e\|_{L^r(M)}^r < 0. \tag{32.12}$$

Decrease η, if necessary, so that $\eta < \|e\|$.
Let $\gamma \in \Gamma(0,e)$. The set

$$A_\gamma := \{t \in [0,1] \mid \|\gamma(t)\| = \eta\}$$

is nonempty and compact. Let $t_0 := \max A_\gamma$. For $t > t_0$, we have $\|\gamma(t)\| > \eta$: if the norm became less than or equal to η again, the intermediate value theorem would yield another point of A_γ after t_0. By (32.11), $G(\gamma(t_0)) > 0$, whereas (32.12) gives $G(\gamma(1)) < 0$. Thus there exists $t_* \in (t_0, 1)$ such that $G(\gamma(t_*)) = 0$. Since $\|\gamma(t_*)\| > \eta$, the point $\gamma(t_*)$ is nonzero and belongs to $\mathcal{N}$. Consequently,

$$\max_{t \in [0,1]} I(\gamma(t)) \ge I(\gamma(t_*)) \ge m.$$

Taking the infimum over γ gives $c_e \ge m$.

Second inequality: $c_e \le m$. Fix $u \in \mathcal{N}$ and set

$$a := \frac{u}{\|u\|}, \qquad b := \frac{e}{\|e\|}.$$

The unit sphere of X is path connected. Indeed, if $b \neq -a$, the path

$$s \longmapsto \frac{(1-s)a + sb}{\|(1-s)a + sb\|}$$

joins a to b; if $b = -a$, choose a unit vector $z \notin \operatorname{span}\{a\}$ and concatenate the normalized paths from a to z and from z to b. Denote one of these paths on the unit sphere by $h\colon [0,1] \to X$.
Such a vector z exists because $X = W_0^{1,p}(M)$ is infinite-dimensional: a sequence of nonzero smooth functions supported in disjoint balls in the interior of M is linearly independent. In particular, $\dim X \ge 2$.
The function $s \mapsto \|h(s)\|_{L^r(M)}^r$ is continuous and strictly positive. By compactness of $[0,1]$, there exists

$$q := \min_{s\in[0,1]} \|h(s)\|_{L^r(M)}^r > 0.$$

Choose $R > \max\{\|u\|, \|e\|\}$ so large that

$$\frac{R^p}{p} - \frac{qR^r}{r} < 0.$$

Then

$$I(Rh(s)) \le \frac{R^p}{p} - \frac{qR^r}{r} < 0 \qquad (0 \le s \le 1). \tag{32.13}$$

We construct $\gamma_u \in \Gamma(0, e)$ in three segments:

$$\gamma_u(t) := \begin{cases} 3tRa, & 0 \le t \le \frac{1}{3}, \\ Rh(3t-1), & \frac{1}{3} \le t \le \frac{2}{3}, \\ \big((3-3t)R + (3t-2)\|e\|\big)\, b, & \frac{2}{3} \le t \le 1. \end{cases}$$

The values agree at the joining points, because $h(0) = a$ and $h(1) = b$. On the first segment, the radial function attains its unique maximum at $\|u\|a = u$; thus the energy is at most $I(u)$. The second segment has negative energy by (32.13). Finally, for $s \ge \|e\|$,

$$I(sb) = \frac{s^p}{p} - \frac{s^r}{r}\|b\|_{L^r(M)}^r < 0,$$

since this inequality holds at $s = \|e\|$ and its equivalent form $s^{r-p} > r/(p\|b\|_{L^r(M)}^r)$ remains valid as s increases. Thus the third segment also has negative energy, and

$$\max_{t\in[0,1]} I(\gamma_u(t)) = I(u).$$

It follows that $c_e \le I(u)$ for every $u \in \mathcal{N}$. Taking the infimum gives $c_e \le m$. Equality with the radial minimax was already proved in (32.6). □

By Theorem 32.4.1, the common level $c_e = m$ is attained at a ground state. By Corollary 31.5.4 and the (PS) condition established in Proposition 31.5.7, it is also a critical level obtained by the mountain pass method. The

two constructions need not select the same function when there are several critical points, but they do select the same minimum energy in this homogeneous model.

32.5 A quasilinear equation on a vector bundle

We now apply the preceding theory to the quasilinear problem studied in [150]. The characterization of the Dirichlet space by the trace allows us to interpret the homogeneous boundary condition, while the Sobolev and Rellich–Kondrashov embeddings provide the integrability and compactness required by the energy functional. We shall establish its Fréchet differentiability, the geometry of its radial functions, and the existence of a ground state by the Nehari method of Szulkin and Weth.

Let $(M,\mathbf{g})$ be a nonempty compact Riemannian manifold of dimension n, with smooth boundary, such that each connected component has nonempty boundary. Let $\mathbf{E}\to M$ be a smooth real vector bundle of positive finite rank, equipped with a bundle metric $\mathbf{h_E}$ and a connection $\nabla^{\mathbf{E}}$ compatible with $\mathbf{h_E}$. The metric $\mathbf{g}$ and the bundle metric $\mathbf{h_E}$ induce the bundle metric $\mathbf{g}\otimes\mathbf{h_E}$ on $T^*M\otimes\mathbf{E}$. Fix

$$2\le p\le q<n,\qquad q^*:=\frac{nq}{n-q},$$

and consider the problem

$$\begin{cases}(\nabla^{\mathbf{E}})^*\Big(a(|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h_E}})|\nabla^{\mathbf{E}}\mathbf{u}|^{p-2}_{\mathbf{g}\otimes\mathbf{h_E}}\nabla^{\mathbf{E}}\mathbf{u}\Big)=f(\mathbf{u}) & \text{in } M,\\ \mathbf{u}=0 & \text{on } \partial M.\end{cases}\tag{32.14}$$

Define $A(t):=\displaystyle\int_0^t a(s)\,ds$. We assume that:

(a1) $a\colon[0,+\infty)\longrightarrow[0,+\infty)$ is continuous and there exist $k_1,k_2,k_3,k_4\ge 0$, with $k_1>0$ and $k_2>0$ when $p<q$, such that

$$k_1t^p+k_2t^q\le a(t^p)t^p\le k_3t^p+k_4t^q$$

for every $t>0$;

(a2) the function $t\longmapsto\dfrac{a(t^p)}{t^{q-p}}$ is nonincreasing on $(0,+\infty)$;

(a3) the function $t\longmapsto A(t^p)$ is convex on $[0,+\infty)$.

Let $\mathcal{F}\colon\mathbf{E}\longrightarrow\mathbb{R}$ be a continuous function whose restriction $\mathcal{F}_x\colon\mathbf{E}_x\longrightarrow\mathbb{R}$ to each fiber is of class C^1. We denote by $f_x\colon\mathbf{E}_x\longrightarrow\mathbf{E}_x$ its gradient with respect to $\mathbf{h_E}$, that is,

$$D\mathcal{F}_x(\xi)(\zeta)=\langle f_x(\xi),\zeta\rangle_{\mathbf{h_E}}.$$

We also assume that the bundle map $f\colon\mathbf{E}\longrightarrow\mathbf{E}$, defined by $f(\xi):=f_{\pi_{\mathbf{E}}(\xi)}(\xi)$, is continuous and that:

(f1) $\displaystyle\lim_{|\xi|_{\mathbf{h_E}}\to0}\frac{|f_x(\xi)|_{\mathbf{h_E}}}{|\xi|^{p-1}_{\mathbf{h_E}}}=0$ uniformly with respect to $x\in M$; that is, for each $\varepsilon>0$ there exists $\delta>0$, independent of x, such that

$$|f_x(\xi)|_{\mathbf{h_E}}\le\varepsilon|\xi|^{p-1}_{\mathbf{h_E}}$$

if $x\in M$ and $0<|\xi|_{\mathbf{h_E}}<\delta$;

(f2) there exist $C_f > 0$ and $r \in (q, q^*)$ such that

$$|f_x(\xi)|_{\mathbf{h_E}} \le C_f\left(1 + |\xi|_{\mathbf{h_E}}^{r-1}\right)$$

for every $x \in M$ and every $\xi \in \mathbf{E}_x$;

(f3) there exists $\theta \in (q, r]$ such that

$$0 < \theta \mathcal{F}_x(\xi) \le \langle f_x(\xi), \xi\rangle_{\mathbf{h_E}}$$

for every $x \in M$ and every $\xi \in \mathbf{E}_x \setminus \{0_x\}$;

(f4) for each $x \in M$ and each $\xi \in \mathbf{E}_x \setminus \{0_x\}$, the function

$$t \longmapsto \frac{\langle f_x(t\xi), t\xi\rangle_{\mathbf{h_E}}}{t^q}$$

is strictly increasing on $(0, +\infty)$.

The preceding hypotheses also determine the value of the potential on the zero section. Fix $x \in M$ and $\xi \in \mathbf{E}_x \setminus \{0_x\}$. By (f3), for every $t > 0$,

$$0 < \theta \mathcal{F}_x(t\xi) \le \langle f_x(t\xi), t\xi\rangle_{\mathbf{h_E}}.$$

Let $\varepsilon > 0$. By (f1), there exists $\delta > 0$ such that, if $0 < t|\xi|_{\mathbf{h_E}} < \delta$, then

$$|f_x(t\xi)|_{\mathbf{h_E}} \le \varepsilon t^{p-1}|\xi|_{\mathbf{h_E}}^{p-1}.$$

Consequently,

$$0 < \mathcal{F}_x(t\xi) \le \frac{\varepsilon}{\theta} t^p |\xi|_{\mathbf{h_E}}^p$$

for every sufficiently small $t > 0$. Thus $\mathcal{F}_x(t\xi) \to 0$ as $t \to 0^+$. Since $\mathcal{F}_x$ is continuous on the fiber, we conclude that $\mathcal{F}_x(0_x) = 0$. Theorem B.6.5, applied to $t \longmapsto \mathcal{F}_x(t\xi)$, then gives

$$\mathcal{F}_x(\xi) = \int_0^1 \langle f_x(t\xi), \xi\rangle_{\mathbf{h_E}}\, dt. \tag{32.15}$$

Global continuity of $\mathcal{F} : \mathbf{E} \longrightarrow \mathbb{R}$ is part of the hypotheses. This condition does not follow merely from continuity of each restriction $\mathcal{F}_x$ and will be used, in particular, when taking minima and maxima over the compact unit sphere and ball bundles.

Take $X := W_0^{1,q}(M, \mathbf{E})$. This space contains a nonzero section: simply multiply an element of a local frame of the bundle by a nonzero smooth function compactly supported in the interior of a trivializing chart. By the Poincaré inequality in Theorem 9.6.8, there exists a constant $C_P > 0$, depending only on M, $\mathbf{g}$, $\mathbf{E}$, $\mathbf{h_E}$, $\nabla^{\mathbf{E}}$, and q, such that, if

$$\|\mathbf{u}\|_X := \left(\int_M |\nabla_w^{\mathbf{E}}\mathbf{u}|_{\mathbf{g}\otimes\mathbf{h_E}}^q\, d\lambda_{\mathbf{g}}\right)^{\frac{1}{q}},$$

then

$$\|\mathbf{u}\|_X \le \|\mathbf{u}\|_{W^{1,q}(M,\mathbf{E})} \le (1 + C_P^q)^{\frac{1}{q}}\|\mathbf{u}\|_X$$

for every $\mathbf{u} \in X$. We use $\|\cdot\|_X$ as the norm on X. Henceforth, we write $\nabla^{\mathbf{E}}\mathbf{u}$ for the weak covariant derivative of $\mathbf{u} \in X$. Since $p \le q$ and the volume is finite, Hölder's inequality gives $W_0^{1,q}(M, \mathbf{E}) \hookrightarrow W_0^{1,p}(M, \mathbf{E})$: a sequence

of compactly supported smooth sections converging in $W^{1,q}$ also converges in $W^{1,p}$. Thus Poincaré's inequality applies to both exponents p and q.

Definition 32.5.1. (Weak solution of the quasilinear problem) Let M be the compact Riemannian manifold with nonempty boundary fixed in this section, and let $\mathbf{E} \to M$ be the vector bundle specified there. A section $\mathbf{u} \in X$ is a weak solution of (32.14) if

$$\int_M a(|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}})|\nabla^{\mathbf{E}}\mathbf{u}|^{p-2}_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\langle\nabla^{\mathbf{E}}\mathbf{u},\nabla^{\mathbf{E}}\boldsymbol{\varphi}\rangle_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\,d\lambda_{\mathbf{g}} = \int_M \langle f_x(\mathbf{u}),\boldsymbol{\varphi}\rangle_{\mathbf{h}_{\mathbf{E}}}\,d\lambda_{\mathbf{g}}$$

for every $\boldsymbol{\varphi} \in X$.

32.5.1 Preliminary estimates

The monotonicity in (a2) relates the primitive A to the term appearing in the Nehari identity.

Lemma 32.5.2. For every $\rho \geq 0$, we have

$$A(\rho^p) \geq \frac{p}{q}a(\rho^p)\rho^p.$$

Proof. The assertion is immediate for $\rho = 0$. Let $\rho > 0$. If $0 < \tau \leq \rho$, hypothesis (a2) implies $\dfrac{a(\tau^p)}{\tau^{q-p}} \geq \dfrac{a(\rho^p)}{\rho^{q-p}}$, and hence $a(\tau^p) \geq a(\rho^p)\left(\dfrac{\tau}{\rho}\right)^{q-p}$.
Using the change of variable $s = \tau^p$, we obtain

$$A(\rho^p) = p\int_0^\rho a(\tau^p)\tau^{p-1}\,d\tau \geq p\,a(\rho^p)\rho^{p-q}\int_0^\rho \tau^{q-1}\,d\tau = \frac{p}{q}a(\rho^p)\rho^p.$$

□

Lemma 32.5.3. (Fiberwise growth estimates) Let M be the compact Riemannian manifold with nonempty boundary fixed in this section, and let $\mathbf{E} \to M$ be the vector bundle specified there. For each $\varepsilon > 0$ there exists $C_\varepsilon > 0$ such that

$$|f_x(\xi)|_{\mathbf{h}_{\mathbf{E}}} \leq \varepsilon|\xi|^{p-1}_{\mathbf{h}_{\mathbf{E}}} + C_\varepsilon|\xi|^{r-1}_{\mathbf{h}_{\mathbf{E}}} \tag{32.16}$$

for every $x \in M$ and every $\xi \in \mathbf{E}_x$. Moreover,

$$|\mathcal{F}_x(\xi)| \leq \frac{\varepsilon}{p}|\xi|^p_{\mathbf{h}_{\mathbf{E}}} + \frac{C_\varepsilon}{r}|\xi|^r_{\mathbf{h}_{\mathbf{E}}}. \tag{32.17}$$

Proof. Let $\varepsilon > 0$. By (f1), there exists $\delta \in (0,1)$ such that

$$|f_x(\xi)|_{\mathbf{h}_{\mathbf{E}}} \leq \varepsilon|\xi|^{p-1}_{\mathbf{h}_{\mathbf{E}}}$$

if $x \in M$ and $0 < |\xi|_{\mathbf{h}_{\mathbf{E}}} \leq \delta$. Letting $\xi \to 0_x$ and using continuity of f_x gives $f_x(0_x) = 0$, so the same inequality holds for $\xi = 0_x$.

If $|\xi|_{\mathbf{h_E}} \geq \delta$, hypothesis (f2) gives

$$|f_x(\xi)|_{\mathbf{h_E}} \leq C_f\left(1 + |\xi|_{\mathbf{h_E}}^{r-1}\right) \leq C_f\left(1 + \delta^{1-r}\right)|\xi|_{\mathbf{h_E}}^{r-1}.$$

Taking $C_\varepsilon \geq C_f(1 + \delta^{1-r})$ yields (32.16) in both regions.
Since $\mathcal{F}_x(0_x) = 0$ and f_x is the fiberwise gradient of $\mathcal{F}_x$, Theorem B.6.5, applied to $t \longmapsto \mathcal{F}_x(t\xi)$, gives

$$\mathcal{F}_x(\xi) = \int_0^1 \langle f_x(t\xi), \xi\rangle_{\mathbf{h_E}}\, dt.$$

By (32.16),

$$|\mathcal{F}_x(\xi)| \leq \int_0^1 |f_x(t\xi)|_{\mathbf{h_E}}|\xi|_{\mathbf{h_E}}\, dt \leq \int_0^1 \left(\varepsilon t^{p-1}|\xi|_{\mathbf{h_E}}^{p-1} + C_\varepsilon t^{r-1}|\xi|_{\mathbf{h_E}}^{r-1}\right)|\xi|_{\mathbf{h_E}}\, dt = \frac{\varepsilon}{p}|\xi|_{\mathbf{h_E}}^{p} + \frac{C_\varepsilon}{r}|\xi|_{\mathbf{h_E}}^{r}.$$

□

Lemma 32.5.4. (Lower bound for the potential) Let M be the compact Riemannian manifold with nonempty boundary fixed in this section, and let $\mathbf{E} \to M$ be the vector bundle specified there. There exist constants $D > 0$ and $D' \geq 0$ such that

$$\mathcal{F}_x(\xi) \geq D|\xi|_{\mathbf{h_E}}^{\theta} - D'$$

for every $x \in M$ and every $\xi \in \mathbf{E}_x$.

Proof. Fix $x \in M$ and $\eta \in \mathbf{E}_x \setminus \{0_x\}$. For $t > 0$, define

$$H_{x,\eta}(t) := \frac{\mathcal{F}_x(t\eta)}{t^\theta}.$$

By (f3), $\mathcal{F}_x(t\eta) > 0$. Moreover,

$$\frac{d}{dt}\log H_{x,\eta}(t) = \frac{\langle f_x(t\eta), t\eta\rangle_{\mathbf{h_E}} - \theta\mathcal{F}_x(t\eta)}{t\mathcal{F}_x(t\eta)} \geq 0.$$

Thus $H_{x,\eta}$ is nondecreasing.
The unit sphere bundle

$$S(\mathbf{E}) := \{\eta \in \mathbf{E} \mid |\eta|_{\mathbf{h_E}} = 1\}$$

is compact, because M is compact and $\mathbf{E}$ has finite rank. The function $\eta \longmapsto \mathcal{F}_{\pi_{\mathbf{E}}(\eta)}(\eta)$ is continuous and, by (f3), positive on $S(\mathbf{E})$. Consequently,

$$D := \min_{\eta \in S(\mathbf{E})} \mathcal{F}_{\pi_{\mathbf{E}}(\eta)}(\eta) > 0.$$

If $|\xi|_{\mathbf{h_E}} \geq 1$, write $\xi = \rho\eta$, with $\rho = |\xi|_{\mathbf{h_E}} \geq 1$ and $|\eta|_{\mathbf{h_E}} = 1$. Monotonicity of $H_{x,\eta}$ implies

$$\mathcal{F}_x(\xi) = \mathcal{F}_x(\rho\eta) \geq \rho^\theta \mathcal{F}_x(\eta) \geq D|\xi|_{\mathbf{h_E}}^{\theta}.$$

The closed unit ball bundle $\{\xi \in \mathbf{E} \mid |\xi|_{\mathbf{h_E}} \leq 1\}$ is compact. Thus the continuous function

$$\xi \longmapsto D|\xi|_{\mathbf{h_E}}^{\theta} - \mathcal{F}_{\pi_{\mathbf{E}}(\xi)}(\xi)$$

attains a maximum $D' \geq 0$ on this set. Hence $\mathcal{F}_x(\xi) \geq D|\xi|^\theta_{\mathbf{h_E}} - D'$ also when $|\xi|_{\mathbf{h_E}} \leq 1$. □

32.5.2 The energy functional

Define

$$I(\mathbf{u}) := \frac{1}{p}\int_M A(|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h_E}})\,d\lambda_{\mathbf{g}} - \int_M \mathcal{F}_x(\mathbf{u}(x))\,d\lambda_{\mathbf{g}}, \qquad \mathbf{u}\in X. \tag{32.18}$$

Proposition 32.5.5. (Differentiability and weak solutions) Let M be the compact Riemannian manifold with nonempty boundary fixed in this section, and let $\mathbf{E}\to M$ be the vector bundle specified there. The functional $I\colon X \longrightarrow \mathbb{R}$ is well defined and belongs to $C^1(X,\mathbb{R})$. For all $\mathbf{u},\mathbf{v}\in X$,

$$DI(\mathbf{u})(\mathbf{v}) = \int_M a(|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h_E}})|\nabla^{\mathbf{E}}\mathbf{u}|^{p-2}_{\mathbf{g}\otimes\mathbf{h_E}}\langle\nabla^{\mathbf{E}}\mathbf{u},\nabla^{\mathbf{E}}\mathbf{v}\rangle_{\mathbf{g}\otimes\mathbf{h_E}}\,d\lambda_{\mathbf{g}} - \int_M \langle f_x(\mathbf{u}(x)),\mathbf{v}(x)\rangle_{\mathbf{h_E}}\,d\lambda_{\mathbf{g}}. \tag{32.19}$$

Consequently, the critical points of I are exactly the weak solutions of (32.14).

Proof. Write $I = J_1 - J_2$, where

$$J_1(\mathbf{u}) := \frac{1}{p}\int_M A(|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h_E}})\,d\lambda_{\mathbf{g}}, \qquad J_2(\mathbf{u}) := \int_M \mathcal{F}_x(\mathbf{u}(x))\,d\lambda_{\mathbf{g}}.$$

We first check that both terms are well defined. By (a1), for each $\rho>0$ we have $a(\rho^p)\leq k_3 + k_4\rho^{q-p}$. Thus

$$A(\rho^p) = p\int_0^\rho a(\tau^p)\tau^{p-1}\,d\tau \leq k_3\rho^p + \frac{pk_4}{q}\rho^q.$$

Since $\nabla^{\mathbf{E}}\mathbf{u}\in L^q(M,T^*M\otimes\mathbf{E})$, $p\leq q$, and $\lambda_{\mathbf{g}}(M)<\infty$, we obtain $A(|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h_E}})\in L^1(M)$.
By Lemma 32.5.3, there exists $C>0$ such that $|\mathcal{F}_x(\xi)|\leq C\big(|\xi|^p_{\mathbf{h_E}} + |\xi|^r_{\mathbf{h_E}}\big)$.
The continuous embeddings $X\hookrightarrow L^p(M,\mathbf{E})$ and $X\hookrightarrow L^r(M,\mathbf{E})$ show that $\mathcal{F}_x(\mathbf{u}(x))\in L^1(M)$. Thus I is well defined.
We now prove that $J_1\in C^1(X,\mathbb{R})$. Let $\mathbf{V} := T^*M\otimes\mathbf{E}$, equipped with the bundle metric $\mathbf{g}\otimes\mathbf{h_E}$, and define the bundle maps

$$\Psi_x\colon \mathbf{V}_x\longrightarrow\mathbf{V}_x, \qquad \Psi_x(\eta) := a(|\eta|^p_{\mathbf{g}\otimes\mathbf{h_E}})|\eta|^{p-2}_{\mathbf{g}\otimes\mathbf{h_E}}\eta, \qquad \Psi_x(0_x) := 0_x,$$

and $\Phi_x\colon \mathbf{V}_x\longrightarrow\mathbb{R}$, $\Phi_x(\eta) := \dfrac{1}{p}A(|\eta|^p_{\mathbf{g}\otimes\mathbf{h_E}})$.
The map $\Psi\colon\mathbf{V}\longrightarrow\mathbf{V}$ is continuous and

$$D\Phi_x(\eta)(\zeta) = \langle\Psi_x(\eta),\zeta\rangle_{\mathbf{g}\otimes\mathbf{h_E}}.$$

Moreover, by (a1),

$$|\Psi_x(\eta)|_{\mathbf{g}\otimes\mathbf{h_E}} \leq k_3|\eta|^{p-1}_{\mathbf{g}\otimes\mathbf{h_E}} + k_4|\eta|^{q-1}_{\mathbf{g}\otimes\mathbf{h_E}} \leq C\big(1+|\eta|^{q-1}_{\mathbf{g}\otimes\mathbf{h_E}}\big).$$

Corollary 29.1.9, applied with $m=q$, implies that $\eta\longmapsto\Psi(\eta)$ defines a continuous operator from $L^q(M,\mathbf{V})$ to $L^{q'}(M,\mathbf{V})$, where $q' := \dfrac{q}{q-1}$.
For $\mathbf{u}\in X$, define $L_{\mathbf{u}}\in X'$ by

$$L_{\mathbf{u}}(\mathbf{v}) := \int_M \langle\Psi_x(\nabla^{\mathbf{E}}\mathbf{u}),\nabla^{\mathbf{E}}\mathbf{v}\rangle_{\mathbf{g}\otimes\mathbf{h_E}}\,d\lambda_{\mathbf{g}}.$$

Hölder's inequality (Proposition B.7.9) gives

$$|L_{\mathbf{u}}(\mathbf{v})| \le \|\Psi(\nabla^{\mathbf{E}}\mathbf{u})\|_{L^{q'}(M,\mathbf{V})}\|\nabla^{\mathbf{E}}\mathbf{v}\|_{L^{q}(M,\mathbf{V})} = \|\Psi(\nabla^{\mathbf{E}}\mathbf{u})\|_{L^{q'}(M,\mathbf{V})}\|\mathbf{v}\|_X,$$

so $L_{\mathbf{u}}$ is linear and continuous.
Let $\mathbf{h} \in X$. For almost every $x \in M$, Theorem B.6.5, applied to

$$s \longmapsto \Phi_x(\nabla^{\mathbf{E}}\mathbf{u}(x) + s\nabla^{\mathbf{E}}\mathbf{h}(x))$$

gives

$$\Phi_x(\nabla^{\mathbf{E}}\mathbf{u} + \nabla^{\mathbf{E}}\mathbf{h}) - \Phi_x(\nabla^{\mathbf{E}}\mathbf{u}) = \int_0^1 \langle \Psi_x(\nabla^{\mathbf{E}}\mathbf{u} + s\nabla^{\mathbf{E}}\mathbf{h}), \nabla^{\mathbf{E}}\mathbf{h}\rangle_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\, ds.$$

Hölder's inequality (Proposition B.7.9) and the preceding bounds show that the integrand belongs to $L^1(M\times[0,1])$. We may apply Fubini's theorem for Bochner integrals B.6.26, in its scalar case, to $(M,\lambda_{\mathbf{g}})\times([0,1],ds)$ and obtain

$$J_1(\mathbf{u}+\mathbf{h}) - J_1(\mathbf{u}) - L_{\mathbf{u}}(\mathbf{h}) = \int_0^1 \int_M \langle \Psi_x(\nabla^{\mathbf{E}}\mathbf{u} + s\nabla^{\mathbf{E}}\mathbf{h}) - \Psi_x(\nabla^{\mathbf{E}}\mathbf{u}), \nabla^{\mathbf{E}}\mathbf{h}\rangle_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\, d\lambda_{\mathbf{g}}\, ds.$$

Consequently,

$$|J_1(\mathbf{u}+\mathbf{h}) - J_1(\mathbf{u}) - L_{\mathbf{u}}(\mathbf{h})| \le \|\mathbf{h}\|_X \int_0^1 \|\Psi(\nabla^{\mathbf{E}}\mathbf{u} + s\nabla^{\mathbf{E}}\mathbf{h}) - \Psi(\nabla^{\mathbf{E}}\mathbf{u})\|_{L^{q'}(M,\mathbf{V})}\, ds.$$

Let $(\mathbf{h}_j)_{j\in\mathbb{N}} \subseteq X$ satisfy $\mathbf{h}_j \to 0$ in X. For each $s \in [0,1]$,

$$\nabla^{\mathbf{E}}\mathbf{u} + s\nabla^{\mathbf{E}}\mathbf{h}_j \longrightarrow \nabla^{\mathbf{E}}\mathbf{u} \quad \text{in } L^q(M,\mathbf{V}),$$

and continuity of the superposition operator induced by Ψ implies

$$\|\Psi(\nabla^{\mathbf{E}}\mathbf{u} + s\nabla^{\mathbf{E}}\mathbf{h}_j) - \Psi(\nabla^{\mathbf{E}}\mathbf{u})\|_{L^{q'}(M,\mathbf{V})} \longrightarrow 0.$$

Since $(\mathbf{h}_j)$ is bounded in X, there exists $R > 0$ such that $\|\nabla^{\mathbf{E}}\mathbf{u} + s\nabla^{\mathbf{E}}\mathbf{h}_j\|_{L^q(M,\mathbf{V})} \le R$ for every j and every $s \in [0,1]$. The growth bound for Ψ provides a constant $C_R > 0$ such that

$$\|\Psi(\nabla^{\mathbf{E}}\mathbf{u} + s\nabla^{\mathbf{E}}\mathbf{h}_j)\|_{L^{q'}(M,\mathbf{V})} + \|\Psi(\nabla^{\mathbf{E}}\mathbf{u})\|_{L^{q'}(M,\mathbf{V})} \le C_R$$

for every j and every $s \in [0,1]$. Theorem B.6.14, applied in the variable s, implies

$$\int_0^1 \|\Psi(\nabla^{\mathbf{E}}\mathbf{u} + s\nabla^{\mathbf{E}}\mathbf{h}_j) - \Psi(\nabla^{\mathbf{E}}\mathbf{u})\|_{L^{q'}(M,\mathbf{V})}\, ds \longrightarrow 0.$$

Thus

$$\lim_{\mathbf{h}\to 0} \frac{|J_1(\mathbf{u}+\mathbf{h}) - J_1(\mathbf{u}) - L_{\mathbf{u}}(\mathbf{h})|}{\|\mathbf{h}\|_X} = 0.$$

Hence J_1 is Fréchet differentiable and $DJ_1(\mathbf{u}) = L_{\mathbf{u}}$.

If $\mathbf{u}_j \to \mathbf{u}$ in X, then $\nabla^{\mathbf{E}}\mathbf{u}_j \to \nabla^{\mathbf{E}}\mathbf{u}$ in $L^q(M,\mathbf{V})$ and

$$\Psi(\nabla^{\mathbf{E}}\mathbf{u}_j) \to \Psi(\nabla^{\mathbf{E}}\mathbf{u}) \quad \text{in } L^{q'}(M,\mathbf{V}).$$

Consequently,

$$\|DJ_1(\mathbf{u}_j) - DJ_1(\mathbf{u})\|_{X'} \le \|\Psi(\nabla^{\mathbf{E}}\mathbf{u}_j) - \Psi(\nabla^{\mathbf{E}}\mathbf{u})\|_{L^{q'}(M,\mathbf{V})} \longrightarrow 0.$$

This proves that $J_1 \in C^1(X,\mathbb{R})$.
We now prove that $J_2 \in C^1(X,\mathbb{R})$. By (32.16) and $p < r$, there exists $C > 0$ such that

$$|f_x(\xi)|_{\mathbf{h}_\mathbf{E}} \le C\big(1 + |\xi|_{\mathbf{h}_\mathbf{E}}^{r-1}\big).$$

Corollary 29.1.9, applied with $m = r$, implies that the operator $\mathbf{u} \longmapsto f(\mathbf{u})$ is continuous from $L^r(M,\mathbf{E})$ to $L^{r'}(M,\mathbf{E})$, where $r' := \dfrac{r}{r-1}$.
For $\mathbf{u} \in X$, define $K_\mathbf{u} \in X'$ by

$$K_\mathbf{u}(\mathbf{v}) := \int_M \langle f_x(\mathbf{u}(x)), \mathbf{v}(x)\rangle_{\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g}.$$

By Hölder's inequality (Proposition B.7.9) and the embedding $X \hookrightarrow L^r(M,\mathbf{E})$, there exists a constant $C_S > 0$ such that

$$|K_\mathbf{u}(\mathbf{v})| \le \|f(\mathbf{u})\|_{L^{r'}(M,\mathbf{E})}\|\mathbf{v}\|_{L^r(M,\mathbf{E})} \le C_S\|f(\mathbf{u})\|_{L^{r'}(M,\mathbf{E})}\|\mathbf{v}\|_X.$$

For $\mathbf{h} \in X$, Theorem B.6.5, applied in each fiber, gives

$$\mathcal{F}_x(\mathbf{u}+\mathbf{h}) - \mathcal{F}_x(\mathbf{u}) = \int_0^1 \langle f_x(\mathbf{u}+s\mathbf{h}), \mathbf{h}\rangle_{\mathbf{h}_\mathbf{E}}\, ds.$$

The embeddings and the growth bound allow us to apply Fubini's theorem for Bochner integrals B.6.26, in its scalar case, to $(M,\lambda_\mathbf{g})\times([0,1],ds)$. Thus

$$J_2(\mathbf{u}+\mathbf{h}) - J_2(\mathbf{u}) - K_\mathbf{u}(\mathbf{h}) = \int_0^1 \int_M \langle f_x(\mathbf{u}+s\mathbf{h}) - f_x(\mathbf{u}), \mathbf{h}\rangle_{\mathbf{h}_\mathbf{E}}\, d\lambda_\mathbf{g}\, ds,$$

and

$$|J_2(\mathbf{u}+\mathbf{h}) - J_2(\mathbf{u}) - K_\mathbf{u}(\mathbf{h})| \le C_S\|\mathbf{h}\|_X \int_0^1 \|f(\mathbf{u}+s\mathbf{h}) - f(\mathbf{u})\|_{L^{r'}(M,\mathbf{E})}\, ds.$$

If $\mathbf{h}_j \to 0$ in X, then $\mathbf{u} + s\mathbf{h}_j \to \mathbf{u}$ in $L^r(M,\mathbf{E})$ for each $s \in [0,1]$. Continuity of the superposition operator induced by f implies

$$\|f(\mathbf{u}+s\mathbf{h}_j) - f(\mathbf{u})\|_{L^{r'}(M,\mathbf{E})} \longrightarrow 0.$$

Since $(\mathbf{h}_j)$ is bounded in X and the embedding $X \hookrightarrow L^r(M,\mathbf{E})$ is continuous, there exists $R > 0$ such that

$$\|\mathbf{u} + s\mathbf{h}_j\|_{L^r(M,\mathbf{E})} \le R$$

for every j and every $s \in [0,1]$. The boundedness estimate in Remark 29.1.10 provides $C_R > 0$ such that

$$\|f(\mathbf{u}+s\mathbf{h}_j) - f(\mathbf{u})\|_{L^{r'}(M,\mathbf{E})} \le \|f(\mathbf{u}+s\mathbf{h}_j)\|_{L^{r'}(M,\mathbf{E})} + \|f(\mathbf{u})\|_{L^{r'}(M,\mathbf{E})} \le C_R$$

for every j and every $s \in [0,1]$. By Theorem B.6.14, applied in the variable s,

$$\int_0^1 \|f(\mathbf{u}+s\mathbf{h}_j)-f(\mathbf{u})\|_{L^{r'}(M,\mathbf{E})}\,ds \longrightarrow 0.$$

It follows that J_2 is Fréchet differentiable and $DJ_2(\mathbf{u}) = K_{\mathbf{u}}$.
Finally, if $\mathbf{u}_j \to \mathbf{u}$ in X, then $\mathbf{u}_j \to \mathbf{u}$ in $L^r(M,\mathbf{E})$ and $f(\mathbf{u}_j) \to f(\mathbf{u})$ in $L^{r'}(M,\mathbf{E})$. Hence

$$\|DJ_2(\mathbf{u}_j)-DJ_2(\mathbf{u})\|_{X'} \le C_S\|f(\mathbf{u}_j)-f(\mathbf{u})\|_{L^{r'}(M,\mathbf{E})} \longrightarrow 0.$$

Therefore $J_2 \in C^1(X,\mathbb{R})$. Identity (32.19) follows from $I = J_1 - J_2$. Comparing it with Definition 32.5.1, we conclude that $DI(\mathbf{u}) = 0$ if and only if $\mathbf{u}$ is a weak solution. □

32.5.3 Radial geometry and the Nehari manifold

Define

$$\mathcal{N} := \{\mathbf{u} \in X \setminus \{0\} \mid DI(\mathbf{u})(\mathbf{u}) = 0\}.$$

Thus $\mathbf{u} \in \mathcal{N}$ if and only if $\mathbf{u} \neq 0$ and

$$\int_M a(|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}})|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\,d\lambda_{\mathbf{g}} = \int_M \langle f_x(\mathbf{u}),\mathbf{u}\rangle_{\mathbf{h}_{\mathbf{E}}}\,d\lambda_{\mathbf{g}}. \tag{32.20}$$

Proposition 32.5.6. (Projection onto the Nehari manifold) Let M be the compact Riemannian manifold with nonempty boundary fixed in this section, and let $\mathbf{E} \to M$ be the vector bundle specified there. For each $\mathbf{u} \in X \setminus \{0\}$ there exists a unique $t_{\mathbf{u}} > 0$ such that $t_{\mathbf{u}}\mathbf{u} \in \mathcal{N}$. Moreover, $t \longmapsto I(t\mathbf{u})$ is strictly increasing on $(0, t_{\mathbf{u}})$ and strictly decreasing on $(t_{\mathbf{u}}, +\infty)$.

Proof. Fix $\mathbf{u} \in X \setminus \{0\}$ and define $\gamma_{\mathbf{u}}(t) := I(t\mathbf{u})$ for $t > 0$. By the chain rule,

$$\gamma_{\mathbf{u}}'(t) = DI(t\mathbf{u})(\mathbf{u}) = \frac{1}{t}DI(t\mathbf{u})(t\mathbf{u}).$$

We first show that $\gamma_{\mathbf{u}}(t) > 0$ for sufficiently small $t > 0$. By Lemma 32.5.2 and (a1),

$$\frac{1}{p}A(t^p|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}) \ge \frac{1}{q}a(t^p|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}})t^p|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}} \ge \frac{k_1}{q}t^p|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}} + \frac{k_2}{q}t^q|\nabla^{\mathbf{E}}\mathbf{u}|^q_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}},$$

where the norms of the derivatives are taken with respect to $\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}$. By (32.17),

$$\mathcal{F}_x(t\mathbf{u}) \le \frac{\varepsilon}{p}t^p|\mathbf{u}|^p_{\mathbf{h}_{\mathbf{E}}} + \frac{C_\varepsilon}{r}t^r|\mathbf{u}|^r_{\mathbf{h}_{\mathbf{E}}}.$$

Let $C_P > 0$ satisfy $\|\mathbf{u}\|_{L^p(M,\mathbf{E})} \le C_P\|\nabla^{\mathbf{E}}\mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})}$. Take $\varepsilon := \dfrac{pk_1}{2qC_P^p}$.
Integrating the preceding inequalities gives

$$\gamma_{\mathbf{u}}(t) \ge \frac{k_1}{2q}t^p\|\nabla^{\mathbf{E}}\mathbf{u}\|^p_{L^p(M,T^*M\otimes\mathbf{E})} + \frac{k_2}{q}t^q\|\nabla^{\mathbf{E}}\mathbf{u}\|^q_{L^q(M,T^*M\otimes\mathbf{E})} - \frac{C_\varepsilon}{r}t^r\|\mathbf{u}\|^r_{L^r(M,\mathbf{E})}.$$

Since $\mathbf{u} \neq 0$, Poincaré's inequality implies $\|\nabla^{\mathbf{E}}\mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})} > 0$. Moreover, $r > q \geq p$. Thus there exists $t_0 > 0$ such that $\gamma_{\mathbf{u}}(t) > 0$ for every $t \in (0, t_0)$.

On the other hand, the upper bound in (a1) implies $A(\rho^p) \leq k_3\rho^p + \dfrac{pk_4}{q}\rho^q$.

Lemma 32.5.4 gives

$$\gamma_{\mathbf{u}}(t) \leq \frac{k_3}{p}t^p\|\nabla^{\mathbf{E}}\mathbf{u}\|^p_{L^p(M,T^*M\otimes\mathbf{E})} + \frac{k_4}{q}t^q\|\nabla^{\mathbf{E}}\mathbf{u}\|^q_{L^q(M,T^*M\otimes\mathbf{E})} - Dt^\theta\|\mathbf{u}\|^\theta_{L^\theta(M,\mathbf{E})} + D'\lambda_{\mathbf{g}}(M).$$

Since $\theta > q \geq p$ and $\mathbf{u} \neq 0$, we have $\gamma_{\mathbf{u}}(t) \to -\infty$ as $t \to +\infty$. We must also rule out a maximizing sequence escaping toward 0. The upper bounds in (a1) and (32.17) give, for $0 < t \leq 1$, a constant $C_{\mathbf{u}} > 0$ such that

$$|\gamma_{\mathbf{u}}(t)| \leq C_{\mathbf{u}}(t^p + t^q + t^r),$$

and hence $\gamma_{\mathbf{u}}(t) \to 0$ as $t \to 0^+$.

Choose $\tau > 0$ with $a := \gamma_{\mathbf{u}}(\tau) > 0$. By the two limits, there exist $0 < \delta < \tau < R$ such that

$$\gamma_{\mathbf{u}}(t) < \frac{a}{2} \quad \text{if } 0 < t \leq \delta \qquad \text{or if } t \geq R.$$

The continuous function $\gamma_{\mathbf{u}}$ attains a maximum on the compact set $[\delta, R]$. Since its value at τ is a, this maximum exceeds all values outside that set and is therefore global. Moreover, it is not attained at the endpoints δ or R; thus there exists $t_{\mathbf{u}} \in (\delta, R)$ with $\gamma'_{\mathbf{u}}(t_{\mathbf{u}}) = 0$, that is, $t_{\mathbf{u}}\mathbf{u} \in \mathcal{N}$.

We now prove uniqueness. Suppose that $0 < s < t$ and $s\mathbf{u}, t\mathbf{u} \in \mathcal{N}$. Dividing the two Nehari identities by s^q and t^q, respectively, gives

$$\int_M a(t^p|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}})t^{p-q}|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\,d\lambda_{\mathbf{g}} = \int_M \frac{\langle f_x(t\mathbf{u}), t\mathbf{u}\rangle_{\mathbf{h}_{\mathbf{E}}}}{t^q}\,d\lambda_{\mathbf{g}}$$

and the analogous identity with s.

If $|\nabla^{\mathbf{E}}\mathbf{u}(x)|_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}} > 0$, apply (a2) to the numbers $s|\nabla^{\mathbf{E}}\mathbf{u}(x)|_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}$ and $t|\nabla^{\mathbf{E}}\mathbf{u}(x)|_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}$. Since $s < t$, we obtain

$$a(t^p|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}})t^{p-q} \leq a(s^p|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}})s^{p-q}.$$

The inequality also holds when $|\nabla^{\mathbf{E}}\mathbf{u}(x)|_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}} = 0$. Thus the principal term corresponding to t is less than or equal to the one corresponding to s.

By contrast, (f4) implies that, for each x such that $\mathbf{u}(x) \neq 0_x$,

$$\frac{\langle f_x(t\mathbf{u}), t\mathbf{u}\rangle_{\mathbf{h}_{\mathbf{E}}}}{t^q} > \frac{\langle f_x(s\mathbf{u}), s\mathbf{u}\rangle_{\mathbf{h}_{\mathbf{E}}}}{s^q}.$$

The set $\{x \in M \mid \mathbf{u}(x) \neq 0_x\}$ has positive measure, since $\mathbf{u} \neq 0$ in $L^q(M, \mathbf{E})$. Upon integration, the potential term corresponding to t is strictly greater than the one corresponding to s. This contradicts the two Nehari identities. Therefore $t_{\mathbf{u}}$ is unique.

Finally, define $H_{\mathbf{u}}(t) := \dfrac{DI(t\mathbf{u})(t\mathbf{u})}{t^q}$. The preceding argument, applied to any $0 < s < t$, shows that $H_{\mathbf{u}}(t) < H_{\mathbf{u}}(s)$. Since $H_{\mathbf{u}}(t_{\mathbf{u}}) = 0$, we have $H_{\mathbf{u}}(t) > 0$ if $0 < t < t_{\mathbf{u}}$ and $H_{\mathbf{u}}(t) < 0$ if $t > t_{\mathbf{u}}$. Because $\gamma'_{\mathbf{u}}(t) = t^{q-1}H_{\mathbf{u}}(t)$, the function $\gamma_{\mathbf{u}}$ is strictly increasing on $(0, t_{\mathbf{u}})$ and strictly decreasing on $(t_{\mathbf{u}}, +\infty)$. □

Lemma 32.5.7. (Positivity of the energy on $\mathcal{N}$) Let M be the compact Riemannian manifold with nonempty boundary fixed in this section, and let $\mathbf{E} \to M$ be the vector bundle specified there. For every $\mathbf{u} \in \mathcal{N}$, we have $I(\mathbf{u}) > 0$.

Proof. Since $DI(\mathbf{u})(\mathbf{u}) = 0$, Lemma 32.5.2 and (f3) give

$$\begin{aligned} I(\mathbf{u}) &= I(\mathbf{u}) - \frac{1}{q} DI(\mathbf{u})(\mathbf{u}) \\ &= \int_M \left[\frac{1}{p} A(|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}) - \frac{1}{q} a(|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}) |\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}} \right] d\lambda_{\mathbf{g}} \\ &\quad + \int_M \left[\frac{1}{q} \langle f_x(\mathbf{u}), \mathbf{u} \rangle_{\mathbf{h}_{\mathbf{E}}} - \mathcal{F}_x(\mathbf{u}) \right] d\lambda_{\mathbf{g}} \\ &\geq \left(\frac{\theta}{q} - 1 \right) \int_M \mathcal{F}_x(\mathbf{u})\, d\lambda_{\mathbf{g}} > 0. \end{aligned}$$

The last integral is positive because $\mathbf{u} \neq 0$ and (f3) implies $\mathcal{F}_x(\mathbf{u}(x)) > 0$ when $\mathbf{u}(x) \neq 0_x$. □

Lemma 32.5.8. (Separation from the origin) Let M be the compact Riemannian manifold with nonempty boundary fixed in this section, and let $\mathbf{E} \to M$ be the vector bundle specified there. There exists $\rho > 0$ such that $\|\mathbf{u}\|_X \geq \rho$ for every $\mathbf{u} \in \mathcal{N}$.

Proof. Let $\mathbf{u} \in \mathcal{N}$. By (32.20), (a1), and (32.16),

$$k_1 \|\nabla^{\mathbf{E}}\mathbf{u}\|^p_{L^p(M,T^*M\otimes\mathbf{E})} + k_2 \|\mathbf{u}\|^q_X \leq \varepsilon \|\mathbf{u}\|^p_{L^p(M,\mathbf{E})} + C_\varepsilon \|\mathbf{u}\|^r_{L^r(M,\mathbf{E})}.$$

Let $C_p, C_r > 0$ be constants such that

$$\|\mathbf{u}\|_{L^p(M,\mathbf{E})} \leq C_p \|\nabla^{\mathbf{E}}\mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})}, \qquad \|\mathbf{u}\|_{L^r(M,\mathbf{E})} \leq C_r \|\mathbf{u}\|_X.$$

Take $\varepsilon := \dfrac{k_1}{2C_p^p}$. Then

$$\frac{k_1}{2} \|\nabla^{\mathbf{E}}\mathbf{u}\|^p_{L^p(M,T^*M\otimes\mathbf{E})} + k_2 \|\mathbf{u}\|^q_X \leq C_\varepsilon C_r^r \|\mathbf{u}\|^r_X. \tag{32.21}$$

If $p < q$, hypothesis (a1) ensures that $k_2 > 0$. Dropping the first term on the left-hand side of (32.21) gives $k_2 \|\mathbf{u}\|^q_X \leq C_\varepsilon C_r^r \|\mathbf{u}\|^r_X$. Since $\mathbf{u} \neq 0$ and $r > q$, $\|\mathbf{u}\|_X \geq \left(\dfrac{k_2}{C_\varepsilon C_r^r} \right)^{\frac{1}{r-q}}$.

If $p = q$, we have $\|\nabla^{\mathbf{E}}\mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})} = \|\mathbf{u}\|_X$. Dropping the term containing k_2 gives $\dfrac{k_1}{2}\|\mathbf{u}\|^q_X \leq C_\varepsilon C_r^r \|\mathbf{u}\|^r_X$, and hence $\|\mathbf{u}\|_X \geq \left(\dfrac{k_1}{2C_\varepsilon C_r^r} \right)^{\frac{1}{r-q}}$.

Taking ρ to be the smaller of the constants corresponding to the possible cases completes the proof. □

Lemma 32.5.9. (Boundedness of Nehari sequences) Let M be the compact Riemannian manifold with nonempty boundary fixed in this section, and let $\mathbf{E} \to M$ be the vector bundle specified there. If $(\mathbf{u}_j)_{j\in\mathbb{N}} \subseteq \mathcal{N}$ and $(I(\mathbf{u}_j))_{j\in\mathbb{N}}$ is bounded above, then $(\mathbf{u}_j)$ is bounded in X.

Proof. For each $\mathbf{u} \in \mathcal{N}$, using (f3), Lemma 32.5.2, and (a1), we obtain

$$I(\mathbf{u}) = I(\mathbf{u}) - \frac{1}{\theta} DI(\mathbf{u})(\mathbf{u}) \geq \int_M \left[\frac{1}{p} A(|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}) - \frac{1}{\theta} a(|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}) |\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}} \right] d\lambda_{\mathbf{g}}$$

$$\geq \left(\frac{1}{q} - \frac{1}{\theta} \right) \int_M a(|\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}) |\nabla^{\mathbf{E}}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}} \, d\lambda_{\mathbf{g}} \geq \left(\frac{1}{q} - \frac{1}{\theta} \right) \left(k_1 \|\nabla^{\mathbf{E}}\mathbf{u}\|^p_{L^p(M,T^*M\otimes\mathbf{E})} + k_2 \|\mathbf{u}\|^q_X \right).$$

If $p < q$, then $k_2 > 0$, and $I(\mathbf{u}) \geq \left(\frac{1}{q} - \frac{1}{\theta} \right) k_2 \|\mathbf{u}\|^q_X$.

If $p = q$, then $\|\nabla^{\mathbf{E}}\mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})} = \|\mathbf{u}\|_X$ and $I(\mathbf{u}) \geq \left(\frac{1}{q} - \frac{1}{\theta} \right) k_1 \|\mathbf{u}\|^q_X$.

In both cases there exists $c_0 > 0$, independent of $\mathbf{u} \in \mathcal{N}$, such that $I(\mathbf{u}) \geq c_0 \|\mathbf{u}\|^q_X$.

The upper bound for $I(\mathbf{u}_j)$ then implies boundedness of $\|\mathbf{u}_j\|_X$. □

Lemma 32.5.10. (Convergence of the nonlinear terms) Let M be the compact Riemannian manifold with nonempty boundary fixed in this section, and let $\mathbf{E} \to M$ be the vector bundle specified there. Let $(\mathbf{u}_j)_{j\in\mathbb{N}} \subseteq L^r(M,\mathbf{E})$ satisfy $\mathbf{u}_j \to \mathbf{u}$ in $L^r(M,\mathbf{E})$. Then $f(\mathbf{u}_j) \to f(\mathbf{u})$ in $L^{r'}(M,\mathbf{E})$, $\int_M \langle f_x(\mathbf{u}_j), \mathbf{u}_j \rangle_{\mathbf{h}_{\mathbf{E}}} \, d\lambda_{\mathbf{g}} \longrightarrow \int_M \langle f_x(\mathbf{u}), \mathbf{u} \rangle_{\mathbf{h}_{\mathbf{E}}} \, d\lambda_{\mathbf{g}}$, and $\int_M \mathcal{F}_x(\mathbf{u}_j) \, d\lambda_{\mathbf{g}} \longrightarrow \int_M \mathcal{F}_x(\mathbf{u}) \, d\lambda_{\mathbf{g}}$.

Proof. The first convergence follows from Corollary 29.1.9, applied to the bundle map $f : \mathbf{E} \longrightarrow \mathbf{E}$ with $m = r$.

Since $\mathbf{u}_j \to \mathbf{u}$ in $L^r(M,\mathbf{E})$, the sequence $(\mathbf{u}_j)$ is bounded in $L^r(M,\mathbf{E})$. By Hölder's inequality (Proposition B.7.9),

$$\left| \int_M \langle f_x(\mathbf{u}_j), \mathbf{u}_j \rangle_{\mathbf{h}_{\mathbf{E}}} \, d\lambda_{\mathbf{g}} - \int_M \langle f_x(\mathbf{u}), \mathbf{u} \rangle_{\mathbf{h}_{\mathbf{E}}} \, d\lambda_{\mathbf{g}} \right|$$
$$\leq \|f(\mathbf{u}_j) - f(\mathbf{u})\|_{L^{r'}(M,\mathbf{E})} \|\mathbf{u}_j\|_{L^r(M,\mathbf{E})} + \|f(\mathbf{u})\|_{L^{r'}(M,\mathbf{E})} \|\mathbf{u}_j - \mathbf{u}\|_{L^r(M,\mathbf{E})}.$$

and the right-hand side converges to zero.

For the potential, Theorem B.6.5, applied in each fiber, gives

$$\mathcal{F}_x(\mathbf{u}_j) - \mathcal{F}_x(\mathbf{u}) = \int_0^1 \langle f_x(\mathbf{u} + s(\mathbf{u}_j - \mathbf{u})), \mathbf{u}_j - \mathbf{u} \rangle_{\mathbf{h}_{\mathbf{E}}} \, ds.$$

By Fubini's theorem for Bochner integrals B.6.26, applied in the scalar case, and Hölder's inequality (Proposition B.7.9),

$$\left| \int_M \mathcal{F}_x(\mathbf{u}_j) \, d\lambda_{\mathbf{g}} - \int_M \mathcal{F}_x(\mathbf{u}) \, d\lambda_{\mathbf{g}} \right| \leq \|\mathbf{u}_j - \mathbf{u}\|_{L^r(M,\mathbf{E})} \int_0^1 \|f(\mathbf{u} + s(\mathbf{u}_j - \mathbf{u}))\|_{L^{r'}(M,\mathbf{E})} \, ds.$$

The family $\mathbf{u} + s(\mathbf{u}_j - \mathbf{u})$ is bounded in $L^r(M,\mathbf{E})$ uniformly with respect to j and $s \in [0,1]$. Remark 29.1.10 shows that the norms of $f(\mathbf{u} + s(\mathbf{u}_j - \mathbf{u}))$ in $L^{r'}(M,\mathbf{E})$ are uniformly bounded. Since $\|\mathbf{u}_j - \mathbf{u}\|_{L^r(M,\mathbf{E})} \to 0$, the difference of the potentials converges to zero. □

32.5.4 Radial reduction and existence of a minimizer

Proposition 32.5.6 allows us to define $m\colon S_X \longrightarrow \mathcal{N}$ by $m(\mathbf{w}) = t_{\mathbf{w}}\mathbf{w}$. To apply Theorem 32.3.1, it remains to verify the uniform bounds required there.

Proposition 32.5.11. (Hypotheses for radial reduction) Let M be the compact Riemannian manifold with nonempty boundary fixed in this section, and let $\mathbf{E} \to M$ be the vector bundle specified there. The space X and the functional I satisfy hypotheses (A1)–(A3) for the radial reduction of Szulkin and Weth.

Proof. Consider the linear map

$$\mathcal{G}\colon X \longrightarrow L^q(M, T^*M \otimes \mathbf{E}), \qquad \mathcal{G}(\mathbf{u}) = \nabla^{\mathbf{E}}\mathbf{u}.$$

The Poincaré inequality in Theorem 9.6.8 shows that $\mathcal{G}$ is injective. Moreover, by the definition of the norm fixed in this section,

$$\|\mathcal{G}(\mathbf{u})\|_{L^q(M,T^*M\otimes\mathbf{E})} = \|\mathbf{u}\|_X.$$

The norm $\|\cdot\|_X$ is equivalent to the norm on $W_0^{1,q}(M,\mathbf{E})$; since the latter space is closed in $W^{1,q}(M,\mathbf{E})$ and complete, $(X, \|\cdot\|_X)$ is a Banach space. Consequently, the image $\mathcal{G}(X)$ is closed in $L^q(M, T^*M\otimes\mathbf{E})$. The proof of Proposition 9.1.18 is pointwise in the fibers and uses only that they are Hilbert spaces; it therefore applies without change on the manifold with boundary and shows that $L^q(M, T^*M \otimes \mathbf{E})$ is uniformly convex. This property is inherited by closed subspaces and preserved under isometries. Thus X is uniformly convex.
To verify (A1), take the normalization function $\varphi(t) := t^{q-1}$. The associated functional is

$$\psi_X(\mathbf{u}) := \int_0^{\|\mathbf{u}\|_X} t^{q-1}\,dt = \frac{1}{q}\|\mathbf{u}\|_X^q = \frac{1}{q}\int_M |\nabla^{\mathbf{E}}\mathbf{u}|^q_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\,d\lambda_{\mathbf{g}}.$$

The functional ψ_X belongs to $C^1(X,\mathbb{R})$. This is the case $p = q$, $a \equiv 1$, and $A(s) = s$ of the calculation for J_1 in the proof of Proposition 32.5.5. In this specialization,

$$D\psi_X(\mathbf{u})(\mathbf{v}) = \int_M |\nabla^{\mathbf{E}}\mathbf{u}|^{q-2}_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\langle\nabla^{\mathbf{E}}\mathbf{u}, \nabla^{\mathbf{E}}\mathbf{v}\rangle_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\,d\lambda_{\mathbf{g}}.$$

Hölder's inequality (Proposition B.7.9) implies $|D\psi_X(\mathbf{u})(\mathbf{v})| \le \|\mathbf{u}\|_X^{q-1}\|\mathbf{v}\|_X$, so the map $\mathcal{J}_X := D\psi_X\colon X \longrightarrow X'$ sends bounded sets to bounded sets. If $\mathbf{w} \in S_X$, then

$$\mathcal{J}_X(\mathbf{w})(\mathbf{w}) = \int_M |\nabla^{\mathbf{E}}\mathbf{w}|^q_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\,d\lambda_{\mathbf{g}} = \|\mathbf{w}\|_X^q = 1.$$

Thus (A1) holds.
Proposition 32.5.6 proves that, for each $\mathbf{u} \in X \setminus \{0\}$, there exists a unique $t_{\mathbf{u}} > 0$ such that $t_{\mathbf{u}}\mathbf{u} \in \mathcal{N}$, and that the function $t \mapsto I(t\mathbf{u})$ is strictly increasing on $(0, t_{\mathbf{u}})$ and strictly decreasing on $(t_{\mathbf{u}}, +\infty)$. This is precisely hypothesis (A2).
We now verify (A3). If $\mathbf{w} \in S_X$, then $t_{\mathbf{w}}\mathbf{w} \in \mathcal{N}$. By Lemma 32.5.8, there exists $\rho > 0$, independent of $\mathbf{w}$, such that $t_{\mathbf{w}} = \|t_{\mathbf{w}}\mathbf{w}\|_X \ge \rho$. This provides the uniform lower bound.
Now let $K \subseteq S_X$ be nonempty and compact; for $K = \varnothing$ the upper bound is vacuous. The function $\mathbf{w} \longmapsto \|\mathbf{w}\|^{\theta}_{L^{\theta}(M,\mathbf{E})}$ is continuous on X and positive on S_X, since $\|\mathbf{w}\|_{L^{\theta}(M,\mathbf{E})} = 0$ would imply $\mathbf{w} = 0$. By compactness,

$\mu_K := \min_{\mathbf{w}\in K} \|\mathbf{w}\|^\theta_{L^\theta(M,\mathbf{E})} > 0$.
By the upper bound for A and Lemma 32.5.4, there exists $C_K > 0$ such that, for every $\mathbf{w} \in K$ and every $t > 0$,

$$I(t\mathbf{w}) \le C_K(t^p + t^q) - D\mu_K t^\theta + D'\lambda_{\mathbf{g}}(M).$$

Since $\theta > q \ge p$, the right-hand side converges to $-\infty$ as $t \to +\infty$, uniformly with respect to $\mathbf{w} \in K$. There exists $R_K > 0$ such that $I(t\mathbf{w}) < 0$ for every $\mathbf{w} \in K$ and every $t \ge R_K$. However, $I(t_{\mathbf{w}}\mathbf{w}) > 0$ by Lemma 32.5.7. Thus $t_{\mathbf{w}} < R_K$ for every $\mathbf{w} \in K$, proving (A3). □

Proposition 32.5.12. (Existence of a minimizer on $\mathcal{N}$) Let M be the compact Riemannian manifold with nonempty boundary fixed in this section, and let $\mathbf{E} \to M$ be the vector bundle specified there. There exists $\mathbf{u}_0 \in \mathcal{N}$ such that

$$I(\mathbf{u}_0) = \inf_{\mathbf{u}\in\mathcal{N}} I(\mathbf{u}).$$

Proof. Define $c := \inf_{\mathbf{u}\in\mathcal{N}} I(\mathbf{u})$. By Lemmas 32.5.7, 32.5.8, and the estimate in Lemma 32.5.9, we have $c > 0$.
Let $(\mathbf{u}_j)_{j\in\mathbb{N}} \subseteq \mathcal{N}$ be a sequence such that $I(\mathbf{u}_j) \to c$. Lemma 32.5.9 implies that $(\mathbf{u}_j)$ is bounded in X. Since $1 < q < \infty$, the space X is reflexive; passing to a subsequence, there exists $\mathbf{u} \in X$ such that $\mathbf{u}_j \rightharpoonup \mathbf{u}$ in X.
By Corollary 9.4.31, and since $p, r < q^*$, $\mathbf{u}_j \to \mathbf{u}$ in $L^p(M,\mathbf{E}) \cap L^r(M,\mathbf{E})$.
We shall prove that $\mathbf{u} \neq 0$. Suppose otherwise. By Lemma 32.5.10, $\int_M \langle f_x(\mathbf{u}_j), \mathbf{u}_j\rangle_{\mathbf{h}_\mathbf{E}}\, d\lambda_{\mathbf{g}} \longrightarrow 0$.
Fix $C_p > 0$ such that $\|\mathbf{v}\|^p_{L^p(M,\mathbf{E})} \le C_p \|\nabla^{\mathbf{E}}\mathbf{v}\|^p_{L^p(M,T^*M\otimes\mathbf{E})}$ for every $\mathbf{v} \in X$, and choose $\varepsilon := \dfrac{k_1}{2C_p}$. By the Nehari identity, (a1), and (32.16),

$$\begin{aligned} k_1\|\nabla^{\mathbf{E}}\mathbf{u}_j\|^p_{L^p(M,T^*M\otimes\mathbf{E})} + k_2\|\mathbf{u}_j\|^q_X &\le \int_M \langle f_x(\mathbf{u}_j), \mathbf{u}_j\rangle_{\mathbf{h}_\mathbf{E}}\, d\lambda_{\mathbf{g}} \\ &\le \varepsilon\|\mathbf{u}_j\|^p_{L^p(M,\mathbf{E})} + C_\varepsilon\|\mathbf{u}_j\|^r_{L^r(M,\mathbf{E})} \\ &\le \frac{k_1}{2}\|\nabla^{\mathbf{E}}\mathbf{u}_j\|^p_{L^p(M,T^*M\otimes\mathbf{E})} + C_\varepsilon\|\mathbf{u}_j\|^r_{L^r(M,\mathbf{E})}. \end{aligned}$$

Thus

$$\frac{k_1}{2}\|\nabla^{\mathbf{E}}\mathbf{u}_j\|^p_{L^p(M,T^*M\otimes\mathbf{E})} + k_2\|\mathbf{u}_j\|^q_X \le C_\varepsilon\|\mathbf{u}_j\|^r_{L^r(M,\mathbf{E})}.$$

If $p < q$, we have $k_2 > 0$ and the right-hand side converges to zero, so $\|\mathbf{u}_j\|_X \to 0$. If $p = q$, the first term on the left-hand side is $\dfrac{k_1}{2}\|\mathbf{u}_j\|^q_X$, giving the same conclusion. This contradicts $\|\mathbf{u}_j\|_X \ge \rho$. Hence $\mathbf{u} \neq 0$.
By Proposition 32.5.6, there exists a unique $t_{\mathbf{u}} > 0$ such that $t_{\mathbf{u}}\mathbf{u} \in \mathcal{N}$. Since $\mathbf{u}_j \in \mathcal{N}$ is the maximum along its own positive ray, $I(t_{\mathbf{u}}\mathbf{u}_j) \le I(\mathbf{u}_j)$ for every j.
Set $\varphi(s) := A(s^p)$ for $s \ge 0$. By (a3), φ is convex; since $a \ge 0$, A and φ are also nondecreasing. The triangle inequality and these two properties give, for $0 \le \lambda \le 1$,

$$\begin{aligned} A\big(|\lambda\eta + (1-\lambda)\zeta|^p_{\mathbf{g}\otimes\mathbf{h}_\mathbf{E}}\big) &= \varphi\big(|\lambda\eta + (1-\lambda)\zeta|_{\mathbf{g}\otimes\mathbf{h}_\mathbf{E}}\big) \\ &\le \varphi\big(\lambda|\eta|_{\mathbf{g}\otimes\mathbf{h}_\mathbf{E}} + (1-\lambda)|\zeta|_{\mathbf{g}\otimes\mathbf{h}_\mathbf{E}}\big) \\ &\le \lambda A(|\eta|^p_{\mathbf{g}\otimes\mathbf{h}_\mathbf{E}}) + (1-\lambda)A(|\zeta|^p_{\mathbf{g}\otimes\mathbf{h}_\mathbf{E}}). \end{aligned}$$

Thus $\eta \mapsto p^{-1}A(|\eta|^p_{\mathbf{g}\otimes\mathbf{h}_\mathbf{E}})$ is convex and continuous. Consequently, for the fixed number $t_\mathbf{u} > 0$, the functional

$$G(\mathbf{v}) := \frac{1}{p}\int_M A(t_\mathbf{u}^p|\nabla^\mathbf{E}\mathbf{v}|^p_{\mathbf{g}\otimes\mathbf{h}_\mathbf{E}})\,d\lambda_\mathbf{g}$$

is convex and continuous on X. By Corollary B.11.17, G is weakly lower semicontinuous; therefore,

$$\frac{1}{p}\int_M A(t_\mathbf{u}^p|\nabla^\mathbf{E}\mathbf{u}|^p_{\mathbf{g}\otimes\mathbf{h}_\mathbf{E}})\,d\lambda_\mathbf{g} \le \liminf_{j\to\infty}\frac{1}{p}\int_M A(t_\mathbf{u}^p|\nabla^\mathbf{E}\mathbf{u}_j|^p_{\mathbf{g}\otimes\mathbf{h}_\mathbf{E}})\,d\lambda_\mathbf{g}.$$

Moreover, $t_\mathbf{u}\mathbf{u}_j \to t_\mathbf{u}\mathbf{u}$ in $L^r(M,\mathbf{E})$, so Lemma 32.5.10 implies

$$\int_M \mathcal{F}_x(t_\mathbf{u}\mathbf{u}_j)\,d\lambda_\mathbf{g} \longrightarrow \int_M \mathcal{F}_x(t_\mathbf{u}\mathbf{u})\,d\lambda_\mathbf{g}.$$

Consequently, $I(t_\mathbf{u}\mathbf{u}) \le \liminf_{j\to\infty} I(t_\mathbf{u}\mathbf{u}_j) \le \lim_{j\to\infty} I(\mathbf{u}_j) = c$.
Since $t_\mathbf{u}\mathbf{u} \in \mathcal{N}$, the definition of c gives $c \le I(t_\mathbf{u}\mathbf{u})$. Thus $I(t_\mathbf{u}\mathbf{u}) = c$. Taking $\mathbf{u}_0 := t_\mathbf{u}\mathbf{u}$ completes the proof. □

Theorem 32.5.13. (Existence of a ground state) Let M be the compact Riemannian manifold with nonempty boundary fixed in this section, and let $\mathbf{E} \to M$ be the vector bundle specified there. Under hypotheses (a1)–(a3) and (f1)–(f4), problem (32.14) has a ground state solution: there exists $\mathbf{u}_0 \in X \setminus \{0\}$ such that $DI(\mathbf{u}_0) = 0$ and

$$I(\mathbf{u}_0) = \inf\{I(\mathbf{u}) \mid \mathbf{u} \in X \setminus \{0\},\ DI(\mathbf{u}) = 0\}.$$

Proof. By Proposition 32.5.12, there exists $\mathbf{u}_0 \in \mathcal{N}$ minimizing I on $\mathcal{N}$. Propositions 32.5.6 and 32.5.11 allow us to apply Theorem 32.3.1. Let $\mathbf{w}_0 := m^{-1}(\mathbf{u}_0) \in S_X$. Since m is a homeomorphism and $\Psi = I \circ m$, the point $\mathbf{w}_0$ minimizes Ψ on the submanifold S_X. Fermat's theorem on manifolds gives $D\Psi(\mathbf{w}_0) = 0$; by part 5 of Theorem 32.3.1, $\mathbf{u}_0 = m(\mathbf{w}_0)$ is a nontrivial critical point of I. By Proposition 32.5.5, $\mathbf{u}_0$ is a weak solution of (32.14).
Every nontrivial critical point $\mathbf{u}$ of I satisfies $DI(\mathbf{u})(\mathbf{u}) = 0$ and therefore belongs to $\mathcal{N}$. It follows that

$$I(\mathbf{u}_0) = \inf_{\mathbf{u}\in\mathcal{N}} I(\mathbf{u}) = \inf\{I(\mathbf{u}) \mid \mathbf{u} \neq 0,\ DI(\mathbf{u}) = 0\}.$$

□

32.5.5 Examples of operators covered by the result

The following examples show that the hypotheses on a encompass several familiar geometric operators. In all of them, we may take

$$\mathcal{F}_x(\xi) := \frac{1}{r}|\xi|^r_{\mathbf{h}_\mathbf{E}}, \qquad f_x(\xi) = |\xi|^{r-2}_{\mathbf{h}_\mathbf{E}}\xi, \qquad r \in (q, q^*).$$

These conditions are verified directly, since $\dfrac{|f_x(\xi)|_{\mathbf{h}_\mathbf{E}}}{|\xi|^{p-1}_{\mathbf{h}_\mathbf{E}}} = |\xi|^{r-p}_{\mathbf{h}_\mathbf{E}} \longrightarrow 0$ uniformly with respect to x, because $r > q \ge p$; moreover, $|f_x(\xi)|_{\mathbf{h}_\mathbf{E}} = |\xi|^{r-1}_{\mathbf{h}_\mathbf{E}}$, $\langle f_x(\xi),\xi\rangle_{\mathbf{h}_\mathbf{E}} = |\xi|^r_{\mathbf{h}_\mathbf{E}} = r\mathcal{F}_x(\xi)$, and, for $\xi \neq 0_x$, $\dfrac{\langle f_x(t\xi), t\xi\rangle_{\mathbf{h}_\mathbf{E}}}{t^q} = t^{r-q}|\xi|^r_{\mathbf{h}_\mathbf{E}}$, which is strictly increasing. Thus (f1)–(f4) hold for any $\theta \in (q, r]$.

Example 32.5.14. (Bochner Laplacian of type p) Suppose that $p = q$ and $a(s) := 1$. Then $a(t^p)t^p = t^p$, so (a1) holds with $k_1 = k_3 = 1$ and $k_2 = k_4 = 0$. Since $\dfrac{a(t^p)}{t^{q-p}} = 1$, (a2) holds. Finally, $A(s) = s$ and $A(t^p) = t^p$ is convex, so (a3) also holds. The principal term in (32.14) reduces to $(\nabla^{\mathbf{E}})^*\big(|\nabla^{\mathbf{E}}\mathbf{u}|^{p-2}_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\nabla^{\mathbf{E}}\mathbf{u}\big)$.

Example 32.5.15. (Bochner operator with (p,q) growth) Let $a(s) := 1 + s^{\frac{q-p}{p}}$. Then $a(t^p)t^p = t^p + t^q$, so (a1) holds with $k_1 = k_2 = k_3 = k_4 = 1$ when $p < q$. If $p = q$, then $a(s) = 2$ for every $s \geq 0$, and (a1) holds, for example, with $k_1 = k_3 = 2$ and $k_2 = k_4 = 0$. For $p < q$, $\dfrac{a(t^p)}{t^{q-p}} = 1 + t^{p-q}$, which is strictly decreasing; for $p = q$ it is constant. Moreover,

$$A(s) = s + \frac{p}{q}s^{\frac{q}{p}}, \qquad A(t^p) = t^p + \frac{p}{q}t^q,$$

and the latter function is convex. Thus (a1)–(a3) hold, and the principal term is the sum $(\nabla^{\mathbf{E}})^*\big(|\nabla^{\mathbf{E}}\mathbf{u}|^{p-2}_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\nabla^{\mathbf{E}}\mathbf{u}\big) + (\nabla^{\mathbf{E}})^*\big(|\nabla^{\mathbf{E}}\mathbf{u}|^{q-2}_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\nabla^{\mathbf{E}}\mathbf{u}\big)$.

Example 32.5.16. (Perturbation of mean curvature type) Suppose that $q = p$ and

$$a(s) := 1 + \frac{1}{(1+s)^{\frac{p-1}{p}}}.$$

Since $1 \leq a(s) \leq 2$, we have $t^p \leq a(t^p)t^p \leq 2t^p$, so (a1) holds with $k_1 = 1$, $k_2 = 0$, $k_3 = 2$, and $k_4 = 0$. Because $q - p = 0$ and $t \mapsto a(t^p)$ is nonincreasing, (a2) holds. Direct integration gives $A(s) = s + p\big((1+s)^{\frac{1}{p}} - 1\big)$, and hence $A(t^p) = t^p + p\big((1+t^p)^{\frac{1}{p}} - 1\big)$.

The function $t \mapsto t^p$ is convex, and $t \mapsto (1+t^p)^{\frac{1}{p}}$ is the restriction to $[0,+\infty)$ of the ℓ^p norm of the vector $(1,t)$; consequently, $A(t^p)$ is convex and (a3) holds. In this case, the additional term

$$(\nabla^{\mathbf{E}})^*\left(\frac{|\nabla^{\mathbf{E}}\mathbf{u}|^{p-2}_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}}\nabla^{\mathbf{E}}\mathbf{u}}{(1+|\nabla^{\mathbf{E}}\mathbf{u}|^{p}_{\mathbf{g}\otimes\mathbf{h}_{\mathbf{E}}})^{\frac{p-1}{p}}}\right).$$

appears.

Remark 32.5.17. The condition $k_2 > 0$ is required only when $p < q$. This distinction is necessary in the coercive estimates on $\mathcal{N}$: if $p < q$, the term $k_2\|\mathbf{u}\|_X^q$ directly controls the norm of X; if $p = q$, this control is provided by the term with coefficient k_1, because $\|\nabla^{\mathbf{E}}\mathbf{u}\|_{L^p(M,T^*M\otimes\mathbf{E})} = \|\mathbf{u}\|_X$.

32.6 Exercises

Exercise 32.6.1. Let $(M,\mathbf{g})$ be a nonempty compact Riemannian manifold with smooth boundary, such that each connected component has nonempty boundary. For the functional in the model case, prove that for each $u \neq 0$ there exists a unique $t_u > 0$ such that $t_u u \in \mathcal{N}$, and compute t_u explicitly. Also show that $u \mapsto t_u u$ is a homeomorphism between the unit sphere of $W^{1,2}_0(M)$ and $\mathcal{N}$.

Exercise 32.6.2. Let $(M,\mathbf{g})$ be a nonempty compact Riemannian manifold with smooth boundary, such that each connected component has nonempty boundary, and let $\mathbf{E}\to M$ be a smooth real vector bundle of positive finite rank, equipped with a bundle metric $\mathbf{h}_{\mathbf{E}}$ and a connection $\nabla^{\mathbf{E}}$ compatible with $\mathbf{h}_{\mathbf{E}}$. Suppose that a satisfies (a1)–(a3) and that $\mathcal{F}$ satisfies (f1)–(f4). Prove directly, without using the existence of the minimizer, that for each $\mathbf{u}\in X\setminus\{0\}$ there exist numbers $0<\alpha_{\mathbf{u}}<\beta_{\mathbf{u}}$ such that $I(t\mathbf{u})>0$ if $0<t<\alpha_{\mathbf{u}}$ and $I(t\mathbf{u})<0$ if $t>\beta_{\mathbf{u}}$. As a hint, first obtain explicit constants $C_1(\mathbf{u}),C_2(\mathbf{u})>0$ for which

$$I(t\mathbf{u})\geq C_1(\mathbf{u})t^{p}-C_2(\mathbf{u})t^{r}$$

when $t>0$, and then use the lower bound of order θ for the potential. Explain why this argument alone does not establish uniqueness of the critical point of the radial function, and identify the precise role of (a2) and (f4) in the proof of uniqueness.

Appendices

A

Topology

This appendix collects the topological notions used in constructing manifolds, bundles, and quotient spaces, together with the results from algebraic topology needed for index theory. For the latter results, we specify the conventions used in the main chapters and give precise references for the topological proofs themselves.

Before beginning, we state the maximality principle that will be used to construct separated nets in metric spaces.

Theorem A.0.1. (Zorn's lemma) Let $(P, \preccurlyeq)$ be a nonempty partially ordered set. If every chain $\mathcal{C} \subseteq P$ has an upper bound in P, then P contains a maximal element.

Remark A.0.2. Zorn's lemma is equivalent to the axiom of choice. In this text, it is used only to construct maximal families of separated balls.

A.1 Topological spaces

Definition A.1.1. (Topological space) A *topological space* is a pair (X, τ), where X is a set and τ is a family of subsets of X such that:

(a) $\varnothing, X \in \tau$,

(b) every arbitrary union of sets in τ belongs to τ,

(c) every finite intersection of sets in τ belongs to τ.

The elements of τ are called *open subsets* of X.

Definition A.1.2. (Subspace topology) Let (X, τ) be a topological space and let $A \subseteq X$. The *subspace topology* on A is

$$\tau_A = \{U \cap A \mid U \in \tau\}.$$

Then (A, τ_A) is a topological space called a *subspace* of X.

Definition A.1.3. (Quotient map and quotient topology) Let (X, τ_X) be a topological space, let Y be a set, and let $q\colon X \longrightarrow Y$ be a surjective map. The *quotient topology* on Y induced by q is defined by

$$\tau_q = \{V \subseteq Y \mid q^{-1}(V) \in \tau_X\}.$$

With this topology, $q\colon (X, \tau_X) \longrightarrow (Y, \tau_q)$ is continuous, and q is called a *quotient map*. Equivalently, a continuous surjective map between topological spaces is a quotient map if $U \subseteq Y$ is open whenever $q^{-1}(U)$ is open in X.

Definition A.1.4. (Quotient space) Let X be a topological space and let $\sim$ be an equivalence relation on X. The *quotient space* $X/\sim$ is defined as the set of equivalence classes

$$X/\sim = \{[x] \mid x \in X\},$$

equipped with the quotient topology induced by the natural projection

$$q\colon X \longrightarrow X/\sim, \qquad q(x) = [x].$$

Thus, $U \subseteq X/\sim$ is open if and only if $q^{-1}(U)$ is open in X.

Example A.1.5. (Circle) The circle $\mathbb{S}^1$ can be described as the quotient

$$\mathbb{S}^1 \cong [0,1]/\sim,$$

where $0 \sim 1$ and all other points of $[0,1]$ remain distinct.

Example A.1.6. (Cylinder) The cylinder is obtained as

$$C \cong \big([0,1] \times [0,1]\big)/\sim,$$

where we identify $(0, y) \sim (1, y)$ for every $y \in [0,1]$. In this case the vertical sides are glued together without a twist.

Example A.1.7. (Möbius strip) The Möbius strip is obtained similarly as

$$M \cong \big([0,1] \times [0,1]\big)/\sim,$$

where the equivalence relation is

$$(0, y) \sim (1, 1-y), \qquad y \in [0,1].$$

This corresponds to gluing the vertical sides of the square after giving one of them a half-turn.

Lemma A.1.8. (Characterization of quotient maps) Let $q\colon X \longrightarrow Y$ be a continuous surjective map between topological spaces. If q is closed, then q is a quotient map; that is, a subset $U \subseteq Y$ is open if and only if $q^{-1}(U)$ is open in X.

Proof. Continuity proves one implication. Conversely, if $q^{-1}(U)$ is open, then $q^{-1}(Y \setminus U)$ is closed. Since q is closed and surjective,

$$Y \setminus U = q\big(q^{-1}(Y \setminus U)\big)$$

is closed. Therefore, U is open. □

A.2 Covering spaces

Definition A.2.1. (Covering map) Let $p\colon Y \longrightarrow X$ be a continuous surjective map between topological spaces. We say that p is a *covering map* if for every $x \in X$ there is an open subset $U \subseteq X$ with $x \in U$ such that

$$p^{-1}(U) = \coprod_{\alpha \in A} V_\alpha,$$

where each V_α is open in Y and the restriction $p\restriction_{V_\alpha}\colon V_\alpha \longrightarrow U$ is a homeomorphism.

Definition A.2.2. (Universal covering map) A covering map $p\colon \widetilde{X} \longrightarrow X$ is called a *universal covering map* if $\widetilde{X}$ is simply connected.

Proposition A.2.3. (Universal covering map of the circle) The map $\varepsilon\colon \mathbb{R} \longrightarrow \mathbb{S}^1$ defined by $\varepsilon(x) = e^{2\pi i x}$ is a universal covering map of $\mathbb{S}^1$.

Proof. Let $z_0 = e^{2\pi i a}$. If

$$U = \left\{ e^{2\pi i t} \,\middle|\, a - \frac{1}{4} < t < a + \frac{1}{4} \right\},$$

then

$$\varepsilon^{-1}(U) = \coprod_{k \in \mathbb{Z}} \left(a - \frac{1}{4} + k, a + \frac{1}{4} + k \right),$$

and each interval projects homeomorphically onto U. Thus, ε is a covering map. Moreover, $\mathbb{R}$ is contractible by the homotopy $H(x,t) = (1-t)x$ and is therefore simply connected. □

Definition A.2.4. (Evenly covered open subsets) Let $p\colon Y \longrightarrow X$ be a covering map of topological spaces. We say that a connected open subset $U \subseteq X$ is *evenly covered* by p if each connected component $\widetilde{U}$ of $p^{-1}(U)$ projects homeomorphically onto U under the restriction $p\restriction_{\widetilde{U}}\colon \widetilde{U} \longrightarrow U$.

Theorem A.2.5. (Arcs covered by the exponential) Let $U \subsetneq \mathbb{S}^1$ be an open arc. Then $\varepsilon^{-1}(U)$ is a disjoint union of open intervals, and the restriction

$$\varepsilon\restriction_{\widetilde{U}}\colon \widetilde{U} \longrightarrow U$$

is a homeomorphism for each component $\widetilde{U}$ of $\varepsilon^{-1}(U)$. Thus every proper open arc is evenly covered in the sense of Definition A.2.4.

Proof. There exist $a \in \mathbb{R}$ and $0 < \ell \leq 1$ such that

$$U = \{e^{2\pi i t} \mid a < t < a + \ell\}.$$

Consequently,

$$\varepsilon^{-1}(U) = \coprod_{k \in \mathbb{Z}} (a + k, a + \ell + k).$$

On each interval in this union, ε is continuous and injective, and its inverse is a continuous branch of the argument divided by 2π. Thus each restriction is a homeomorphism onto U. □

A.3 Complex bundles and stable equivalence

In what follows, topological vector bundles have finite rank and complex fibers. Compact base spaces are assumed to be Hausdorff. Noncompact base spaces are assumed to be locally compact, Hausdorff, and paracompact. Paracompactness is the hypothesis that allows the construction of the partitions of unity used to complement and smooth bundles; local compactness and separation ensure that the one-point compactification is Hausdorff. All manifolds in this book satisfy these conditions.

Theorem A.3.1. (Stable complement) Let $\mathbf{E} \longrightarrow X$ be a complex vector bundle over a compact Hausdorff space. There exist a bundle $\mathbf{E}' \longrightarrow X$ and an integer $N \geq 0$ such that

$$\mathbf{E} \oplus \mathbf{E}' \cong X \times \mathbb{C}^N.$$

In particular, every stable bundle class can be represented as the difference between a bundle and a trivial bundle.

The proof, including the construction of an embedding of $\mathbf{E}$ into a trivial bundle by means of a finite partition of unity, can be found in [76, Proposition 1.4, pp. 13–14]. The equivalent formulation in terms of the Grothendieck group appears in [21, Theorem 10.5 and Exercises 10.9–10.12, pp. 262–265].

Theorem A.3.2. (Homotopy invariance of pullback) Let $\mathbf{E} \longrightarrow Y$ be a complex vector bundle and let $f_0, f_1 \colon X \longrightarrow Y$ be homotopic maps. If X is paracompact, then

$$f_0^* \mathbf{E} \cong f_1^* \mathbf{E}.$$

Consequently, the induced homomorphisms $f_0^*, f_1^* \colon K^0(Y) \longrightarrow K^0(X)$ agree.

A proof that trivializes the induced bundle over pieces of $X \times [0,1]$ and glues the consecutive identifications is given in [76, Theorem 1.6, pp. 19–21].

Proposition A.3.3. (Gluing bundles) Let $X = X_0 \cup X_1$, with X_0 and X_1 closed, and let $\mathbf{E}_i \longrightarrow X_i$ be complex bundles. Each isomorphism

$$\varphi \colon \mathbf{E}_0 \restriction_{X_0 \cap X_1} \longrightarrow \mathbf{E}_1 \restriction_{X_0 \cap X_1}$$

determines a bundle $\mathbf{E}_0 \cup_\varphi \mathbf{E}_1 \longrightarrow X$, unique up to isomorphism. A homotopy of gluing isomorphisms produces isomorphic bundles. In particular, bundles over a suspension are described by transition functions

on the equator.

The quotient construction and the verification of local triviality are developed in [76, Section 1.2, pp. 22–27]. The parametrized form used in Bott periodicity can be found in [21, Exercise 10.19, pp. 269–270].

A.4 Relative K-theory and compact support

For a compact pointed space (X, x_0), define

$$\widetilde{K}^0(X) := \ker\bigl(i_{x_0}^* \colon K^0(X) \longrightarrow K^0(\{x_0\})\bigr).$$

If $A \subseteq X$ is closed, set

$$K^0(X, A) := \widetilde{K}^0(X/A).$$

For a locally compact space Y, denote its one-point compactification by $Y^+ = Y \cup \{\infty\}$ and set

$$K_c^0(Y) := \widetilde{K}^0(Y^+).$$

If SX is the reduced suspension of a pointed space X, we adopt the convention

$$\widetilde{K}^1(X) := \widetilde{K}^0(SX), \qquad K_c^1(Y) := \widetilde{K}^1(Y^+).$$

Proposition A.4.1. (Suspension and product with the line) For every locally compact Hausdorff paracompact space Y, there is a natural isomorphism

$$K_c^1(Y) \cong K_c^0(\mathbb{R} \times Y). \tag{A.1}$$

This isomorphism is compatible with pullbacks by proper maps, the external product, and extensions associated with open inclusions.

Proof. The one-point compactification of the product admits a pointed homeomorphism

$$(\mathbb{R} \times Y)^+ \cong S^1 \wedge Y^+.$$

To see this, take the one-point compactification of $\mathbb{R}$ and consider the quotient map

$$S^1 \times Y^+ \longrightarrow \frac{S^1 \times Y^+}{S^1 \times \{\infty\} \cup \{\infty\} \times Y^+} = S^1 \wedge Y^+.$$

Its restriction to $\mathbb{R} \times Y$ is a homeomorphism onto the complement of the base point. Neighborhoods of the base point correspond exactly to complements of compact subsets of $\mathbb{R} \times Y$; the universal property of the one-point compactification gives the stated homeomorphism. Consequently,

$$K_c^0(\mathbb{R} \times Y) = \widetilde{K}^0\bigl((\mathbb{R} \times Y)^+\bigr) \cong \widetilde{K}^0(S^1 \wedge Y^+) = \widetilde{K}^1(Y^+) = K_c^1(Y).$$

All these identifications arise from natural quotient maps. Naturality with respect to proper maps and compatibility with external products follow. For an open inclusion, the homeomorphism preserves the

base point and the complement of the open subset, so it also commutes with extension by zero. □

It is also useful to have a description in which the support remains explicit. If $K \subseteq Y$ is compact, let $\mathcal{K}^0_K(Y)$ denote the group of classes of complexes

$$\mathbf{E}^0 \xrightarrow{a} \mathbf{E}^1$$

of complex bundles over Y for which a_y is invertible when $y \notin K$. Two complexes are identified if, after adding complexes invertible throughout Y, they can be joined by isomorphisms and a homotopy of bundle homomorphisms that remains invertible outside K. For the spaces above, there is a natural identification

$$K^0_c(Y) \cong \varinjlim_{K \Subset Y} \mathcal{K}^0_K(Y).$$

Support is a notion belonging to this model by complexes, in which the bundle homomorphism is defined on all of Y; no support is assigned to a relative triple whose bundle homomorphism is defined only on the subspace of the pair.

Theorem A.4.2. (Exactness, excision, and external product) The following properties hold.

(i) For every compact pair (X, A) with A closed, the cyclic sequence

$$K^0(X,A) \longrightarrow K^0(X) \longrightarrow K^0(A) \longrightarrow K^1(X,A) \longrightarrow K^1(X) \longrightarrow K^1(A) \longrightarrow K^0(X,A)$$

is exact.

(ii) If $U \subseteq X$ is open and $A \subseteq X$ is closed, with $\overline{U} \subseteq \operatorname{int}(A)$, the quotient of pairs induces the corresponding excision isomorphisms. In particular, if $j\colon V \hookrightarrow Y$ is an open inclusion of locally compact spaces, there is an extension homomorphism

$$j_!\colon K^q_c(V) \longrightarrow K^q_c(Y), \qquad q \in \{0,1\},$$

that depends only on the inclusion and agrees with extension by zero for complexes exact outside a compact set. More precisely, if $K \Subset V$, restriction to V and extension to Y induce inverse isomorphisms

$$\mathcal{K}^0_K(V) \xrightarrow{\cong} \mathcal{K}^0_K(Y).$$

Taking the limit over compact subsets $K \Subset V$ gives $j_!$.

(iii) For locally compact spaces X, Y, there is a natural associative external product

$$\boxtimes\colon K^p_c(X) \otimes K^q_c(Y) \longrightarrow K^{p+q}_c(X \times Y),$$

where the degree is taken modulo two. The product commutes with proper pullbacks and extensions associated with open inclusions.

Exactness in degree zero is proved in [76, Proposition 2.9, pp. 51–52]; suspension and periodicity produce the full cyclic sequence in [76, Section 2.2, pp. 51–59]. The construction using one-point compactification and the external product can be found in [21, Section 10.4 and Theorem 10.16, pp. 266–268]. The description by

complexes with support and excision in the form just stated are proved in [21, Definition 12.6 and subsequent discussion, pp. 287–289].

Theorem A.4.3. (Relative representation by triples) Let X be a compact Hausdorff space and let $A \subseteq X$ be closed. The classes of $K^0(X, A)$, with the convention $K^0(X, \varnothing) = K^0(X)$, are represented by triples $(\mathbf{E}, \mathbf{F}, \alpha)$, where $\mathbf{E}, \mathbf{F} \longrightarrow X$ are complex bundles and

$$\alpha : \mathbf{E}\restriction_A \longrightarrow \mathbf{F}\restriction_A$$

is an isomorphism. Two triples represent the same class if, after adding triples that extend to isomorphisms over X, they are related by an isomorphism and a homotopy of the maps over A. Addition is direct sum, and

$$[(\mathbf{E}, \mathbf{F}, \alpha)] + [(\mathbf{F}, \mathbf{G}, \gamma)] = [(\mathbf{E}, \mathbf{G}, \gamma \circ \alpha)].$$

If $Y = X \setminus A$ and $X/A \cong Y^{+}$, this model identifies the group with $K^0_c(Y)$. Under this identification, the model by complexes described above allows us to choose a bundle homomorphism defined on Y that is invertible outside a compact set.

The construction using the double of X, gluing over A, and the difference element can be found in [21, Definition 12.6, pp. 287–289]; the relative model is developed in [9, Chapter I, Sections 2–3]. For compact Hausdorff spaces, extension of a trivialization from a closed subset and exactness are established in [76, Proposition 2.9 and Section 2.2, pp. 51–55]. The proof of Theorem 17.2.4 constructs the isomorphism using the double and verifies the relations, surjectivity, and injectivity by means of these properties. In particular, the statement applies to $(X \times \Lambda, A \times \Lambda)$ and its homotopies for any compact Hausdorff space Λ, without requiring Λ to be CW.

Theorem A.4.4. (Smoothing bundles and homomorphisms) Let M be a compact smooth manifold with or without boundary.

(i) Every continuous complex vector bundle over M is isomorphic, as a continuous bundle, to a smooth complex vector bundle.

(ii) If $\mathbf{E}, \mathbf{F} \longrightarrow M$ are smooth, every continuous bundle homomorphism $a : \mathbf{E} \longrightarrow \mathbf{F}$ can be uniformly approximated by smooth bundle homomorphisms.

(iii) If a is an isomorphism and the approximation a_1 satisfies

$$\sup_{x \in M} \| a_1(x) - a(x) \| < \left(\sup_{x \in M} \| a(x)^{-1} \| \right)^{-1},$$

then the segment $a_t = (1 - t)a + t a_1$ consists of isomorphisms. In particular, a and a_1 define the same relative class.

The first assertion and approximation compatible with trivializations are proved in [82, p. 101]; see also [21, Exercise B.13(b), pp. 719–720]. The final assertion follows from

$$a_t = a\big(I + t\, a^{-1}(a_1 - a)\big)$$

and the Neumann series, since the norm of the second summand is less than one uniformly in x and t.

A.5 Bott periodicity and complex orientation

Let $\mathbf{H} \longrightarrow \mathbb{CP}^1 \cong \mathbb{S}^2$ be the tautological line bundle. We identify $\mathbb{R}^2$ with $\mathbb{S}^2 \setminus \{\infty\}$ and take as the Bott class

$$\beta := [\mathbf{H}^*] - [\mathbb{C}] \in \widetilde{K}^0(\mathbb{S}^2) = K_c^0(\mathbb{R}^2).$$

With the gluing in Definition 18.1.1, the tautological bundle is $\mathbf{H} = \mathbf{E}_1$ and its dual is $\mathbf{H}^* = \mathbf{E}_{-1}$; hence β agrees with the class b used in Chapter 18. This identification is checked directly, since dualizing a bundle inverts its gluing function. The description of the tautological bundle through gluing by z is given in [21, Exercise B.11, p. 719]. In the index theory chapters, this choice is retained in all Thom isomorphisms. In particular, when a complex line is identified with $\mathbb{R}^2$ by $(u, v) \mapsto u + iv$ and $J(u, v) = (-v, u)$ is used, the Thom class satisfies $\lambda_{\mathbb{C}} = -\beta$. This convention simultaneously fixes the sign of the Bott generator, that of the Euclidean model operator, and that of the normal orientation in the embedding proof.

Theorem A.5.1. (Complex Bott periodicity) For every locally compact space X and every $q \in \{0, 1\}$, external product with β defines a natural isomorphism

$$\mathcal{B}_X \colon K_c^q(X) \longrightarrow K_c^q(X \times \mathbb{R}^2), \qquad \mathcal{B}_X(a) = a \boxtimes \beta.$$

In particular,

$$K_c^0(\mathbb{R}^{2r}) \cong \mathbb{Z}, \qquad K_c^0(\mathbb{R}^{2r+1}) = 0,$$

and $\beta^{\boxtimes r}$ generates the first group.

The proof based on families of Wiener–Hopf operators, including the normalization of the generator and the verification that the two homomorphisms are inverses, is given in [21, Theorems 10.20 and 10.22, pp. 270–272]. Another complete proof, formulated using the fundamental product, appears in [76, Theorems 2.2 and 2.11, pp. 41–55]. The original source for the formulation by complex bundles is [10, pp. 229–247].

Constructing the pushforward for a nontrivial normal bundle requires the equivariant version of this normalization. If a compact group G acts on a space Y, let $K_{G,c}^0(Y)$ denote the group defined by G-equivariant complexes that are exact outside a compact set. For a point, one obtains the complex representation ring

$$K_G^0(\{*\}) = R(G).$$

Theorem A.5.2. (Equivariant Bott normalization) Let $G = O(r)$ act on $\mathbb{R}^r$ by the standard representation, and let $i \colon \{0\} \hookrightarrow \mathbb{R}^r$. The equivariant Thom class

$$\beta_r := i_!(1) \in K_{G,c}^0(T^*\mathbb{R}^r)$$

has a G-equivariant elliptic representative on the compactification $S^r = \mathbb{R}^r \cup \{\infty\}$, elementary near ∞, whose equivariant index satisfies

$$\operatorname{Ind}_G(\beta_r) = [\mathbb{C}] \quad \text{in } R(G),$$

where G acts trivially on $\mathbb{C}$. The result is natural under formation of bundles associated with a principal bundle $O(r)$.

The construction of the class using the frame bundle, equivariant descent, and conic cutoffs is developed in [21, equations (12.8)–(12.16), pp. 293–301]. The equivariant index identity is formulated in [21, p. 295]. The precise role of [11, Proposition 4.4, p. 505] is as follows: it proves that axioms (B1), (B2′), and (B3″) imply the Bott axiom (B2). Within that proof, the normalization

$$\operatorname{Ind}_G(i_!1) = 1 \quad \text{in } R(G),$$

is established first for blocks of rank one and two, using $O(1)$ and $SO(2)$, and then in every rank by block decomposition and multiplicativity. Thus the proposition does not assume the identity needed here: it obtains that identity as the normalization step recovering the full Bott axiom.

This normalization agrees with the conventions of the book. In rank one, we write $z = u+iv$ and $J(u,v) = (-v,u)$; the associated Koszul symbol has model index $+1$. The gluing function chosen for b has the opposite orientation, so $\lambda_{\mathbb{C}} = -b$, as in (18.7). Consequently, $i_!(1) = \lambda_{\mathbb{C}}$ has equivariant index equal to the trivial representation, with no isolated change of sign. This is the equivariant normalization used for the normal bundle of the embedding.

Now let $\pi\colon \mathbf{V} \longrightarrow X$ be a complex Hermitian bundle of rank r. On $\mathbf{V}$, consider the graded bundles

$$\pi^*\Lambda^{\mathrm{ev}}\mathbf{V} := \bigoplus_{j \text{ even}} \pi^*\Lambda^j\mathbf{V}, \qquad \pi^*\Lambda^{\mathrm{odd}}\mathbf{V} := \bigoplus_{j \text{ odd}} \pi^*\Lambda^j\mathbf{V}.$$

At the point $v \in \mathbf{V}_x$, exterior multiplication by v and its adjoint define

$$c_{\mathbf{V}}(v) := \varepsilon(v) - \varepsilon(v)^*\colon \Lambda^{\mathrm{ev}}\mathbf{V}_x \longrightarrow \Lambda^{\mathrm{odd}}\mathbf{V}_x.$$

The exterior algebra relations give

$$c_{\mathbf{V}}(v)^* c_{\mathbf{V}}(v) = \|v\|^2 \operatorname{Id},$$

so $c_{\mathbf{V}}(v)$ is invertible for $v \neq 0$. The triple consisting of the two bundles and $c_{\mathbf{V}}$ determines the Thom class

$$\lambda_{\mathbf{V}} \in K^0_X(\mathbf{V}),$$

where the subscript indicates support on the zero section. If X is compact, this group is identified with $K^0_c(\mathbf{V})$. For the trivial line identified with $\mathbb{R}^2$ by $(u,v) \mapsto u + iv$ and with $J(u,v) = (-v,u)$, this convention satisfies

$$\lambda_{\mathbb{C}} = -\beta.$$

The verification using transition functions is given in (18.7).

Theorem A.5.3. (Thom isomorphism in K-theory) For every complex vector bundle $\pi\colon \mathbf{V} \longrightarrow X$ over a compact base, the homomorphism

$$\mathrm{Th}_{\mathbf{V}}\colon K^0(X) \longrightarrow K^0_c(\mathbf{V}), \qquad \mathrm{Th}_{\mathbf{V}}(a) = \pi^*a \cdot \lambda_{\mathbf{V}},$$

is an isomorphism. It is natural with respect to pullbacks, multiplicative with respect to direct sums, and compatible with the external product. If the base is merely locally compact, the class with vertical support induces the isomorphism

$$\mathrm{Th}_{\mathbf{V}}\colon K^0_c(X) \longrightarrow K^0_c(\mathbf{V}).$$

The statement, its normalization, and the comparison with Bott appear in [21, Theorem 12.8 and Remark 12.9, pp. 289–290]. A proof using Clifford modules is developed in [92, Appendix C, Theorem C.8 and Remark C.13]. Independence of the Hermitian metric also follows directly from the contractibility of the space of such metrics.

A.6 Pushforwards in K-theory

Let $f\colon X \hookrightarrow Y$ be a proper embedding of smooth manifolds, and let $\nu_f \longrightarrow X$ be its normal bundle. When ν_f has a complex structure, a tubular neighborhood identifies a neighborhood of the zero section of ν_f with an open subset $U \subseteq Y$. Define

$$f_!\colon K_c^0(X) \longrightarrow K_c^0(Y), \qquad f_! := j_! \circ \mathrm{Th}_{\nu_f},$$

where $j\colon U \hookrightarrow Y$ is the open inclusion.

Theorem A.6.1. (Properties of the pushforward) The preceding homomorphism is independent of the metric, tubular neighborhood, and auxiliary identifications. Moreover:

(i) isotopic embeddings, with compatible complex orientations of their normal bundles, induce the same map;

(ii) if $f\colon X \hookrightarrow Y$ and $g\colon Y \hookrightarrow Z$ are proper embeddings with compatible orientations, then $(g\circ f)_! = g_! \circ f_!$;

(iii) for $a \in K_c^0(X)$ and $b \in K_c^0(Y)$, the projection formula holds:

$$f_!\big(a \cdot f^*b\big) = f_!(a)\cdot b;$$

(iv) pushforwards commute with external products.

The proofs using homotopies of tubular neighborhoods, naturality of Thom, and excision are given in [92, Chapter III, §§12–13]. The construction in the form used for the index theorem appears in [21, (12.3)–(12.4), pp. 290–291].

For an embedding $f\colon M \hookrightarrow \mathbb{R}^N$, the tangent embedding $Tf\colon TM \hookrightarrow T\mathbb{R}^N$ has normal bundle isomorphic to

$$\pi^*(\nu_f \oplus \nu_f) \longrightarrow TM.$$

The rule

$$J(u,v) = (-v,u)$$

canonically makes it a complex bundle. Thus, without imposing a complex structure on M, there is a map

$$(Tf)_!\colon K_c^0(TM) \longrightarrow K_c^0(T\mathbb{R}^N) \cong K_c^0(\mathbb{R}^{2N}).$$

This is the complex orientation that enters the definition of the general topological index.

Theorem A.6.2. (Whitney embedding theorem) Every Hausdorff second-countable smooth manifold of dimension n, with or without boundary, admits a proper smooth embedding into $\mathbb{R}^{2n+1}$. If the manifold is compact, its image is automatically closed.

The proof using local embeddings, partitions of unity, and generic projections can be found in [94, Theorem 6.15]. The existence and construction of the required tubular neighborhoods were already proved in Theorem 2.12.3.

A.7 Characteristic classes and comparison of Thom isomorphisms

Let $\mathbf{E} \longrightarrow X$ be a complex bundle of rank r. The splitting principle allows us, after a pullback that is injective in cohomology, to work as though

$$\mathbf{E} = \mathbf{L}_1 \oplus \cdots \oplus \mathbf{L}_r.$$

If $x_j = c_1(\mathbf{L}_j)$, the elements $x_1, \ldots, x_r$ are called formal Chern roots. The following symmetric expressions descend to well-defined classes on X:

$$c(\mathbf{E}) = \prod_{j=1}^{r} (1 + x_j),$$

$$\operatorname{ch}(\mathbf{E}) = \sum_{j=1}^{r} e^{x_j},$$

$$\operatorname{Td}(\mathbf{E}) = \prod_{j=1}^{r} \frac{x_j}{1 - e^{-x_j}}.$$

In each fixed dimension, the series truncate, so the last two expressions belong to $H^{\mathrm{ev}}(X;\mathbb{Q})$. For a formal difference, set

$$\operatorname{ch}([\mathbf{E}] - [\mathbf{F}]) = \operatorname{ch}(\mathbf{E}) - \operatorname{ch}(\mathbf{F}).$$

Theorem A.7.1. (Chern character) The Chern character defines a natural transformation of rings

$$\operatorname{ch}\colon K^0(X) \longrightarrow H^{\mathrm{ev}}(X;\mathbb{Q}).$$

If X is a finite CW complex, it induces an isomorphism

$$K^0(X) \otimes_{\mathbb{Z}} \mathbb{Q} \cong H^{\mathrm{ev}}(X;\mathbb{Q}).$$

There is also a compactly supported version

$$\operatorname{ch}_c\colon K_c^0(Y) \longrightarrow H_c^{\mathrm{ev}}(Y;\mathbb{Q})$$

compatible with external products, proper pullbacks, and extensions associated with open inclusions.

Chern classes, the splitting principle, and the Chern character are constructed in [76, Sections 2.3, 3.1 and 4.1, pp. 66–87 and 109–112]. The compactly supported version and its compatibility with Thom are developed in [21, Section 13.1, pp. 311–315].

Theorem A.7.2. (Cohomological Thom isomorphism and noncompact fundamental class) Let $\pi\colon \mathbf{V} \longrightarrow X$ be an oriented real bundle of rank r over a compact base of finite CW type. There is a class $U_{\mathbf{V}} \in H_c^r(\mathbf{V};\mathbb{Z})$ whose restriction to each oriented fiber generates $H_c^r(\mathbb{R}^r;\mathbb{Z})$, and product with this class defines an

isomorphism

$$\mathrm{Th}^{H}_{\mathbf{V}}\colon H^{q}(X;R)\longrightarrow H^{q+r}_{c}(\mathbf{V};R),\qquad \mathrm{Th}^{H}_{\mathbf{V}}(\omega)=\pi^{*}\omega\smile U_{\mathbf{V}},$$

for $R=\mathbb{Z},\mathbb{Q}$ or $\mathbb{R}$. The Thom class is natural under oriented pullbacks and multiplicative for oriented direct sums.

If Y is an oriented smooth manifold without boundary of dimension d, not necessarily compact, it has a Borel–Moore fundamental class $[Y]_{\mathrm{BM}}\in H^{\mathrm{BM}}_{d}(Y;\mathbb{Z})$. The pairing

$$H^{d}_{c}(Y;\mathbb{R})\times H^{\mathrm{BM}}_{d}(Y;\mathbb{Z})\longrightarrow\mathbb{R}$$

agrees, under the compactly supported de Rham theorem, with $[\omega]\mapsto\displaystyle\int_{Y}\omega$.

The construction of the cohomological orientation, the compactly supported Thom isomorphism, its naturality, and evaluation on the fundamental class are developed in [21, Section 13.1, pp. 311–315].

With the Thom class fixed above, comparison of the Thom isomorphisms in K-theory and cohomology introduces the Todd factor. Under the exterior multiplication convention of $\lambda_{\mathbf{V}}$, for a complex bundle of rank r one has

$$\mathrm{ch}_{c}(\lambda_{\mathbf{V}})=(-1)^{r}\,\mathrm{Th}^{H}_{\mathbf{V}}\big(\mathrm{Td}(\overline{\mathbf{V}})^{-1}\big),$$

where $\mathrm{Th}^{H}_{\mathbf{V}}$ is the Thom isomorphism in cohomology with rational coefficients.

Theorem A.7.3. (Cohomological formula for the topological index) Let M be a closed smooth manifold of dimension n, and let $u\in K^{0}_{c}(T^{*}M)$. Identify $T^{*}M$ with TM using a metric and orient TM by the almost complex structure that takes the horizontal directions as real and the vertical directions as imaginary. If $a=(\sharp_{g})_{*}u\in K^{0}_{c}(TM)$, then

$$\mathrm{ind}_{t}(u)=(-1)^{n}\int_{TM}\mathrm{ch}_{c}(a)\smile\pi^{*}\,\mathrm{Td}(TM\otimes_{\mathbb{R}}\mathbb{C}).$$

The integrand has compact support in the fiber direction; the integral means evaluation of its degree-$2n$ component on the fundamental class of TM.

The full comparison of the two Thom classes, including the conjugate bundle and the sign $(-1)^{n}$ for these conventions, is given in [21, Theorem 13.1, pp. 313–315]. This is the formulation used in the chapter devoted to the Atiyah–Singer theorem.

A.8 De Rham cohomology, spin structures, and the Euler class

The results in this section are used only to identify the indices of geometric operators topologically. Their proofs belong to algebraic and differential topology and are not reproduced here.

We first recall the obstruction that arises for spin structures. For a real vector bundle $\mathbf{V}\to X$ of rank r over a paracompact space, its *Stiefel–Whitney classes* are the classes

$$w_{j}(\mathbf{V})\in H^{j}(X;\mathbb{Z}_{2}),\qquad 0\le j\le r,$$

characterized by naturality, $w_0(\mathbf{V}) = 1$, the Whitney formula

$$w(\mathbf{V} \oplus \mathbf{W}) = w(\mathbf{V}) \smile w(\mathbf{W}), \qquad w(\mathbf{V}) := 1 + w_1(\mathbf{V}) + \cdots + w_r(\mathbf{V}),$$

and the normalization $w_1(\gamma^1) \neq 0$ for the real tautological bundle $\gamma^1 \to \mathbb{RP}^\infty$. In particular,

$$w_2(\mathbf{V}) \in H^2(X; \mathbb{Z}_2)$$

is the degree-two component of the total class. The vanishing of $w_1(\mathbf{V})$ is equivalent to orientability of $\mathbf{V}$; once an orientation has been chosen, $w_2(\mathbf{V})$ is the obstruction to lifting the principal bundle of oriented frames through the covering map $\mathrm{Spin}(r) \to \mathrm{SO}(r)$.

The universal construction of these classes, the orientation criterion, and the interpretation of w_2 as the spin obstruction can be found in [21, Definition 17.18 and Proposition 17.20, pp. 527–529]. We will use only those topological results; Clifford algebras, the spin covering map, and spinor bundles are constructed geometrically in Section 2.17.

Theorem A.8.1. (De Rham theorem and Euler characteristic) Let M be a smooth manifold with or without boundary. Integration of forms over smooth chains induces, for each q, a natural isomorphism

$$H^q_{\mathrm{dR}}(M; \mathbb{C}) \cong H^q_{\mathrm{sing}}(M; \mathbb{C}).$$

If M is a closed manifold of dimension n, these spaces are finite-dimensional and

$$\chi(M) = \sum_{q=0}^{n} (-1)^q \dim_{\mathbb{C}} H^q_{\mathrm{dR}}(M; \mathbb{C}).$$

The identification with singular cohomology and its relation to the Euler characteristic are presented in [21, Section 13.4, in particular (13.18), pp. 319–323]; the Hodge–de Rham decomposition that complements this identification appears in [21, Theorem 17.62 and Corollary 17.63, pp. 602–604].

Theorem A.8.2. (Euler class and Euler characteristic) Let $\mathbf{V} \longrightarrow X$ be an oriented real vector bundle of rank r over a compact base. If $\mathbf{s}_0 \colon X \longrightarrow \mathbf{V}$ is the zero section and $U_{\mathbf{V}}$ is the cohomological Thom class, the Euler class is defined by

$$e(\mathbf{V}) := \mathbf{s}_0^* U_{\mathbf{V}} \in H^r(X; \mathbb{Z}).$$

This class is natural under oriented pullbacks and multiplicative with respect to oriented direct sums. If M is a closed oriented smooth manifold of dimension n, then

$$\langle e(TM), [M] \rangle = \chi(M).$$

The construction using the zero section and evaluation on the fundamental class can be found in [21, Theorem 13.6(d), pp. 320–321] when the dimension is even. In odd dimensions, Poincaré duality pairs Betti numbers in complementary degrees and gives $\chi(M) = 0$. On the other hand, $-\mathrm{Id}_{TM}$ reverses the orientation of each fiber, so naturality of the Thom class implies $e(TM) = -e(TM)$. Since $H^n(M; \mathbb{Z})$ is free for a closed oriented manifold, it follows that $e(TM) = 0$. This proves the statement in every dimension. This equality is the general topological form of the Gauss–Bonnet–Chern theorem.

Let

$$0 \longrightarrow \mathbb{Z} \xrightarrow{\times 2} \mathbb{Z} \longrightarrow \mathbb{Z}_2 \longrightarrow 0$$

be the exact sequence of coefficients, and let

$$\beta \colon H^2(X;\mathbb{Z}_2) \longrightarrow H^3(X;\mathbb{Z})$$

be its Bockstein homomorphism. For an oriented real bundle $\mathbf{V} \to X$, define the third integral Stiefel–Whitney class by

$$W_3(\mathbf{V}) := \beta\big(w_2(\mathbf{V})\big).$$

By exactness, $W_3(\mathbf{V}) = 0$ if and only if $w_2(\mathbf{V})$ is the reduction modulo two of a class in $H^2(X;\mathbb{Z})$.

Theorem A.8.3. (Spin^c orientation) An oriented real bundle $\mathbf{V} \longrightarrow X$ over a paracompact base admits a Spin^c structure if and only if $W_3(\mathbf{V}) = 0$; equivalently, if and only if $w_2(\mathbf{V})$ is the reduction modulo two of an integral class of degree two. The determinant line $\mathbf{L}$ of a chosen structure satisfies

$$c_1(\mathbf{L}) \bmod 2 = w_2(\mathbf{V}).$$

If the rank of $\mathbf{V}$ is even, Clifford multiplication between the half-spinor bundles defines a Thom class in $K^0_X(\mathbf{V})$, the group with support on the zero section; when X is compact, this is identified with $K^0_c(\mathbf{V})$. Every complex bundle $\mathbf{E}$, regarded as an oriented real bundle, has a canonical Spin^c structure induced by $U(r) \to \mathrm{Spin}^c(2r)$; its determinant line is $\det_{\mathbb{C}} \mathbf{E}$ and its Thom class agrees with the class constructed using the exterior algebra.

The existence criterion is proved in [21, Theorem 18.35, pp. 655–656] and in [92, Appendix D, Theorem D.2]. The canonical orientation of a complex bundle and comparison of the two Thom classes are developed in [92, Appendix D, Example D.6; Appendix C, Theorems C.8 and C.12].

Theorem A.8.4. (Spin obstruction and half-spinor bundles) Let $\mathbf{V} \to X$ be an oriented real bundle of rank n over a paracompact base. Its oriented frame bundle admits a principal lift with group $\mathrm{Spin}(n)$ if and only if

$$w_2(\mathbf{V}) = 0 \in H^2(X;\mathbb{Z}_2).$$

When such a lift exists, the set of equivalence classes of spin structures is a principal homogeneous space for $H^1(X;\mathbb{Z}_2)$. If $n = 2m$, each spin structure determines Hermitian half-spinor bundles $\mathbf{S}^+$ and $\mathbf{S}^-$, and Clifford multiplication by a nonzero vector defines an isomorphism

$$c(v) \colon \mathbf{S}^+_x \longrightarrow \mathbf{S}^-_x, \qquad v \in \mathbf{V}_x \setminus \{0\}.$$

The class of this isomorphism is the spinorial Thom orientation of $\mathbf{V}$ in complex K-theory, with support on the zero section. If the formal roots of $\mathbf{V} \otimes_{\mathbb{R}} \mathbb{C}$ are ordered as $x_1, -x_1, \dots, x_m, -x_m$, then

$$\mathrm{ch}(\mathbf{S}^+) - \mathrm{ch}(\mathbf{S}^-) = \prod_{j=1}^{m} \left(e^{-\frac{x_j}{2}} - e^{\frac{x_j}{2}} \right), \qquad \widehat{A}(\mathbf{V}) = \prod_{j=1}^{m} \frac{\frac{x_j}{2}}{\sinh\left(\frac{x_j}{2}\right)}.$$

Here the orientation is chosen so that $e(\mathbf{V}) = x_1 \cdots x_m$; the order of the two exponents is determined by the

chirality convention in Section 2.17.

The construction of w_2 and the existence criterion can be found in [21, Definition 17.18 and Proposition 17.20, pp. 527–529]. The bundles $\mathbf{S}^{\pm}$, Clifford multiplication, and the twisted Dirac operator are constructed in [21, Definitions 17.22–17.23, pp. 531–532]; the comparison of its symbol class with the Thom class is developed in [92, Appendix C, Theorem C.12]. The calculation of the weights of the half-spinor representations that produces $\operatorname{ch}(\mathbf{S}^+)-\operatorname{ch}(\mathbf{S}^-)$ is given in [21, pp. 519–522]; the class $\widehat{A}$ and its relation to the Dirac index appear in [21, equations (17.43)–(17.45), pp. 545–546].

Theorem A.8.5. (Chern defect of the spinorial Thom class) Let $\mathbf{V} \to X$ be a real spin bundle of rank $2m$ over a compact base, and let

$$s(\mathbf{V}) = [\pi^*\mathbf{S}^+, \pi^*\mathbf{S}^-; c(v)] \in K_c^0(\mathbf{V})$$

be its spinorial Thom class with the preceding orientations. Then

$$(\mathrm{Th}_{\mathbf{V}}^{H})^{-1} \operatorname{ch}_c\big(s(\mathbf{V})\big) = (-1)^m \widehat{A}(\mathbf{V})^{-1}. \tag{A.2}$$

The formula, including the sign determined by the choice of chirality, is Proposition 12.5 in Chapter III, §12, of [92].

Proposition A.8.6. (Topological facts for extinction by surgery) Let $M_1, \dots, M_k$ be closed connected manifolds of dimension at least three. Then

$$\pi_1(M_1 \# \cdots \# M_k) \cong \pi_1(M_1) * \cdots * \pi_1(M_k).$$

If $N = S^3/\Gamma$ is a three-dimensional spherical space form, where Γ is finite and acts freely, then $\pi_1(N) \cong \Gamma$; in particular, N is simply connected if and only if $N \cong S^3$. If $Z \to S^1$ is a bundle with fiber S^2, trivial or twisted, then $\pi_1(Z) \cong \mathbb{Z}$.
Consequently, if a closed connected manifold M is a connected sum of spherical space forms and S^2-bundles over S^1, and $\pi_1(M) = 0$, there are no bundle factors and all the groups Γ are trivial. Since S^3 is the identity for connected sum, $M \cong S^3$.

Proof. The first identity is Seifert–van Kampen applied to the neck of the connected sum. The second follows because S^3 is the universal covering space of S^3/Γ, and the third follows from the homotopy exact sequence of the bundle, since $\pi_1(S^2) = 0$. A free product is trivial only if each of its factors is trivial; this gives the conclusion. □

Every simply connected manifold is orientable. Moreover, a closed two-sided surface in an orientable 3-manifold inherits an orientation from the ambient orientation and a global normal; hence such a manifold contains no two-sided embedded $\mathbb{RP}^2$. The topological effect of surgeries and the reconstruction by connected sums that we will use are formulated in [104, Chapter 15]; the extinction used at the end is treated in Chapters 18–19 of the same reference.

Theorem A.8.7. (Gauss–Bonnet for surfaces) Let $(M, \mathbf{g})$ be a closed Riemannian surface and let $K_{\mathbf{g}}$ be its

Gaussian curvature. Then

$$\int_M K_{\mathbf{g}}\, d\lambda_{\mathbf{g}} = 2\pi\chi(M).$$

Since $R_{\mathbf{g}} = 2K_{\mathbf{g}}$, it follows that

$$\int_M R_{\mathbf{g}}\, d\lambda_{\mathbf{g}} = 4\pi\chi(M).$$

The formulation using the Euler class can be found in [21, Theorem 13.6(d), pp. 320–321]; a proof using the Gauss–Bonnet–Chern form appears in [21, Theorem 17.68, pp. 612–613]. If M is nonorientable, apply the formula to its orientable two-sheeted covering space: the integral and the Euler characteristic are both multiplied by two, so the same identity descends to M.

B

Mathematical analysis

This appendix collects the results from real analysis, metric spaces, functional analysis, measure theory, and Lebesgue spaces used throughout the book. Its purpose is not to replace a systematic treatment of these subjects, but to fix notation, recall frequently used tools, and provide precise internal references for the main chapters. More extensive treatments can be found in [4, 68, 16, 38, 45, 28, 87, 123, 120].

The order follows the natural dependencies between the topics. We begin with some facts from real analysis and metric spaces; continue with normed spaces, linear operators, and Hilbert spaces; and then study measure theory, the Lebesgue and Bochner integrals, and L^p spaces. Finally, we introduce topological vector spaces and weak topologies, which play an essential role in the compactness and semicontinuity arguments used in the calculus of variations.

B.1 Real analysis and metric spaces

We begin with some basic facts from real analysis and metric spaces. These results will be used mainly to control local arguments, completions, and convergence.

Proposition B.1.1. Let $f:(a,b)\longrightarrow\mathbb{R}$ be a function differentiable on $(a,b)\setminus\{c\}$, with $c\in(a,b)$, and continuous at (a,b), such that $\lim_{x\to c^+} f'(x) = L = \lim_{x\to c^-} f'(x)$. Then f is differentiable at c and $f'(c) = L$.

Proof. Let $x\in(a,b)\setminus\{c\}$. If $x>c$, the mean value theorem applied to f on $[c,x]$ gives a point $\xi_x\in(c,x)$ such that

$$\frac{f(x)-f(c)}{x-c} = f'(\xi_x).$$

As $x\to c^+$, necessarily $\xi_x\to c^+$, and therefore

$$\lim_{x\to c^+}\frac{f(x)-f(c)}{x-c} = L.$$

If $x < c$, the same argument applied to the interval $[x, c]$ produces $\xi_x \in (x, c)$ and gives

$$\frac{f(x) - f(c)}{x - c} = f'(\xi_x).$$

Now $\xi_x \to c^-$ as $x \to c^-$, so the left-hand limit of the difference quotient is also L. The two one-sided limits agree; consequently, f is differentiable at c and $f'(c) = L$. □

Proposition B.1.2. For every $x \in \mathbb{R}^n$, the following hold:

(a) $\|x\|_r \le \|x\|_s$ if $1 \le s \le r \le \infty$,

(b) $\|x\|_s \le n^{\frac{r-s}{sr}} \|x\|_r$ if $1 \le s \le r < \infty$,

(c) $\|x\|_\infty \le \|x\|_s \le n^{\frac{1}{s}} \|x\|_\infty$ if $1 \le s < \infty$.

In particular, all norms $\|\cdot\|_p$ with $p \in [1, \infty]$ are equivalent on $\mathbb{R}^n$.

Proof. If $x = 0$, all the inequalities are immediate. Suppose that $x \neq 0$. First let $1 \le s \le r < \infty$ and set

$$a_i := \frac{|x_i|}{\|x\|_s}, \qquad 1 \le i \le n.$$

Then $0 \le a_i \le 1$ and $\sum_{i=1}^n a_i^s = 1$. Since $r \ge s$, we have $a_i^r \le a_i^s$, and hence

$$\frac{\|x\|_r^r}{\|x\|_s^r} = \sum_{i=1}^n a_i^r \le \sum_{i=1}^n a_i^s = 1.$$

This proves $\|x\|_r \le \|x\|_s$. For $r = \infty$, the same inequality follows directly from $|x_i|^s \le \sum_{j=1}^n |x_j|^s$ for each i.

For the reverse inequality, the case $s = r$ is trivial. If $1 \le s < r < \infty$, apply Hölder's inequality with conjugate exponents r/s and $r/(r-s)$:

$$\sum_{i=1}^n |x_i|^s \le \left(\sum_{i=1}^n |x_i|^r \right)^{s/r} \left(\sum_{i=1}^n 1^{r/(r-s)} \right)^{(r-s)/r} = \|x\|_r^s n^{1-s/r}.$$

Taking sth roots gives

$$\|x\|_s \le n^{1/s - 1/r} \|x\|_r = n^{(r-s)/(sr)} \|x\|_r.$$

Finally, for $1 \le s < \infty$,

$$\|x\|_\infty^s \le \sum_{i=1}^n |x_i|^s \le n \|x\|_\infty^s,$$

and taking roots gives part (c). The inequalities in parts (a)–(c) show that the identity between any two of these normed spaces is continuous in both directions; hence all the indicated norms are equivalent. □

Proposition B.1.3. If $\Omega \subseteq \mathbb{R}^n$ is open and $f : \Omega \longrightarrow \mathbb{R}^m$ is of class C^1, then for every compact convex set $K \subseteq \Omega$, the restriction $f \restriction_K$ is Lipschitz.

Proof. If $K = \varnothing$, there is nothing to prove. Since Df is continuous and K is compact, there exists

$$L := \max_{z \in K} \|Df(z)\|_{\mathrm{op}} < \infty.$$

Given $x, y \in K$, convexity of K implies that the segment $\gamma(t) := x + t(y - x)$, $0 \le t \le 1$, is contained in K. The chain rule and the fundamental theorem of calculus, applied componentwise to $f \circ \gamma$, give

$$f(y) - f(x) = \int_0^1 \frac{d}{dt} f(\gamma(t))\, dt = \int_0^1 Df(\gamma(t))(y - x)\, dt.$$

Consequently,

$$\|f(y) - f(x)\| \le \int_0^1 \|Df(\gamma(t))\|_{\mathrm{op}} \|y - x\|\, dt \le L\|y - x\|.$$

Thus $f \restriction_K$ is L-Lipschitz. □

Remark B.1.4. The convexity hypothesis can be replaced by uniform control of the lengths of curves in K joining any two points of K. In particular, the result applies locally on closed balls contained in Ω, which is the case used most frequently.

Definition B.1.5. Let X be a set. A **metric** on X is a function $d \colon X \times X \longrightarrow [0, \infty)$ such that:

(a) $d(x, y) = 0$ if and only if $x = y$.

(b) $d(x, y) = d(y, x)$ for all $x, y \in X$.

(c) $d(x, z) \le d(x, y) + d(y, z)$ for all $x, y, z \in X$.

A **metric space** is a pair (X, d), where X is a set and d is a metric on X.

Theorem B.1.6. (McShane extension theorem) Let (X, d) be a metric space, $A \subseteq X$ a nonempty subset, and $f \colon A \longrightarrow \mathbb{R}$ an L-Lipschitz function, with $L \ge 0$. Then there is an extension $F \colon X \longrightarrow \mathbb{R}$ of f that is also L-Lipschitz. An explicit choice is

$$F(x) := \inf_{a \in A} \big(f(a) + L\, d(x, a) \big).$$

Proof. Fix $a_0 \in A$. For any $x \in X$ and $a \in A$, the Lipschitz property and the triangle inequality give

$$f(a) + L\, d(x, a) \ge f(a_0) - L\, d(a, a_0) + L\, d(x, a) \ge f(a_0) - L\, d(x, a_0).$$

On the other hand, taking $a = a_0$ gives $F(x) \le f(a_0) + L\, d(x, a_0)$. Thus the infimum defining $F(x)$ is finite. If $x \in A$, the inequality $f(x) \le f(a) + L\, d(x, a)$ holds for every $a \in A$, so $f(x) \le F(x)$; choosing $a = x$ gives the reverse inequality. Thus $F \restriction_A = f$. Finally, for any $x, y \in X$ and $a \in A$,

$$f(a) + L\, d(x, a) \le f(a) + L\, d(y, a) + L\, d(x, y).$$

Taking the infimum over a gives $F(x) \le F(y) + L\, d(x, y)$. Interchanging x and y yields $|F(x) - F(y)| \le L\, d(x, y)$. □

Definition B.1.7. A sequence in a metric space $X = (X, d)$ is a function $x\colon \mathbb{N} \longrightarrow X$. The value of this function at k is called the k**th term** of the sequence and is denoted by x_k. A sequence is usually denoted by (x_k) or $\{x_k\}_{k\in\mathbb{N}}$, or by similar notation according to context.
We say that (x_k) converges to a point $x \in X$ if for every $\varepsilon > 0$ there exists $N \in \mathbb{N}$ such that if $k \geq N$, then $d(x_k, x) < \varepsilon$.
We say that a sequence (x_k) is Cauchy if for every $\varepsilon > 0$ there exists $N \in \mathbb{N}$ such that if $k, l \geq N$, then $d(x_k, x_l) < \varepsilon$.

In every metric space, convergent sequences are Cauchy, but a Cauchy sequence need not converge. This leads to the following definition:

Definition B.1.8. A metric space (X, d) is a **complete metric space** if every Cauchy sequence in X converges in X.

Definition B.1.9. Let (X, d_X) and (Y, d_Y) be metric spaces. A function $\varphi\colon X \longrightarrow Y$ is an **isometry** if $d_Y(\varphi(x), \varphi(y)) = d_X(x, y)$ for all $x, y \in X$.

Definition B.1.10. Let X be a metric space. A complete metric space $\overline{X}$ is called a ***completion*** of X if there is an isometry $i\colon X \longrightarrow \overline{X}$ such that $i(X)$ is dense in $\overline{X}$.

We will prove that every metric space admits a completion up to isometry, but first we need some lemmas.

Lemma B.1.11. Let (X, d) be a metric space, (b_n) a Cauchy sequence in X, and (a_n) a sequence in X such that $d(a_n, b_n) < \dfrac{1}{n}$ for every $n \in \mathbb{N}$. Then:

(a) (a_n) is a Cauchy sequence in X.

(b) $a_n \to x \in X$ if and only if $b_n \to x \in X$.

Proof. For (a), the triangle inequality gives

$$d(a_n, a_m) \leq d(a_n, b_n) + d(b_n, b_m) + d(b_m, a_m)$$

, and by hypothesis there exists $N_1 \in \mathbb{N}$ such that if $n, m \geq N_1$, then $d(a_n, b_n) < \dfrac{\varepsilon}{3}$ and $d(b_m, a_m) < \dfrac{\varepsilon}{3}$.
Finally, since (b_n) is Cauchy, there exists $N_2 \in \mathbb{N}$ such that if $n, m \geq N_2$, then $d(b_n, b_m) < \dfrac{\varepsilon}{3}$. Thus, if $n, m \geq \max\{N_1, N_2\}$, then $d(a_n, a_m) < 3\dfrac{\varepsilon}{3} = \varepsilon$.
For (b), if $a_n \to x$, then $d(a_n, x) \to 0$ whenever $n \to \infty$. By the triangle inequality, $d(b_n, x) \leq d(b_n, a_n) + d(a_n, x) < \dfrac{1}{n} + d(a_n, x)$. Taking $n \to \infty$, we conclude that $d(b_n, x) \to 0$, and hence $b_n \to x$. The converse is proved analogously. □

Theorem B.1.12. Every metric space admits a completion, unique up to isometry.

Proof. Let $CS(X)$ be the set of Cauchy sequences in X. On $CS(X)$, define the relation

$$(x_n) \sim (y_n) \iff \lim_{n\to\infty} d(x_n, y_n) = 0.$$

Reflexivity and symmetry are immediate. For transitivity, if $(x_n) \sim (y_n)$ and $(y_n) \sim (z_n)$, the triangle inequality gives $0 \le d(x_n, z_n) \le d(x_n, y_n) + d(y_n, z_n)$; passing to the limit yields $(x_n) \sim (z_n)$. Thus $\sim$ is an equivalence relation.

Let $\overline{X} := CS(X)/\sim$. For $[(x_n)], [(y_n)] \in \overline{X}$, set

$$\overline{d}\big([(x_n)], [(y_n)]\big) := \lim_{n\to\infty} d(x_n, y_n).$$

The limit exists, since for any $m, n \in \mathbb{N}$ the triangle inequality implies

$$\big|d(x_n, y_n) - d(x_m, y_m)\big| \le d(x_n, x_m) + d(y_n, y_m),$$

and the right-hand side tends to zero because (x_n) and (y_n) are Cauchy. This estimate shows that $(d(x_n, y_n))$ is a Cauchy sequence in $\mathbb{R}$.

The definition is independent of the representatives. If $(x_n) \sim (x'_n)$ and $(y_n) \sim (y'_n)$, then

$$\big|d(x_n, y_n) - d(x'_n, y'_n)\big| \le d(x_n, x'_n) + d(y_n, y'_n),$$

so the two limits agree. The metric properties follow directly from the corresponding properties of d; in particular, the triangle inequality is obtained by passing to the limit in $d(x_n, z_n) \le d(x_n, y_n) + d(y_n, z_n)$. Thus $(\overline{X}, \overline{d})$ is a metric space.

For each $x \in X$, let $x^* := [(x, x, \dots)]$ and define $i\colon X \longrightarrow \overline{X}$ by $i(x) := x^*$. If $x, y \in X$, then

$$\overline{d}(i(x), i(y)) = \lim_{n\to\infty} d(x, y) = d(x, y),$$

so i is an isometric embedding. Its image is dense. Given a class $[(x_n)] \in \overline{X}$, the sequence (x^*_m) satisfies

$$\overline{d}(x^*_m, [(x_n)]) = \lim_{n\to\infty} d(x_m, x_n) \longrightarrow 0$$

as $m \to \infty$, since (x_n) is Cauchy.

We now prove that $\overline{X}$ is complete. Let (a_n) be a Cauchy sequence in $\overline{X}$. By density of $i(X)$, for each n we can choose $x_n \in X$ such that $\overline{d}(i(x_n), a_n) < \frac{1}{n}$. Lemma B.1.11 shows that $(i(x_n))$ is Cauchy in $\overline{X}$. Since i is an isometry, (x_n) is Cauchy in X, and the construction of $\overline{X}$ gives $i(x_n) \to [(x_n)]$. Another application of the same lemma yields $a_n \to [(x_n)]$. This proves that $\overline{X}$ is a completion of X.

It remains to verify uniqueness. Let (Y, d_Y) be another completion of X, and let $j\colon X \longrightarrow Y$ be an isometric embedding with dense image. For each $y \in Y$, choose a sequence (x_n) in X such that $j(x_n) \to y$ and define

$$G(y) := [(x_n)] \in \overline{X}.$$

The map G is well defined: if also $j(x'_n) \to y$, then $d(x_n, x'_n) = d_Y(j(x_n), j(x'_n)) \to 0$, so both sequences determine the same class. Moreover, for $y, y' \in Y$ and sequences $j(x_n) \to y$, $j(x'_n) \to y'$, we have

$$\overline{d}(G(y), G(y')) = \lim_{n\to\infty} d(x_n, x'_n) = \lim_{n\to\infty} d_Y(j(x_n), j(x'_n)) = d_Y(y, y').$$

Therefore G is an isometry. It is surjective because every class $[(x_n)] \in \overline{X}$ is obtained from the limit in Y of the Cauchy sequence $(j(x_n))$. Consequently, G is a bijective isometry and the completion is unique up to

isometry. □

Completeness yields one of the structural principles underlying much of functional analysis. We first recall the corresponding topological notion.

Definition B.1.13. A topological space is called a **Baire space** if every countable intersection of open dense subsets is dense. Equivalently, no nonempty open subset can be written as a countable union of closed sets with empty interior.

Theorem B.1.14. (Baire category theorem) Every complete metric space is a Baire space.

Proof. Let (X,d) be a complete metric space, and let $(G_n)_{n\in\mathbb{N}}$ be open dense subsets of X. We must prove that $\bigcap_{n=1}^{\infty} G_n$ meets every nonempty open subset $U \subseteq X$. Choose $x_1 \in U \cap G_1$ and $r_1 \in (0,1)$ such that $\overline{B}_d(x_1,r_1) \subseteq U \cap G_1$. Once x_n and r_n have been chosen, density of G_{n+1} allows us to choose $x_{n+1} \in B_d(x_n, \frac{r_n}{2}) \cap G_{n+1}$ and $r_{n+1} \in (0, 2^{-n-1})$ so that $\overline{B}_d(x_{n+1},r_{n+1}) \subseteq B_d(x_n,\frac{r_n}{2}) \cap G_{n+1}$.
This construction implies that $\overline{B}_d(x_{n+1},r_{n+1}) \subseteq \overline{B}_d(x_n,r_n)$ and $d(x_{n+1},x_n) < 2^{-n}$. Therefore (x_n) is Cauchy and converges to some $x \in X$. For each n, all terms x_m with $m \geq n$ belong to $\overline{B}_d(x_n,r_n)$; since this ball is closed, $x \in \overline{B}_d(x_n,r_n) \subseteq G_n$. Moreover, $x \in \overline{B}_d(x_1,r_1) \subseteq U$. Consequently, $x \in U \cap \bigcap_{n=1}^{\infty} G_n$. □

B.2 Normed spaces

Normed spaces provide the basic setting for measuring the size of vectors and operators. In this section we fix the notation for $\mathcal{L}(X,Y)$, recall the fundamental theorems on continuous linear operators, and introduce closed and compact operators. The exposition follows, among other references, [45, Chapters 1 and 2] and [28, 87, 123].

Definition B.2.1. Let X be a vector space over $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$. A **norm** on X is a function $\|\cdot\|_X \colon X \longrightarrow [0,\infty)$ such that, for all $x,y \in X$ and $\lambda \in \mathbb{K}$,

(a) $\|x\|_X = 0$ if and only if $x = 0$;

(b) $\|\lambda x\|_X = |\lambda| \|x\|_X$;

(c) $\|x+y\|_X \leq \|x\|_X + \|y\|_X$.

The pair $(X, \|\cdot\|_X)$ is called a **normed space**. The distance induced by the norm is $d_X(x,y) := \|x-y\|_X$.

Definition B.2.2. A normed space is called a **Banach space** if it is complete with respect to the distance induced by its norm.

The metric completion of a normed space naturally retains the vector space operations.

Theorem B.2.3. (Completion of a normed space) For every normed space $(X, \|\cdot\|_X)$, there exist a Banach space $(\widehat{X}, \|\cdot\|_{\widehat{X}})$ and a linear isometry $\iota \colon X \longrightarrow \widehat{X}$ with dense image. This completion is unique up to linear isometries that fix the copy of X.

Proof. Let $(\widehat{X}, \widehat{d})$ be a completion of the metric space (X, d_X), and let $\iota\colon X \longrightarrow \widehat{X}$ be the isometry with dense image provided by Theorem B.1.12. Given $u, v \in \widehat{X}$, choose sequences (x_n) and (y_n) in X such that $\iota(x_n) \to u$ and $\iota(y_n) \to v$, and define

$$u + v := \lim_{n\to\infty} \iota(x_n + y_n), \qquad \lambda u := \lim_{n\to\infty} \iota(\lambda x_n).$$

The inequalities $\|(x_n + y_n) - (x_m + y_m)\|_X \leq \|x_n - x_m\|_X + \|y_n - y_m\|_X$ and $\|\lambda x_n - \lambda x_m\|_X = |\lambda|\|x_n - x_m\|_X$ show that the limits exist. The same estimates show that they do not depend on the chosen sequences. These operations make $\widehat{X}$ a vector space and make ι linear.
Define $\|u\|_{\widehat{X}} := \widehat{d}(u, 0)$. If $\iota(x_n) \to u$, then $\|u\|_{\widehat{X}} = \lim_{n\to\infty} \|x_n\|_X$. The norm properties follow by taking limits in the corresponding properties of $\|\cdot\|_X$. Since $\widehat{X}$ is complete with respect to $\widehat{d}$, it is a Banach space. Metric uniqueness of the completion and density of $\iota(X)$ imply that the isometry between two completions is necessarily linear. □

B.2.1 Continuous linear operators

Definition B.2.4. Let X and Y be vector spaces over the same field $\mathbb{K}$. A map $T\colon X \longrightarrow Y$ is called a **linear operator** if $T(x + y) = T(x) + T(y)$ and $T(\lambda x) = \lambda T(x)$ for all $x, y \in X$ and $\lambda \in \mathbb{K}$.

Definition B.2.5. Let X and Y be normed spaces. A linear operator $T\colon X \longrightarrow Y$ is called **bounded** if there exists $C \geq 0$ such that $\|T(x)\|_Y \leq C\|x\|_X$ for every $x \in X$.
Let $\mathcal{L}(X, Y)$ denote the vector space of all continuous linear operators from X to Y, and write $\mathcal{L}(X) := \mathcal{L}(X, X)$. The **operator norm** is given by

$$\|T\|_{\mathcal{L}(X,Y)} := \sup_{\substack{x\in X \\ \|x\|_X \leq 1}} \|T(x)\|_Y = \sup_{x\in X\setminus\{0\}} \frac{\|T(x)\|_Y}{\|x\|_X}.$$

When there is no risk of confusion, we will simply write $\|T\|$. The identity operator on X is denoted by I_X, or by I when the space is clear from context.

Definition B.2.6. The **continuous dual** of a normed space X is $X' := \mathcal{L}(X, \mathbb{K})$. Its elements are called **continuous linear functionals**.

Proposition B.2.7. Let X and Y be normed spaces, and let $T\colon X \longrightarrow Y$ be linear. The following statements are equivalent:

(a) T is continuous on X;

(b) T is continuous at 0;

(c) T is bounded.

In this case, $\|T(x)\|_Y \leq \|T\|_{\mathcal{L}(X,Y)}\|x\|_X$ for every $x \in X$.

Proof. The implication $(a) \Rightarrow (b)$ is immediate. Suppose that (b). There exists $\delta > 0$ such that $\|T(x)\|_Y < 1$ whenever $\|x\|_X < \delta$. If $x \neq 0$, then $\left\| \frac{\delta x}{2\|x\|_X} \right\|_X = \frac{\delta}{2}$ and, by linearity, $\|T(x)\|_Y < \frac{2}{\delta}\|x\|_X$. The same inequality is

trivial for $x = 0$, so T is bounded. Finally, if (c) holds with a constant C, then $\|T(x) - T(y)\|_Y \le C\|x - y\|_X$ for all $x, y \in X$, and hence T is Lipschitz and continuous. □

Proposition B.2.8. Let X, Y, and Z be normed spaces. If $T, S \in \mathcal{L}(X, Y)$, $R \in \mathcal{L}(Y, Z)$, and $\lambda \in \mathbb{K}$, then

$$\|T + S\| \le \|T\| + \|S\|, \qquad \|\lambda T\| = |\lambda|\|T\|, \qquad \|R \circ T\| \le \|R\|\|T\|.$$

In particular, $\mathcal{L}(X)$ is a normed algebra under composition.

Proof. The first two identities follow directly from the definition. For the third, $\|R(Tx)\|_Z \le \|R\|\|Tx\|_Y \le \|R\|\|T\|\|x\|_X$ for every $x \in X$. □

Theorem B.2.9. Let X be a normed space and Y a Banach space. Then $\mathcal{L}(X, Y)$ is a Banach space. In particular, X' is a Banach space for every normed space X.

Proof. Let (T_n) be a Cauchy sequence in $\mathcal{L}(X, Y)$. For each $x \in X$, the inequality $\|T_n x - T_m x\|_Y \le \|T_n - T_m\|\|x\|_X$ shows that $(T_n x)$ is Cauchy in Y. Define $T(x) := \lim_{n\to\infty} T_n x$. The map T is linear. Moreover, there exists $N \in \mathbb{N}$ such that $\|T_n - T_m\| < 1$ for $n, m \ge N$, so $\|T_n\| \le 1 + \|T_N\|$ for $n \ge N$. Taking limits gives $\|T(x)\|_Y \le (1 + \|T_N\|)\|x\|_X$, and hence $T \in \mathcal{L}(X, Y)$.
Given $\varepsilon > 0$, there exists $N_\varepsilon \in \mathbb{N}$ such that $\|T_n - T_m\| < \varepsilon$ for $n, m \ge N_\varepsilon$. Letting $m \to \infty$, we obtain $\|(T_n - T)x\|_Y \le \varepsilon\|x\|_X$ for every $x \in X$ and $n \ge N_\varepsilon$. Therefore, $\|T_n - T\| \le \varepsilon$. □

Theorem B.2.10. (Neumann series) Let X be a Banach space and let $T \in \mathcal{L}(X)$ satisfy $\|T\| < 1$. Then $I - T$ is invertible and

$$(I - T)^{-1} = \sum_{n=0}^{\infty} T^n$$

in the norm of $\mathcal{L}(X)$. Moreover, $\|(I - T)^{-1}\| \le \dfrac{1}{1 - \|T\|}$.

Proof. The series converges in $\mathcal{L}(X)$ because $\sum_{n=0}^{\infty} \|T^n\| \le \sum_{n=0}^{\infty} \|T\|^n < \infty$ and $\mathcal{L}(X)$ is complete. If $S_N := \sum_{n=0}^{N} T^n$, then $(I - T)S_N = S_N(I - T) = I - T^{N+1}$. Letting $N \to \infty$ gives $(I - T)S = S(I - T) = I$, where $S := \sum_{n=0}^{\infty} T^n$. The norm estimate follows from the geometric series. □

Corollary B.2.11. Let X be a Banach space, let $T \in \mathcal{L}(X)$ be invertible, and let $S \in \mathcal{L}(X)$ satisfy $\|T^{-1}(S - T)\| < 1$. Then S is invertible.

Proof. Since $S = T[I + T^{-1}(S - T)]$, the conclusion follows from Theorem B.2.10 applied to $-T^{-1}(S - T)$. □

Definition B.2.12. Let X be a complex Banach space and let $T \in \mathcal{L}(X)$. The **resolvent set** of T is

$$\rho(T) := \{\lambda \in \mathbb{C} \mid \lambda I - T \text{ is invertible in } \mathcal{L}(X)\},$$

and the **spectrum** of T is $\sigma(T) := \mathbb{C} \setminus \rho(T)$. For $\lambda \in \rho(T)$, the operator $R(\lambda, T) := (\lambda I - T)^{-1}$ is called the **resolvent** of T.

Proposition B.2.13. If X is a complex Banach space and $T \in \mathcal{L}(X)$, then $\{\lambda \in \mathbb{C} \mid |\lambda| > \|T\|\} \subseteq \rho(T)$ and $\rho(T)$ is open. In particular, $\sigma(T)$ is compact and is contained in $\{\lambda \in \mathbb{C} \mid |\lambda| \le \|T\|\}$.

Proof. If $|\lambda| > \|T\|$, then $\lambda I - T = \lambda\left(I - \frac{T}{\lambda}\right)$ and the Neumann series gives its inverse. If $\lambda_0 \in \rho(T)$, we write

$$\lambda I - T = (\lambda_0 I - T)\big[I + (\lambda - \lambda_0)(\lambda_0 I - T)^{-1}\big].$$

The second factor is invertible when $|\lambda - \lambda_0|\|(\lambda_0 I - T)^{-1}\| < 1$, so $\rho(T)$ is open. The remaining assertions are immediate. □

Theorem B.2.14. If $X \neq \{0\}$ is a complex Banach space and $T \in \mathcal{L}(X)$, then $\sigma(T)$ is nonempty.

The proof uses Liouville's theorem applied to the scalar functions $\lambda \mapsto \varphi((\lambda I - T)^{-1}x)$, with $x \in X$ and $\varphi \in X'$, and can be found in [45, Section 2.1] or [123].

B.2.2 Fundamental principles of operator theory

Theorem B.2.15. (Banach–Steinhaus) Let X be a Banach space, let Y be a normed space, and let $\mathcal{F} \subseteq \mathcal{L}(X, Y)$. If $\sup_{T \in \mathcal{F}} \|T(x)\|_Y < \infty$ for every $x \in X$, then $\sup_{T \in \mathcal{F}} \|T\|_{\mathcal{L}(X,Y)} < \infty$.

Proof. For each $n \in \mathbb{N}$, define $E_n := \{x \in X \mid \|T(x)\|_Y \le n \text{ for every } T \in \mathcal{F}\}$. Each E_n is closed and, by pointwise boundedness, $X = \bigcup_{n=1}^{\infty} E_n$. Theorem B.1.14 gives $N \in \mathbb{N}$, $x_0 \in X$, and $r > 0$ such that $B_{d_X}(x_0, r) \subseteq E_N$, where d_X is the metric induced by the norm of X.
If $\|h\|_X < r$, then $x_0 + h, x_0 \in E_N$ and $\|T(h)\|_Y \le \|T(x_0 + h)\|_Y + \|T(x_0)\|_Y \le 2N$ for every $T \in \mathcal{F}$. For $x \neq 0$, we apply this estimate to $h := \dfrac{rx}{2\|x\|_X}$ and obtain $\|T(x)\|_Y \le \dfrac{4N}{r}\|x\|_X$. Therefore, $\|T\| \le \frac{4N}{r}$ for every $T \in \mathcal{F}$. □

Theorem B.2.16. (Open mapping theorem) Let X and Y be Banach spaces and let $T \in \mathcal{L}(X, Y)$ be surjective. Then T is an open map.

Proof. Let $\mathbb{B}_X := B_{d_X}(0, 1)$, where d_X is the metric induced by the norm. Since $Y = \bigcup_{n=1}^{\infty} T(n\mathbb{B}_X)$, Theorem B.1.14 implies that the closure of $T(n_0\mathbb{B}_X)$ has nonempty interior for some $n_0 \in \mathbb{N}$. Using linearity and the symmetry of balls, we find $r > 0$ such that $B_{d_Y}(0, r) \subseteq \overline{T(\mathbb{B}_X)}$.
We claim that $B_{d_Y}(0, \frac{r}{2}) \subseteq T(\mathbb{B}_X)$. Let $y \in B_{d_Y}(0, \frac{r}{2})$. Since $B_{d_Y}(0, \frac{r}{2}) \subseteq \overline{T(B_{d_X}(0, \frac{1}{2}))}$, there exists $x_1 \in B_{d_X}(0, \frac{1}{2})$ such that $\|y - Tx_1\|_Y < \frac{r}{4}$. Inductively, we choose $x_n \in B_{d_X}(0, 2^{-n})$ so that

$$\left\| y - T\left(\sum_{j=1}^{n} x_j\right)\right\|_Y < \frac{r}{2^{n+1}}.$$

The series $\sum_{n=1}^{\infty} x_n$ converges in X to an element x with $\|x\|_X < 1$, and the continuity of T implies that $T(x) = y$. Thus, $T(\mathbb{B}_X)$ contains a ball around the origin. By linearity, the image of every open ball is open, and hence so is the image of any open set. □

Corollary B.2.17. (Bounded inverse theorem) Let X and Y be Banach spaces. If $T \in \mathcal{L}(X, Y)$ is bijective, then $T^{-1} \in \mathcal{L}(Y, X)$.

Proof. Theorem B.2.16 implies that the inverse operator T^{-1} is continuous. □

Proposition B.2.18. Let X and Y be Banach spaces and let $T \in \mathcal{L}(X, Y)$ be injective. Then $\operatorname{Ran}(T)$ is closed if and only if there exists $c > 0$ such that $\|Tx\|_Y \geq c\|x\|_X$ for every $x \in X$.

Proof. If the estimate holds and $Tx_n \to y$ in Y, then (x_n) is Cauchy and converges to some $x \in X$; by continuity, $Tx = y$, so the range is closed. Conversely, if $\operatorname{Ran}(T)$ is closed, it is a Banach space and $T\colon X \longrightarrow \operatorname{Ran}(T)$ is bijective. Theorem B.2.17 implies that T^{-1} is continuous, and therefore $\|x\|_X \leq \|T^{-1}\|\|Tx\|_Y$. □

Quotient spaces allow us to factor out a closed subspace while retaining a normed structure and, when the original space is Banach, completeness. Closedness is essential: without it, the expression below defines only a seminorm.

Definition B.2.19. Let X be a vector space and let $Y \subseteq X$ be a subspace. The **quotient vector space** X/Y is the set of classes

$$X/Y := \{x + Y \mid x \in X\}, \qquad [x] := x + Y,$$

with the operations

$$[x] + [z] := [x + z], \qquad \alpha[x] := [\alpha x] \quad (\alpha \in \mathbb{K}).$$

These operations do not depend on the representatives: if $x - x' \in Y$ and $z - z' \in Y$, then $(x + z) - (x' + z') \in Y$ and $\alpha x - \alpha x' \in Y$.

Proposition B.2.20. (Quotient norm) Let X be a normed space and let $Y \subseteq X$ be a closed subspace. For $[x] = x + Y \in X/Y$, set

$$\|[x]\|_{X/Y} := \inf_{y \in Y} \|x - y\|_X = \operatorname{dist}_X(x, Y). \tag{B.1}$$

Then (B.1) defines a norm on X/Y. The canonical projection

$$\pi\colon X \longrightarrow X/Y, \qquad \pi(x) = [x],$$

is linear, continuous, and open, and satisfies $\|\pi\| \leq 1$. If X is a Banach space, then X/Y is also a Banach space.

Proof. If $x' = x + y_0$ with $y_0 \in Y$, then

$$\inf_{y \in Y} \|x' - y\|_X = \inf_{y \in Y} \|x - (y - y_0)\|_X = \inf_{z \in Y} \|x - z\|_X,$$

so the expression does not depend on the representative of the class. Homogeneity is immediate. Given $x, z \in X$ and $y_1, y_2 \in Y$, we have

$$\operatorname{dist}_X(x+z, Y) \le \|(x+z)-(y_1+y_2)\|_X \le \|x-y_1\|_X + \|z-y_2\|_X.$$

Taking the infimum over y_1 and y_2 gives the triangle inequality. Moreover, $\|[x]\|_{X/Y} = 0$ if and only if $x \in \overline{Y} = Y$, that is, if and only if $[x] = 0$. Therefore, (B.1) is a norm.

The linearity of π follows from the quotient operations, and $\|\pi(x)\|_{X/Y} \le \|x\|_X$, so π is continuous and $\|\pi\| \le 1$. If $r > 0$, then for every class $[z]$ with $\|[z]\|_{X/Y} < r$ there exists $y \in Y$ such that $\|z-y\|_X < r$ and $[z] = [z-y]$. Consequently, every class of norm less than r belongs to $\pi(B_{d_X}(0,r))$. The reverse inclusion follows from $\|\pi(x)\|_{X/Y} \le \|x\|_X$. Therefore, the image of the open ball of radius r in X is the open ball of radius r in X/Y. Translations and linearity show that π is open.

Finally, suppose that X is complete and let $([x_n])$ be a Cauchy sequence in X/Y. Choose a subsequence $([x_{n_j}])$ such that

$$\|[x_{n_{j+1}}] - [x_{n_j}]\|_{X/Y} < 2^{-j-1} \qquad (j \in \mathbb{N}).$$

By the definition of the infimum, for each j there exists $y_j \in Y$ such that

$$\|(x_{n_{j+1}} - x_{n_j}) - y_j\|_X < 2^{-j}.$$

Define $z_1 := x_{n_1}$ and, for $j \ge 2$,

$$z_j := x_{n_j} - \sum_{i=1}^{j-1} y_i.$$

Then $[z_j] = [x_{n_j}]$ and

$$\|z_{j+1} - z_j\|_X = \|(x_{n_{j+1}} - x_{n_j}) - y_j\|_X < 2^{-j}.$$

Consequently, (z_j) is Cauchy in X and converges to some $z \in X$. The continuity of π implies that $[x_{n_j}] = [z_j] \to [z]$. Since the original sequence is Cauchy, the entire sequence converges to $[z]$. This proves the completeness of X/Y. □

Differential operators are usually unbounded when considered on a single function space. To handle them, we must distinguish the domain of the operator from the ambient space.

Definition B.2.21. Let X and Y be normed spaces. A **linear operator** from X to Y is a linear map $A\colon \mathcal{D}(A) \subseteq X \longrightarrow Y$, where $\mathcal{D}(A)$ is a vector subspace called the **domain** of A; we also write $\operatorname{Dom}(A)$. The operator is **densely defined** if $\overline{\mathcal{D}(A)} = X$.

The **graph** of A is $\mathcal{G}(A) := \{(x, Ax) \mid x \in \mathcal{D}(A)\} \subseteq X \times Y$. We say that A is **closed** if $\mathcal{G}(A)$ is closed. Equivalently, if $x_n \in \mathcal{D}(A)$, $x_n \to x$ in X, and $Ax_n \to y$ in Y, then $x \in \mathcal{D}(A)$ and $Ax = y$.

Theorem B.2.22. (Closed graph theorem) Let X and Y be Banach spaces and let $A\colon X \longrightarrow Y$ be linear. Then A is continuous if and only if its graph is closed.

Proof. If A is continuous, its graph is immediately seen to be closed. Conversely, suppose that $\mathcal{G}(A)$ is closed. Then $\mathcal{G}(A)$ is a Banach space with the norm inherited from $X \times Y$. The projection $\pi_1\colon \mathcal{G}(A) \longrightarrow X$, given by $\pi_1(x, Ax) = x$, is linear, continuous, and bijective. By Theorem B.2.17, π_1^{-1} is continuous. Since $A = \pi_2 \circ \pi_1^{-1}$,

where $\pi_2 \colon X \times Y \longrightarrow Y$ is the second projection, A is continuous. □

Proposition B.2.23. Let X and Y be Banach spaces and let $A \colon \mathcal{D}(A) \subseteq X \longrightarrow Y$ be linear. The formula $\|x\|_A := \|x\|_X + \|Ax\|_Y$ defines a norm on $\mathcal{D}(A)$. The operator A is closed if and only if $(\mathcal{D}(A), \|\cdot\|_A)$ is a Banach space.

Proof. The map $J \colon \mathcal{D}(A) \longrightarrow X \times Y$, given by $J(x) = (x, Ax)$, is an isometry from $(\mathcal{D}(A), \|\cdot\|_A)$ onto $\mathcal{G}(A)$ when $X \times Y$ is equipped with the norm $\|(x,y)\| := \|x\|_X + \|y\|_Y$. Therefore, $\mathcal{D}(A)$ is complete if and only if $\mathcal{G}(A)$ is closed in the Banach space $X \times Y$. □

Definition B.2.24. A linear operator $A \colon \mathcal{D}(A) \subseteq X \longrightarrow Y$ is called **closable** if the closure of $\mathcal{G}(A)$ is the graph of an operator. This operator is denoted by $\overline{A}$ and is called the **closure** of A.

Proposition B.2.25. A linear operator $A \colon \mathcal{D}(A) \subseteq X \longrightarrow Y$ is closable if and only if, for every sequence (x_n) in $\mathcal{D}(A)$, the convergences $x_n \to 0$ in X and $Ax_n \to y$ in Y imply $y = 0$.

Proof. The closure of $\mathcal{G}(A)$ is the graph of an operator if and only if it contains no element $(0, y)$ with $y \neq 0$. Since $X \times Y$ is metrizable, a point belongs to the closure if and only if it is the limit of a sequence of elements of $\mathcal{G}(A)$, which gives precisely the stated condition. □

B.2.3 The Hahn–Banach theorem and duality

The Hahn–Banach theorem allows us to extend linear functionals while retaining the estimates that ensure their continuity. Its consequences will be used both in the dual characterization of the norm and in separation arguments.

Remark B.2.26. A function $p \colon X \longrightarrow \mathbb{R}$ defined on a real vector space is called **sublinear** if $p(x+y) \leq p(x) + p(y)$ for all $x, y \in X$ and $p(\lambda x) = \lambda p(x)$ for every $x \in X$ and $\lambda \geq 0$.

Theorem B.2.27. (Hahn–Banach theorem, analytic form) Let X be a real vector space, let $M \subseteq X$ be a subspace, and let $p \colon X \longrightarrow \mathbb{R}$ be sublinear. If $\ell \colon M \longrightarrow \mathbb{R}$ is linear and $\ell(x) \leq p(x)$ for every $x \in M$, then there exists a linear functional $\widetilde{\ell} \colon X \longrightarrow \mathbb{R}$ such that $\widetilde{\ell}\,|_M = \ell$ and $\widetilde{\ell}(x) \leq p(x)$ for every $x \in X$.

Proof. We begin with extension by one dimension. Let $N \subsetneq X$ be a subspace, let $f \colon N \to \mathbb{R}$ be linear and dominated by p, and let $x_0 \in X \setminus N$. Define

$$\alpha := \sup_{y \in N} \bigl(f(y) - p(y - x_0)\bigr), \qquad \beta := \inf_{z \in N} \bigl(p(z + x_0) - f(z)\bigr).$$

For any $y, z \in N$, the linearity of f, domination by p, and subadditivity of p imply

$$f(y) + f(z) = f(y+z) \leq p(y+z) \leq p(y - x_0) + p(z + x_0).$$

Therefore,

$$f(y) - p(y - x_0) \leq p(z + x_0) - f(z)$$

for every pair $y, z \in N$. In particular, $\alpha \le \beta$, and we may choose $a \in [\alpha, \beta]$.
Every element of $N + \mathbb{R}x_0$ has a unique representation as $y + tx_0$, with $y \in N$ and $t \in \mathbb{R}$. Define

$$f_1(y + tx_0) := f(y) + ta.$$

The map f_1 is linear and extends f. Let us verify domination. If $t > 0$, then $a \le \beta$ and, taking $z = y/t$, we obtain

$$f_1(y + tx_0) = t\big(f(y/t) + a\big) \le t\, p(y/t + x_0) = p(y + tx_0).$$

If $t < 0$, write $t = -s$ with $s > 0$. Since $a \ge \alpha$, applied now to y/s, we have

$$f_1(y - sx_0) = s\big(f(y/s) - a\big) \le s\, p(y/s - x_0) = p(y - sx_0).$$

The case $t = 0$ is precisely the hypothesis $f \le p$ on N. Thus, f_1 is dominated by p on all of $N + \mathbb{R}x_0$.
Consider the set $\mathcal{E}$ of all pairs (N, f) such that $M \subseteq N \subseteq X$, $f\colon N \to \mathbb{R}$ is linear, $f \restriction_M = \ell$, and $f \le p$ on N. Order this set by extension:

$$(N_1, f_1) \le (N_2, f_2) \quad \Longleftrightarrow \quad N_1 \subseteq N_2 \text{ and } f_2 \restriction_{N_1} = f_1.$$

The set is nonempty because it contains (M, ℓ). If $\mathcal{C} \subseteq \mathcal{E}$ is a chain, the union of its domains

$$N_{\mathcal{C}} := \bigcup_{(N,f)\in\mathcal{C}} N$$

is a subspace. On this subspace, define $f_{\mathcal{C}}(x) := f(x)$ using any element of the chain whose domain contains x. The definition is independent of this choice, since any two elements of a chain are comparable; moreover, $f_{\mathcal{C}}$ is linear, extends ℓ, and is dominated by p. Thus every chain has an upper bound in $\mathcal{E}$.
Zorn's lemma, Theorem A.0.1, gives a maximal element $(N_{\max}, f_{\max})$. If $N_{\max} \neq X$, we may choose $x_0 \in X \setminus N_{\max}$ and apply the preceding one-dimensional construction, obtaining a proper extension of $f_{\max}$ that is still dominated by p. This contradicts maximality. Hence $N_{\max} = X$, and $\widetilde{\ell} := f_{\max}$ is the desired extension. □

Remark B.2.28. On a complex vector space, the corresponding version is obtained by assuming that p is subadditive, that $p(\lambda x) = |\lambda| p(x)$ for all $\lambda \in \mathbb{C}$ and $x \in X$, and that $|\ell(x)| \le p(x)$ on the initial subspace. Indeed, regard X and M as real vector spaces and apply the theorem to $u := \operatorname{Re}\ell$. We obtain a real-linear extension $U\colon X \to \mathbb{R}$ such that $U \le p$. Since $p(-x) = p(x)$, we also have

$$-U(x) = U(-x) \le p(-x) = p(x),$$

so $|U(x)| \le p(x)$. Define

$$\widetilde{\ell}(x) := U(x) - iU(ix).$$

The real linearity of U shows that

$$\widetilde{\ell}(ix) = U(ix) - iU(-x) = i\widetilde{\ell}(x),$$

and therefore $\widetilde{\ell}$ is complex-linear. If $x \in M$, then

$$U(x) = \operatorname{Re}\ell(x), \qquad U(ix) = \operatorname{Re}(i\ell(x)) = -\operatorname{Im}\ell(x),$$

so $\widetilde{\ell}(x) = \ell(x)$.
Finally, given $x \in X$, choose $\lambda \in \mathbb{C}$, $|\lambda| = 1$, so that $\lambda\widetilde{\ell}(x) = |\widetilde{\ell}(x)|$. Since $\operatorname{Re}\widetilde{\ell} = U$,

$$|\widetilde{\ell}(x)| = \operatorname{Re}\widetilde{\ell}(\lambda x) = U(\lambda x) \le p(\lambda x) = p(x).$$

This proves the complex version and, in particular, the estimate used in the following corollary.

Corollary B.2.29. (Norm-preserving extension) Let X be a real or complex normed space, let $M \subseteq X$ be a subspace equipped with the induced norm, and let $\ell \in M'$. Then there exists $\widetilde{\ell} \in X'$ such that $\widetilde{\ell}\restriction_M = \ell$ and $\|\widetilde{\ell}\|_{X'} = \|\ell\|_{M'}$.

Proof. Define $p(x) := \|\ell\|_{M'}\|x\|_X$. In the real case, $\ell(x) \le |\ell(x)| \le p(x)$ for every $x \in M$, so Theorem B.2.27 gives an extension $\widetilde{\ell}$ dominated by p. In the complex case, we apply Remark B.2.28. In both cases, $|\widetilde{\ell}(x)| \le \|\ell\|_{M'}\|x\|_X$, so $\|\widetilde{\ell}\|_{X'} \le \|\ell\|_{M'}$. The reverse inequality follows from $\widetilde{\ell}\restriction_M = \ell$. □

Corollary B.2.30. (Dual characterization of the norm) Let X be a real or complex normed space. For each $x \in X$,

$$\|x\|_X = \max\left\{|\varphi(x)| \,\middle|\, \varphi \in X',\ \|\varphi\|_{X'} \le 1\right\}.$$

More precisely, if $x \neq 0$, there exists $\varphi \in X'$ such that $\|\varphi\|_{X'} = 1$ and $\varphi(x) = \|x\|_X$.

Proof. If $x \neq 0$, define $\ell\colon \operatorname{span}\{x\} \longrightarrow \mathbb{K}$ by $\ell(\lambda x) := \lambda\|x\|_X$. Then $\|\ell\| = 1$. Corollary B.2.29 gives $\varphi \in X'$ with $\|\varphi\| = 1$ and $\varphi(x) = \|x\|_X$. On the other hand, $|\psi(x)| \le \|\psi\|\|x\|_X \le \|x\|_X$ for every $\psi \in X'$ with $\|\psi\| \le 1$. The case $x = 0$ is immediate. □

B.2.4 Adjoint and compact operators on Banach spaces

For compactness of the adjoint and the Riesz–Schauder alternative, we follow [45, Proposition 2.2.8 and Theorem 2.2.9].

Definition B.2.31. Let X and Y be normed spaces and let $T \in \mathcal{L}(X, Y)$. The **Banach adjoint** of T is the operator $T'\colon Y' \longrightarrow X'$ defined by $T'(\varphi) := \varphi \circ T$.

Proposition B.2.32. Let X, Y, and Z be normed spaces, and let $T \in \mathcal{L}(X, Y)$ and $S \in \mathcal{L}(Y, Z)$. Then $T' \in \mathcal{L}(Y', X')$, $\|T'\| = \|T\|$, and $(S \circ T)' = T' \circ S'$.

Proof. For $\varphi \in Y'$ and $x \in X$, $|T'\varphi(x)| \le \|\varphi\|\|T\|\|x\|_X$, so $\|T'\| \le \|T\|$. By the dual characterization of the norm, for each $x \in X$ with $\|x\|_X \le 1$ there exists $\varphi \in Y'$ with $\|\varphi\| = 1$ and $|\varphi(Tx)| = \|Tx\|_Y$. Therefore, $\|Tx\|_Y \le \|T'\|$, and taking the supremum gives $\|T\| \le \|T'\|$. The identity for compositions is verified by evaluating both sides at each functional. □

Definition B.2.33. Let X and Y be normed spaces. A linear operator $K\colon X \longrightarrow Y$ is called **compact** if, for every bounded sequence (x_n) in X, the sequence (Kx_n) has a subsequence converging in Y. We denote the space of compact operators from X to Y by $\mathcal{K}(X,Y)$ and write $\mathcal{K}(X) := \mathcal{K}(X,X)$.

Proposition B.2.34. Every compact linear operator is bounded. Moreover, every *continuous* linear operator of finite rank is compact.

Proof. If a compact operator K were unbounded, there would exist a sequence (x_n) with $\|x_n\|_X \leq 1$ and $\|Kx_n\|_Y \geq n$, which would prevent (Kx_n) from having a convergent subsequence. If K is continuous and has finite rank, the image of every bounded sequence is bounded in the finite-dimensional space $\operatorname{Ran}(K)$ and therefore has a convergent subsequence. □

Proposition B.2.35. Let X, Y, and Z be normed spaces.

(a) If $K \in \mathcal{K}(X,Y)$ and $S \in \mathcal{L}(Y,Z)$, then $S \circ K \in \mathcal{K}(X,Z)$.

(b) If $T \in \mathcal{L}(Z,X)$ and $K \in \mathcal{K}(X,Y)$, then $K \circ T \in \mathcal{K}(Z,Y)$.

(c) If Y is Banach, then $\mathcal{K}(X,Y)$ is a closed subspace of $\mathcal{L}(X,Y)$.

Proof. The first two assertions follow directly from the definition. For the third, let $K_n \to K$ in the operator norm, with $K_n \in \mathcal{K}(X,Y)$, and let (x_j) be a bounded sequence in X. A diagonal argument gives a subsequence, still denoted by (x_j), such that $(K_n x_j)_j$ converges for each n. If $M := \sup_{j\in\mathbb{N}} \|x_j\|_X$, then

$$\|Kx_j - Kx_k\|_Y \leq 2M\|K - K_n\| + \|K_n x_j - K_n x_k\|_Y.$$

First choose n so that the first term is less than $\frac{\varepsilon}{2}$, and then j,k so that the second is less than $\frac{\varepsilon}{2}$. Thus, (Kx_j) is Cauchy and converges in Y. □

Theorem B.2.36. (Continuous and compact extension from a dense subspace) Let X be a normed space, let $D \subseteq X$ be a dense vector subspace, and let Y be a Banach space. Every continuous linear operator $T\colon D \longrightarrow Y$ has a unique continuous linear extension $\widetilde{T}\colon X \longrightarrow Y$. Moreover,

$$\|\widetilde{T}\|_{\mathcal{L}(X,Y)} = \|T\|_{\mathcal{L}(D,Y)}.$$

If T is compact, then $\widetilde{T}$ is also compact.

Proof. Let $x \in X$ and choose a sequence $(x_n) \subseteq D$ such that $x_n \to x$. The estimate $\|T(x_n) - T(x_m)\|_Y \leq \|T\|\|x_n - x_m\|_X$ shows that $(T(x_n))$ is Cauchy in Y. Since Y is complete, we may define $\widetilde{T}(x) := \lim_{n\to\infty} T(x_n)$. If $(y_n) \subseteq D$ also converges to x, then $\|T(x_n) - T(y_n)\|_Y \leq \|T\|\|x_n - y_n\|_X \to 0$, so the limit does not depend on the chosen sequence.
Linearity follows by approximating two points of X by sequences in D and passing to the limit. Similarly,

$$\|\widetilde{T}(x)\|_Y = \lim_{n\to\infty} \|T(x_n)\|_Y \leq \|T\| \lim_{n\to\infty} \|x_n\|_X = \|T\|\|x\|_X,$$

so $\widetilde{T}$ is continuous and $\|\widetilde{T}\| \le \|T\|$. The reverse inequality follows from $\widetilde{T} \restriction_D = T$. Uniqueness follows from the density of D: two continuous extensions that agree on D agree on all of X.
Now suppose that T is compact and let (x_n) be a bounded sequence in X. For each n, choose $y_n \in D$ such that $\|x_n - y_n\|_X < \frac{1}{n}$. The sequence (y_n) is also bounded, so there exists a subsequence (y_{n_k}) for which $(T(y_{n_k}))$ converges in Y. On the other hand,

$$\|\widetilde{T}(x_{n_k}) - T(y_{n_k})\|_Y \le \|T\|\|x_{n_k} - y_{n_k}\|_X < \frac{\|T\|}{n_k},$$

and the right-hand side tends to zero. Consequently, $(\widetilde{T}(x_{n_k}))$ converges in Y, proving that $\widetilde{T}$ is compact. □

Corollary B.2.37. (Extension to the completions) Let X and Y be normed spaces, and let $\widehat{X}$ and $\widehat{Y}$ be their completions. Every operator $T \in \mathcal{L}(X,Y)$ has a unique extension $\widehat{T} \in \mathcal{L}(\widehat{X},\widehat{Y})$ compatible with the canonical inclusions. We have $\|\widehat{T}\| = \|T\|$ and, if T is compact, then $\widehat{T}$ is compact.

Proof. Identify X and Y with their isometric images in $\widehat{X}$ and $\widehat{Y}$. The result follows by applying Theorem B.2.36 to the operator $X \longrightarrow \widehat{Y}$ induced by T. □

Theorem B.2.38. (Schauder's theorem) Let X and Y be Banach spaces and let $K \in \mathcal{L}(X,Y)$. Then K is compact if and only if $K' \colon Y' \longrightarrow X'$ is compact.

Proof. First suppose that K is compact and set

$$C := \overline{\{Kx \mid \|x\|_X \le 1\}} \subseteq Y.$$

Every sequence in C has a convergent subsequence. Indeed, approximate its term j by an element Kx_j, with $\|x_j\|_X \le 1$, at a distance less than $1/j$. The compactness of K gives a convergent subsequence of (Kx_j) and hence of the original sequence, whose limit belongs to C because this set is closed. In particular, C has a finite net of any radius $\delta > 0$: if no finite union of balls of that radius covered C, we could inductively choose a sequence of points whose pairwise distances are at least δ, contradicting the preceding property.
Let (φ_j) be a bounded sequence in Y' and choose $M \ge 1$ such that $\|\varphi_j\|_{Y'} \le M$ for every j. The restrictions $f_j := \varphi_j \restriction_C$ satisfy

$$|f_j(y)| \le M\|K\|, \qquad |f_j(y) - f_j(z)| \le M\|y - z\|_Y, \qquad y, z \in C.$$

Let us give the uniform compactness argument needed here. For each integer $q \ge 1$, choose a finite net of radius $1/q$ in C. The union of these nets is a countable dense subset of C. A diagonal argument, applied to the bounded scalar sequences at its points, gives a subsequence of (f_j) that converges at every point of that union. Retain the same indices for the subsequence.
Given $\varepsilon > 0$, choose from these points a finite net $\{y_1, \dots, y_l\}$ of radius less than $\varepsilon/(4M)$. For sufficiently large j, k, $|f_j(y_i) - f_k(y_i)| < \varepsilon/2$ at every point of the net. If $y \in C$ and $\|y - y_i\|_Y < \varepsilon/(4M)$, then

$$|f_j(y) - f_k(y)| \le 2M\|y - y_i\|_Y + |f_j(y_i) - f_k(y_i)| < \varepsilon.$$

Thus the subsequence is uniformly Cauchy on C. Consequently,

$$\|K'\varphi_j - K'\varphi_k\|_{X'} = \sup_{\substack{x\in X\\ \|x\|_X\le 1}} |(\varphi_j-\varphi_k)(Kx)| \le \sup_{y\in C}|f_j(y)-f_k(y)| \longrightarrow 0.$$

Theorem B.2.9 shows that X' is complete; the subsequence of $(K'\varphi_j)$ converges in X'. This proves that K' is compact.

Conversely, suppose that K' is compact. The duals Y' and X' are Banach spaces, so the implication already proved, applied to K', shows that $K''\colon X''\to Y''$ is compact. For a normed space Z, define

$$J_Z\colon Z\longrightarrow Z'', \qquad (J_Z z)(\ell) := \ell(z), \quad \ell\in Z'.$$

Corollary B.2.30 gives $\|J_Z z\|_{Z''} = \|z\|_Z$, so J_Z is a linear isometry. Moreover, evaluating at $\varphi\in Y'$ gives

$$(K''J_X x)(\varphi) = (J_X x)(K'\varphi) = \varphi(Kx) = (J_Y Kx)(\varphi).$$

Hence $K''J_X = J_Y K$. If (x_j) is bounded in X, the compactness of K'' gives a subsequence along which $(J_Y Kx_j)$ converges in Y''. Since J_Y is an isometry, the corresponding subsequence of (Kx_j) is Cauchy in Y and converges because Y is complete. Thus K is compact. □

Theorem B.2.39. (Riesz–Schauder theorem) Let X be a Banach space and let $K\in\mathcal{K}(X)$. Then $\ker(I-K)$ is finite-dimensional, $\operatorname{Ran}(I-K)$ is closed, and

$$\operatorname{Ran}(I-K)=X \quad\Longleftrightarrow\quad \ker(I-K)=\{0\}.$$

Moreover, $\dim\ker(I-K)=\dim\ker(I-K')$.

Proof. Set $T := I-K$ and $N := \ker T$. We first use an elementary separation fact. If F is a proper closed subspace of a normed space E, choose $z\in E\setminus F$ and set $d := \operatorname{dist}(z,F) > 0$. There exists $y\in F$ such that $\|z-y\| < 2d$. The vector

$$u := \frac{z-y}{\|z-y\|}$$

satisfies $\|u\|=1$ and $\operatorname{dist}(u,F) = d/\|z-y\| > 1/2$. Recall also that every finite-dimensional subspace is closed and that its coordinate functionals are continuous: for a basis $e_1,\dots,e_l$, the function $\|\sum_{i=1}^{l} a_i e_i\|$ attains a positive minimum on the Euclidean sphere $\sum_{i=1}^{l}|a_i|^2=1$. Homogeneity gives equivalence with the coordinate norm, from which both assertions follow.

The subspace N is closed because T is continuous. If it were infinite-dimensional, we could apply the separation fact successively to the subspaces spanned by the vectors already chosen. We would obtain a sequence $(u_j)\subseteq N$, with $\|u_j\|_X=1$, such that $\|u_j-u_k\|_X > 1/2$ for $j\neq k$. But $Ku_j = u_j$, contradicting the compactness of K. Thus, $\dim N<\infty$.

We now prove the estimate

$$\operatorname{dist}_X(x,N)\le C\|Tx\|_X, \qquad x\in X,$$

for some constant $C > 0$. If it were false, after normalizing and subtracting an element of N, we could choose $x_j \in X$ such that

$$\operatorname{dist}_X(x_j, N) = 1, \qquad \|x_j\|_X < 2, \qquad \|Tx_j\|_X < 1/j.$$

In detail, take a vector whose distance to N is greater than $j\|Tx\|_X$, divide by this distance, and choose a representative of the same class modulo N with norm less than two. The compactness of K allows us to pass to a subsequence along which Kx_j converges. Since $x_j = Tx_j + Kx_j$, x_j also converges, say to x. By continuity, $Tx = 0$ and $\operatorname{dist}_X(x, N) = 1$, a contradiction. By Proposition B.2.20, the estimate is a lower bound for the operator induced by T on X/N.

Now let $Tx_j \to y$ in X. Choose $n_j \in N$ so that

$$z_j := x_j - n_j, \qquad \|z_j\|_X \le 2\operatorname{dist}_X(x_j, N) + 1/j \le 2C\|Tx_j\|_X + 1/j.$$

The sequence (z_j) is bounded. Along a subsequence, Kz_j converges; since $Tz_j = Tx_j \to y$, $z_j = Tz_j + Kz_j$ also converges to some z. The continuity of T gives $Tz = y$. Hence $\operatorname{Ran} T$ is closed.

Let us prove the equivalence between injectivity and surjectivity. For $j \ge 0$, write

$$R_j := \operatorname{Ran} T^j, \qquad N_j := \ker T^j, \qquad R_0 = X, \quad N_0 = \{0\}.$$

Each N_j is closed. For $j \ge 1$, the operator

$$L_j := I - T^j = \sum_{l=1}^{j} (-1)^{l+1} \binom{j}{l} K^l$$

is compact by Proposition B.2.35. The closed range argument just proved, applied to $T^j = I - L_j$, shows that each R_j is closed. Moreover, K commutes with T and therefore preserves all the spaces R_j and N_j.

Suppose that T is injective but not surjective. The inclusions $R_{j+1} \subseteq R_j$ are then strict for every $j \ge 0$. Indeed, if $R_j = R_{j+1}$, then for each $x \in X$ there would exist $y \in X$ with $T^j x = T^{j+1} y$; the injectivity of T^j would imply $x = Ty$, a contradiction. The separation fact gives vectors

$$x_j \in R_{j-1}, \qquad \|x_j\|_X = 1, \qquad \operatorname{dist}_X(x_j, R_j) > 1/2, \qquad j \ge 1.$$

If $k > j$, we have $Tx_j \in R_j$ and $Kx_k \in R_{k-1} \subseteq R_j$. Consequently,

$$\|Kx_j - Kx_k\|_X = \|x_j - (Tx_j + Kx_k)\|_X > 1/2,$$

contradicting the compactness of K. Thus injectivity implies surjectivity.

Conversely, suppose that T is surjective and $N_1 \neq \{0\}$. The inclusions $N_j \subseteq N_{j+1}$ are strict for every $j \ge 0$. If $N_j = N_{j+1}$ and $0 \neq z \in N_1$, the surjectivity of T^j would give an y with $T^j y = z$. Then $y \in N_{j+1} = N_j$, which would force $z = 0$, a contradiction. By separation, choose

$$x_j \in N_j, \qquad \|x_j\|_X = 1, \qquad \operatorname{dist}_X(x_j, N_{j-1}) > 1/2, \qquad j \ge 1.$$

If $j > k$, then $Tx_j \in N_{j-1}$ and $Kx_k \in N_k \subseteq N_{j-1}$. The same identity gives $\|Kx_j - Kx_k\|_X > 1/2$, again contradicting compactness. This proves the stated equivalence for every compact perturbation of the identity.

It remains to compare the dimensions. By Theorem B.2.38, K' is compact on the Banach space X'. The finite-dimensional kernel argument at the beginning of this proof, applied to $I - K' = T'$, gives

$$m := \dim \ker T' < \infty.$$

Set $R := \operatorname{Ran} T$ and $Z := X/R$, with the quotient norm. The map

$$Z' \longrightarrow \ker T', \qquad \ell \longmapsto \ell \circ \pi,$$

where $\pi\colon X \to X/R$ is the projection, is a linear isomorphism. Indeed, $T'\varphi = 0$ is equivalent to φ vanishing on R; in that case, $\ell([x]) := \varphi(x)$ is well-defined and

$$|\ell([x])| = |\varphi(x - r)| \le \|\varphi\|_{X'} \|x - r\|_X, \qquad r \in R.$$

Taking the infimum gives continuity in the quotient norm. The canonical injection $Z \to Z''$ is injective by Corollary B.2.30. Since $\dim Z' = m$, it follows that Z is finite-dimensional; in finite dimensions, the dual has the same dimension. Therefore,

$$\dim(X/R) = \dim Z = \dim Z' = m.$$

Let $n := \dim N$ and choose a basis $e_1, \dots, e_n$ of N. The coordinate functionals of this basis extend to functionals $f_1, \dots, f_n \in X'$ by Corollary B.2.29. Then

$$Px := \sum_{i=1}^{n} f_i(x) e_i, \qquad X_0 := \ker P,$$

define a continuous projection onto N and a decomposition $X = N \oplus X_0$. The operator $T \restriction_{X_0}$ is a bijection from X_0 onto R: it is injective because $N \cap X_0 = \{0\}$ and surjective because $T(x - Px) = Tx$.
Choose $y_1, \dots, y_m \in X$ whose classes form a basis of X/R. With $Y_0 := \operatorname{span}\{y_1, \dots, y_m\}$, we have $X = R \oplus Y_0$. Set $r := \min\{n, m\}$ and define the continuous finite-rank operator

$$Fx := \sum_{i=1}^{r} f_i(x) y_i.$$

Empty sums are interpreted as zero. By Propositions B.2.34 and B.2.35, $K - F$ is compact. The operator $S := T + F = I - (K - F)$ satisfies the equivalence between injectivity and surjectivity already proved. For $x = x_0 + \sum_{i=1}^{n} a_i e_i$, with $x_0 \in X_0$, we have

$$Sx = Tx_0 + \sum_{i=1}^{r} a_i y_i.$$

The direct sum $X = R \oplus Y_0$ and the bijectivity of $T \restriction_{X_0}$ give

$$\ker S = \operatorname{span}\{e_{r+1}, \dots, e_n\}, \qquad \operatorname{Ran} S = R \oplus \operatorname{span}\{y_1, \dots, y_r\}.$$

If $n \le m$, then $r = n$ and S is injective; hence it is surjective, which forces $r = m$. If $m \le n$, then $r = m$ and S

is surjective; hence it is injective, which forces $r = n$. In both cases, $n = m$, that is,

$$\dim\ker(I-K) = \dim\ker(I-K').$$

This completes the proof. □

Definition B.2.40. Let X and Y be Banach spaces. An operator $T \in \mathcal{L}(X,Y)$ is called **Fredholm** if $\ker T$ is finite-dimensional, $\operatorname{Ran}(T)$ is closed, and $Y/\operatorname{Ran}(T)$ is finite-dimensional. Its **index** is

$$\operatorname{ind}(T) := \dim\ker T - \dim\big(Y/\operatorname{Ran}(T)\big).$$

In particular, Theorem B.2.39 implies that $I-K$ is Fredholm of index zero for every $K \in \mathcal{K}(X)$.

B.3 Hilbert spaces

Hilbert spaces combine completeness with a Euclidean geometry given by an inner product. This structure allows us to define orthogonal complements, projections, adjoints, and gradients, and provides the natural setting for many linear and quadratic variational problems. We mainly follow [45, Section 1.2], [28, 87, 120].

Definition B.3.1. Let V be a vector space over $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$. An **inner product** on V is a map $\langle\cdot,\cdot\rangle_V : V\times V \longrightarrow \mathbb{K}$ such that, for all $x,y,z \in V$ and $\lambda \in \mathbb{K}$,

(a) $\langle x+y,z\rangle_V = \langle x,z\rangle_V + \langle y,z\rangle_V$ and $\langle \lambda x,z\rangle_V = \lambda\langle x,z\rangle_V$;

(b) $\langle x,y\rangle_V = \overline{\langle y,x\rangle_V}$;

(c) $\langle x,x\rangle_V \geq 0$, and $\langle x,x\rangle_V = 0$ if and only if $x = 0$.

Thus, in the complex case, we adopt the convention of linearity in the first variable and antilinearity in the second.

Theorem B.3.2. (Cauchy–Schwarz inequality) For any $x,y \in V$, we have $|\langle x,y\rangle_V| \leq \langle x,x\rangle_V^{\frac{1}{2}}\langle y,y\rangle_V^{\frac{1}{2}}$.

Proof. If $y = 0$, the assertion is immediate. If $y \neq 0$, positivity of the inner product applied to $x - \dfrac{\langle x,y\rangle_V}{\langle y,y\rangle_V}y$ gives

$$0 \leq \langle x,x\rangle_V - \frac{|\langle x,y\rangle_V|^2}{\langle y,y\rangle_V},$$

from which the inequality follows. □

Proposition B.3.3. The formula $\|x\|_V := \langle x,x\rangle_V^{\frac{1}{2}}$ defines a norm on V. Moreover, the parallelogram identity holds:

$$\|x+y\|_V^2 + \|x-y\|_V^2 = 2\|x\|_V^2 + 2\|y\|_V^2.$$

Proof. Only the triangle inequality requires justification. By Cauchy–Schwarz,

$$\|x+y\|_V^2 = \|x\|_V^2 + 2\,\mathrm{Re}\langle x,y\rangle_V + \|y\|_V^2 \le (\|x\|_V + \|y\|_V)^2.$$

The parallelogram identity follows by expanding both sides. □

Definition B.3.4. A vector space with an inner product is called a **Hilbert space** if it is complete in the norm induced by that inner product.

B.3.1 Orthogonality and projections

Definition B.3.5. Let H be a Hilbert space and let $M \subseteq H$. The **orthogonal complement** of M is

$$M^{\perp} := \{x \in H \mid \langle m, x\rangle_H = 0 \text{ for every } m \in M\}.$$

Two subsets $A, B \subseteq H$ are orthogonal if $\langle a, b\rangle_H = 0$ for all $a \in A$ and $b \in B$.

Proposition B.3.6. For every $M \subseteq H$, the set $M^{\perp}$ is a closed subspace. If M is a subspace, then $M \cap M^{\perp} = \{0\}$.

Proof. For each $m \in M$, the map $x \mapsto \langle m, x\rangle_H$ is continuous, so $M^{\perp}$ is an intersection of closed kernels. If $x \in M \cap M^{\perp}$, then $\|x\|_H^2 = \langle x, x\rangle_H = 0$, and therefore $x = 0$. □

Theorem B.3.7. (Projection onto closed convex sets) Let H be a Hilbert space and let $C \subseteq H$ be nonempty, closed, and convex. For each $x \in H$, there exists a unique $P_C x \in C$ such that

$$\|x - P_C x\|_H = \inf_{z \in C} \|x - z\|_H.$$

This element is characterized by

$$\mathrm{Re}\langle x - P_C x, z - P_C x\rangle_H \le 0 \qquad \text{for every } z \in C.$$

Proof. Let $d := \inf_{z\in C} \|x-z\|_H$ and choose (z_n) in C such that $\|x - z_n\|_H^2 < d^2 + \frac{1}{n}$. The parallelogram identity and convexity of C imply

$$\|z_n - z_m\|_H^2 = 2\|x - z_n\|_H^2 + 2\|x - z_m\|_H^2 - 4\left\|x - \frac{z_n + z_m}{2}\right\|_H^2 \le \frac{2}{n} + \frac{2}{m}.$$

Therefore, (z_n) is Cauchy and converges to some $y \in C$; necessarily, $\|x - y\|_H = d$. The same identity applied to two minimizers proves uniqueness.
Let $z \in C$. For $t \in (0,1)$, the point $y + t(z-y)$ belongs to C, so

$$\|x-y\|_H^2 \le \|x - y - t(z-y)\|_H^2 = \|x-y\|_H^2 - 2t\,\mathrm{Re}\langle x-y, z-y\rangle_H + t^2\|z-y\|_H^2.$$

Dividing by t and letting $t \to 0^+$ gives the characterizing inequality. Conversely, this inequality implies $\|x-z\|_H^2 \ge \|x-y\|_H^2$ for every $z \in C$. □

Corollary B.3.8. (Orthogonal decomposition) If M is a closed subspace of a Hilbert space H, then

$$H = M \oplus M^{\perp}.$$

For each $x \in H$, the element $P_M x$ is the unique vector in M such that $x - P_M x \in M^{\perp}$. The operator $P_M \in \mathcal{L}(H)$ is called the **orthogonal projection** onto M and satisfies $P_M^2 = P_M$, $\|P_M\| = 1$ if $M \neq \{0\}$, and

$$\langle P_M x, y\rangle_H = \langle x, P_M y\rangle_H \qquad \text{for all } x, y \in H.$$

Proof. Apply Theorem B.3.7 to $C = M$. Since M is a subspace, the characterizing inequality applied to $z = P_M x \pm m$ and, in the complex case, to $z = P_M x \pm im$ implies $\langle m, x - P_M x\rangle_H = 0$ for every $m \in M$. Uniqueness of the decomposition is immediate. The linearity of P_M follows from this characterization, and $\|P_M x\|_H \leq \|x\|_H$ follows from the Pythagorean theorem. The last identity follows by decomposing x and y into their components in M and $M^{\perp}$. □

Corollary B.3.9. For every subset $M \subseteq H$, we have

$$(M^{\perp})^{\perp} = \overline{\operatorname{span}(M)}.$$

Proof. The inclusion $\overline{\operatorname{span}(M)} \subseteq (M^{\perp})^{\perp}$ is immediate. Applying Corollary B.3.8 to the closed subspace $N := \overline{\operatorname{span}(M)}$, we write $x = P_N x + (x - P_N x)$. If $x \in (M^{\perp})^{\perp}$, then $x - P_N x \in N^{\perp} = M^{\perp}$, and therefore $\|x - P_N x\|_H^2 = \langle x, x - P_N x\rangle_H = 0$. Thus, $x = P_N x \in N$. □

B.3.2 Orthonormal systems and Riesz representation

Definition B.3.10. A family $(e_j)_{j\in J}$ in a Hilbert space H is **orthonormal** if $\langle e_j, e_k\rangle_H = 0$ for $j \neq k$ and $\|e_j\|_H = 1$. It is called an **orthonormal basis** if $\overline{\operatorname{span}\{e_j \mid j \in J\}} = H$.

Theorem B.3.11. (Bessel and Parseval) If $(e_j)_{j\in J}$ is an orthonormal family in H, then for every $x \in H$ and every finite subset $F \subseteq J$,

$$\sum_{j\in F} |\langle x, e_j\rangle_H|^2 \leq \|x\|_H^2.$$

If $(e_j)_{j\in J}$ is an orthonormal basis, then

$$x = \sum_{j\in J} \langle x, e_j\rangle_H e_j, \qquad \|x\|_H^2 = \sum_{j\in J} |\langle x, e_j\rangle_H|^2,$$

where only countably many coefficients can be nonzero.

Proof. For finite $F \subseteq J$, the vector $p_F := \sum_{j\in F} \langle x, e_j\rangle_H e_j$ satisfies $x - p_F \perp p_F$. By the Pythagorean theorem, $\|x\|_H^2 = \|x - p_F\|_H^2 + \sum_{j\in F} |\langle x, e_j\rangle_H|^2$. Parseval's identity follows by enlarging F and using the density of the subspace spanned by the family. □

Theorem B.3.12. (Riesz representation theorem) Let H be a Hilbert space and let $\ell \in H'$. There exists a unique $v \in H$ such that

$$\ell(x) = \langle x, v\rangle_H \qquad \text{for every } x \in H.$$

Moreover, $\|\ell\|_{H'} = \|v\|_H$. In the real case, the map $J\colon H \longrightarrow H'$, given by $J(v)(x) = \langle x, v\rangle_H$, is a linear isometry; in the complex case, it is an antilinear isometry.

Proof. If $\ell = 0$, take $v = 0$. Suppose that $\ell \neq 0$ and let $M := \ker \ell$, which is a closed subspace. By Corollary B.3.8, $H = M \oplus M^\perp$. The space $M^\perp$ is one-dimensional: the restriction of ℓ to $M^\perp$ is injective and takes values in $\mathbb{K}$. Choose $e \in M^\perp$ with $\|e\|_H = 1$. Each $x \in H$ has a unique representation as $x = m + \alpha e$, with $m \in M$, and $\ell(x) = \alpha\ell(e)$.
In the real case, define $v := \ell(e)e$, and in the complex case, $v := \overline{\ell(e)}e$. With our convention of linearity in the first variable, $\langle x, v\rangle_H = \alpha\ell(e) = \ell(x)$. Uniqueness follows because $\langle x, v - w\rangle_H = 0$ for every $x \in H$ implies $v = w$. Cauchy–Schwarz gives $\|\ell\| \leq \|v\|_H$, while, if $v \neq 0$, evaluating at $\dfrac{v}{\|v\|_H}$ gives the reverse inequality. □

Corollary B.3.13. (Complex-linear form of Riesz representation) Let H be a complex Hilbert space with inner product linear in the first variable. Then

$$\mathscr{R}_H\colon \overline{H} \longrightarrow H', \qquad \mathscr{R}_H(\overline{v})(x) := \langle x, v\rangle_H,$$

is a complex-linear isometric isomorphism. In particular, every complex-linear identification of a complex Hilbert space with its dual obtained from its inner product must have the conjugate space $\overline{H}$ as its domain; the direct map $H \to H'$ is antilinear.

Proof. Theorem B.3.12 proves bijectivity and equality of norms. If $\lambda \in \mathbb{C}$, scalar multiplication in $\overline{H}$ satisfies $\lambda\overline{v} = \overline{\overline{\lambda}v}$; therefore,

$$\mathscr{R}_H(\lambda\overline{v})(x) = \langle x, \overline{\lambda}v\rangle_H = \lambda\langle x, v\rangle_H = \lambda\mathscr{R}_H(\overline{v})(x).$$

□

Theorem B.3.14. (Lax–Milgram theorem) Let H be a real Hilbert space and let $a\colon H \times H \longrightarrow \mathbb{R}$ be bilinear. Suppose there exist constants $C \geq 0$ and $\alpha > 0$ such that

$$|a(u, v)| \leq C\|u\|_H\|v\|_H, \qquad a(u, u) \geq \alpha\|u\|_H^2$$

for all $u, v \in H$. Then, for every $F \in H'$, there exists a unique $u \in H$ such that $a(u, v) = F(v)$ for every $v \in H$. Moreover, $\|u\|_H \leq \dfrac{\|F\|_{H'}}{\alpha}$.

Proof. By Theorem B.3.12, for each $u \in H$ there exists a unique $Tu \in H$ such that $a(u, v) = \langle v, Tu\rangle_H$ for every $v \in H$. The operator T is linear and continuous. Coercivity implies

$$\alpha\|u\|_H^2 \leq \langle u, Tu\rangle_H \leq \|u\|_H\|Tu\|_H,$$

so $\|Tu\|_H \geq \alpha\|u\|_H$. In particular, T is injective and its range is closed. If $w \perp \operatorname{Ran}(T)$, then $0 = \langle w, Tw\rangle_H =$

$a(w,w) \geq \alpha \|w\|_H^2$, so $w = 0$. Therefore, the range of T is dense and closed, hence is all of H.
Let $f \in H$ be the Riesz representative of F. There exists a unique $u \in H$ such that $Tu = f$, and then $a(u,v) = \langle v, f\rangle_H = F(v)$. Finally, $\alpha\|u\|_H \leq \|Tu\|_H = \|f\|_H = \|F\|_{H'}$. □

B.3.3 Adjoint operators on Hilbert spaces

Theorem B.3.15. Let H_1 and H_2 be Hilbert spaces and let $T \in \mathcal{L}(H_1, H_2)$. There exists a unique operator $T^* \in \mathcal{L}(H_2, H_1)$ such that

$$\langle Tx, y\rangle_{H_2} = \langle x, T^* y\rangle_{H_1} \qquad \text{for all } x \in H_1,\ y \in H_2.$$

Moreover, $\|T^*\| = \|T\|$, $(S \circ T)^* = T^* \circ S^*$, and $(T^*)^* = T$.

Proof. For each $y \in H_2$, the map $x \mapsto \langle Tx, y\rangle_{H_2}$ belongs to H_1'. Theorem B.3.12 gives a unique vector $T^* y \in H_1$ satisfying the identity. Uniqueness allows us to verify the linearity of T^*, and Cauchy–Schwarz gives $\|T^* y\|_{H_1} \leq \|T\|\|y\|_{H_2}$. Applying the same construction to T^* and using the defining identity gives $(T^*)^* = T$, and therefore $\|T\| \leq \|T^*\|$. The remaining identities are verified using the inner product. □

Definition B.3.16. Let H be a Hilbert space and let $T \in \mathcal{L}(H)$.

(a) T is **self-adjoint** if $T = T^*$.

(b) T is **positive** if $\langle Tx, x\rangle_H \geq 0$ for every $x \in H$.

(c) T is **unitary** if $T^*T = TT^* = I$.

For unbounded operators, the definition of the adjoint must include its domain.

Definition B.3.17. Let H_1 and H_2 be Hilbert spaces and let $A\colon \mathcal{D}(A) \subseteq H_1 \longrightarrow H_2$ be a densely defined linear operator. Define

$$\mathcal{D}(A^*) := \left\{ y \in H_2 \,\middle|\, \text{there exists } z \in H_1 \text{ such that } \langle Ax, y\rangle_{H_2} = \langle x, z\rangle_{H_1} \text{ for every } x \in \mathcal{D}(A) \right\}.$$

For $y \in \mathcal{D}(A^*)$, the vector z is unique, and we define $A^* y := z$.

Proposition B.3.18. The adjoint of every densely defined linear operator is closed.

Proof. Let $y_n \in \mathcal{D}(A^*)$ satisfy $y_n \to y$ in H_2 and $A^* y_n \to z$ in H_1. For each $x \in \mathcal{D}(A)$,

$$\langle Ax, y\rangle_{H_2} = \lim_{n\to\infty} \langle Ax, y_n\rangle_{H_2} = \lim_{n\to\infty} \langle x, A^* y_n\rangle_{H_1} = \langle x, z\rangle_{H_1}.$$

Therefore, $y \in \mathcal{D}(A^*)$ and $A^* y = z$. □

Theorem B.3.19. Let $A\colon \mathcal{D}(A) \subseteq H_1 \longrightarrow H_2$ be linear and densely defined. Then A is closable if and only if $\mathcal{D}(A^*)$ is dense in H_2. In this case, $\overline{A} = A^{**}$.

The proof relies on identifying H_j with H_j' by Theorem B.3.12 and on the relation between the graph of A and its orthogonal complement. It can be found in [120, 28].

Definition B.3.20. Let H be a Hilbert space and let $A\colon \mathcal{D}(A)\subseteq H \longrightarrow H$ be linear and densely defined. We say that A is **symmetric** if $\langle Ax,y\rangle_H = \langle x,Ay\rangle_H$ for all $x,y\in\mathcal{D}(A)$, which is equivalent to $A\subseteq A^*$. We say that A is **self-adjoint** if $\mathcal{D}(A)=\mathcal{D}(A^*)$ and $A=A^*$ on this domain.

Proposition B.3.21. Let H be a complex Hilbert space and let $A\colon \mathcal{D}(A)\subseteq H\longrightarrow H$ be a densely defined symmetric operator. The following assertions are equivalent:

(a) A is self-adjoint.

(b) A is closed and $\ker(A^*-iI)=\ker(A^*+iI)=\{0\}$.

(c) $\operatorname{Ran}(A-iI)=\operatorname{Ran}(A+iI)=H$.

Proof. For every $x\in\mathcal{D}(A)$, symmetry implies

$$\|(A\pm iI)x\|_H^2 = \|Ax\|_H^2+\|x\|_H^2.$$

If A is closed, this estimate shows that the ranges of $A\pm iI$ are closed. Moreover,

$$\operatorname{Ran}(A+iI)^\perp=\ker(A^*-iI),\qquad \operatorname{Ran}(A-iI)^\perp=\ker(A^*+iI).$$

If A is self-adjoint, it is closed and the preceding kernels are trivial; therefore, $(a)\Rightarrow(b)$. If (b) holds, both ranges are closed and their orthogonal complements are trivial, so both equal H. Thus, $(b)\Rightarrow(c)$.
Suppose (c) and let $y\in\mathcal{D}(A^*)$. Choose $x\in\mathcal{D}(A)$ such that $(A+iI)x=(A^*+iI)y$. Since $A\subseteq A^*$, we have $(A^*+iI)(y-x)=0$. Now $\ker(A^*+iI)=\operatorname{Ran}(A-iI)^\perp=\{0\}$, so $y=x\in\mathcal{D}(A)$. Consequently, $\mathcal{D}(A^*)\subseteq\mathcal{D}(A)$ and A is self-adjoint. This proves $(c)\Rightarrow(a)$. □

B.3.4 Compact self-adjoint operators

Proposition B.3.22. Let H_1 and H_2 be Hilbert spaces. An operator $K\in\mathcal{L}(H_1,H_2)$ is compact if and only if there exists a sequence of finite-rank operators (K_n) such that $\|K_n-K\|_{\mathcal{L}(H_1,H_2)}\to 0$.

Proof. If K is the norm limit of finite-rank operators, then it is compact by Propositions B.2.34 and B.2.35. Conversely, suppose that K is compact and set

$$C:=\overline{K(B_{d_{H_1}}(0,1))},\qquad M:=\overline{\operatorname{span}(C)}.$$

The set C is compact because $K(B_{d_{H_1}}(0,1))$ is relatively compact. For each $r\in\mathbb{N}$, choose a finite set $F_r\subseteq C$ such that the balls of radius $\dfrac{1}{r}$ centered at the points of F_r cover C. The union $D:=\bigcup_{r=1}^{\infty}F_r$ is countable and dense in C.
Enumerate $D=\{y_1,y_2,\dots\}$ and let $\mathbb{K}_0:=\mathbb{Q}$ in the real case and $\mathbb{K}_0:=\mathbb{Q}+i\mathbb{Q}$ in the complex case. The set

$$D_0:=\left\{\sum_{j=1}^{s}a_j y_{n_j}\,\middle|\, s\in\mathbb{N},\ n_1,\dots,n_s\in\mathbb{N},\ a_1,\dots,a_s\in\mathbb{K}_0\right\}$$

is countable, since it is a countable union of images of the countable sets $\mathbb{N}^s \times \mathbb{K}_0^s$.
Let us verify that D_0 is dense in M. It suffices to approximate the elements of $\operatorname{span}(C)$, since this subspace is dense in M by definition. Let $z = \sum_{j=1}^{s} \alpha_j c_j$, with $c_j \in C$, $\alpha_j \in \mathbb{K}$, and let $\varepsilon > 0$. For each j, choose $y_{n_j} \in D$ sufficiently close to c_j that

$$\sum_{j=1}^{s} |\alpha_j| \|c_j - y_{n_j}\|_{H_2} < \frac{\varepsilon}{2}.$$

Then choose $a_j \in \mathbb{K}_0$ so that

$$\sum_{j=1}^{s} |\alpha_j - a_j| \|y_{n_j}\|_{H_2} < \frac{\varepsilon}{2};$$

if any of the vectors y_{n_j} is zero, the corresponding term imposes no condition on a_j. Then $w := \sum_{j=1}^{s} a_j y_{n_j}$ belongs to D_0 and

$$\|z - w\|_{H_2} \le \sum_{j=1}^{s} |\alpha_j| \|c_j - y_{n_j}\|_{H_2} + \sum_{j=1}^{s} |\alpha_j - a_j| \|y_{n_j}\|_{H_2} < \varepsilon.$$

Consequently, D_0 is countable and dense in M, so M is separable.
For every $x \in H_1$, we have $Kx \in M$: if $x \neq 0$, simply write $Kx = 2\|x\|_{H_1} K\left(\frac{x}{2\|x\|_{H_1}}\right)$, and the vector in parentheses belongs to $B_{d_{H_1}}(0,1)$; the case $x = 0$ is immediate. If M is finite-dimensional, this shows that K already has finite rank. Thus, suppose that M is infinite-dimensional. Applying the Gram–Schmidt procedure to a dense sequence in M, and at each step discarding the vectors that belong to the subspace spanned by the preceding ones, gives a countable orthonormal basis $(e_j)_{j\in\mathbb{N}}$ of M. Let P_n be the orthogonal projection from H_2 onto $\operatorname{span}\{e_1, \dots, e_n\}$. Since $K(H_1) \subseteq M$, the operator $K_n := P_n K$ has finite rank.
By Theorem B.3.11, $P_n y \to y$ for every $y \in M$. This convergence is uniform on C. To verify this, let $\varepsilon > 0$ and choose a finite net $\{z_1, \dots, z_s\} \subseteq C$ of radius $\frac{\varepsilon}{2}$. There exists $N \in \mathbb{N}$ such that $\|(I - P_n)z_i\|_{H_2} < \frac{\varepsilon}{2}$ for every $i \in \{1, \dots, s\}$ and $n \ge N$. Given $y \in C$, choose z_i with $\|y - z_i\|_{H_2} < \frac{\varepsilon}{2}$. Since $I - P_n$ is an orthogonal projection and therefore has norm at most one,

$$\|(I - P_n)y\|_{H_2} \le \|(I - P_n)(y - z_i)\|_{H_2} + \|(I - P_n)z_i\|_{H_2} < \varepsilon.$$

Consequently,

$$\|K - K_n\| = \sup_{\substack{x \in H_1 \\ \|x\|_{H_1} \le 1}} \|(I - P_n)Kx\|_{H_2} \le \sup_{y \in C} \|(I - P_n)y\|_{H_2} \longrightarrow 0.$$

□

Proposition B.3.23. (Bilinear forms and self-adjoint operators) Let H be a real Hilbert space. For every continuous bilinear form $B\colon H \times H \longrightarrow \mathbb{R}$, there exists a unique operator $A_B \in \mathcal{L}(H)$ such that

$$B(x, y) = \langle A_B x, y \rangle_H$$

for all $x, y \in H$. The correspondence $B \longmapsto A_B$ is a linear isometric isomorphism between $\mathcal{L}^2(H; \mathbb{R})$ and $\mathcal{L}(H)$. Moreover, B is symmetric if and only if A_B is self-adjoint.
Define the rank of B to be the rank of A_B. With this convention, symmetric bilinear forms of finite rank

correspond exactly to self-adjoint operators of finite rank. If $\mathcal{F}_s(H)$ denotes the subspace of these forms, then its closure in $\mathcal{L}^2_s(H;\mathbb{R})$ corresponds to the space of compact self-adjoint operators. In particular, if H is infinite-dimensional and $B_0(x,y) := \langle x, y\rangle_H$, then $B_0 \notin \overline{\mathcal{F}_s(H)}$.

Proof. For fixed $x \in H$, the map $y \longmapsto B(x,y)$ belongs to H'. Theorem B.3.12 gives a unique vector $A_B x \in H$ satisfying $B(x,y) = \langle A_B x, y\rangle_H$ for every $y \in H$. Uniqueness of the Riesz representatives shows that A_B is linear. Similarly,

$$\|A_B x\|_H = \sup_{\substack{y\in H\\ \|y\|_H\le 1}} |B(x,y)| \le \|B\|\,\|x\|_H,$$

so $A_B \in \mathcal{L}(H)$ and $\|A_B\| \le \|B\|$. The reverse inequality follows from $|B(x,y)| \le \|A_B\|\|x\|_H\|y\|_H$, so $\|A_B\| = \|B\|$. Linearity and surjectivity of the correspondence follow by associating the form $B_A(x,y) := \langle Ax, y\rangle_H$ to $A \in \mathcal{L}(H)$.

Symmetry of B is equivalent to the identity $\langle A_B x, y\rangle_H = \langle x, A_B y\rangle_H$ for all $x, y \in H$, which is precisely condition $A_B = A_B^*$ of Theorem B.3.15. The assertion about rank is then immediate from the definition adopted.

It remains to identify the closure of $\mathcal{F}_s(H)$. Every norm limit of finite-rank self-adjoint operators is compact by Proposition B.2.35 and self-adjoint by the continuity of the adjoint established in Theorem B.3.15. Conversely, let $K \in \mathcal{K}(H)$ be self-adjoint. Proposition B.3.22 gives finite-rank operators T_n such that $T_n \to K$ in norm. The adjoint T_n^* also has finite rank. Indeed, $\operatorname{Ran}(T_n)$ is closed because it is finite-dimensional; if P_n is the orthogonal projection onto this range, then $T_n = P_n T_n$, and therefore $T_n^* = T_n^* P_n$. Thus the range of T_n^* is contained in the image under T_n^* of the finite-dimensional space $\operatorname{Ran}(P_n)$. Consequently, the operators $S_n := \dfrac{1}{2}(T_n + T_n^*)$ are self-adjoint and have finite rank. Moreover, using $K^* = K$ and $\|T_n^* - K^*\| = \|T_n - K\|$ gives $\|S_n - K\| \le \|T_n - K\| \to 0$.

Finally, if H is infinite-dimensional, an orthonormal sequence $(e_n)_{n\in\mathbb{N}}$ can be constructed inductively. Since $\|e_n - e_m\|_H = \sqrt{2}$ for $n \neq m$, the sequence (e_n) has no convergent subsequences. The identity on H is therefore not compact. Since B_0 corresponds to the identity, we conclude that $B_0 \notin \overline{\mathcal{F}_s(H)}$. □

Corollary B.3.24. Let H be a real Hilbert space and let $\ell, m \in H'$. The symmetric bilinear form

$$B_{\ell,m} := \ell \otimes m + m \otimes \ell, \qquad B_{\ell,m}(x,y) = \ell(x)m(y) + m(x)\ell(y),$$

has rank at most two.

Proof. Let $v_\ell, v_m \in H$ be the Riesz representatives of ℓ and m. The operator associated with $B_{\ell,m}$ is $x \longmapsto \ell(x)v_m + m(x)v_\ell$, whose image is contained in $\operatorname{span}\{v_\ell, v_m\}$. □

Theorem B.3.25. (Spectral theorem for compact self-adjoint operators) Let H be a Hilbert space and let $K \in \mathcal{K}(H)$ be self-adjoint. The nonzero eigenvalues of K are real, have finite multiplicity, and can accumulate only at 0. There exists an orthonormal family $(e_j)_{j\in J}$ of eigenvectors, with real eigenvalues $(\lambda_j)_{j\in J}$, such that

$$\overline{\operatorname{Ran}(K)} = \overline{\operatorname{span}\{e_j \mid j \in J\}}, \qquad Kx = \sum_{j\in J} \lambda_j \langle x, e_j\rangle_H e_j$$

for every $x \in H$, and for each $\varepsilon > 0$ there are only finitely many indices j with $|\lambda_j| \ge \varepsilon$. In particular, if H is separable, this family can be extended by an orthonormal basis of $\ker K$ to obtain an orthonormal basis of

H consisting of eigenvectors of K.

The proof can be found in [45, Theorem 2.2.16] and [120, 28].

B.3.5 Weak and strong regularity of Hilbert-space-valued maps

Scalar regularity of all the components of a Hilbert-space-valued map determines almost all of its norm regularity. Although the conclusion is formulated in terms of differentiability, the argument relies on the uniform boundedness principle and Riesz representation; it does not require differential calculus on Banach manifolds. For this reason, we include the result in this section.

Theorem B.3.26. (Weak and strong differentiability) Let $U \subseteq \mathbb{R}^n$ be open, let H be a Hilbert space, and let $k \in \mathbb{N}$. Suppose that $F\colon U \longrightarrow H$ is of class C^k in the weak sense, that is, for each $h \in H$ the scalar function $x \mapsto \langle F(x), h\rangle_H$ belongs to $C^k(U)$. Then F is of class C^{k-1} in norm. More precisely, for each multiindex α with $|\alpha| \le k$ there exists a unique map $F_\alpha\colon U \longrightarrow H$ such that

$$\langle F_\alpha(x), h\rangle_H = D^\alpha \langle F(\cdot), h\rangle_H(x), \qquad h \in H,$$

and, if $|\alpha| \le k-1$, the map F_α is norm-continuous and equals $D^\alpha F$. In particular, every weakly smooth map with values in H is smooth in norm. The same assertion holds for maps defined on a finite-dimensional manifold with or without boundary, after working in charts.

Another formulation of this result can be found in [74, Appendix B.5].

Proof. For $h \in H$, write $\varphi_h(y) := \langle F(y), h\rangle_H$. We begin by constructing the vectors $F_\alpha(x)$. If $\alpha = 0$, set $F_0 := F$. Now fix $x \in U$ and a multiindex α of length $r := |\alpha| \ge 1$. Choose indices $i_1, \dots, i_r \in \{1, \dots, n\}$ in which each i occurs exactly α_i times and, for a function G defined near y, denote its finite difference in the direction e_i by $\Delta_{t,i}G(y) := G(y + te_i) - G(y)$.
Take a sequence $t_\nu > 0$ tending to zero and small enough that all the points appearing in the following differences belong to U. Define

$$v_\nu := \frac{1}{t_\nu^r} \Delta_{t_\nu, i_1} \cdots \Delta_{t_\nu, i_r} F(x) \in H.$$

The fundamental theorem of calculus, applied successively to the scalar function φ_h, gives

$$\langle v_\nu, h\rangle_H = \int_{[0,1]^r} D^\alpha \varphi_h \left(x + t_\nu \sum_{j=1}^{r} s_j e_{i_j} \right) ds_1 \cdots ds_r.$$

Since $D^\alpha \varphi_h$ is continuous, it follows that $\langle v_\nu, h\rangle_H \longrightarrow D^\alpha \varphi_h(x)$ for every $h \in H$. In particular, the sequence of continuous antilinear functionals $T_\nu\colon H \longrightarrow \mathbb{K}$, given by $T_\nu(h) := \langle v_\nu, h\rangle_H$, is pointwise bounded. The Banach–Steinhaus theorem, Theorem B.2.15, applied to the linear functionals $h \mapsto \overline{T_\nu(h)}$, implies that there exists $C_{x,\alpha} > 0$ such that $\|T_\nu\| \le C_{x,\alpha}$ for every ν. Consequently, the pointwise limit

$$T_{x,\alpha}(h) := D^\alpha \varphi_h(x)$$

is antilinear and continuous and satisfies $|T_{x,\alpha}(h)| \le C_{x,\alpha}\|h\|_H$. The antilinear version of the Riesz representation theorem, Theorem B.3.12, obtained by conjugating the functional, determines a unique vector

$F_\alpha(x) \in H$ such that $T_{x,\alpha}(h) = \langle F_\alpha(x), h\rangle_H$ for every $h \in H$. Since x was arbitrary, this constructs $F_\alpha \colon U \longrightarrow H$ for each $|\alpha| \le k$. Uniqueness follows because the inner product separates points. Moreover, the identity

$$\langle F_\alpha(x), h\rangle_H = D^\alpha \varphi_h(x)$$

shows that each F_α is weakly continuous.

We now prove norm continuity for $|\alpha| \le k-1$. Fix a closed convex Euclidean ball $K \subseteq U$. For each $h \in H$ and each $i \in \{1,\dots,n\}$, the function $z \mapsto \langle F_{\alpha+e_i}(z), h\rangle_H = D^{\alpha+e_i}\varphi_h(z)$ is continuous and therefore bounded on K. Applying Banach–Steinhaus to the linear functionals $h \mapsto \overline{\langle F_{\alpha+e_i}(z), h\rangle_H}$, with $z \in K$ and $i \in \{1,\dots,n\}$, gives a constant $C_{K,\alpha} > 0$ such that

$$\|F_{\alpha+e_i}(z)\|_H \le C_{K,\alpha}$$

for every $z \in K$ and every i. If $x, y \in K$, the segment $x + t(y-x)$ is contained in K. The fundamental theorem of calculus applied to $D^\alpha\varphi_h$ gives

$$\langle F_\alpha(y) - F_\alpha(x), h\rangle_H = \int_0^1 \sum_{i=1}^n (y_i - x_i)\langle F_{\alpha+e_i}(x + t(y-x)), h\rangle_H \, dt.$$

Taking the supremum over $\|h\|_H \le 1$ yields

$$\|F_\alpha(y) - F_\alpha(x)\|_H \le C_{K,\alpha} \sum_{i=1}^n |y_i - x_i| \le \sqrt{n}\, C_{K,\alpha}\|y - x\|.$$

Thus, F_α is locally Lipschitz and, in particular, norm-continuous for $|\alpha| \le k-1$.

It remains to identify these maps with the strong derivatives of F. Let $|\alpha| \le k-2$ and define $A_\alpha(x) \in \mathcal{L}(\mathbb{R}^n, H)$ by

$$A_\alpha(x)v := \sum_{i=1}^n v_i F_{\alpha+e_i}(x).$$

Fix $x \in U$ and take v small enough that the segment $x + tv$, with $0 \le t \le 1$, is contained in a closed ball $K \subseteq U$. For every $h \in H$, the fundamental theorem of calculus gives

$$\begin{aligned}\langle F_\alpha(x+v) - F_\alpha(x) - A_\alpha(x)v, h\rangle_H &\\ = \int_0^1 \sum_{i=1}^n v_i \left\langle F_{\alpha+e_i}(x+tv) - F_{\alpha+e_i}(x), h\right\rangle_H dt.&\end{aligned}$$

Taking the supremum over $\|h\|_H \le 1$ again, we obtain

$$\frac{\|F_\alpha(x+v) - F_\alpha(x) - A_\alpha(x)v\|_H}{\|v\|_{\mathbb{R}^n}} \le \sqrt{n} \max_{1\le i\le n} \sup_{0\le t\le 1} \|F_{\alpha+e_i}(x+tv) - F_{\alpha+e_i}(x)\|_H.$$

The right-hand side tends to zero as $v \to 0$, because the maps $F_{\alpha+e_i}$ are norm-continuous. This proves that F_α is Fréchet differentiable and that $DF_\alpha(x) = A_\alpha(x)$. Since the $F_{\alpha+e_i}$ are continuous, $x \mapsto A_\alpha(x)$ is also continuous in the operator norm. Induction on $|\alpha|$ shows that $F \in C^{k-1}(U, H)$ and that its coordinate derivatives are the corresponding maps F_α.

If the domain is a finite-dimensional manifold, the argument applies to F in each chart; since norm regularity is a local property invariant under smooth changes of coordinates, the conclusions fit together glob-

ally. □

B.4 Closed forms, spectral calculus, and contraction semigroups

The elliptic operators appearing in global analysis are generally unbounded. Their domain is part of the definition and cannot be omitted. In L^2, closed quadratic forms provide a particularly stable way to construct self-adjoint realizations; in L^p, strongly continuous semigroups and their generators play the corresponding role. We collect here the results used in constructing the heat semigroup and Bessel potentials. For closed forms we follow [74, Appendix B], and for semigroups, [60, Chapter II].

B.4.1 Closed forms and the Friedrichs realization

Definition B.4.1. Let H be a complex Hilbert space. A **sesquilinear form** on H is a map

$$\mathfrak{a}\colon V \times V \longrightarrow \mathbb{C},$$

where $V \subseteq H$ is a dense vector subspace, linear in the first variable and antilinear in the second. The form is called:

(a) **symmetric** if $\mathfrak{a}(u,v) = \overline{\mathfrak{a}(v,u)}$;

(b) **nonnegative** if $\mathfrak{a}(u,u) \geq 0$;

(c) **bounded below** if there exists $c \in \mathbb{R}$ such that $\mathfrak{a}(u,u) \geq c\|u\|_H^2$;

(d) **closed** if V is complete with respect to the norm

$$\|u\|_{\mathfrak{a}}^2 := \mathfrak{a}(u,u) + (1-c)\|u\|_H^2,$$

where c is any lower bound strictly less than 1.

The space V is called the domain of the form and is denoted by $\mathcal{D}(\mathfrak{a})$.

Up to equivalence, the preceding norm does not depend on the chosen lower bound. For a nonnegative form we simply use

$$\|u\|_{\mathfrak{a}}^2 := \|u\|_H^2 + \mathfrak{a}(u,u).$$

Theorem B.4.2. (First representation theorem for closed forms) Let $\mathfrak{a}$ be a densely defined, symmetric, nonnegative, closed sesquilinear form on a Hilbert space H. There exists a unique nonnegative self-adjoint operator

$$A\colon \mathcal{D}(A) \subseteq H \longrightarrow H$$

such that $\mathcal{D}(A) \subseteq \mathcal{D}(\mathfrak{a})$ and

$$\mathfrak{a}(u,v) = \langle Au, v\rangle_H, \qquad u \in \mathcal{D}(A), \quad v \in \mathcal{D}(\mathfrak{a}).$$

More precisely,

$$\mathcal{D}(A) = \{u \in \mathcal{D}(\mathfrak{a}) \mid \text{there exists } f \in H \text{ such that } \mathfrak{a}(u,v) = \langle f, v\rangle_H \text{ for every } v \in \mathcal{D}(\mathfrak{a})\},$$

and then $Au = f$.

Proof. Equip $V := \mathcal{D}(\mathfrak{a})$ with the inner product

$$\langle u, v\rangle_{\mathfrak{a}} := \langle u, v\rangle_H + \mathfrak{a}(u, v).$$

Since the form is closed, V is a Hilbert space. For each $f \in H$, the antilinear functional $v \mapsto \langle f, v\rangle_H$ is continuous on V, since $\|v\|_H \le \|v\|_{\mathfrak{a}}$. The antilinear version of Theorem B.3.12 provides a unique $Rf \in V$ such that

$$\langle Rf, v\rangle_H + \mathfrak{a}(Rf, v) = \langle f, v\rangle_H, \qquad v \in V.$$

The operator $R\colon H \longrightarrow H$, obtained by composing with the inclusion $V \hookrightarrow H$, is linear and bounded. It is injective: if $Rf = 0$, then $\langle f, v\rangle_H = 0$ for every $v \in V$, and density of V gives $f = 0$. For $f, h \in H$, apply the defining identity to (f, Rh) and (h, Rf); symmetry of $\mathfrak{a}$ gives

$$\langle f, Rh\rangle_H = \langle Rf, h\rangle_H.$$

Thus R is self-adjoint. Taking $v = Rf$ gives

$$\langle f, Rf\rangle_H = \|Rf\|_H^2 + \mathfrak{a}(Rf, Rf) \ge 0,$$

so R is positive. Its range is dense: if $h \perp \mathrm{Ran}(R)$, self-adjointness implies $Rh = 0$ and injectivity gives $h = 0$. Define

$$A := R^{-1} - I, \qquad \mathcal{D}(A) := \mathrm{Ran}(R).$$

If $u = Rf$, the identity defining R becomes

$$\mathfrak{a}(u, v) = \langle f - u, v\rangle_H = \langle Au, v\rangle_H, \qquad v \in V.$$

This formula proves the characterization of the domain and nonnegativity. Moreover, A is symmetric and $A + I = R^{-1}$ is surjective. If $y \in \mathcal{D}(A^*)$, choose $x \in \mathcal{D}(A)$ with

$$(A + I)x = (A^* + I)y.$$

Since $A \subseteq A^*$, we have $(A^* + I)(y - x) = 0$. But

$$\ker(A^* + I) = \mathrm{Ran}(A + I)^{\perp} = \{0\},$$

so $y = x \in \mathcal{D}(A)$. Thus $A = A^*$, without using the spectral calculus introduced in the next subsection. Uniqueness follows from the characterization of the domain.

□

Corollary B.4.3. (Variational characterization of the resolvent) Let A be the operator associated with the form $\mathfrak{a}$ in Theorem B.4.2. If $\lambda > 0$ and $f \in H$, then $u = (\lambda I + A)^{-1} f$ is the unique element of $\mathcal{D}(\mathfrak{a})$ satisfying

$$\mathfrak{a}(u, v) + \lambda\langle u, v\rangle_H = \langle f, v\rangle_H$$

for every $v \in \mathcal{D}(\mathfrak{a})$.

Proof. The expression $\langle u, v\rangle_{\mathfrak{a},\lambda} := \mathfrak{a}(u,v) + \lambda\langle u, v\rangle_H$ defines an inner product on $\mathcal{D}(\mathfrak{a})$ whose norm is equivalent to the form norm. For $f \in H$, the functional $v \mapsto \langle f, v\rangle_H$ is continuous with respect to that norm. The Riesz representation theorem, Theorem B.3.12, provides a unique $u \in \mathcal{D}(\mathfrak{a})$ satisfying the identity in the statement. Rewriting it as $\mathfrak{a}(u,v) = \langle f - \lambda u, v\rangle_H$ and using the characterization of $\mathcal{D}(A)$ in Theorem B.4.2 gives $u \in \mathcal{D}(A)$ and $Au = f - \lambda u$. Therefore $(\lambda I + A)u = f$, and the uniqueness already proved shows that $u = (\lambda I + A)^{-1} f$. □

Definition B.4.4. (Friedrichs realization) Let S be a symmetric, densely defined operator bounded below on H, and choose $c \in \mathbb{R}$ such that $S \geq cI$. The nonnegative form

$$\mathfrak{b}_c(u,v) := \langle Su, v\rangle_H - c\langle u, v\rangle_H, \qquad u, v \in \mathcal{D}(S),$$

is closable. Let B_c be the operator associated with its closure by Theorem B.4.2. The operator

$$S_F := B_c + cI, \qquad \mathcal{D}(S_F) := \mathcal{D}(B_c),$$

is called the **Friedrichs realization** of S. It is independent of the chosen lower bound c and is a self-adjoint extension of S with the same lower bound.

Proof. Complete $\mathcal{D}(S)$ with respect to the inner product

$$(u,v)_c := \langle u, v\rangle_H + \mathfrak{b}_c(u,v)$$

and denote the resulting Hilbert space by V_c. The inclusion into H extends to a continuous operator $J_c \colon V_c \to H$. We prove that it is injective. If $w \in \ker J_c$, choose $u_j \in \mathcal{D}(S)$ such that $u_j \to w$ in V_c; then $u_j \to 0$ in H. For each $v \in \mathcal{D}(S)$, symmetry of S gives

$$(w,v)_c = \lim_{j\to\infty} (u_j, v)_c = \lim_{j\to\infty} \langle u_j, (S + (1-c)I)v\rangle_H = 0.$$

Density of $\mathcal{D}(S)$ in V_c implies $w = 0$. We may therefore identify V_c with a subspace of H. The limit of $\mathfrak{b}_c(u_j, v_j)$ for sequences converging in V_c defines a closed form on this subspace. It is precisely the closure of $\mathfrak{b}_c$, since $\mathcal{D}(S)$ is dense in the form norm.

If $u \in \mathcal{D}(S)$, the identity $\mathfrak{b}_c(u,v) = \langle (S - cI)u, v\rangle_H$, initially for $v \in \mathcal{D}(S)$, passes to the limit for every $v \in V_c$. The characterization of the domain of the associated operator shows that $B_c u = (S - cI)u$; thus S_F extends S. For two lower bounds c, d, the form norms are equivalent, since their squares differ by $(d-c)\|u\|_H^2$ and both dominate $\|u\|_H^2$. Their completions are therefore identified with the same subspace of H. The closed forms satisfy

$$\overline{\mathfrak{b}_c}(u,v) + c\langle u, v\rangle_H = \overline{\mathfrak{b}_d}(u,v) + d\langle u, v\rangle_H.$$

The variational characterization of their operators gives $B_c + cI = B_d + dI$, including their domains. This proves independence of the choice of lower bound. □

Proposition B.4.5. (Criterion for essential self-adjointness) Let S be a symmetric, densely defined operator on a complex Hilbert space. Suppose that $S \geq 0$. Then S is essentially self-adjoint if and only if

$$\ker(S^* + I) = \{0\}.$$

More generally, if $S \geq -cI$, one may replace I by λI with $\lambda > c$.

Proof. For $u \in \mathcal{D}(S)$,

$$\|(S+I)u\|_H \|u\|_H \geq \operatorname{Re}\langle (S+I)u, u\rangle_H \geq \|u\|_H^2,$$

so $\|(S+I)u\|_H \geq \|u\|_H$. The same estimate holds for the closure $\overline{S}$, so $\operatorname{Ran}(\overline{S}+I)$ is closed. On the other hand,

$$\operatorname{Ran}(S+I)^{\perp} = \ker(S^* + I).$$

If this kernel is trivial, $\operatorname{Ran}(S+I)$ is dense. The preceding estimate also shows that

$$\operatorname{Ran}(\overline{S}+I) = \overline{\operatorname{Ran}(S+I)} = H.$$

Let $y \in \mathcal{D}(S^*) = \mathcal{D}((\overline{S})^*)$. Choose $x \in \mathcal{D}(\overline{S})$ such that

$$(\overline{S}+I)x = (S^*+I)y.$$

Since $\overline{S} \subseteq S^*$, we obtain $(S^*+I)(y-x) = 0$. The hypothesis gives $y = x$, so $\mathcal{D}(S^*) \subseteq \mathcal{D}(\overline{S})$ and $\overline{S}$ is self-adjoint. Conversely, if $\overline{S}$ is self-adjoint and nonnegative, then -1 belongs to its resolvent set; hence $\ker(S^*+I) = \ker(\overline{S}+I) = \{0\}$. For $S \geq -cI$, apply the same argument to $S + cI$ and any shift $\lambda > c$. □

B.4.2 Spectral calculus for self-adjoint operators

Theorem B.4.6. (Spectral theorem) Let A be a self-adjoint operator on a complex Hilbert space H. There exists a unique spectral measure E_A on $\mathbb{R}$ such that

$$A = \int_{\mathbb{R}} \lambda \, dE_A(\lambda).$$

If $m\colon \mathbb{R} \longrightarrow \mathbb{C}$ is Borel measurable, define

$$m(A) := \int_{\mathbb{R}} m(\lambda)\, dE_A(\lambda)$$

with domain

$$\mathcal{D}(m(A)) = \left\{ u \in H \,\middle|\, \int_{\mathbb{R}} |m(\lambda)|^2 \, d\mu_u(\lambda) < \infty \right\},$$

where $\mu_u(B) := \langle E_A(B)u, u\rangle_H$. We have

$$\|m(A)u\|_H^2 = \int_{\mathbb{R}} |m(\lambda)|^2 \, d\mu_u(\lambda).$$

If m is bounded, then $m(A) \in \mathcal{L}(H)$ and

$$\|m(A)\|_{\mathcal{L}(H)} \le \|m\|_{\infty,\mathbb{R}} := \sup_{\lambda \in \mathbb{R}} |m(\lambda)|.$$

Moreover, the calculus respects sums, products, and conjugation on their natural domains.

A complete proof, in this formulation using spectral measures and Borel functional calculus, is given in [74, Theorems B.4 and B.5]. The norm formula and the rules of the functional calculus are first obtained for simple functions, then for bounded Borel functions, and finally by spectral truncation.

Corollary B.4.7. (Square-root domain associated with a closed form) Let $\mathfrak{a}$ be a form as in Theorem B.4.2, and let A be its associated self-adjoint operator. Then

$$\mathcal{D}(A^{\frac{1}{2}}) = \mathcal{D}(\mathfrak{a}), \qquad \mathfrak{a}(u,v) = \langle A^{\frac{1}{2}} u, A^{\frac{1}{2}} v \rangle_H.$$

Proof. Return to $V = \mathcal{D}(\mathfrak{a})$ and the resolvent R constructed in the proof of Theorem B.4.2. The subspace $\mathcal{D}(A) = \mathrm{Ran}(R)$ is dense in V for the form norm. Indeed, if $w \in V$ is orthogonal to $\mathrm{Ran}(R)$ with respect to $\langle \cdot, \cdot \rangle_{\mathfrak{a}}$, then, for every $f \in H$,

$$0 = \langle Rf, w \rangle_{\mathfrak{a}} = \langle f, w \rangle_H,$$

and hence $w = 0$.
For $u \in \mathcal{D}(A)$, the spectral calculus and the representation of the form give

$$\mathfrak{a}(u,u) = \langle Au, u \rangle_H = \|A^{\frac{1}{2}} u\|_H^2.$$

Moreover, $\mathcal{D}(A)$ is a core for $A^{\frac{1}{2}}$. If $u \in \mathcal{D}(A^{\frac{1}{2}})$ and $u_N := E_A([0,N])u$, then $u_N \in \mathcal{D}(A)$ and

$$\|u_N - u\|_H^2 + \|A^{\frac{1}{2}}(u_N - u)\|_H^2 = \int_{(N,+\infty)} (1+\lambda)\, d\mu_u(\lambda) \longrightarrow 0.$$

Thus V and $\mathcal{D}(A^{\frac{1}{2}})$ are the completions of $\mathcal{D}(A)$ with respect to the same norm. They agree as subspaces of H, and the sesquilinear identity follows by polarization. □

Corollary B.4.8. Let A be self-adjoint and nonnegative. For $s \in \mathbb{R}$, define $(I+A)^s$ and, for $s \ge 0$, A^s by the spectral calculus. If $s > 0$, then $(I+A)^{-s}$ is bounded, injective, and

$$\mathrm{Ran}\big((I+A)^{-s}\big) = \mathcal{D}\big((I+A)^{s}\big).$$

The operators $(I+A)^s$ and $(I+A)^{-s}$ are inverses of one another on these domains.

Proof. The assertions are verified on each spectral fiber using the functions $(1+\lambda)^{\pm s}$. Injectivity follows from the fact that $(1+\lambda)^{-s} > 0$ for every $\lambda \ge 0$. □

Proposition B.4.9. (Spectral semigroup) Let A be self-adjoint and nonnegative. Then $T_t := e^{-tA}$, $t \ge 0$, is a strongly continuous semigroup of self-adjoint contractions. For each $u \in H$, $T_t u \in \mathcal{D}(A^m)$ if $t > 0$ and $m \in \mathbb{N}$,

and

$$\frac{d}{dt}T_t u = -AT_t u \qquad (t > 0).$$

If $u \in \mathcal{D}(A)$, the right derivative at $t = 0$ also exists and equals $-Au$.

Proof. The algebraic properties follow from $e^{-(t+s)\lambda} = e^{-t\lambda}e^{-s\lambda}$, and the bound $|e^{-t\lambda}| \le 1$ gives contractivity. For strong continuity, observe that

$$\|T_t u - u\|_H^2 = \int_{[0,+\infty)} |e^{-t\lambda} - 1|^2 \, d\mu_u(\lambda).$$

The integrand converges pointwise to zero as $t \to 0^+$ and is dominated by the constant 4, which is integrable with respect to the finite measure μ_u; dominated convergence proves $T_t u \to u$.
If $t > 0$, then

$$\|A^m T_t u\|_H^2 = \int_{[0,+\infty)} \lambda^{2m} e^{-2t\lambda} \, d\mu_u(\lambda) \le \left(\sup_{\lambda \ge 0} \lambda^{2m} e^{-2t\lambda} \right) \|u\|_H^2,$$

so $T_t u \in \mathcal{D}(A^m)$. Now fix $t_0 > 0$ and take $|h| < \frac{t_0}{2}$. The mean value theorem gives

$$\left| \frac{e^{-(t_0+h)\lambda} - e^{-t_0\lambda}}{h} \right| \le \lambda e^{-\frac{t_0}{2}\lambda}.$$

Thus the difference between this quotient and $-\lambda e^{-t_0\lambda}$ is dominated by $2\lambda e^{-\frac{t_0}{2}\lambda}$, a bounded function of λ. Dominated convergence with respect to μ_u proves differentiability at t_0 and identity $\frac{d}{dt}T_t u = -AT_t u$.
Finally, if $u \in \mathcal{D}(A)$, then

$$\left| \frac{e^{-t\lambda} - 1}{t} \right| \le \lambda$$

for $t > 0$. The square of the dominating function is integrable with respect to μ_u, precisely because $u \in \mathcal{D}(A)$. One last application of dominated convergence gives the right derivative at $t = 0$. □

B.4.3 Strongly continuous semigroups on Banach spaces

Definition B.4.10. Let X be a Banach space. A family $(T_t)_{t \ge 0} \subseteq \mathcal{L}(X)$ is a **strongly continuous semigroup**, or a C_0-semigroup, if

$$T_0 = I, \qquad T_{t+s} = T_t T_s, \qquad \lim_{t \to 0^+} \|T_t x - x\|_X = 0$$

for every $x \in X$. It is a **contraction semigroup** if $\|T_t\| \le 1$ for every $t \ge 0$.

Definition B.4.11. The **infinitesimal generator** of a C_0-semigroup (T_t) is the operator

$$Gx := \lim_{t \to 0^+} \frac{T_t x - x}{t}$$

defined on the set $\mathcal{D}(G)$ of elements for which the limit exists in X.

Proposition B.4.12. Let G be the generator of a C_0-semigroup $(T_t)_{t\ge 0}$ on X. Then G is closed and densely defined, and $\mathcal{D}(G^m)$ is dense in X for every $m \in \mathbb{N}$. Moreover, $T_t\mathcal{D}(G) \subseteq \mathcal{D}(G)$, $GT_t x = T_t G x$ for $x \in \mathcal{D}(G)$, and

$$T_t x - x = \int_0^t T_s G x \, ds, \qquad x \in \mathcal{D}(G).$$

Proof. For $x \in X$ and $h > 0$, define $x_h := \frac{1}{h}\int_0^h T_s x \, ds$. Strong continuity shows that $x_h \to x$. A calculation using the semigroup property gives

$$\frac{T_t x_h - x_h}{t} = \frac{1}{h}\left(\frac{1}{t}\int_h^{h+t} T_s x \, ds - \frac{1}{t}\int_0^t T_s x \, ds\right),$$

and letting $t \to 0^+$ yields $x_h \in \mathcal{D}(G)$. Thus the domain is dense. To obtain density for the powers, define recursively $S_h x := \frac{1}{h}\int_0^h T_s x \, ds$ and $S_{h_1,\dots,h_m} x := S_{h_m} \cdots S_{h_1} x$. The preceding calculation shows that $S_h(X) \subseteq \mathcal{D}(G)$ and, since S_h commutes with T_t, it also commutes with G on $\mathcal{D}(G)$. Induction gives $S_{h_1,\dots,h_m} x \in \mathcal{D}(G^m)$. If we first let $h_m \to 0^+$, then $h_{m-1} \to 0^+$, and so on, strong continuity implies $S_{h_1,\dots,h_m} x \to x$. Hence $\mathcal{D}(G^m)$ is dense in X.

If $x_n \to x$ and $Gx_n \to y$, the integral identity gives

$$T_t x_n - x_n = \int_0^t T_s G x_n \, ds.$$

Passing to the limit yields $T_t x - x = \int_0^t T_s y \, ds$. Dividing by t and letting $t \to 0^+$ shows that $x \in \mathcal{D}(G)$ and $Gx = y$, so G is closed. The remaining identities follow by using $T_{t+h} = T_t T_h$ and differentiating in the strong topology. □

Definition B.4.13. Let $A\colon \mathcal{D}(A) \subseteq X \longrightarrow X$ be densely defined. The operator A is called **dissipative** if for each $x \in \mathcal{D}(A)$ there exists $x^* \in X'$ such that

$$\|x^*\|_{X'} = \|x\|_X, \qquad x^*(x) = \|x\|_X^2, \qquad \operatorname{Re} x^*(Ax) \le 0.$$

It is called **accretive** if $-A$ is dissipative. A dissipative operator is **maximally dissipative** if $\operatorname{Ran}(\lambda I - A) = X$ for some, and hence every, $\lambda > 0$.

Proposition B.4.14. (Resolvent as a Laplace transform) Let $(T_t)_{t\ge 0}$ be a contraction C_0-semigroup with generator G. For each $\lambda > 0$ and $x \in X$, the Bochner integral

$$R_\lambda x := \int_0^\infty e^{-\lambda t} T_t x \, dt$$

converges, and

$$R_\lambda = (\lambda I - G)^{-1}, \qquad \|R_\lambda\| \le \frac{1}{\lambda}.$$

Proof. Convergence and the bound follow from

$$\int_0^\infty e^{-\lambda t}\|T_t x\|_X\,dt \le \frac{1}{\lambda}\|x\|_X.$$

If $x \in \mathcal{D}(G)$, then $\dfrac{d}{dt}T_t x = T_t G x$. Integrating by parts gives

$$R_\lambda(\lambda I - G)x = -\int_0^\infty \frac{d}{dt}\left(e^{-\lambda t}T_t x\right)dt = x.$$

On the other hand, the truncated integrals belong to $\mathcal{D}(G)$, and an analogous calculation shows that $(\lambda I - G)R_\lambda x = x$. Closedness of G allows passage to the limit at the infinite endpoint. □

Theorem B.4.15. (Lumer–Phillips) Let A be a closed, densely defined linear operator on a Banach space X. The following assertions are equivalent:

(a) A is the generator of a contraction C_0-semigroup;

(b) A is maximally dissipative;

(c) A is dissipative and $\operatorname{Ran}(\lambda I - A) = X$ for some $\lambda > 0$.

In this case,

$$\|(\lambda I - A)^{-1}\|_{\mathcal{L}(X)} \le \frac{1}{\lambda}, \qquad \lambda > 0.$$

Proof. First suppose that A generates a contraction semigroup. For $x \in \mathcal{D}(A)$, choose by Hahn–Banach an element $x^* \in X'$ with $\|x^*\| = \|x\|$ and $x^*(x) = \|x\|^2$. Since $\operatorname{Re} x^*(T_t x) \le \|x\|^2$, dividing the difference by $t > 0$ and passing to the limit gives $\operatorname{Re} x^*(Ax) \le 0$. Proposition B.4.14 proves surjectivity of $\lambda I - A$ for every $\lambda > 0$.
Now suppose (c). Dissipativity implies, for $x \in \mathcal{D}(A)$ and $\lambda > 0$,

$$\lambda\|x\|^2 \le \operatorname{Re} x^*((\lambda I - A)x) \le \|x\|\,\|(\lambda I - A)x\|.$$

Thus $\lambda I - A$ is injective and its inverse on its range has norm at most $1/\lambda$. The set I of positive parameters for which it is surjective is nonempty by hypothesis. It is open by the Neumann series. It is also closed in $(0,\infty)$: if $\lambda_j \in I$ and $\lambda_j \to \lambda > 0$, the resolvent identity and its bounds show that $R_{\lambda_j} := (\lambda_j I - A)^{-1}$ is Cauchy in norm, since

$$\|R_{\lambda_j} - R_{\lambda_k}\| \le \frac{|\lambda_j - \lambda_k|}{\lambda_j \lambda_k}.$$

If its limit is R, for $y \in X$ we have $R_{\lambda_j} y \to Ry$ and $AR_{\lambda_j} y = \lambda_j R_{\lambda_j} y - y \to \lambda Ry - y$. Closedness of A gives $(\lambda I - A)Ry = y$. Since $(0,\infty)$ is connected, $I = (0,\infty)$.
For each $\lambda > 0$, consider the Yosida approximants

$$A_\lambda := \lambda A(\lambda I - A)^{-1}.$$

They are bounded, since $A_\lambda = \lambda^2 R_\lambda - \lambda I$, and

$$\|e^{tA_\lambda}\| \le e^{-\lambda t}e^{t\lambda^2\|R_\lambda\|} \le 1, \qquad t \ge 0.$$

Moreover, $\lambda R_\lambda y \to y$ for every $y \in X$. Indeed, for $y \in \mathcal{D}(A)$,

$$\lambda R_\lambda y - y = R_\lambda A y, \qquad \|R_\lambda A y\| \le \lambda^{-1}\|Ay\|,$$

and density of $\mathcal{D}(A)$, together with $\|\lambda R_\lambda\| \le 1$, extends the limit to every X. Thus $A_\lambda x = \lambda R_\lambda A x \to Ax$ if $x \in \mathcal{D}(A)$.

The resolvent identity shows that A_λ and A_μ commute. Differentiating $s \mapsto e^{(t-s)A_\lambda} e^{sA_\mu} x$ and integrating gives

$$\|e^{tA_\lambda} x - e^{tA_\mu} x\| \le t\|(A_\lambda - A_\mu)x\|, \qquad x \in \mathcal{D}(A).$$

Thus the contractions converge strongly, uniformly for $0 \le t \le T$, on the dense subspace $\mathcal{D}(A)$. The uniform bound by one extends this convergence to all of X. Denote the limit by T_t. Passing to the limit in $e^{(t+s)A_\lambda} = e^{tA_\lambda} e^{sA_\lambda}$ gives the semigroup property. For $x \in \mathcal{D}(A)$, $\|T_t x - x\| \le t\|Ax\|$; density and contractivity give strong continuity at zero for every $x \in X$.

If G is its generator, the identity

$$e^{tA_\lambda} x - x = \int_0^t e^{sA_\lambda} A_\lambda x \, ds$$

passes to the limit, for $x \in \mathcal{D}(A)$, as $T_t x - x = \displaystyle\int_0^t T_s A x \, ds$. Dividing by t gives $Gx = Ax$, so $A \subseteq G$. For $y \in \mathcal{D}(G)$, choose $x \in \mathcal{D}(A)$ with $(\lambda I - A)x = (\lambda I - G)y$. Then $(\lambda I - G)(y - x) = 0$. The semigroup resolvent formula implies $y = x$, and hence $G = A$. This proves (a). The argument also proves that surjectivity for one parameter is equivalent to surjectivity for all parameters, completing the equivalence with (b) and the resolvent bound. □

Proposition B.4.16. (Exponential formula) If G generates a contraction C_0-semigroup (T_t), then

$$T_t x = \lim_{n\to\infty} \left(I - \frac{t}{n} G\right)^{-n} x$$

for every $x \in X$, uniformly for t in compact intervals of $[0, \infty)$.

Proof. For $h > 0$, the Laplace formula for the resolvent gives

$$(I - hG)^{-1} x = \int_0^\infty e^{-r} T_{hr} x \, dr.$$

Iterating this identity, Fubini and the semigroup property yield

$$(I - hG)^{-n} x = \frac{1}{(n-1)!} \int_0^\infty e^{-r} r^{n-1} T_{hr} x \, dr.$$

To verify the factor, the step from n to $n+1$ integrates over $0 < s < r$ and uses $\displaystyle\int_0^r s^{n-1} \, ds = r^n/n$. The measure $d\nu_n(r) := e^{-r} r^{n-1} dr/(n-1)!$ has mass one, mean n, and variance n, as is checked by integrating by parts the moments of orders zero, one, and two. Fix $T > 0$ and take $h = t/n$, with $0 < t \le T$. Then

$$\int_0^\infty \left|\frac{tr}{n} - t\right|^2 d\nu_n(r) = \frac{t^2}{n} \le \frac{T^2}{n}.$$

The function $s \mapsto T_s x$ is uniformly continuous on $[0, T+1]$. Given $0 < \delta < 1$, split the integral according to $|tr/n - t| < \delta$ or $|tr/n - t| \geq \delta$. If $\omega_x(\delta)$ is its modulus of continuity on that interval, contractivity and Chebyshev's inequality give

$$\sup_{0<t\leq T} \|(I - (t/n)G)^{-n} x - T_t x\| \leq \omega_x(\delta) + \frac{2\|x\|T^2}{n\delta^2}.$$

First let $n \to \infty$, then $\delta \downarrow 0$. For $t = 0$, both operators are the identity, so convergence is uniform on $[0, T]$. □

Proposition B.4.17. (Bounded perturbations of generators) Let G be the generator of a C_0-semigroup $(T_t)_{t\geq 0}$ on a Banach space X, and suppose that

$$\|T_t\|_{\mathcal{L}(X)} \leq e^{\omega t}, \qquad t \geq 0,$$

for some $\omega \in \mathbb{R}$. If $B \in \mathcal{L}(X)$, then the operator

$$G + B, \qquad \mathcal{D}(G + B) = \mathcal{D}(G),$$

generates a C_0-semigroup $(S_t)_{t\geq 0}$. This semigroup is given by the Dyson–Phillips series

$$S_t = \sum_{j=0}^{\infty} S_j(t), \qquad S_0(t) := T_t, \qquad S_{j+1}(t)x := \int_0^t T_{t-\tau} B S_j(\tau) x \, d\tau, \tag{B.2}$$

which converges in operator norm uniformly for t in compact intervals. Moreover,

$$\|S_t\|_{\mathcal{L}(X)} \leq e^{(\omega + \|B\|)t}.$$

In particular, if (T_t) is a contraction semigroup and $\mu \geq \|B\|$, then $(e^{-\mu t} S_t)_{t\geq 0}$ is a contraction C_0-semigroup with generator $G + B - \mu I$.

Proof. The estimate follows by induction. For $j = 0$, it is the hypothesis on T_t. If it holds for j, then

$$\begin{aligned} \|S_{j+1}(t)\| &\leq \int_0^t e^{\omega(t-\tau)} \|B\| e^{\omega\tau} \frac{\|B\|^j \tau^j}{j!} \, d\tau \\ &= e^{\omega t} \frac{\|B\|^{j+1} t^{j+1}}{(j+1)!}. \end{aligned}$$

Thus the series in (B.2) converges absolutely in $\mathcal{L}(X)$, uniformly as t ranges over a compact interval, and

$$\|S_t\| \leq e^{\omega t} \sum_{j=0}^{\infty} \frac{(t\|B\|)^j}{j!} = e^{(\omega + \|B\|)t}.$$

Strong continuity follows from continuity of T_t, the preceding estimate, and uniform convergence of the series. The semigroup identity is first verified term by term using Fubini and the relation $T_t T_s = T_{t+s}$, after which the absolutely convergent series are summed.

If $x \in \mathcal{D}(G)$, the first iteration satisfies

$$\frac{1}{t} S_1(t)x = \frac{1}{t} \int_0^t T_{t-\tau} B T_\tau x \, d\tau \longrightarrow Bx$$

as $t \to 0^+$. For the terms with $j \geq 2$ and $0 < t \leq 1$, the bound already proved gives

$$\left\| \sum_{j=2}^{\infty} S_j(t) \right\| \leq e^{\max\{\omega,0\}} \sum_{j=2}^{\infty} \frac{(t\|B\|)^j}{j!} \leq \frac{1}{2} e^{\max\{\omega,0\}+\|B\|} \|B\|^2 t^2.$$

The last inequality follows from $e^a - 1 - a \leq \frac{1}{2} e^{\|B\|} a^2$ for $0 \leq a \leq \|B\|$. Thus, upon dividing the sum by t, its norm tends to zero as $t \to 0^+$. Together with $\frac{T_t x - x}{t} \to Gx$, this shows that the generator of (S_t) extends $G + B$ on $\mathcal{D}(G)$. Denote this generator by H. The integral formula

$$S_t x = T_t x + \int_0^t T_{t-\tau} B S_\tau x \, d\tau$$

also allows us to prove the reverse inclusion of domains. Indeed, if $x \in \mathcal{D}(H)$, then

$$\frac{T_t x - x}{t} = \frac{S_t x - x}{t} - \frac{1}{t} \int_0^t T_{t-\tau} B S_\tau x \, d\tau.$$

The first term on the right-hand side converges to Hx as $t \to 0^+$. For the integrand of the second term, write

$$T_{t-\tau} B S_\tau x - Bx = T_{t-\tau} B (S_\tau x - x) + (T_{t-\tau} - I) Bx.$$

If $0 < t \leq 1$, the norm of the first summand is bounded by $e^{\max\{\omega,0\}} \|B\| \sup_{0 \leq s \leq t} \|S_s x - x\|$, and that of the second by $\sup_{0 \leq s \leq t} \|(T_s - I)Bx\|$. Both bounds tend to zero by strong continuity at time zero. Thus

$$\left\| \frac{1}{t} \int_0^t T_{t-\tau} B S_\tau x \, d\tau - Bx \right\| \leq \sup_{0 \leq \tau \leq t} \|T_{t-\tau} B S_\tau x - Bx\| \longrightarrow 0.$$

It follows that $\lim_{t \to 0^+} (T_t x - x)/t = Hx - Bx$. The definition of G implies that $x \in \mathcal{D}(G)$ and $Gx = Hx - Bx$. Hence $\mathcal{D}(H) \subseteq \mathcal{D}(G)$; together with the preceding inclusion, this proves that $\mathcal{D}(H) = \mathcal{D}(G)$ and $H = G + B$. Finally, $e^{-\mu t} S_t$ has generator $G + B - \mu I$ and, if $\omega = 0$ and $\mu \geq \|B\|$, its norm does not exceed one. □

B.4.4 Bessel potentials associated with a semigroup

Lemma B.4.18. (Beta–gamma identity) If $a, b > 0$, then

$$\int_0^1 \theta^{a-1} (1-\theta)^{b-1} \, d\theta = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}.$$

Proof. By Tonelli's theorem,

$$\Gamma(a)\Gamma(b) = \int_0^\infty \int_0^\infty x^{a-1} y^{b-1} e^{-(x+y)} \, dy \, dx.$$

With the change of variables $r = x+y$, $\theta = \dfrac{x}{x+y}$, whose Jacobian is r, the right-hand side becomes

$$\left(\int_0^\infty r^{a+b-1}e^{-r}\,dr\right)\left(\int_0^1 \theta^{a-1}(1-\theta)^{b-1}\,d\theta\right).$$

The first integral is $\Gamma(a+b)$. □

Theorem B.4.19. (Bessel potentials of a contraction semigroup) Let $(T_t)_{t\geq 0}$ be a contraction C_0-semigroup on a Banach space X, and let $-A$ be its generator. For $s > 0$, define

$$J_s x := \frac{1}{\Gamma\left(\frac{s}{2}\right)}\int_0^\infty t^{\frac{s}{2}-1}e^{-t}T_t x\,dt.$$

Then:

(a) $J_s \in \mathcal{L}(X)$ and $\|J_s\| \leq 1$;

(b) $J_s J_r = J_{s+r}$ for $r, s > 0$;

(c) $J_2 = (I+A)^{-1}$ and $J_{2m} = (I+A)^{-m}$ for $m \in \mathbb{N}$;

(d) each J_s is injective and has dense range in X.

For $s > 0$, let $X_s := J_s(X)$ with the norm $\|J_s x\|_{X_s} := \|x\|_X$; let $X_0 := X$ and, for $s < 0$, let X_s be the completion of X with respect to $\|x\|_{X_s} := \|J_{-s}x\|_X$. Then each X_s is a Banach space, $X_{s_1} \hookrightarrow X_{s_0}$ continuously if $s_1 > s_0$, and J_r extends uniquely to an isometric isomorphism

$$J_r \colon X_s \longrightarrow X_{s+r}$$

for any $s \in \mathbb{R}$ and $r > 0$.

Proof. The estimate

$$\|J_s x\|_X \leq \frac{\|x\|_X}{\Gamma\left(\frac{s}{2}\right)}\int_0^\infty t^{\frac{s}{2}-1}e^{-t}\,dt = \|x\|_X$$

proves (a). For (b), Fubini and the semigroup property give

$$J_s J_r x = \frac{1}{\Gamma\left(\frac{s}{2}\right)\Gamma\left(\frac{r}{2}\right)}\int_0^\infty\int_0^\infty t^{\frac{s}{2}-1}\tau^{\frac{r}{2}-1}e^{-(t+\tau)}T_{t+\tau}x\,d\tau\,dt.$$

The change of variables $a = t+\tau$, $\theta = \frac{t}{a}$ and Lemma B.4.18 transform this integral into $J_{s+r}x$. Part (c) follows from Proposition B.4.14 with $G = -A$ and $\lambda = 1$.
If $J_s x = 0$, choose m with $2m > s$. Then

$$J_{2m}x = J_{2m-s}J_s x = 0.$$

Since $J_{2m} = (I+A)^{-m}$ is injective, $x = 0$. Moreover, $\mathrm{Ran}(J_s)$ contains $\mathrm{Ran}(J_{2m}) = \mathcal{D}((I+A)^m)$, which is dense in X. This proves (d).
For $s > 0$, $J_s \colon X \longrightarrow X_s$ is a surjective isometry, so X_s is complete. The negative-order spaces are complete by

construction. If $s_1 > s_0 \geq 0$ and $u = J_{s_1} x$, then

$$u = J_{s_0} J_{s_1 - s_0} x, \qquad \|u\|_{X_{s_0}} = \|J_{s_1 - s_0} x\|_X \leq \|x\|_X = \|u\|_{X_{s_1}}.$$

This identity defines J_r on the positive-order spaces. On the negative-order spaces, the estimate $\|J_r x\|_{X_{s+r}} = \|x\|_{X_s}$ is first verified on the dense subspace X and allows the operator to be extended to the completion. Density of the ranges of the J_s shows that these extensions have closed and dense range; hence they are surjective. The semigroup identities prove that they are isometries and that their inverses are the corresponding shifts in the scale. □

Lemma B.4.20. (Integral formula for the square root of a generator) Let $-A$ be the generator of a contraction C_0-semigroup $(e^{-tA})_{t\geq 0}$ on a Banach space X, let $a > 0$, and set $B := aI + A$. Define the bounded operator

$$C := \frac{1}{\sqrt{\pi}} \int_0^\infty t^{-1/2} e^{-tB}\, dt.$$

Then $C^2 = B^{-1}$; in particular, C is injective and has dense range. Set

$$B^{-1/2} := C, \qquad \mathcal{D}(B^{1/2}) := \mathrm{Ran}(C), \qquad B^{1/2} := C^{-1} : \mathrm{Ran}(C) \longrightarrow X.$$

For every $x \in \mathcal{D}(B)$, the Bochner integral

$$\frac{1}{2\sqrt{\pi}} \int_0^\infty t^{-\frac{3}{2}} \left(x - e^{-tB} x\right) dt \tag{B.3}$$

converges in X and equals $B^{\frac{1}{2}} x$. Since $\mathcal{D}(B)$ is dense in $\mathcal{D}(B^{\frac{1}{2}})$ for the norm $\|x\|_{1/2} := \|B^{1/2} x\|_X$, which is equivalent to the graph norm, this identity determines $B^{\frac{1}{2}}$ by closure.

Proof. If $x \in \mathcal{D}(B)$, then

$$x - e^{-tB} x = \int_0^t e^{-sB} B x\, ds.$$

Thus

$$\|x - e^{-tB} x\|_X \leq \min\{t\|Bx\|_X, 2\|x\|_X\}.$$

This bound proves convergence of (B.3) both near zero and at infinity.
The bound $\|e^{-tB}\| \leq e^{-at}$ allows Fubini's theorem to be applied to the integral defining C^2. With $r = t + s$ and $\theta = t/r$, the beta identity gives

$$\begin{aligned} C^2 x &= \frac{1}{\pi} \int_0^\infty \int_0^\infty t^{-1/2} s^{-1/2} e^{-(t+s)B} x\, ds\, dt \\ &= \frac{1}{\pi} \int_0^\infty e^{-rB} x \left(\int_0^1 \theta^{-1/2} (1-\theta)^{-1/2}\, d\theta \right) dr \\ &= \int_0^\infty e^{-rB} x\, dr = B^{-1} x. \end{aligned}$$

Hence C is injective and $\mathrm{Ran}(C) \supset \mathrm{Ran}(C^2) = \mathrm{Ran}(B^{-1}) = \mathcal{D}(B)$ is dense.

Let $f \in X$ and take $x = B^{-1} f$. Fubini's theorem for Bochner integrals and the preceding identity give

$$\begin{aligned}
&\frac{1}{2\sqrt{\pi}} \int_0^\infty t^{-\frac{3}{2}} \left(B^{-1} f - e^{-tB} B^{-1} f \right) dt \\
&\quad = \frac{1}{2\sqrt{\pi}} \int_0^\infty t^{-\frac{3}{2}} \int_0^t e^{-sB} f \, ds \, dt \\
&\quad = \frac{1}{\sqrt{\pi}} \int_0^\infty s^{-\frac{1}{2}} e^{-sB} f \, ds = B^{-\frac{1}{2}} f.
\end{aligned}$$

In the last equality we used the definition of C. Since $B^{-1} f = C^2 f = C(Cf)$, the computed value is $Cf = C^{-1} x = B^{1/2} x$. Finally, under the isometry

$$C^{-1} \colon (\mathcal{D}(B^{1/2}), \|\cdot\|_{1/2}) \longrightarrow X,$$

the subspace $\mathcal{D}(B) = \operatorname{Ran}(C^2)$ corresponds to $\operatorname{Ran}(C)$, which is dense in X. This proves the asserted density. Moreover, $\|x\|_X \le \|C\|_{\mathcal{L}(X)} \|x\|_{1/2}$, so $\|\cdot\|_{1/2}$ is equivalent to the graph norm. □

Proposition B.4.21. (Laplace calculus for a contraction semigroup) Let $(T_t)_{t \ge 0}$ be a contraction C_0-semigroup on a Banach space X. If ν is a finite real or complex Borel measure on $[0, \infty)$, then the Bochner integral

$$\mathcal{L}_\nu(T) x := \int_{[0,\infty)} T_t x \, d\nu(t)$$

defines a bounded operator on X, and

$$\|\mathcal{L}_\nu(T)\|_{\mathcal{L}(X)} \le |\nu|([0,\infty)).$$

If μ is another finite measure and $\nu * \mu$ denotes their convolution, then

$$\mathcal{L}_\nu(T) \mathcal{L}_\mu(T) = \mathcal{L}_{\nu * \mu}(T).$$

In particular, the product of two Laplace transforms of finite measures is represented by the product of the corresponding operators.

Proof. Strong continuity of $t \mapsto T_t x$ ensures Bochner measurability, and contractivity gives

$$\int_{[0,\infty)} \|T_t x\|_X \, d|\nu|(t) \le |\nu|([0,\infty)) \|x\|_X.$$

This proves existence of the integral and the bound. For the product rule, Fubini's theorem for Bochner integrals gives

$$\begin{aligned}
\mathcal{L}_\nu(T) \mathcal{L}_\mu(T) x &= \int_{[0,\infty)} \int_{[0,\infty)} T_{t+s} x \, d\mu(s) \, d\nu(t) \\
&= \int_{[0,\infty)} T_r x \, d(\nu * \mu)(r),
\end{aligned}$$

where we used $T_t T_s = T_{t+s}$. The last assertion follows by taking scalar Laplace transforms. □

Lemma B.4.22. (Independence of the positive shift) Let $-A$ be the generator of a contraction C_0-semigroup $(e^{-tA})_{t\ge 0}$ on a Banach space X. For $a>0$ and $s>0$, define

$$J_s^{(a)}x := \frac{1}{\Gamma\left(\frac{s}{2}\right)}\int_0^\infty t^{\frac{s}{2}-1}e^{-at}e^{-tA}x\,dt.$$

Each $J_s^{(a)}$ is injective. Equip its range with the norm

$$\left\|J_s^{(a)}x\right\|_{\mathrm{Ran}(J_s^{(a)})} := \|x\|_X.$$

If $a,b>0$, then

$$\mathrm{Ran}(J_s^{(a)}) = \mathrm{Ran}(J_s^{(b)}),$$

and the two range norms are equivalent.

Proof. Set $\alpha = \frac{s}{2}$. The Laplace formula for negative powers gives

$$J_s^{(a)} = (aI+A)^{-\alpha}.$$

The semigroup property of these powers and the identity $J_{2m}^{(a)} = (aI+A)^{-m}$ show that $J_s^{(a)}$ is injective. Indeed, if $J_s^{(a)}x = 0$, choose $m\in\mathbb{N}$ with $2m>s$ and obtain

$$(aI+A)^{-m}x = J_{2m-s}^{(a)}J_s^{(a)}x = 0.$$

The resolvent of $-A$ is injective, so $x=0$. Thus the norm in the statement is well defined. Begin with two shifts $c,d>0$ satisfying $|d-c|<c$. For $\lambda\ge 0$, the binomial series converges absolutely, and

$$\left(\frac{d+\lambda}{c+\lambda}\right)^\alpha = \left(1+\frac{d-c}{c+\lambda}\right)^\alpha = 1+\sum_{k=1}^\infty \binom{\alpha}{k}(d-c)^k(c+\lambda)^{-k}.$$

For $k\ge 1$, we have

$$(c+\lambda)^{-k} = \int_0^\infty e^{-\lambda t}\frac{t^{k-1}e^{-ct}}{(k-1)!}\,dt.$$

Thus the preceding function is the Laplace transform of

$$\nu_{c,d} := \delta_0 + \sum_{k=1}^\infty \binom{\alpha}{k}(d-c)^k\frac{t^{k-1}e^{-ct}}{(k-1)!}\,dt.$$

This series converges in total variation because

$$\sum_{k=1}^\infty \left|\binom{\alpha}{k}\right|\left(\frac{|d-c|}{c}\right)^k < \infty.$$

Proposition B.4.21 then defines a bounded operator $Q_{c,d}$ whose scalar multiplier is $\left(\frac{d+\lambda}{c+\lambda}\right)^\alpha$. The product rule gives

$$(cI+A)^{-\alpha} = (dI+A)^{-\alpha}Q_{c,d}. \tag{B.4}$$

For arbitrary shifts $a, b > 0$, choose $N \in \mathbb{N}$ so that $\left(\frac{b}{a}\right)^{\frac{1}{N}} < 2$, and set

$$a_j := a\left(\frac{b}{a}\right)^{\frac{j}{N}}, \qquad j \in \{0, \dots, N\}.$$

Then $|a_{j+1} - a_j| < a_j$ for every j. Iterating (B.4) gives a bounded operator $Q_{a,b}$ such that

$$(aI + A)^{-\alpha} = (bI + A)^{-\alpha} Q_{a,b}.$$

If $u = J_s^{(a)} x$, this identity writes $u = J_s^{(b)} Q_{a,b} x$ and, consequently,

$$\|u\|_{\mathrm{Ran}(J_s^{(b)})} \le \|Q_{a,b}\| \, \|u\|_{\mathrm{Ran}(J_s^{(a)})}.$$

Interchanging a and b gives the reverse inclusion and estimate. □

Proposition B.4.23. (Complex-linear duality of consistent scales) Let X and Y be complex Banach spaces, and let $\mathfrak{b}\colon X \times Y \to \mathbb{C}$ be a continuous bilinear form such that

$$Y \longrightarrow X', \qquad w \longmapsto \mathfrak{b}(\cdot, w),$$

is a complex-linear isometric isomorphism. Let $(T_t)_{t\ge 0}$ and $(S_t)_{t\ge 0}$ be contraction semigroups on X and Y, respectively, and suppose that

$$\mathfrak{b}(T_t u, w) = \mathfrak{b}(u, S_t w) \tag{B.5}$$

for $t \ge 0$ and u, w in respective dense invariant subspaces. If X_s and Y_s are the scales from Theorem B.4.19, then the duality $\mathfrak{b}$ extends uniquely to a complex-linear isometric isomorphism

$$Y_{-s} \xrightarrow{\cong} (X_s)', \qquad s \in \mathbb{R}.$$

In the application to a Hermitian bundle $\mathbf{E}$, take $X = L^p(M, \mathbf{E})$, $Y = L^{p'}(M, \overline{\mathbf{E}})$, and $\mathfrak{b}(u, \overline{v}) = \displaystyle\int_M \mathbf{h}_{\mathbf{E}}(u, v)\, d\lambda_{\mathbf{g}}$; thus the space representing the complex dual of a scale on $\mathbf{E}$ is a scale on $\overline{\mathbf{E}}$, not another complex-linear copy of the scale on $\mathbf{E}$.

Proof. The identity (B.5), first on the dense subspaces and then by continuity, and the Bochner integral defining the Bessel potentials imply, for every $r > 0$,

$$\mathfrak{b}(J_r^X u, w) = \mathfrak{b}(u, J_r^Y w). \tag{B.6}$$

First suppose that $s > 0$. If $w \in Y$ and $v = J_s^X u \in X_s$, then

$$|\mathfrak{b}(v, w)| = |\mathfrak{b}(u, J_s^Y w)| \le \|v\|_{X_s} \|w\|_{Y_{-s}}.$$

By density, the map $w \mapsto \mathfrak{b}(\cdot, w)$ extends isometrically from Y_{-s} to $(X_s)'$. To see that it is surjective, let $F \in (X_s)'$. The functional $u \mapsto F(J_s^X u)$ on X is represented by a unique $z \in Y$. Since $J_s^Y\colon Y_{-s} \to Y$ is an isometric isomorphism, there exists a unique $w \in Y_{-s}$ with $J_s^Y w = z$. Identity (B.6), extended by density,

gives $F(v) = \mathfrak{b}(v, w)$ and preserves the norm.
Now let $s = -r < 0$. If $w = J_r^Y z \in Y_r$, then, for $u \in X$,

$$|\mathfrak{b}(u, w)| = |\mathfrak{b}(J_r^X u, z)| \le \|u\|_{X_{-r}} \|z\|_Y = \|u\|_{X_s} \|w\|_{Y_r}.$$

This extends w to an element of $(X_s)'$. Conversely, if $F \in (X_{-r})'$, its restriction to X is represented by some $w \in Y$. The bound on F makes the functional $J_r^X u \mapsto \mathfrak{b}(u, w)$ continuous on $\operatorname{Ran}(J_r^X)$; since that range is dense in X, it extends to a functional represented by some $z \in Y$. Then (B.6) gives $\mathfrak{b}(u, w) = \mathfrak{b}(u, J_r^Y z)$ for every $u \in X$, hence $w = J_r^Y z \in Y_r$. The argument preserves norms. The case $s = 0$ is the duality $Y \cong X'$ already mentioned. □

B.5 Measure spaces

We now turn to the basic concepts of measure theory. The aim of this section is to establish a unified language for defining Lebesgue and Bochner integrals, L^p spaces, and measures induced by geometric structures.

Definition B.5.1. Let X be a set. A family $\mathcal{A} \subseteq \mathcal{P}(X)$ is a **σ-algebra on** X if $X \in \mathcal{A}$, if $X \setminus A \in \mathcal{A}$ for each $A \in \mathcal{A}$, and if $\bigcup_{n=1}^{\infty} A_n \in \mathcal{A}$ for every sequence $(A_n)_{n\in\mathbb{N}} \subseteq \mathcal{A}$. In this case, $(X, \mathcal{A})$ is called a **measurable space**, and the elements of $\mathcal{A}$ are called **$\mathcal{A}$-measurable** sets, or simply **measurable** sets when the σ-algebra is understood.

Definition B.5.2. Let $(X, \mathcal{A})$ be a measurable space. A **measure** on $(X, \mathcal{A})$ is a function $\mu\colon \mathcal{A} \longrightarrow [0, \infty]$ such that $\mu(\varnothing) = 0$ and $\mu\left(\bigcup_{n=1}^{\infty} A_n\right) = \sum_{n=1}^{\infty} \mu(A_n)$ for every sequence $(A_n)_{n\in\mathbb{N}} \subseteq \mathcal{A}$ of pairwise disjoint sets. The triple $(X, \mathcal{A}, \mu)$ is called a **measure space**.

Before constructing specific measures, we recall how the σ-algebras determining measurable sets are generated.

Definition B.5.3. Let X be a set, and let $\mathcal{S} \subseteq \mathcal{P}(X)$. The **$\sigma$-algebra generated by** $\mathcal{S}$ is $\sigma(\mathcal{S}) := \bigcap \{\mathcal{A} \subseteq \mathcal{P}(X) \mid \mathcal{S} \subseteq \mathcal{A} \text{ and } \mathcal{A} \text{ is a } \sigma\text{-algebra on } X\}$. If (X, τ) is a topological space, the **Borel σ-algebra** of X is $\mathcal{B}(X) := \sigma(\tau)$, and its elements are called Borel sets.

Definition B.5.4. Let $(X, \mathcal{A}, \mu)$ be a measure space. A set $N \in \mathcal{A}$ is **μ-null** if $\mu(N) = 0$. The measure μ, or equivalently the space $(X, \mathcal{A}, \mu)$, is **complete** if every subset of a μ-null set belongs to $\mathcal{A}$; by monotonicity, that subset is then also μ-null.

Definition B.5.5. Let $(X, \mathcal{A}, \mu)$ be a measure space. We say that μ is **finite** if $\mu(X) < \infty$, and **σ-finite** if there exists a sequence $(A_n)_{n\in\mathbb{N}} \subseteq \mathcal{A}$ such that $X = \bigcup_{n=1}^{\infty} A_n$ and $\mu(A_n) < \infty$ for every $n \in \mathbb{N}$.

Carathéodory's construction produces a complete measure from a function initially defined on all subsets of X. Complete proofs of this construction, regularity of Lebesgue measure, and the signed measure decomposition theorems stated below can be found in [68, 22, 40].

Definition B.5.6. An **outer measure** on a set X is a function $\mu^*\colon \mathcal{P}(X) \longrightarrow [0,\infty]$ such that $\mu^*(\varnothing) = 0$, $\mu^*(A) \le \mu^*(B)$ whenever $A \subseteq B$, and $\mu^*\left(\bigcup_{k=1}^{\infty} A_k\right) \le \sum_{k=1}^{\infty} \mu^*(A_k)$ for every sequence $(A_k)_{k\in\mathbb{N}} \subseteq \mathcal{P}(X)$.

Theorem B.5.7. For a compact rectangle $R = \prod_{i=1}^{n} [a_i, b_i]$, define $\mathrm{vol}_n(R) := \prod_{i=1}^{n} (b_i - a_i)$. Given $A \subseteq \mathbb{R}^n$, let $\mathcal{C}(A)$ be the family of sequences $(R_j)_{j\in\mathbb{N}}$ of compact rectangles such that $A \subseteq \bigcup_{j=1}^{\infty} R_j$, and define $\lambda_n^*(A) := \inf_{(R_j)\in\mathcal{C}(A)} \sum_{j=1}^{\infty} \mathrm{vol}_n(R_j)$. Then λ_n^* is an outer measure on $\mathbb{R}^n$, called n-**dimensional Lebesgue outer measure**.

Not every subset of a space equipped with an outer measure is necessarily measurable. The following condition selects precisely those on which the outer measure becomes countably additive.

Definition B.5.8. Let μ^* be an outer measure on X. A subset $A \subseteq X$ is μ^*-**measurable** if $\mu^*(D) = \mu^*(D \cap A) + \mu^*(D \setminus A)$ for each $D \subseteq X$. Denote by $\mathcal{A}(\mu^*)$ the family of all μ^*-measurable subsets of X.

Theorem B.5.9. (Carathéodory) Let μ^* be an outer measure on X. Then $\mathcal{A}(\mu^*)$ is a σ-algebra on X, and the restriction $\mu^* \restriction_{\mathcal{A}(\mu^*)}$ is a complete measure. This restriction is called the **measure induced by** μ^*.

Definition B.5.10. The σ-algebra of **Lebesgue measurable** subsets of $\mathbb{R}^n$ is $\mathcal{L}(\mathbb{R}^n) := \mathcal{A}(\lambda_n^*)$, and n-**dimensional Lebesgue measure** is the complete measure $\lambda_n := \lambda_n^* \restriction_{\mathcal{L}(\mathbb{R}^n)}$. When there is no risk of confusion, we simply write dx in place of $d\lambda_n(x)$.

To relate measure theory to topology, we introduce regularity and local finiteness.

Definition B.5.11. Let X be a topological space, and let $(X, \mathcal{A}, \mu)$ be a measure space such that $\mathcal{B}(X) \subseteq \mathcal{A}$. The measure μ is **regular** if, for each $A \in \mathcal{A}$, we have $\mu(A) = \inf\{\mu(U) \mid U \subseteq X \text{ is open and } A \subseteq U\} = \sup\{\mu(K) \mid K \subseteq A \text{ is compact}\}$. The measure μ is **locally finite** if each $x \in X$ has an open neighborhood U such that $\mu(U) < \infty$.

Proposition B.5.12. Let X be a topological space, let $(X, \mathcal{A}, \mu)$ be a measure space, and suppose that $\mathcal{B}(X) \subseteq \mathcal{A}$. If μ is locally finite, then $\mu(K) < \infty$ for every compact set $K \subseteq X$. Conversely, if each point of X has a compact neighborhood and $\mu(K) < \infty$ for every compact set $K \subseteq X$, then μ is locally finite.

Proof. If $K \subseteq X$ is compact, for each $x \in K$ there exists an open neighborhood U_x with $\mu(U_x) < \infty$. By compactness, there exist $x_1, \dots, x_r \in K$ such that $K \subseteq \bigcup_{i=1}^{r} U_{x_i}$, so $\mu(K) \le \sum_{i=1}^{r} \mu(U_{x_i}) < \infty$. Conversely, let $x \in X$, and let K be a compact neighborhood of x. There exists an open set U such that $x \in U \subseteq K$, and then $\mu(U) \le \mu(K) < \infty$. □

Definition B.5.13. Let $(X, \mathcal{A}, \mu)$ be a measure space, and let $P(x)$ be a property defined for $x \in X$. We say that P holds μ-**almost everywhere**, or for μ-**almost every** $x \in X$, if there exists a set $N \in \mathcal{A}$ with $\mu(N) = 0$ such that $P(x)$ holds for every $x \in X \setminus N$. When the measure is understood, we simply write **almost everywhere**.

Theorem B.5.14. Lebesgue measure λ_n is regular and locally finite.

Regularity of λ_n allows any Lebesgue measurable set to be approximated by Borel sets, changing it only on a null set. Recall that an F_σ set is a countable union of closed sets, and a G_δ set is a countable intersection of open sets.

Theorem B.5.15. Let $A \in \mathcal{L}(\mathbb{R}^n)$. There exist an F_σ set, denoted by F, and a G_δ set, denoted by G, such that $F \subseteq A \subseteq G$ and $\lambda_n(A \setminus F) = \lambda_n(G \setminus A) = 0$. In particular, $\lambda_n(F) = \lambda_n(A) = \lambda_n(G)$. If A is bounded, G may be chosen bounded.

Definition B.5.16. Let X be a topological space.

(a) We say that X is **locally compact** if each point of X has a compact neighborhood.

(b) We say that X is **σ-compact** if there exists a sequence $(K_j)_{j\in\mathbb{N}}$ of compact subsets of X such that $X = \bigcup_{j=1}^{\infty} K_j$.

(c) If X is locally compact and Hausdorff, a measure μ defined on a σ-algebra $\mathcal{A}$ with $\mathcal{B}(X) \subseteq \mathcal{A}$ is called a **Radon measure** if it is regular and locally finite. We say that μ is **massive** if, in addition, it is complete and $\mu(U) > 0$ for every nonempty open set $U \subseteq X$.

The following two properties of Lebesgue measurability will be used when formulating the change-of-variables theorem on subsets that need not be open.

Proposition B.5.17. Let $\Omega \subseteq \mathbb{R}^n$ be open, $A \in \mathcal{L}(\mathbb{R}^n)$ with $A \subseteq \Omega$, and $f \in C^1(\Omega, \mathbb{R}^m)$, where $m \geq n$. Then $f(A) \in \mathcal{L}(\mathbb{R}^m)$.

Proof. By Theorem B.5.15, there exists an F_σ set such that $F \subseteq A$ and $N := A \setminus F$ is λ_n-null. Writing $F = \bigcup_{j=1}^{\infty} C_j$ with each C_j closed and observing that $C_j \subseteq \Omega$, we obtain $F = \bigcup_{j,k=1}^{\infty} (C_j \cap \overline{B}_{\mathrm{euc}}(0,k))$ as a countable union of compact sets. By continuity, $f(F)$ is an F_σ set and, in particular, is Borel. On the other hand, Ω admits a countable cover by convex open balls $(U_r)_{r\in\mathbb{N}}$ with $\overline{U_r} \subseteq \Omega$, and the restriction of f to each U_r is Lipschitz, since Df is bounded on $\overline{U_r}$. A Lipschitz map from a subset of $\mathbb{R}^n$ to $\mathbb{R}^m$, with $m \geq n$, sends λ_n-null sets to λ_m-null sets; to check this, cover the null set by cubes of arbitrarily small diameters and use the fact that the image of each cube is contained in a ball whose diameter is bounded by the Lipschitz constant times the diameter of the cube. Consequently, each $f(N \cap U_r)$ is λ_m-null, and so is $f(N) = \bigcup_{r=1}^{\infty} f(N \cap U_r)$. Finally, $f(A) = f(F) \cup f(N)$ is Lebesgue measurable. □

Proposition B.5.18. A subset $A \subseteq \mathbb{R}^n$ is Lebesgue measurable if and only if for each $x \in A$ there exists an open set $U_x \subseteq \mathbb{R}^n$ such that $x \in U_x$ and $A \cap U_x$ is Lebesgue measurable.

Proof. Necessity is immediate upon taking $U_x = \mathbb{R}^n$. Conversely, the family $(U_x)_{x\in A}$ is an open cover of A. Since $\mathbb{R}^n$ is second countable and hence Lindelöf, there exists a countable subcover $(U_{x_j})_{j\in\mathbb{N}}$. Thus $A = \bigcup_{j=1}^{\infty}(A \cap U_{x_j})$ is Lebesgue measurable. □

B.5.1 Signed measures

To represent linear functionals that need not be positive, we must allow measures taking values of both signs. We combine the finitely additive and countably additive versions in a single definition.

Definition B.5.19. Let X be a nonempty set, and let $\mathcal{A}$ be an algebra of subsets of X, that is, a nonempty family closed under complements relative to X and finite unions. A function $\lambda\colon \mathcal{A} \longrightarrow [-\infty,\infty]$ is a **finitely additive signed measure** if $\lambda(\varnothing) = 0$, it takes at most one of the values ∞ and $-\infty$, and $\lambda(E\cup F) = \lambda(E)+\lambda(F)$ whenever $E, F \in \mathcal{A}$ are disjoint. If $\mathcal{A}$ is a σ-algebra and, for every sequence $(E_n)_{n\in\mathbb{N}} \subseteq \mathcal{A}$ of pairwise disjoint sets, $\lambda\left(\bigcup_{n=1}^{\infty} E_n\right) = \sum_{n=1}^{\infty} \lambda(E_n)$ holds, then λ is called a **signed measure**.

Definition B.5.20. Two positive measures μ and ν on a measurable space $(X,\mathcal{A})$ are **mutually singular**, written $\mu \perp \nu$, if there exists $P \in \mathcal{A}$ such that $\mu(X \setminus P) = 0$ and $\nu(P) = 0$.

The Hahn–Jordan theorem shows that every signed measure decomposes canonically as the difference of two mutually singular positive measures.

Theorem B.5.21. (Hahn–Jordan decomposition) Let $(X,\mathcal{A})$ be a measurable space, and let $\lambda\colon \mathcal{A} \longrightarrow [-\infty,\infty]$ be a signed measure. There exist unique positive measures λ^+ and λ^- such that $\lambda^+ \perp \lambda^-$ and $\lambda = \lambda^+ - \lambda^-$; moreover, one of them is finite. For each $E \in \mathcal{A}$, we have $\lambda^+(E) = \sup\{\lambda(F) \mid F \in \mathcal{A},\ F \subseteq E\}$ and $\lambda^-(E) = -\inf\{\lambda(F) \mid F \in \mathcal{A},\ F \subseteq E\}$. The measures λ^+ and λ^- are called the **positive variation** and **negative variation** of λ, respectively, while $|\lambda| := \lambda^+ + \lambda^-$ is called the **total variation**. We say that λ is finite if $|\lambda|(X) < \infty$.

Definition B.5.22. Let X be a locally compact Hausdorff space. A signed measure ν on $\mathcal{B}(X)$ is called a **signed Radon measure** if its variations ν^+ and ν^- are positive Radon measures.
A **local signed Radon measure** is a family $(\nu_U)_U$, indexed by open sets $U \subseteq X$ with compact closure, such that each ν_U is a finite signed Radon measure on U and

$$\nu_V \restriction_U = \nu_U \qquad \text{if } U \subseteq V.$$

For $u \in C_c(X)$, choose one of these open sets U containing $\operatorname{supp}(u)$ and define

$$\int_X u\,d\nu := \int_U u\,d\nu_U.$$

The value does not depend on U: two choices may be compared on their union, which also has compact closure. The same compatibility and uniqueness in Hahn–Jordan allow the variations ν^+, ν^-, and $|\nu|$ to be defined on relatively compact Borel sets through the variations of ν_U. In particular, $|\nu|(K) < \infty$ for each compact set $K \subseteq X$. A global signed Radon measure determines such a family by restriction, but a local

family need not admit values on all Borel subsets of X.

In what follows, $C_c(X)$ denotes the vector space of continuous functions $u\colon X \longrightarrow \mathbb{R}$ with compact support. On a general locally compact space, the regularity of representing measures should be specified separately. When X is σ-compact, the positive measures in the following theorem are Radon measures under the regularity convention fixed above.

Theorem B.5.23. (Riesz representation theorem on C_c) Let X be a locally compact Hausdorff topological space, and let $L\colon C_c(X) \longrightarrow \mathbb{R}$ be a linear functional.

(a) If L is positive, that is, $L(u) \geq 0$ for every $u \in C_c(X)$ with $u \geq 0$, then there exists a unique positive Borel measure μ, finite on compact sets, outer regular on Borel sets, and inner regular on open sets and on Borel sets of finite measure, such that $L(u) = \displaystyle\int_X u\, d\mu$ for every $u \in C_c(X)$. Uniqueness is understood among measures with these regularity properties.

(b) If L is locally bounded, that is, if for each compact set $K \subseteq X$ there exists $c_K > 0$ such that $|L(u)| \leq c_K \|u\|_{K,\infty}$ for every $u \in C_c(X)$ with $\operatorname{supp}(u) \subseteq K$, where $\|u\|_{K,\infty} := \sup\limits_{x\in K} |u(x)|$, then there exists a unique local signed Radon measure ν such that $L(u) = \displaystyle\int_X u\, d\nu$ for every $u \in C_c(X)$. Moreover, there exist positive Borel measures μ_1 and μ_2, with the finiteness and regularity properties in part (a), such that

$$L(u) = \int_X u\, d\mu_1 - \int_X u\, d\mu_2, \qquad u \in C_c(X).$$

On each open set U with compact closure, we have $\nu_U = \mu_1 \restriction_U - \mu_2 \restriction_U$.

If X is σ-compact, the positive measures in both parts are Radon measures in the sense of Definition B.5.16. This applies, in particular, to open subsets of $\mathbb{R}^n$ and to second-countable smooth manifolds.

Proof. The positive representation in part (a), with its regularity and uniqueness properties, is Riesz's theorem; see [22, 40]. We shall deduce part (b) from it without assuming that one of the representing measures has finite total mass.

For $f \in C_c(X)$ with $f \geq 0$, set

$$L^+(f) := \sup\{L(g) \mid g \in C_c(X),\ 0 \leq g \leq f\}.$$

If $K = \operatorname{supp}(f)$, every admissible function g is supported in K and $\|g\|_\infty \leq \|f\|_\infty$. By local boundedness of L,

$$0 \leq L^+(f) \leq c_K \|f\|_\infty < \infty.$$

Homogeneity for nonnegative scalars follows directly from the definition, including the zero scalar.

Let $f, h \in C_c(X)$ be nonnegative. If $0 \leq g_1 \leq f$ and $0 \leq g_2 \leq h$, then $0 \leq g_1 + g_2 \leq f + h$. Taking suprema gives $L^+(f+h) \geq L^+(f) + L^+(h)$. For the reverse inequality, let $0 \leq g \leq f + h$ and define

$$g_1 := \min\{g, f\}, \qquad g_2 := g - g_1.$$

These functions are continuous and compactly supported, and satisfy $0 \leq g_1 \leq f$ and $0 \leq g_2 \leq h$. Thus $L(g) = L(g_1) + L(g_2) \leq L^+(f) + L^+(h)$. Taking the supremum over g shows that L^+ is additive on the positive

cone.

Extend L^+ to all of $C_c(X)$ by $L^+(f-h) := L^+(f) - L^+(h)$ for $f, h \geq 0$. If $f - h = f_1 - h_1$, then $f + h_1 = f_1 + h$, and the additivity just proved shows that both expressions give the same value. We thus obtain a positive linear functional. Since $g = f$ is admissible in the supremum when $f \geq 0$, we have $L^+(f) \geq L(f)$. Consequently, $L^- := L^+ - L$ is also a positive linear functional. Applying (a) to L^+ and L^- yields the measures μ_1, μ_2 with the asserted representation. Both integrals are finite for each $u \in C_c(X)$ because the measures are finite on its support.

Now let $U \subseteq X$ be open with compact closure. Then $\mu_i(U) \leq \mu_i(\overline{U}) < \infty$ for $i = 1, 2$. The restrictions of μ_i to U are regular: all their Borel sets have finite measure, and outer regularity is preserved by intersecting the approximating open sets with U. The difference

$$\nu_U := \mu_1 \restriction_U - \mu_2 \restriction_U$$

is a finite signed measure. To check that its variations are regular, set $\eta := \mu_1 \restriction_U + \mu_2 \restriction_U$. The Hahn decomposition gives $0 \leq \nu_U^{\pm} \leq \eta$. Given a Borel set $E \subseteq U$ and $\varepsilon > 0$, regularity and finiteness of η allow us to choose a compact set $K \subseteq E$ and an open set $O \supseteq E$ in U such that $\eta(O \setminus K) < \varepsilon$. Then

$$0 \leq \nu_U^{\pm}(O) - \nu_U^{\pm}(K) = \nu_U^{\pm}(O \setminus K) < \varepsilon.$$

This proves regularity of both variations. Thus ν_U is a finite signed Radon measure. These differences are compatible under restriction from one open set to another, so they define a local signed Radon measure ν.

For uniqueness, let ν and $\widetilde{\nu}$ be two representing families, and fix U as above. A function in $C_c(U)$ extends by zero to an element of $C_c(X)$, so the finite measure $\lambda := \nu_U - \widetilde{\nu}_U$ vanishes on $C_c(U)$. By Hahn–Jordan, $\int_U u \, d\lambda^+ = \int_U u \, d\lambda^-$ for every $u \in C_c(U)$. Uniqueness in (a) implies $\lambda^+ = \lambda^-$; since they are mutually singular, both vanish. Thus $\nu_U = \widetilde{\nu}_U$ for every U.

Finally, suppose that X is σ-compact, and let μ be any of the positive measures obtained. Choose increasing compact sets K_j covering X. For a Borel set E, continuity from below gives

$$\mu(E) = \lim_{j \to \infty} \mu(E \cap K_j).$$

Each $E \cap K_j$ has finite measure and is inner regular by (a). Hence $\mu(E) = \sup\{\mu(K) \mid K \subseteq E,\ K \text{ compact}\}$, also when $\mu(E) = \infty$. Outer regularity is already part of (a), and finiteness on compact sets implies local finiteness on a locally compact space. This proves the last assertion. □

The local family ν must not be confused with a difference defined on all Borel subsets of X: when $\mu_1(E) = \mu_2(E) = \infty$, the expression $\mu_1(E) - \mu_2(E)$ is not meaningful. For example, $L(u) = \int_{\mathbb{R}} xu(x)\,dx$ is locally bounded on $C_c(\mathbb{R})$ and is represented by $\max\{x, 0\}\,dx$ and $\max\{-x, 0\}\,dx$, both of infinite total mass. On each relatively compact open set, however, both measures are finite and their difference is well defined.

B.6 Lebesgue and Bochner integration

Having fixed the basic notions of measure, we recall the construction of the Lebesgue integral and its extension to Banach-valued functions through the Bochner integral. We begin with the vector-valued Riemann integral, which provides a natural way to introduce compatibility of integration with linear operators. For a more detailed

treatment of the Bochner integral, see [45].

B.6.1 The Banach-valued Riemann integral

Definition B.6.1. Let E be a Banach space, let $a, b \in \mathbb{R}$ with $a < b$, and let $f : [a,b] \longrightarrow E$. A **tagged partition** of $[a,b]$ is a pair consisting of a partition $\mathcal{P} = \{a = t_0 < t_1 < \cdots < t_n = b\}$ and points $\tau_i \in [t_{i-1}, t_i]$, $i \in \{1, \ldots, n\}$. Define the mesh of the partition by $|\mathcal{P}| := \max_{1 \le i \le n} (t_i - t_{i-1})$. We say that f is **Riemann integrable** if there exists $I \in E$ such that, for each $\varepsilon > 0$, there exists $\delta > 0$ with the property that $\left\| \sum_{i=1}^{n} f(\tau_i)(t_i - t_{i-1}) - I \right\|_E < \varepsilon$ for every tagged partition with $|\mathcal{P}| < \delta$. In this case, I is unique and is denoted by $\int_a^b f(t)\,dt$.

Theorem B.6.2. (Graves) Let E be a Banach space. Every continuous function $f : [a,b] \longrightarrow E$ is Riemann integrable.

Proof. Since $[a,b]$ is compact, f is uniformly continuous. For a tagged partition $(\mathcal{P}, \tau)$, denote its Riemann sum by

$$S(f; \mathcal{P}, \tau) := \sum_{i=1}^{n} f(\tau_i)(t_i - t_{i-1})$$

Fix $\varepsilon > 0$. Uniform continuity allows us to choose $\delta > 0$ so that

$$|s - t| < \delta \quad \Longrightarrow \quad \|f(s) - f(t)\|_E < \frac{\varepsilon}{4(b-a)}.$$

Let $(\mathcal{P}, \tau)$ and $(\mathcal{Q}, \sigma)$ be two tagged partitions with mesh less than δ, and let $\mathcal{R}$ be the partition obtained by combining and ordering the points of $\mathcal{P}$ and $\mathcal{Q}$. Choose a tag in each subinterval of $\mathcal{R}$. Each such subinterval is contained in an interval of $\mathcal{P}$; its tag and the corresponding tag of $\mathcal{P}$ are less than δ apart. By the triangle inequality,

$$\left\| S(f; \mathcal{P}, \tau) - S(f; \mathcal{R}, \rho) \right\|_E \le \frac{\varepsilon}{4(b-a)} \sum_{J \in \mathcal{R}} |J| = \frac{\varepsilon}{4}.$$

The same estimate holds with $\mathcal{Q}$ in place of $\mathcal{P}$. Consequently,

$$\left\| S(f; \mathcal{P}, \tau) - S(f; \mathcal{Q}, \sigma) \right\|_E < \frac{\varepsilon}{2}.$$

For each $k \in \mathbb{N}$, choose a tagged partition $(\mathcal{P}_k, \tau^{(k)})$ with mesh less than $1/k$, and set $S_k := S(f; \mathcal{P}_k, \tau^{(k)})$. The preceding estimate shows that (S_k) is Cauchy. Since E is complete, there exists $I \in E$ such that $S_k \to I$.
It remains to check that all sufficiently fine sums converge to I. Given $\varepsilon > 0$, repeat the preceding argument with ε in place of the quantity fixed at the beginning and obtain the corresponding δ. Choose k so large that $|\mathcal{P}_k| < \delta$ and $\|S_k - I\|_E < \varepsilon/2$. For any tagged partition $(\mathcal{P}, \tau)$ with $|\mathcal{P}| < \delta$, comparison through a common refinement gives

$$\|S(f; \mathcal{P}, \tau) - I\|_E \le \|S(f; \mathcal{P}, \tau) - S_k\|_E + \|S_k - I\|_E < \varepsilon.$$

This is precisely Riemann integrability of f. □

Proposition B.6.3. Let E be a Banach space, and let $f, g\colon [a,b] \longrightarrow E$ be Riemann integrable functions. Then $\alpha f + \beta g$ is Riemann integrable for any $\alpha, \beta \in \mathbb{K}$ and $\displaystyle\int_a^b (\alpha f + \beta g)(t)\,dt = \alpha \int_a^b f(t)\,dt + \beta \int_a^b g(t)\,dt$. Moreover, $\displaystyle\left\| \int_a^b f(t)\,dt \right\|_E \leq \int_a^b \|f(t)\|_E\,dt$. In particular, the map $\mathcal{I}\colon C([a,b],E) \longrightarrow E$, given by $\mathcal{I}(f) := \displaystyle\int_a^b f(t)\,dt$, is linear and bounded, and satisfies $\|\mathcal{I}\|_{\mathcal{L}(C([a,b],E),E)} \leq b-a$ with respect to the norm $\|f\|_{C([a,b],E)} := \max\limits_{t\in[a,b]} \|f(t)\|_E$.

Proof. Linearity follows by taking linear combinations of Riemann sums. For the inequality, every Riemann sum satisfies $\displaystyle\left\| \sum_{i=1}^n f(\tau_i)(t_i - t_{i-1}) \right\|_E \leq \sum_{i=1}^n \|f(\tau_i)\|_E (t_i - t_{i-1})$; passing to the limit gives the assertion. Finally, $\displaystyle\int_a^b \|f(t)\|_E\,dt \leq (b-a)\|f\|_{C([a,b],E)}$. □

The integral also commutes with continuous linear operators and, under an additional integrability hypothesis, with closed linear operators.

Proposition B.6.4. Let E and F be Banach spaces, and let $f\colon [a,b] \longrightarrow E$ be Riemann integrable.

(a) If $T \in \mathcal{L}(E,F)$, then $T \circ f$ is Riemann integrable and $\displaystyle T\left(\int_a^b f(t)\,dt\right) = \int_a^b T(f(t))\,dt$.

(b) If $T\colon \mathrm{Dom}(T) \subseteq E \longrightarrow F$ is a closed linear operator, $f(t) \in \mathrm{Dom}(T)$ for every $t \in [a,b]$, and $T \circ f$ is Riemann integrable, then $\displaystyle\int_a^b f(t)\,dt \in \mathrm{Dom}(T)$ and the same equality holds.

Proof. The first assertion follows by applying T to Riemann sums and using continuity. For the second, let $(S_k)_{k\in\mathbb{N}}$ be a sequence of Riemann sums of f associated with partitions whose mesh tends to zero. Since $\mathrm{Dom}(T)$ is a vector subspace, $S_k \in \mathrm{Dom}(T)$ and $T(S_k)$ is the corresponding Riemann sum for $T \circ f$. Thus $S_k \longrightarrow \displaystyle\int_a^b f(t)\,dt$ in E and $T(S_k) \longrightarrow \displaystyle\int_a^b T(f(t))\,dt$ in F. Closedness of T completes the proof. □

Theorem B.6.5. (Fundamental theorem of calculus for Banach-valued functions) Let E be a Banach space, and let $F\colon [a,b] \longrightarrow E$ be a function of class C^1. Then

$$F(b) - F(a) = \int_a^b F'(t)\,dt.$$

More generally, for any $s, t \in [a,b]$ with $s \leq t$, we have $F(t) - F(s) = \displaystyle\int_s^t F'(\tau)\,d\tau$.

Proof. Continuity of F' and Theorem B.6.2 ensure that the integral is well defined. Let $\varphi \in E'$. The scalar function $\varphi \circ F$ is of class C^1 and, by the chain rule, $(\varphi \circ F)'(t) = \varphi(F'(t))$. The fundamental theorem of calculus for real-valued functions and Proposition B.6.4 imply

$$\varphi(F(b) - F(a)) = \int_a^b \varphi(F'(t))\,dt = \varphi\left(\int_a^b F'(t)\,dt\right).$$

Thus $\varphi\left(F(b)-F(a)-\int_a^b F'(t)\,dt\right)=0$ for every $\varphi\in E'$. Since the continuous dual separates points, the identity follows. The formula on $[s,t]$ is proved in the same way. □

Proposition B.6.6. (Integration by parts for Banach-valued functions) Let E be a Banach space, let $\alpha\colon[a,b]\longrightarrow\mathbb{K}$ be of class C^1, and let $F\colon[a,b]\longrightarrow E$ be of class C^1. Then

$$\int_a^b \alpha(t)F'(t)\,dt=\alpha(b)F(b)-\alpha(a)F(a)-\int_a^b \alpha'(t)F(t)\,dt. \tag{B.7}$$

Proof. The map $B\colon\mathbb{K}\times E\longrightarrow E$, defined by $B(\lambda,v):=\lambda v$, is continuous and bilinear. The product rule gives

$$\frac{d}{dt}\big(\alpha(t)F(t)\big)=\alpha'(t)F(t)+\alpha(t)F'(t).$$

Applying Theorem B.6.5 to the function $t\longmapsto\alpha(t)F(t)$ and using linearity of the integral, we obtain

$$\alpha(b)F(b)-\alpha(a)F(a)=\int_a^b \alpha'(t)F(t)\,dt+\int_a^b \alpha(t)F'(t)\,dt.$$

Solving for the last integral gives (B.7). □

B.6.2 The Lebesgue integral

From now on, $(M,\mathcal{A},\mu)$ denotes a measure space. Measurability of a function will always be understood with respect to the σ-algebra $\mathcal{A}$ on the domain and the Borel σ-algebra on the codomain.

Definition B.6.7. Let Y be a topological space. A function $f\colon M\longrightarrow Y$ is **$\mathcal{A}$-measurable**, or simply **measurable**, if $f^{-1}(U)\in\mathcal{A}$ for every open set $U\subseteq Y$. In particular, for functions $f\colon M\longrightarrow\overline{\mathbb{R}}:=[-\infty,\infty]$, we equip $\overline{\mathbb{R}}$ with the order topology.

The Lebesgue integral is first constructed for nonnegative simple functions. We use a single notion of simple function, valid for both scalar-valued and vector-valued functions.

Definition B.6.8. Let V be a vector space. A function $s\colon M\longrightarrow V$ is **simple** if there exist pairwise disjoint measurable sets $A_1,\dots,A_r\in\mathcal{A}$ and vectors $v_1,\dots,v_r\in V$ such that $s=\sum_{i=1}^{r} v_i\mathbf{1}_{A_i}$, where $\mathbf{1}_A$ denotes the indicator function of A.

Definition B.6.9. Let $s\colon M\longrightarrow[0,\infty)$ be a simple function, and write $s=\sum_{i=1}^{r} a_i\mathbf{1}_{A_i}$, where $a_i\geq 0$ and the sets A_i are measurable and pairwise disjoint. Define $\int_M s\,d\mu:=\sum_{i=1}^{r} a_i\mu(A_i)$, with the convention $0\cdot\infty=0$. This definition is independent of the chosen representation of s.

Definition B.6.10. Let $f\colon M \longrightarrow [0,\infty]$ be measurable. Define its **Lebesgue integral** by $\int_M f\,d\mu := \sup\left\{\int_M s\,d\mu \;\middle|\; s\colon M \longrightarrow [0,\infty) \text{ is simple and } 0 \le s \le f\right\}$. If $A \in \mathcal{A}$, define $\int_A f\,d\mu := \int_M f\mathbf{1}_A\,d\mu$.

The first fundamental convergence theorem expresses continuity of the integral with respect to increasing limits.

Theorem B.6.11. (Monotone convergence theorem) Let $(f_n)_{n\in\mathbb{N}}$ be a sequence of measurable functions $f_n\colon M \longrightarrow [0,\infty]$ such that $f_n \le f_{n+1}$ for every $n \in \mathbb{N}$ and $f_n(x) \longrightarrow f(x)$ for μ-almost every $x \in M$. Then f is measurable and $\int_A f\,d\mu = \lim_{n\to\infty}\int_A f_n\,d\mu$ for every $A \in \mathcal{A}$.

Proof. Modifying all the functions on a single null set, we may suppose that convergence and monotonicity hold at every point. Then $f = \sup_{n\in\mathbb{N}} f_n$, so f is measurable. It suffices to prove the equality for $A = M$, since the general case follows by applying the same argument to $f_n\mathbf{1}_A$.
By monotonicity of the integral, the sequence $\int_M f_n\,d\mu$ is increasing and

$$I := \lim_{n\to\infty}\int_M f_n\,d\mu \le \int_M f\,d\mu.$$

For the reverse inequality, let s be a nonnegative simple function with $s \le f$, and fix $c \in (0,1)$. Define

$$A_n := \{x \in M \mid f_n(x) \ge c\,s(x)\}.$$

The sets A_n are measurable, form an increasing sequence, and have union M: if $s(x) = 0$, then $x \in A_n$ for every n; if $s(x) > 0$, convergence $f_n(x) \to f(x) \ge s(x) > c\,s(x)$ implies that $x \in A_n$ for sufficiently large n. Thus

$$\int_M f_n\,d\mu \ge c\int_{A_n} s\,d\mu.$$

If $s = \sum_{j=1}^{r} a_j\mathbf{1}_{B_j}$ with $a_j \ge 0$ and the B_j pairwise disjoint, continuity from below of the measure gives

$$\lim_{n\to\infty}\int_{A_n} s\,d\mu = \sum_{j=1}^{r} a_j \lim_{n\to\infty}\mu(A_n \cap B_j) = \sum_{j=1}^{r} a_j\mu(B_j) = \int_M s\,d\mu.$$

Consequently, $I \ge c\int_M s\,d\mu$. Letting $c \uparrow 1$ and then taking the supremum over all simple functions $0 \le s \le f$ gives

$$I \ge \int_M f\,d\mu.$$

Together with the first inequality, this proves equality. □

Lemma B.6.12. (Fatou) Let $(f_n)_{n\in\mathbb{N}}$ be a sequence of measurable functions $f_n\colon M \longrightarrow [0,\infty]$. Then

$$\int_M \liminf_{n\to\infty} f_n \, d\mu \le \liminf_{n\to\infty} \int_M f_n \, d\mu.$$

Proof. For each $n \in \mathbb{N}$, define $g_n := \inf_{k\ge n} f_k$. The sequence (g_n) is increasing and converges pointwise to $\liminf_{n\to\infty} f_n$. By Theorem B.6.11,

$$\int_M \liminf_{n\to\infty} f_n \, d\mu = \lim_{n\to\infty} \int_M g_n \, d\mu.$$

Since $g_n \le f_k$ for every $k \ge n$, we have $\int_M g_n \, d\mu \le \inf_{k\ge n} \int_M f_k \, d\mu$. Letting $n \to \infty$ yields the desired inequality. □

Definition B.6.13. Let $f\colon M \longrightarrow \overline{\mathbb{R}}$ be measurable, and define $f^+ := \max\{f, 0\}$ and $f^- := \max\{-f, 0\}$. Whenever at least one of the quantities $\int_M f^+ \, d\mu$ and $\int_M f^- \, d\mu$ is finite, define $\int_M f \, d\mu := \int_M f^+ \, d\mu - \int_M f^- \, d\mu$. We say that f is **Lebesgue integrable**, or simply **integrable**, if $\int_M |f| \, d\mu < \infty$. Denote by $\mathcal{L}^1(M,\mu)$ the vector space of integrable functions and by $L^1(M,\mu)$ the space of their equivalence classes modulo equality almost everywhere. For $A \in \mathcal{A}$, write $\int_A f \, d\mu := \int_M f \mathbf{1}_A \, d\mu$.

Theorem B.6.14. (Lebesgue dominated convergence theorem) Let $(f_n)_{n\in\mathbb{N}}$ be a sequence of measurable functions $f_n\colon M \longrightarrow \overline{\mathbb{R}}$ such that $f_n(x) \longrightarrow f(x)$ for μ-almost every $x \in M$. Suppose that there exists $g \in \mathcal{L}^1(M,\mu)$ such that $|f_n| \le g$ μ-almost everywhere for every $n \in \mathbb{N}$. Then $f \in \mathcal{L}^1(M,\mu)$, $\int_M |f_n - f| \, d\mu \longrightarrow 0$, and $\int_A f \, d\mu = \lim_{n\to\infty} \int_A f_n \, d\mu$ for every $A \in \mathcal{A}$.

Proof. The inequality $|f_n| \le g$ implies $g \ge 0$ almost everywhere; if desired, g may be replaced by $|g|$. We may modify the functions on a common null set and assume that convergence and domination hold at every point. The pointwise limit f is measurable and satisfies $|f| \le g$, so $f \in \mathcal{L}^1(M,\mu)$. Moreover,

$$0 \le |f_n - f| \le 2g \quad \text{and} \quad 2g - |f_n - f| \longrightarrow 2g$$

pointwise. Applying Fatou's lemma to the nonnegative functions $2g - |f_n - f|$ gives

$$2\int_M g \, d\mu \le \liminf_{n\to\infty} \left(2\int_M g \, d\mu - \int_M |f_n - f| \, d\mu \right) = 2\int_M g \, d\mu - \limsup_{n\to\infty} \int_M |f_n - f| \, d\mu.$$

Since $\int_M g \, d\mu < \infty$, it follows that

$$\lim_{n\to\infty} \int_M |f_n - f| \, d\mu = 0.$$

Finally, for every $A \in \mathcal{A}$,

$$\left| \int_A f_n \, d\mu - \int_A f \, d\mu \right| \le \int_A |f_n - f| \, d\mu \le \int_M |f_n - f| \, d\mu \longrightarrow 0.$$

□

In Euclidean spaces, the Lebesgue integral transforms through the Jacobian of a diffeomorphism.

Theorem B.6.15. (Change-of-variables theorem) Let $\Omega, \Omega' \subseteq \mathbb{R}^n$ be open sets, and let $\varphi\colon \Omega \longrightarrow \Omega'$ be a diffeomorphism of class C^1.

(a) If $f\colon \Omega' \longrightarrow [0,\infty]$ is measurable, then $\displaystyle\int_{\Omega} f(\varphi(x))\,|\det D\varphi(x)|\,d\lambda_n(x) = \int_{\Omega'} f(y)\,d\lambda_n(y)$.

(b) A measurable function $f\colon \Omega' \longrightarrow \mathbb{R}$ is integrable if and only if $(f\circ\varphi)\,|\det D\varphi|$ is integrable on Ω, and in this case the same equality holds.

A proof based on approximation by cubes and the local behavior of a C^1 diffeomorphism can be found in [68, 22].

Corollary B.6.16. Let $\Omega \subseteq \mathbb{R}^n$ be open, and let $A \in \mathcal{L}(\mathbb{R}^n)$ satisfy $A \subseteq \Omega$ and $\lambda_n(A \setminus \operatorname{int}(A)) = 0$. Suppose that $\Phi \in C^1(\Omega, \mathbb{R}^n)$ and that $\Phi\restriction_{\operatorname{int}(A)}\colon \operatorname{int}(A) \longrightarrow \Phi(\operatorname{int}(A))$ is a diffeomorphism.

(a) If $f\colon \Phi(A) \longrightarrow [0,\infty]$ is measurable, then $\displaystyle\int_{\Phi(A)} f(y)\,d\lambda_n(y) = \int_A f(\Phi(x))\,|\det D\Phi(x)|\,d\lambda_n(x)$.

(b) A measurable function $f\colon \Phi(A) \longrightarrow \mathbb{R}$ is integrable if and only if $(f\circ\Phi)\,|\det D\Phi|$ is integrable on A, and in this case the same equality holds.

Proof. Let $N := A \setminus \operatorname{int}(A)$. By Proposition B.5.17, $\Phi(N)$ is Lebesgue measurable and $\lambda_n(\Phi(N)) = 0$, since Φ is locally Lipschitz. Moreover, $\Phi(A) \setminus \Phi(\operatorname{int}(A)) \subseteq \Phi(N)$. Thus the integrals over A and $\Phi(A)$ do not change when these sets are replaced by $\operatorname{int}(A)$ and $\Phi(\operatorname{int}(A))$, respectively. The result follows from Theorem B.6.15. □

Theorem B.6.17. (Tonelli's theorem) Let $(X, \mathcal{A}, \mu)$ and $(Y, \mathcal{B}, \nu)$ be σ-finite measure spaces. If $f\colon X \times Y \longrightarrow [0,\infty]$ is measurable, then the functions

$$x \longmapsto \int_Y f(x,y)\,d\nu(y), \qquad y \longmapsto \int_X f(x,y)\,d\mu(x)$$

are measurable and

$$\int_{X\times Y} f\,d(\mu\otimes\nu) = \int_X \left(\int_Y f(x,y)\,d\nu(y)\right) d\mu(x) = \int_Y \left(\int_X f(x,y)\,d\mu(x)\right) d\nu(y),$$

with values in $[0,\infty]$ allowed.

Proof. The equality is first verified for indicators of measurable rectangles and, by additivity, for nonnegative simple functions. If f_k is an increasing sequence of nonnegative simple functions with $f_k \to f$, Theorem B.6.11, applied first to the inner integrals and then to the outer ones, allows passage to the limit and proves all three equalities. Measurability of the partial integrals follows in the same step as an increasing limit of measurable functions. □

Theorem B.6.18. (Fubini's theorem) Let $1 \le m < n$, and identify $\mathbb{R}^n = \mathbb{R}^m \times \mathbb{R}^{n-m}$. If $f \in \mathcal{L}^1(\mathbb{R}^n, \lambda_n)$, then, for λ_{n-m}-almost every $y \in \mathbb{R}^{n-m}$, the function $x \longmapsto f(x,y)$ belongs to $\mathcal{L}^1(\mathbb{R}^m, \lambda_m)$. The function $F(y) := \int_{\mathbb{R}^m} f(x,y)\, d\lambda_m(x)$, defined arbitrarily on the exceptional set, belongs to $\mathcal{L}^1(\mathbb{R}^{n-m}, \lambda_{n-m})$, and $\int_{\mathbb{R}^n} f\, d\lambda_n = \int_{\mathbb{R}^{n-m}} F(y)\, d\lambda_{n-m}(y)$. Similarly, for λ_m-almost every $x \in \mathbb{R}^m$, the function $y \longmapsto f(x,y)$ is integrable. If $H(x) := \int_{\mathbb{R}^{n-m}} f(x,y)\, d\lambda_{n-m}(y)$, then $H \in \mathcal{L}^1(\mathbb{R}^m, \lambda_m)$ and $\int_{\mathbb{R}^n} f\, d\lambda_n = \int_{\mathbb{R}^m} H(x)\, d\lambda_m(x)$.

Proof. Apply Tonelli's theorem to the nonnegative function $|f|$. Since

$$\int_{\mathbb{R}^{n-m}} \left(\int_{\mathbb{R}^m} |f(x,y)|\, d\lambda_m(x) \right) d\lambda_{n-m}(y) = \int_{\mathbb{R}^n} |f|\, d\lambda_n < \infty,$$

the inner integral of $|f|$ is finite for λ_{n-m}-almost every y. For these y, the function $x \mapsto f(x,y)$ is integrable. Writing $f = f^+ - f^-$ and applying Tonelli separately to f^+ and f^- gives measurability of

$$F(y) = \int_{\mathbb{R}^m} f(x,y)\, d\lambda_m(x)$$

outside the exceptional set and the identity

$$\int_{\mathbb{R}^{n-m}} F(y)\, d\lambda_{n-m}(y) = \int_{\mathbb{R}^n} f^+\, d\lambda_n - \int_{\mathbb{R}^n} f^-\, d\lambda_n = \int_{\mathbb{R}^n} f\, d\lambda_n.$$

Likewise,

$$|F(y)| \le \int_{\mathbb{R}^m} |f(x,y)|\, d\lambda_m(x)$$

for almost every y, and the right-hand side is integrable; thus $F \in \mathcal{L}^1(\mathbb{R}^{n-m})$. Interchanging the roles of x and y in this argument gives the assertions about H. □

Before stating the consequence ensuring uniqueness of weak derivatives, we define local integrability.

Definition B.6.19. Let $\Omega \subseteq \mathbb{R}^n$ be open. A measurable function $f : \Omega \longrightarrow \overline{\mathbb{R}}$ is **locally integrable** if $\int_K |f|\, d\lambda_n < \infty$ for every compact set $K \subseteq \Omega$. Denote by $\mathcal{L}^1_{\mathrm{loc}}(\Omega)$ the space of such functions and by $L^1_{\mathrm{loc}}(\Omega)$ the space of their equivalence classes modulo equality almost everywhere.

The following consequence states that a locally integrable function is determined, up to a null set, by its integrals against test functions. It will be used repeatedly to justify uniqueness of weak derivatives.

Proposition B.6.20. Let $\Omega \subseteq \mathbb{R}^n$ be open. If $f \in L^1_{\mathrm{loc}}(\Omega)$ satisfies $\int_\Omega f(x)\varphi(x)\, d\lambda_n(x) = 0$ for every $\varphi \in C_c^\infty(\Omega)$, then $f = 0$ almost everywhere on Ω.

Proof. Suppose, for a contradiction, that f does not vanish almost everywhere. An exhaustion of Ω by compact sets and the decomposition $\{|f| > 0\} = \bigcup_{j \ge 1} \{|f| \ge j^{-1}\}$ provide a compact set $K \Subset \Omega$ and a $j \ge 1$ for which $K \cap \{|f| \ge j^{-1}\}$ has positive measure. Divide the unit circle into finitely many sectors of angular width

less than $\frac{\pi}{2}$. One of them determines a measurable set $A \subseteq K$ of positive measure and a number $\omega \in \mathbb{C}$, $|\omega| = 1$, such that

$$\operatorname{Re}(\omega f) \geq c|f| \geq \frac{c}{j} \quad \text{on } A$$

for some constant $c > 0$. In the real case, it suffices to take one of the two signs.

By regularity of Lebesgue measure, choose a compact set $C \subseteq A$ of positive measure. Then $I_C := \int_C |f|\,d\lambda_n > 0$. Absolute continuity of the integral and outer regularity allow us to choose an open set U with $C \subseteq U \Subset \Omega$ and

$$\int_{U\setminus C} |f|\,d\lambda_n < \frac{c}{2} I_C.$$

By Proposition 1.3.6, there exists $\eta \in C_c^\infty(U)$ such that $0 \leq \eta \leq 1$ and $\eta = 1$ on C. Applying the hypothesis to $\varphi = \omega\eta$ instead gives

$$\operatorname{Re} \int_\Omega f\varphi\,d\lambda_n \geq cI_C - \int_{U\setminus C} |f|\,d\lambda_n > \frac{c}{2} I_C > 0,$$

a contradiction. Therefore $f = 0$ almost everywhere on Ω. □

B.6.3 The Bochner integral

We now consider functions defined on $(M, \mathcal{A}, \mu)$ with values in a Banach space E. The notion of simple function introduced above remains valid upon taking $V = E$; strong measurability is obtained by pointwise approximation by these functions, whereas the Bochner integral is obtained by approximation in the L^1 norm.

Definition B.6.21. Let E be a Banach space.

(a) A function $f\colon M \longrightarrow E$ is **strongly measurable** if there exists a sequence $(s_k)_{k\in\mathbb{N}}$ of simple functions $s_k\colon M \longrightarrow E$ such that $s_k(x) \longrightarrow f(x)$ for μ-almost every $x \in M$.

(b) A simple function $s\colon M \longrightarrow E$ is **integrable** if $\int_M \|s\|_E\,d\mu < \infty$. If $s = \sum_{i=1}^r v_i \mathbf{1}_{A_i}$, where the A_i are measurable and pairwise disjoint and terms with $v_i = 0$ have been omitted, then $\mu(A_i) < \infty$ for each i, and we define $\int_M s\,d\mu := \sum_{i=1}^r v_i \mu(A_i)$.

(c) A strongly measurable function $f\colon M \longrightarrow E$ is **Bochner integrable** if there exists a sequence $(s_k)_{k\in\mathbb{N}}$ of integrable simple functions such that $\int_M \|f - s_k\|_E\,d\mu \longrightarrow 0$. In this case, define $\int_M f\,d\mu := \lim_{k\to\infty} \int_M s_k\,d\mu$. Denote by $\mathcal{L}^1(M,\mu,E)$ the space of Bochner integrable functions and by $L^1(M,\mu,E)$ the space of their equivalence classes modulo equality almost everywhere. For $A \in \mathcal{A}$, define $\int_A f\,d\mu := \int_M f\mathbf{1}_A\,d\mu$.

Lemma B.6.22. The integral of an integrable simple function $s\colon M \longrightarrow E$ is well defined, that is, independent of the representation of s, and satisfies $\left\| \int_M s\,d\mu \right\|_E \leq \int_M \|s\|_E\,d\mu$.

Proof. Two representations of s admit a common refinement consisting of intersections of their level sets, and the sum defining the integral agrees when computed on this refinement. If $s = \sum_{i=1}^{r} v_i \mathbf{1}_{A_i}$ with the A_i pairwise disjoint, then $\left\| \int_M s \, d\mu \right\|_E = \left\| \sum_{i=1}^{r} v_i \mu(A_i) \right\|_E \leq \sum_{i=1}^{r} \|v_i\|_E \mu(A_i) = \int_M \|s\|_E \, d\mu$. □

The following criterion shows that, once strong measurability has been established, Bochner integrability is characterized entirely by integrability of the norm.

Proposition B.6.23. Let E be a Banach space, and let $f : M \longrightarrow E$ be strongly measurable. Then f is Bochner integrable if and only if $\|f\|_E \in \mathcal{L}^1(M,\mu)$. In this case, the Bochner integral is well defined, and the map $\mathcal{I}_B : \mathcal{L}^1(M,\mu,E) \longrightarrow E$, given by $\mathcal{I}_B(f) := \int_M f \, d\mu$, is linear and satisfies $\left\| \int_M f \, d\mu \right\|_E \leq \int_M \|f\|_E \, d\mu$.

Proof. Since the norm is continuous, strong measurability of f implies measurability of $\|f\|_E$. First suppose that f is Bochner integrable, and let $(s_k)_{k\in\mathbb{N}}$ be a sequence of integrable simple functions such that $\int_M \|f - s_k\|_E \, d\mu \longrightarrow 0$. By Lemma B.6.22, $\left\| \int_M s_k \, d\mu - \int_M s_\ell \, d\mu \right\|_E \leq \int_M \|s_k - s_\ell\|_E \, d\mu \leq \int_M \|s_k - f\|_E \, d\mu + \int_M \|f - s_\ell\|_E \, d\mu$, so the sequence of integrals is Cauchy. The same argument applied simultaneously to two approximating sequences shows that the limit is independent of the choice of sequence. Moreover, for any k we have $\int_M \|f\|_E \, d\mu \leq \int_M \|f - s_k\|_E \, d\mu + \int_M \|s_k\|_E \, d\mu < \infty$, and $\left| \int_M \|s_k\|_E \, d\mu - \int_M \|f\|_E \, d\mu \right| \leq \int_M \|s_k - f\|_E \, d\mu \longrightarrow 0$. Consequently, $\left\| \int_M f \, d\mu \right\|_E = \lim_{k\to\infty} \left\| \int_M s_k \, d\mu \right\|_E \leq \lim_{k\to\infty} \int_M \|s_k\|_E \, d\mu = \int_M \|f\|_E \, d\mu$. Linearity follows by approximating two Bochner integrable functions by simple functions and taking linear combinations.

Conversely, suppose that $\|f\|_E \in \mathcal{L}^1(M,\mu)$. By strong measurability, there exists a sequence of simple functions $(t_k)_{k\in\mathbb{N}}$ such that $t_k(x) \longrightarrow f(x)$ for μ-almost every $x \in M$. Define $B_k := \{x \in M \mid \|t_k(x)\|_E \leq 2\|f(x)\|_E\}$ and $s_k := t_k \mathbf{1}_{B_k}$. Each B_k is measurable, s_k is simple, and $\|s_k\|_E \leq 2\|f\|_E$, so s_k is integrable. If $f(x) \neq 0$, then $\|t_k(x)\|_E \longrightarrow \|f(x)\|_E$, and hence there exists $k_x \in \mathbb{N}$ such that $x \in B_k$ for every $k \geq k_x$; if $f(x) = 0$, then $s_k(x) = 0$ for every $k \in \mathbb{N}$. Thus $s_k(x) \longrightarrow f(x)$ for μ-almost every $x \in M$. Finally, $\|s_k - f\|_E \leq 3\|f\|_E$ and Theorem B.6.14 imply that $\int_M \|s_k - f\|_E \, d\mu \longrightarrow 0$. Consequently, f is Bochner integrable. □

Stability of strong measurability under almost everywhere pointwise limits will be used in the dominated convergence theorem.

Lemma B.6.24. Let $(f_k)_{k\in\mathbb{N}}$ be a sequence of strongly measurable functions $f_k : M \longrightarrow E$. If $f_k(x) \longrightarrow f(x)$ for μ-almost every $x \in M$, then f is strongly measurable.

Proof. For each k, the essential range of f_k is contained in a separable subspace of E, since f_k is an almost everywhere pointwise limit of simple functions. Thus, outside a null set, the ranges of all the f_k and of f lie in a single closed separable subspace $E_0 \subseteq E$. Moreover, each f_k is measurable and, since E is metrizable, its almost everywhere pointwise limit f is also measurable after modification on a null set. Let $(e_j)_{j\in\mathbb{N}}$ be a dense subset of E_0. For each $r \in \mathbb{N}$, choose at every point an element of $\{e_1, \ldots, e_r\}$ at minimum distance from $f(x)$, resolving ties by choosing the smallest index. The resulting functions are simple and converge pointwise to f, since $\min_{1\leq j\leq r} \|f(x) - e_j\|_E \longrightarrow 0$. Consequently, f is strongly measurable. □

The vector-valued dominated convergence theorem is now a direct consequence of the preceding criterion.

Theorem B.6.25. (Bochner dominated convergence theorem) Let $(f_k)_{k\in\mathbb{N}}$ be a sequence of strongly measurable functions $f_k\colon M \longrightarrow E$ such that $f_k(x) \longrightarrow f(x)$ for μ-almost every $x \in M$. Suppose that there exists $g \in \mathcal{L}^1(M,\mu)$ such that $\|f_k\|_E \le g$ μ-almost everywhere for every $k \in \mathbb{N}$. Then f is strongly measurable, $f_k, f \in \mathcal{L}^1(M,\mu,E)$, and $\displaystyle\int_M \|f_k - f\|_E \, d\mu \longrightarrow 0$. In particular, $\displaystyle\int_M f_k \, d\mu \longrightarrow \int_M f \, d\mu$ in E.

Proof. By Lemma B.6.24, f is strongly measurable. Moreover, $\|f\|_E \le g$ almost everywhere and $\|f_k - f\|_E \le 2g$. Theorem B.6.14 applied to the scalar functions $\|f_k - f\|_E$ implies convergence in $\mathcal{L}^1$, while Proposition B.6.23 ensures Bochner integrability. Finally, $\displaystyle\left\| \int_M f_k \, d\mu - \int_M f \, d\mu \right\|_E \le \int_M \|f_k - f\|_E \, d\mu \longrightarrow 0$. □

Theorem B.6.26. (Fubini's theorem for Bochner integrals) Let $(X,\mathcal{A},\mu)$ and $(Y,\mathcal{B},\nu)$ be σ-finite measure spaces, let E be a Banach space, and let $F\colon X \times Y \longrightarrow E$ be strongly measurable. If

$$\int_{X\times Y} \|F(x,y)\|_E \, d(\mu\otimes\nu)(x,y) < \infty,$$

then $F(x,\cdot)$ is Bochner integrable for μ-almost every x, and $F(\cdot,y)$ is Bochner integrable for ν-almost every y. The functions obtained by integrating in one variable are strongly measurable and integrable in the other variable, and

$$\begin{aligned}\int_{X\times Y} F \, d(\mu\otimes\nu) &= \int_X \left(\int_Y F(x,y)\, d\nu(y) \right) d\mu(x) \\ &= \int_Y \left(\int_X F(x,y)\, d\mu(x) \right) d\nu(y).\end{aligned}$$

Proof. By Proposition B.6.23, F is Bochner integrable on $X \times Y$. Choose integrable simple functions $S_k\colon X \times Y \longrightarrow E$ such that

$$\int_{X\times Y} \|F - S_k\|_E \, d(\mu\otimes\nu) \longrightarrow 0.$$

Tonelli's theorem B.6.17, applied to $\|F - S_k\|_E$, allows us to extract a subsequence, which we do not relabel, for which

$$\int_Y \|F(x,y) - S_k(x,y)\|_E \, d\nu(y) \longrightarrow 0$$

for μ-almost every x. In particular, these sections of F are strongly measurable and Bochner integrable. For a simple function S_k, Tonelli applied to the indicators of its level sets proves directly that

$$\int_{X\times Y} S_k \, d(\mu\otimes\nu) = \int_X \left(\int_Y S_k(x,y)\, d\nu(y) \right) d\mu(x).$$

Moreover,

$$\int_X \left\| \int_Y (F - S_k)(x,y)\, d\nu(y) \right\|_E d\mu(x) \le \int_{X\times Y} \|F - S_k\|_E \, d(\mu\otimes\nu).$$

The right-hand side tends to zero. Thus the partial integrals form a convergent sequence in $L^1(X,\mu,E)$, its limit agrees almost everywhere with $x \mapsto \displaystyle\int_Y F(x,y)\, d\nu(y)$, and we may pass to the limit in the identity for S_k. Interchanging X and Y proves the second equality. □

Like the Riemann integral, the Bochner integral is compatible with continuous and closed linear operators.

Proposition B.6.27. Let E and F be Banach spaces, and let $f\colon M \longrightarrow E$ be Bochner integrable.

(a) If $T \in \mathcal{L}(E,F)$, then $T \circ f$ is Bochner integrable and $\displaystyle\int_M T(f)\,d\mu = T\left(\int_M f\,d\mu\right)$.

(b) If $T\colon \operatorname{Dom}(T) \subseteq E \longrightarrow F$ is a closed linear operator, $f(x) \in \operatorname{Dom}(T)$ for μ-almost every $x \in M$, and $T \circ f$ is Bochner integrable, then $\displaystyle\int_M f\,d\mu \in \operatorname{Dom}(T)$ and the same equality holds.

Proof. If $T \in \mathcal{L}(E,F)$ and $(s_k)_{k\in\mathbb{N}}$ approximates f in $\mathcal{L}^1$, then $T \circ s_k$ is simple, $\displaystyle\int_M \|T(f) - T(s_k)\|_F\,d\mu \le \|T\| \int_M \|f - s_k\|_E\,d\mu \longrightarrow 0$, and the equality follows first for simple functions and then by passage to the limit.

For the second assertion, modifying f and $T \circ f$ on a null set, we may assume that $f(x) \in \operatorname{Dom}(T)$ for every $x \in M$. Consider $G\colon M \longrightarrow E \times F$, given by $G(x) := (f(x), T(f(x)))$, and equip $E \times F$ with the norm $\|(u,v)\| := \|u\|_E + \|v\|_F$. The function G is strongly measurable and $\displaystyle\int_M \|G\|\,d\mu < \infty$, so it is Bochner integrable. The coordinate projections and the first part show that $\displaystyle\int_M G\,d\mu = \left(\int_M f\,d\mu, \int_M T(f)\,d\mu\right)$. Since the graph $\mathcal{G}(T)$ is a closed subspace of $E \times F$, the quotient map $Q\colon E \times F \longrightarrow (E \times F)/\mathcal{G}(T)$ is linear and continuous. Because $Q \circ G = 0$ almost everywhere, the first part implies $\displaystyle Q\left(\int_M G\,d\mu\right) = \int_M Q(G)\,d\mu = 0$. Thus $\displaystyle\int_M G\,d\mu \in \mathcal{G}(T)$, which is equivalent to the conclusion. □

Remark B.6.28. If $f\colon M \longrightarrow E$ is Bochner integrable and $\varphi \in E'$, Proposition B.6.27 applied to $\varphi\colon E \longrightarrow \mathbb{K}$ shows that $\varphi \circ f$ is integrable and $\displaystyle\varphi\left(\int_A f\,d\mu\right) = \int_A \varphi(f)\,d\mu$ for every $A \in \mathcal{A}$. In particular, every Bochner integrable function is Pettis integrable and hence Dunford integrable; all three integrals agree under the canonical inclusion $E \hookrightarrow E''$.

Theorem B.6.29. (Radon–Nikodym) Let μ and ν be σ-finite measures on $(X,\mathcal{A})$, with ν positive and $\nu \ll \mu$. There exists a measurable function $h\colon X \longrightarrow [0,\infty)$, unique μ-almost everywhere, such that

$$\nu(A) = \int_A h\,d\mu, \qquad A \in \mathcal{A}.$$

If ν is a signed or complex measure, $\nu \ll \mu$, and its total variation $|\nu|$ is σ-finite, there similarly exists a measurable density $h\colon X \to \mathbb{K}$. More precisely, one may choose a measurable exhaustion $X_k \uparrow X$ with $\mu(X_k) + |\nu|(X_k) < \infty$, and then $h\mathbf{1}_{X_k} \in L^1(X,\mu)$ and

$$\nu(A \cap X_k) = \int_{A\cap X_k} h\,d\mu \qquad (A \in \mathcal{A},\ k \in \mathbb{N}).$$

In particular, if $|\nu|(X) < \infty$, we have $h \in L^1(X,\mu)$. This formulation replaces the notation $L^1_{\mathrm{loc}}(X,\mu)$, which is not canonical on an abstract measure space without a topological notion of locality.

Proof. First suppose that $\mu(X)+\nu(X)<\infty$, and set $\lambda := \mu+\nu$. The functional

$$L(f) := \int_X f\, d\nu$$

is continuous on $L^2(X,\lambda)$, since Cauchy–Schwarz gives $|L(f)| \le \nu(X)^{\frac{1}{2}}\|f\|_{L^2(X,\lambda)}$. By Theorem B.3.12, there exists $g \in L^2(X,\lambda)$ such that

$$\int_X f\, d\nu = \int_X f g\, d\lambda$$

for every $f \in L^2(X,\lambda)$. Applying the identity to indicators gives $0 \le g \le 1$ almost everywhere and $\mu(A) = \int_A (1-g)\, d\lambda$. On the set $\{g=1\}$, μ vanishes; the hypothesis $\nu \ll \mu$ implies that ν also vanishes, so this set is λ-null. Thus

$$h := \frac{g}{1-g}$$

is defined almost everywhere, and $d\nu = h\, d\mu$.

In the σ-finite case, choose a measurable partition $X = \bigsqcup_{k\in\mathbb{N}} X_k$ with $\mu(X_k)+\nu(X_k)<\infty$ and apply the preceding case on each X_k; the densities glue by uniqueness. If two densities h_1, h_2 represent ν, integration over $\{h_1 > h_2\}$ and $\{h_2 > h_1\}$ proves that they agree almost everywhere. For a signed or complex measure, choose an exhaustion on which μ and $|\nu|$ are finite and apply the positive case to the Jordan parts of the real and imaginary components. The resulting densities are integrable on each X_k and glue by the same uniqueness argument. □

B.7 The L^p spaces

The L^p spaces will be the starting point for Sobolev spaces and several weak formulations of partial differential equations. We recall their basic properties and some inequalities used later.

Definition B.7.1. Let $(X,\mathcal{A},\mu)$ be a measure space, and fix $p \in (0,\infty)$. Define

$$\mathcal{L}^p(X) := \left\{ f : X \longrightarrow \mathbb{K} \;\middle|\; f \text{ is measurable and } \int_X |f|^p\, d\mu < \infty \right\}.$$

Define $\|\cdot\|_{\mathcal{L}^p(X)} : \mathcal{L}^p(X) \longrightarrow \mathbb{R}$ by

$$\|f\|_{\mathcal{L}^p(X)} = \left(\int_X |f|^p\, d\mu \right)^{\frac{1}{p}}.$$

If $p=\infty$, define

$$\mathcal{L}^\infty(X) := \{ f : X \longrightarrow \mathbb{K} \mid f \text{ is measurable and bounded almost everywhere on } X \},$$

and

$$\|f\|_{\mathcal{L}^\infty(X)} := \inf\{a>0 \mid \mu(\{x\in X \mid |f(x)|>a\}) = 0\}.$$

Definition B.7.2. Fix $p \in [1,\infty]$. Define a relation $\sim$ on $\mathcal{L}^p(X)$ as follows:

$$f \sim g \iff \|f-g\|_{\mathcal{L}^p(X)} = 0.$$

Note that $\sim$ is an equivalence relation; write $L^p(X) := \mathcal{L}^p(X)/\sim$. If $[f] \in L^p(X)$, define $\|[f]\|_{L^p(X)} = \|f\|_{\mathcal{L}^p(X)}$, and in practice identify $[f]$ with f.

Theorem B.7.3. (Lebesgue spaces) Let $p \in [1,\infty]$. Then:

(a) If $p < \infty$, $\|\cdot\|_{L^p(X)}$ is a norm on $L^p(X)$ and $(L^p(X), \|\cdot\|_{L^p(X)})$ is a Banach space. The triangle inequality in $L^p(X)$ is known as Minkowski's inequality.

(b) If $p = \infty$, $\|\cdot\|_{L^\infty(X)}$ is a norm on $L^\infty(X)$ and $(L^\infty(X), \|\cdot\|_{L^\infty(X)})$ is a Banach space.

Proof. First consider $1 \le p < \infty$. Homogeneity and separation of points modulo equality almost everywhere follow directly from the definition. To prove the triangle inequality when $1 < p < \infty$, first recall Hölder's inequality. If $u \in L^p(X)$, $v \in L^{p'}(X)$, and both norms are nonzero, Young's inequality applied to

$$\frac{|u|}{\|u\|_{L^p(X)}} \quad \text{and} \quad \frac{|v|}{\|v\|_{L^{p'}(X)}}$$

and integrated over X gives

$$\int_X |uv|\,d\mu \le \|u\|_{L^p(X)}\|v\|_{L^{p'}(X)}.$$

If either norm vanishes, the same inequality is immediate. Applying it with $v = |f+g|^{p-1}$ gives

$$\begin{aligned}\|f+g\|_{L^p(X)}^p &\le \int_X |f||f+g|^{p-1}\,d\mu + \int_X |g||f+g|^{p-1}\,d\mu \\ &\le \big(\|f\|_{L^p(X)} + \|g\|_{L^p(X)}\big)\big\||f+g|^{p-1}\big\|_{L^{p'}(X)} \\ &= \big(\|f\|_{L^p(X)} + \|g\|_{L^p(X)}\big)\|f+g\|_{L^p(X)}^{p-1}.\end{aligned}$$

If $\|f+g\|_{L^p(X)} = 0$, there is nothing to prove; otherwise, divide by $\|f+g\|_{L^p(X)}^{p-1}$. For $p = 1$, the inequality follows by integrating $|f+g| \le |f| + |g|$. This proves that $\|\cdot\|_{L^p(X)}$ is a norm.

We now prove completeness. Let (f_n) be a Cauchy sequence in $L^p(X)$. We may choose a subsequence (f_{n_k}) such that

$$\|f_{n_{k+1}} - f_{n_k}\|_{L^p(X)} \le 2^{-k}, \qquad k \in \mathbb{N}.$$

Set $g_k := |f_{n_{k+1}} - f_{n_k}|$. By Minkowski's inequality, already proved,

$$\left\|\sum_{k=1}^{N} g_k\right\|_{L^p(X)} \le \sum_{k=1}^{N} \|g_k\|_{L^p(X)} \le 1 \qquad (N \in \mathbb{N}).$$

The monotone convergence theorem applied to $(\sum_{k=1}^{N} g_k)^p$ shows that

$$G := \sum_{k=1}^{\infty} g_k \quad \text{belongs to } L^p(X) \quad \text{and} \quad \|G\|_{L^p(X)} \le 1.$$

Outside a null set, the series

$$\sum_{k=1}^{\infty} \bigl(f_{n_{k+1}} - f_{n_k}\bigr)$$

converges absolutely. Define there

$$f := f_{n_1} + \sum_{k=1}^{\infty} \bigl(f_{n_{k+1}} - f_{n_k}\bigr)$$

and extend f arbitrarily to the exceptional set. The function f is measurable. Moreover, for each j,

$$|f - f_{n_j}| \le \sum_{k=j}^{\infty} g_k$$

almost everywhere. Applying monotone convergence again to the tails and using Minkowski for their finite sums gives

$$\|f - f_{n_j}\|_{L^p(X)} \le \sum_{k=j}^{\infty} 2^{-k} \longrightarrow 0.$$

In particular, $f \in L^p(X)$. Since the original sequence is Cauchy and a subsequence converges to f, the entire sequence converges to f.

Now consider $p = \infty$. The norm properties follow from the pointwise inequalities

$$|\lambda f| = |\lambda||f|, \qquad |f + g| \le |f| + |g|$$

outside null sets. If (f_n) is Cauchy in $L^\infty(X)$, choose a subsequence such that

$$\|f_{n_{k+1}} - f_{n_k}\|_\infty \le 2^{-k}.$$

After modifying representatives on the union of a countable family of null sets, we may assume that

$$|f_{n_{k+1}}(x) - f_{n_k}(x)| \le 2^{-k}$$

for every k and every x outside a single null set N. By the Weierstrass test, f_{n_k} converges uniformly on $X \setminus N$ to a measurable function f, which we extend arbitrarily to N, and

$$\|f - f_{n_j}\|_\infty \le \sum_{k=j}^{\infty} 2^{-k} \longrightarrow 0.$$

Again, the Cauchy property implies that the entire sequence converges to f in $L^\infty(X)$. Thus $L^\infty(X)$ is complete as well. □

Proposition B.7.4. (Reverse Minkowski inequality for exponents less than one) Let $(X, \mathcal{A}, \mu)$ be a measure space, let $0 < r < 1$, and let $f, g \colon X \longrightarrow [0, \infty]$ be measurable functions such that $\int_X f^r \, d\mu < \infty$ and $\int_X g^r \, d\mu < \infty$. Then

$$\left(\int_X (f+g)^r \, d\mu \right)^{\frac{1}{r}} \geq \left(\int_X f^r \, d\mu \right)^{\frac{1}{r}} + \left(\int_X g^r \, d\mu \right)^{\frac{1}{r}}.$$

Proof. Set

$$A := \left(\int_X f^r \, d\mu \right)^{\frac{1}{r}}, \qquad B := \left(\int_X g^r \, d\mu \right)^{\frac{1}{r}}.$$

If $A = 0$ or $B = 0$, one of the functions vanishes almost everywhere and the inequality is immediate. Thus suppose that $A, B > 0$ and define $\theta := \dfrac{A}{A+B}$. Concavity of $t \mapsto t^r$ on $[0, \infty)$ gives

$$\left(\theta \frac{f}{A} + (1-\theta) \frac{g}{B} \right)^r \geq \theta \left(\frac{f}{A} \right)^r + (1-\theta) \left(\frac{g}{B} \right)^r.$$

Upon integration, the right-hand side has integral one. Since

$$f + g = (A+B) \left(\theta \frac{f}{A} + (1-\theta) \frac{g}{B} \right),$$

we obtain

$$\int_X (f+g)^r \, d\mu \geq (A+B)^r.$$

Taking the rth root completes the proof. □

Proposition B.7.5. (Density of simple functions) Let $(X, \mathcal{A}, \mu)$ be a σ-finite measure space, and let $1 \leq p < \infty$. Simple functions whose support has finite measure are dense in $L^p(X)$.

Proof. Choose increasing sets $X_k \in \mathcal{A}$ of finite measure with $\bigcup_{k \in \mathbb{N}} X_k = X$. For $f \in L^p(X)$, the dominated convergence theorem B.6.14 gives

$$f \mathbf{1}_{X_k \cap \{|f| \leq k\}} \longrightarrow f \quad \text{in } L^p(X).$$

Each function on the left-hand side is bounded and has support of finite measure. Approximate its positive and negative parts from below by step functions with step size 2^{-m}; the pointwise error is at most 2^{-m} on X_k, so the error in $L^p(X)$ tends to zero. For complex-valued functions, apply the argument to the real and imaginary parts. □

Lemma B.7.6. (Hölder's inequality for two factors) Let $1 \leq p \leq \infty$, and let p' be its conjugate exponent. If $f \in L^p(X)$ and $g \in L^{p'}(X)$, then $fg \in L^1(X)$ and

$$\int_X |fg| \, d\mu \leq \|f\|_{L^p(X)} \|g\|_{L^{p'}(X)}.$$

Proof. The cases $p = 1$ and $p = \infty$ follow directly from the definition of the essential supremum. If $1 < p < \infty$ and both norms are nonzero, apply Young's inequality $ab \leq \frac{a^p}{p} + \frac{b^{p'}}{p'}$ pointwise to $a = \dfrac{|f|}{\|f\|_{L^p(X)}}$ and $b = \dfrac{|g|}{\|g\|_{L^{p'}(X)}}$

and integrate. If either norm vanishes, the conclusion is immediate. □

Theorem B.7.7. (Duality, reflexivity, and separability of L^p) Let $(X, \mathcal{A}, \mu)$ be a σ-finite measure space, and let $1 \le p < \infty$. If p' is the conjugate exponent, the map

$$\overline{L^{p'}(X)} \longrightarrow (L^p(X))', \qquad \overline{g} \longmapsto \left[f \mapsto \int_X f\,\overline{g}\,d\mu \right]$$

is a complex-linear isometric isomorphism (in the real case, the bars are omitted). Equivalently, the direct map $g \mapsto [f \mapsto \int_X f\,\overline{g}\,d\mu]$ is antilinear. Consequently, $L^p(X)$ is reflexive if $1 < p < \infty$. If, in addition, the σ-algebra modulo null sets is generated by a countable family—in particular, for an open subset of $\mathbb{R}^n$ with Lebesgue measure—then $L^p(X)$ is separable.

Proof. Lemma B.7.6 shows that each $\overline{g} \in \overline{L^{p'}(X)}$ defines a functional of norm at most $\|g\|_{L^{p'}(X)}$. The map is complex-linear because $\lambda\overline{g} = \overline{\overline{\lambda} g}$ in the conjugate space. Conversely, let $\Lambda \in (L^p(X))'$, and choose an increasing exhaustion $X = \bigcup_{k\in\mathbb{N}} X_k$, with $\mu(X_k) < \infty$. The restriction of Λ to $L^p(X_k)$ defines $\nu_k(A) := \Lambda(\mathbf{1}_A)$ for measurable $A \subset X_k$. If (A_j) is a disjoint family, the partial sums of its indicators converge in $L^p(X_k)$ to the indicator of its union; by continuity, ν_k is countably additive. For a finite partition $(A_j)_{j=1}^N$ of a subset of X_k, choose numbers θ_j of modulus one such that $\theta_j \nu_k(A_j) = |\nu_k(A_j)|$. Then

$$\sum_{j=1}^{N} |\nu_k(A_j)| = \Lambda\left(\sum_{j=1}^{N} \theta_j \mathbf{1}_{A_j} \right) \le \|\Lambda\|\, \mu(X_k)^{1/p}.$$

Thus ν_k has finite total variation; moreover, $\nu_k \ll \mu$. Theorem B.6.29 gives $d\nu_k = \overline{g}_k\, d\mu$. Uniqueness of the densities on $X_k \cap X_\ell$ allows them to be glued into a measurable function g on X.
If $1 < p < \infty$, apply Λ to $f_{N,k} := \operatorname{sgn}(g)|g|^{p'-1}\mathbf{1}_{X_k \cap \{|g|\le N\}}$ and obtain

$$\int_{X_k\cap\{|g|\le N\}} |g|^{p'}\,d\mu \le \|\Lambda\| \left(\int_{X_k\cap\{|g|\le N\}} |g|^{p'}\,d\mu \right)^{\frac{1}{p}}.$$

By monotone convergence, $g \in L^{p'}(X)$ and $\|g\|_{L^{p'}(X)} \le \|\Lambda\|$. For $p = 1$, applying Λ to indicators multiplied by the phase of g shows that $\|g\|_{L^\infty(X)} \le \|\Lambda\|$. Equality of norms and the representation for every $f \in L^p(X)$ follow by density of simple functions.
If $1 < p < \infty$, applying the preceding representation twice, while respecting the conjugate spaces, identifies the canonical inclusion $L^p(X) \to (L^p(X))''$ with an isomorphism; this proves reflexivity. Finally, simple functions with values in $\mathbb{Q} + i\mathbb{Q}$ (in the real case, in $\mathbb{Q}$) and sets belonging to the countable generating algebra form a countable dense subset, proving separability in the stated case. □

Corollary B.7.8. (L^p duality for Hermitian bundles) Let $(M, \mathbf{g})$ be a Riemannian manifold with or without boundary satisfying the second axiom of countability, and let $\mathbf{E} \to M$ be a smooth complex Hermitian bundle of finite rank. For $1 \le p < \infty$, the map

$$L^{p'}(M, \overline{\mathbf{E}}) \longrightarrow (L^p(M, \mathbf{E}))', \qquad \overline{\mathbf{v}} \longmapsto \left[u \longmapsto \int_M \mathcal{R}_{\mathbf{E}}(\overline{\mathbf{v}})(u)\, d\lambda_{\mathbf{g}} \right]$$

is a complex-linear isometric isomorphism.

Proof. A countable coordinate cover and a disjoint measurable refinement $M = \bigsqcup_{j\ge 1} A_j$ allow us to choose a measurable unitary frame of $\mathbf{E}$ on each A_j. Thus

$$L^p(M,\mathbf{E}) \cong \left(\bigoplus_{j\ge 1} L^p(A_j;\mathbb{C}^r) \right)_{\ell^p}$$

isometrically. Applying Theorem B.7.7 to each of the r components and using the discrete version of Lemma B.7.6, every element of $L^{p'}(M,\overline{\mathbf{E}})$ defines a functional of the same norm.
Conversely, the restriction of a functional to sections supported in A_j is represented by a unique $\mathbf{v}_j \in L^{p'}(A_j,\overline{\mathbf{E}})$. For every finite subset F of indices, finite-dimensional duality for $\ell^p(F)$ gives

$$\left(\sum_{j\in F} \|\mathbf{v}_j\|^{p'}_{L^{p'}(A_j,\overline{\mathbf{E}}\restriction_{A_j})} \right)^{\frac{1}{p'}} \le \|\Lambda\|$$

if $1 < p < \infty$, and $\sup_{j\in F} \|\mathbf{v}_j\|_{L^\infty(A_j,\overline{\mathbf{E}}\restriction_{A_j})} \le \|\Lambda\|$ if $p = 1$. As F increases, the sections $\mathbf{v}_j$ glue into an element $\mathbf{v} \in L^{p'}(M,\overline{\mathbf{E}})$ of norm at most $\|\Lambda\|$. Density of measurable sections supported in finitely many of the A_j proves the representation; the reverse norm inequality follows by evaluating on truncated Hölder extremizers. This proves the isometry and surjectivity. □

Proposition B.7.9. (Hölder's inequality) Let $(X,\mathcal{A},\mu)$ be a measure space, and consider $r, p_1, \dots, p_m \in [1,\infty]$ such that $\dfrac{1}{p_1} + \cdots + \dfrac{1}{p_m} = \dfrac{1}{r}$, with the convention $\dfrac{1}{\infty} = 0$. Then for any $f_j \in L^{p_j}(X)$, $1 \le j \le m$, we have $\prod_{j=1}^m f_j \in L^r(X)$ and

$$\left\| \prod_{j=1}^m f_j \right\|_{L^r(X)} \le \prod_{j=1}^m \|f_j\|_{L^{p_j}(X)}.$$

Proof. Factors with $p_j = \infty$ are taken out using their norm in $L^\infty(X)$, so it suffices to consider indices with $p_j < \infty$. If any of them satisfies $\|f_j\|_{L^{p_j}(X)} = 0$, the assertion is immediate. Otherwise, set $q_j := \dfrac{p_j}{r}$; then $q_j \ge 1$ and $\sum_{j=1}^m \dfrac{1}{q_j} = 1$. If some $q_j = 1$, it is the only finite index and the assertion is immediate. In the remaining case, the generalized numerical Young inequality,

$$\prod_j a_j \le \sum_{j=1}^m \frac{a_j^{q_j}}{q_j}, \qquad a_j \ge 0,$$

follows by iterating $ab \le \dfrac{a^q}{q} + \dfrac{b^{q'}}{q'}$. To prove the latter, with $b \ge 0$ fixed, minimize $t \mapsto \dfrac{t^q}{q} - tb + \dfrac{b^{q'}}{q'}$; its

minimum, attained when $t^{q-1} = b$, is zero. Applying the generalized inequality to

$$a_j(x) := \frac{|f_j(x)|^r}{\|f_j\|_{L^{p_j}(X)}^r}$$

and integrating gives

$$\int_X \prod_j a_j \, d\mu \le \sum_{j=1}^m \frac{1}{q_j} \int_X a_j^{q_j} \, d\mu = \sum_{j=1}^m \frac{1}{q_j} = 1.$$

Multiplying by the norms taken out and taking the rth root proves the result. The case in which all exponents are infinite is the pointwise inequality for the essential supremum. □

Proposition B.7.10. Let $(X, \mathcal{A}, \mu)$ be a finite measure space, and let $p \in (0, \infty)$. If $r \in (0, p)$ and $f \in \mathcal{L}^p(X)$, then $f \in \mathcal{L}^r(X)$ and

$$\|f\|_{\mathcal{L}^r(X)} \le \|f\|_{\mathcal{L}^p(X)} \mu(X)^{\frac{1}{r} - \frac{1}{p}}.$$

Proof. Apply Proposition B.7.9 to $|f|^r$ and the constant function 1, with exponents $\frac{p}{r}$ and $\frac{p}{p-r}$. Thus

$$\int_X |f|^r \, d\mu \le \left(\int_X |f|^p \, d\mu \right)^{\frac{r}{p}} \mu(X)^{1 - \frac{r}{p}}.$$

Taking the rth root gives the stated inequality. □

Proposition B.7.11. (Jensen's inequality) Let $(X, \mathcal{A}, \mu)$ be a finite measure space with $\mu(X) = 1$, let $\varphi \colon \mathbb{R} \longrightarrow \mathbb{R}$ be convex, and let $f \in \mathcal{L}^1(X)$. Then, whenever the right-hand side is well defined,

$$\varphi\left(\int_X f \, d\mu \right) \le \int_X \varphi(f) d\mu$$

Proof. Set $a := \int_X f \, d\mu$. Convexity of φ implies that there exists a supporting slope $c \in \mathbb{R}$ at a: indeed, any number between the one-sided slopes

$$\sup_{x \in (-\infty, a)} \frac{\varphi(a) - \varphi(x)}{a - x} \quad \text{and} \quad \inf_{y > a} \frac{\varphi(y) - \varphi(a)}{y - a}$$

satisfies $\varphi(t) \ge \varphi(a) + c(t - a)$ for every $t \in \mathbb{R}$. Applying this inequality to $t = f(x)$ and integrating gives

$$\int_X \varphi(f) \, d\mu \ge \varphi(a) + c \left(\int_X f \, d\mu - a\mu(X) \right) = \varphi(a).$$

□

Proposition B.7.12. Let $\omega \subseteq \Omega \subseteq \mathbb{R}^n$ be open sets, and let $p \in [1, \infty]$. Then:

(a) If $f \in L^p(\Omega)$, then $f \mathbf{1}_\omega \in L^p(\omega)$ and

$$\|f \mathbf{1}_\omega\|_{L^p(\omega)} \le \|f\|_{L^p(\Omega)}$$

(b) If $f \in L^p(\Omega)$ and X is a measurable subset of Ω with $\lambda_n(X) < \infty$, then:

(a) if $p < \infty$, we have $f\mathbf{1}_X \in L^r(\Omega)$ for every $r \in [1,p]$ and

$$\|f\mathbf{1}_X\|_{L^r(\Omega)} \le \lambda_n(X)^{\frac{p-r}{rp}} \|f\|_{L^p(\Omega)};$$

(b) if $p = \infty$, we have $f\mathbf{1}_X \in L^r(\Omega)$ for every $r \in [1,\infty)$ and

$$\|f\mathbf{1}_X\|_{L^r(\Omega)} \le \lambda_n(X)^{\frac{1}{r}} \|f\|_{L^\infty(\Omega)}.$$

(c) If $f_k \to f$ in $L^p(\Omega)$ and $\lambda_n(\omega) < \infty$, then:

(a) if $p < \infty$, $f_k\mathbf{1}_\omega \to f\mathbf{1}_\omega$ in $L^r(\omega)$ for every $r \in [1,p]$;

(b) if $p = \infty$, $f_k\mathbf{1}_\omega \to f\mathbf{1}_\omega$ in $L^r(\omega)$ for every $r \in [1,\infty)$.

Proof. Part (a) follows directly by integrating over $\omega \subseteq \Omega$. For (b), if $1 \le r < p < \infty$, apply Proposition B.7.9 on X to $|f|^r$ and 1, with exponents $\frac{p}{r}$ and $\frac{p}{p-r}$; if $r = p$, the assertion is immediate. For $p = \infty$, use $|f| \le \|f\|_{L^\infty(\Omega)}$ almost everywhere on X. This gives exactly the two bounds in (b). Finally, apply these bounds to $(f_k - f)\mathbf{1}_\omega$ to obtain (c). □

Proposition B.7.13. If $f = (f_1,\dots,f_m)$ and $f_1,\dots,f_m \in L^s(\Omega)$, define

$$\|f\|_{(L^s(\Omega))^m} := \begin{cases} \left(\sum_{j=1}^m \|f_j\|_{L^s(\Omega)}^s\right)^{\frac{1}{s}}, & 1 \le s < \infty, \\ \max\limits_{1\le j\le m} \|f_j\|_{L^\infty(\Omega)}, & s = \infty. \end{cases}$$

If $\lambda_n(\Omega) < \infty$, $1 \le p < s \le \infty$, and $f_1,\dots,f_m \in L^s(\Omega)$, then

$$\begin{cases} \|f\|_{(L^p(\Omega))^m} \le (m\lambda_n(\Omega))^{\frac{s-p}{sp}} \|f\|_{(L^s(\Omega))^m} & \text{if } s \in [1,\infty), \\ \|f\|_{(L^p(\Omega))^m} \le (m\lambda_n(\Omega))^{\frac{1}{p}} \|f\|_{(L^\infty(\Omega))^m} & \text{if } s = \infty. \end{cases}$$

Proof. Consider $\Omega \times \{1,\dots,m\}$ with the product of Lebesgue measure and counting measure, and define $F(x,j) := f_j(x)$. This space has measure $m\lambda_n(\Omega)$, and

$$\|F\|_{L^t(\Omega\times\{1,\dots,m\})} = \|f\|_{(L^t(\Omega))^m}$$

for $1 \le t \le \infty$. If $s < \infty$, Proposition B.7.9, applied to $|F|^p$ and 1 with exponents $\frac{s}{p}$ and $\frac{s}{s-p}$, gives the first inequality. The second follows by integrating the bound $|F| \le \|F\|_{L^\infty(\Omega\times\{1,\dots,m\})}$. □

Proposition B.7.14. If $0 < \lambda_n(\Omega) < \infty$ and $f \in L^\infty(\Omega)$, then

$$\|f\|_{L^\infty(\Omega)} = \lim_{p\to\infty} \lambda_n(\Omega)^{-\frac{1}{p}} \|f\|_{L^p(\Omega)}.$$

Proof. The inequality

$$\lambda_n(\Omega)^{-\frac{1}{p}}\|f\|_{L^p(\Omega)} \le \|f\|_{L^\infty(\Omega)}$$

gives the upper bound. If $0 < a < \|f\|_{L^\infty(\Omega)}$, the set $A_a := \{x \in \Omega \mid |f(x)| > a\}$ has positive measure and

$$\lambda_n(\Omega)^{-\frac{1}{p}}\|f\|_{L^p(\Omega)} \ge a\left(\frac{\lambda_n(A_a)}{\lambda_n(\Omega)}\right)^{\frac{1}{p}}.$$

The right-hand side converges to a as $p \to \infty$. Then letting $a \uparrow \|f\|_{L^\infty(\Omega)}$ gives the lower bound and hence the limit. □

Proposition B.7.15. Let (f_k) be a sequence in $L^p(\Omega)$ such that $f_k \to f$ in $L^p(\Omega)$.

(a) If $p \in [1,\infty)$, there exist a subsequence (f_{k_j}) of (f_k) and a function $g \in L^p(\Omega)$ such that $f_{k_j}(x) \to f(x)$ for almost every $x \in \Omega$, and $|f_{k_j}| \le g(x)$ for almost every $x \in \Omega$, for every $j \in \mathbb{N}$.

(b) If $p = \infty$, then $f_k(x) \to f(x)$ for almost every $x \in \Omega$, and there exists $c \in \mathbb{R}$ such that $|f_k(x)| \le c$ for almost every $x \in \Omega$ and every $k \in \mathbb{N}$.

Proof. First suppose $p < \infty$. Choosing a subsequence inductively, we may ensure that

$$\|f_{k_{j+1}} - f_{k_j}\|_{L^p(\Omega)} \le 2^{-j} \qquad (j \in \mathbb{N}).$$

Minkowski's inequality and Theorem B.6.11 show that

$$g := |f_{k_1}| + \sum_{j\in\mathbb{N}} |f_{k_{j+1}} - f_{k_j}|$$

belongs to $L^p(\Omega)$. The series of differences converges absolutely almost everywhere; hence (f_{k_j}) converges almost everywhere to a function h, and $|f_{k_j}| \le g$. Moreover, $|h| \le g$ almost everywhere. The dominated convergence theorem B.6.14, applied to $|f_{k_j} - h|^p \le (2g)^p$, shows that $f_{k_j} \to h$ in $L^p(\Omega)$. Since also $f_{k_j} \to f$ in $L^p(\Omega)$, uniqueness of the limit gives $h = f$ almost everywhere.
If $p = \infty$, choose representatives and a common null set outside which

$$|f_k(x) - f(x)| \le \|f_k - f\|_{L^\infty(\Omega)} \longrightarrow 0.$$

The sequence of norms $\|f_k - f\|_{L^\infty(\Omega)}$ is bounded; this gives a constant c dominating all the $|f_k|$ outside a null set. □

Theorem B.7.16. (Interpolation inequality) Let $1 \le p < s < r \le \infty$. If $f \in L^p(\Omega) \cap L^r(\Omega)$, then $f \in L^s(\Omega)$ and

$$\|f\|_{L^s(\Omega)} \le \|f\|^{1-\alpha}_{L^p(\Omega)}\|f\|^{\alpha}_{L^r(\Omega)},$$

where $\alpha \in (0,1)$ satisfies $\dfrac{1}{s} = \dfrac{1-\alpha}{p} + \dfrac{\alpha}{r}$ if $r < \infty$ and $\alpha := 1 - \dfrac{p}{s}$ if $r = \infty$.

Proof. If $r < \infty$, apply Proposition B.7.9 to

$$|f|^s = |f|^{(1-\alpha)s}|f|^{\alpha s}$$

with exponents $\dfrac{p}{(1-\alpha)s}$ and $\dfrac{r}{\alpha s}$, which are conjugate by the relation between p, s, r and α. Taking the sth root yields the inequality. If $r = \infty$, then $s = (1-\alpha)^{-1}p$ and

$$\int_\Omega |f|^s \, d\lambda_n \le \|f\|_{L^\infty(\Omega)}^{s-p} \int_\Omega |f|^p \, d\lambda_n,$$

which gives the same conclusion. □

Proposition B.7.17. If $\lambda_n(\Omega) < \infty$ and $1 \le p < s \le \infty$, then $L^s(\Omega) \subseteq L^p(\Omega)$ and this inclusion is continuous. Moreover, for every $f \in L^s(\Omega)$,

$$\begin{cases} \|f\|_{L^p(\Omega)} \le (\lambda_n(\Omega))^{\frac{s-p}{sp}} \|f\|_{L^s(\Omega)} & \text{if } s \in [1,\infty), \\ \|f\|_{L^p(\Omega)} \le (\lambda_n(\Omega))^{\frac{1}{p}} \|f\|_{L^\infty(\Omega)} & \text{if } s = \infty. \end{cases}$$

Proof. If $s < \infty$, apply Proposition B.7.9 to $|f|^p$ and 1 with exponents $\dfrac{s}{p}$ and $\dfrac{s}{s-p}$. If $s = \infty$, integrate the inequality $|f|^p \le \|f\|_{L^\infty(\Omega)}^p$. The resulting bounds also prove continuity of the inclusion. □

Proposition B.7.18. $C_c^\infty(\Omega)$ is dense in $L^p(\Omega)$ for every $p \in [1,\infty)$.

Proof. By Proposition B.7.5, it suffices to approximate in $L^p(\Omega)$ the indicator of a measurable set $A \subseteq \Omega$ of finite measure. Regularity of Lebesgue measure in Theorem B.5.15 allows us to choose a compact set $K \subseteq A$ and an open set U with $K \subseteq U \Subset \Omega$ such that

$$\lambda_n(A \setminus K) + \lambda_n(U \setminus K) < \varepsilon^p.$$

By Proposition 1.3.6, there exists $\eta \in C_c^\infty(\Omega)$ such that $0 \le \eta \le 1$, $\eta = 1$ on K, and $\operatorname{supp}(\eta) \subseteq U$. Then

$$\|\mathbf{1}_A - \eta\|_{L^p(\Omega)}^p \le \lambda_n(A \setminus K) + \lambda_n(U \setminus K) < \varepsilon^p.$$

Approximating each term of a simple function and using the triangle inequality proves density. □

Proposition B.7.19. Let $p \in [1,\infty)$, let $\Omega \subseteq \mathbb{R}^n$ be open, and let $\mathcal{K} \subseteq L^p(\Omega)$ be bounded with the following properties:

(a) For each $\varepsilon > 0$ and each open set $\omega \Subset \Omega$, there exists $\delta \in (0, d(\omega, \mathbb{R}^n \setminus \Omega))$ such that $\|T_\xi f - f\|_{L^p(\omega)} < \varepsilon$ for every $\xi \in \mathbb{R}^n$ with $\|\xi\| < \delta$ and every $f \in \mathcal{K}$.

(b) For each $\varepsilon > 0$, there exists an open set $\omega \Subset \Omega$ such that $\|f\|_{L^p(\Omega \setminus \omega)} < \varepsilon$ for every $f \in \mathcal{K}$.

Here $T_\xi f(x) := f(x + \xi)$ whenever $x, x + \xi \in \Omega$. Then $\mathcal{K}$ is relatively compact in $L^p(\Omega)$.

Proof. Fix $\varepsilon > 0$. By (b), choose $\omega \Subset \Omega$ so that $\|f\|_{L^p(\Omega\setminus\omega)} < \varepsilon$ for every $f \in \mathcal{K}$, and choose ω_1 with $\omega \Subset \omega_1 \Subset \Omega$. For small $h > 0$, take a finite family of disjoint cubes $(Q_\ell)_{\ell=1}^N$, of side length h, contained in ω_1, whose union U_h contains ω. Define

$$P_h f := \sum_{\ell=1}^{N} \left(\frac{1}{|Q_\ell|} \int_{Q_\ell} f(y)\, dy \right) \mathbf{1}_{Q_\ell}.$$

Jensen's inequality and Theorem B.6.17 give

$$\|P_h f - f\|_{L^p(U_h)}^p \le \frac{1}{h^n} \sum_{\ell=1}^{N} \int_{Q_\ell} \int_{Q_\ell} |f(y) - f(x)|^p \, dy\, dx.$$

Writing $y = x + z$ and observing that $\|z\| \le \sqrt{n}h$, the right-hand side is bounded by

$$Ch^{-n} \int_{\{\|z\| \le \sqrt{n}h\}} \|T_z f - f\|_{L^p(\omega_1)}^p \, dz.$$

Condition (a) makes this quantity less than $C\varepsilon^p$ uniformly in $f \in \mathcal{K}$ if h is sufficiently small. Since $P_h f = 0$ outside U_h and $\Omega \setminus U_h \subseteq \Omega \setminus \omega$, we obtain $\|P_h f - f\|_{L^p(\Omega)} \le C\varepsilon$.

The set $P_h(\mathcal{K})$ is bounded in the finite-dimensional space spanned by $(\mathbf{1}_{Q_\ell})_{\ell=1}^N$ and is therefore totally bounded. The preceding uniform approximation shows that $\mathcal{K}$ is totally bounded in the complete space $L^p(\Omega)$; its closure is compact. □

B.8 Integral inequalities and tools from harmonic analysis

In this section we collect several tools that will appear repeatedly in the Littlewood–Paley decomposition and the study of Besov and Triebel–Lizorkin spaces. The first part contains integral and discrete inequalities allowing norms, integrals, and sums over scales to be interchanged. We then introduce Rademacher functions and the Hardy–Littlewood and Fefferman–Stein maximal estimates. Finally, we record the Calderón–Zygmund decomposition and Peetre maximal control, which allow families of frequency-localized functions to be treated uniformly.

Throughout this section, $\mathcal{M}$ denotes the uncentered Hardy–Littlewood maximal operator on $\mathbb{R}^n$.

Proposition B.8.1. (Cavalieri and Chebyshev) If $f : X \longrightarrow [0,\infty]$ is measurable and $0 < p < \infty$, then

$$\int_X f^p \, d\mu = p \int_0^\infty \lambda^{p-1} \mu(\{f > \lambda\})\, d\lambda.$$

In particular, if $f \in L^p(X)$ and $\lambda > 0$, then

$$\mu(\{|f| > \lambda\}) \le \lambda^{-p} \|f\|_{L^p(X)}^p.$$

Proof. For each $x \in X$,

$$f(x)^p = \int_0^{f(x)} p\lambda^{p-1}\, d\lambda = \int_0^\infty p\lambda^{p-1} \mathbf{1}_{\{f(x)>\lambda\}}\, d\lambda.$$

Theorem B.6.17 allows us to integrate first with respect to x and then with respect to λ, giving Cavalieri's

identity. For Chebyshev's inequality, observe that

$$\|f\|_{L^p(X)}^p \geq \int_{\{|f|>\lambda\}} |f|^p \, d\mu \geq \lambda^p \mu(\{|f| > \lambda\}).$$

□

Theorem B.8.2. (Minkowski's integral inequality) Let (X, μ) and (Y, ν) be σ-finite measure spaces, and let $1 \leq p \leq \infty$. If $F\colon X \times Y \longrightarrow \mathbb{C}$ is measurable and

$$\int_Y \|F(\cdot, y)\|_{L^p(X)} \, d\nu(y) < \infty,$$

then $x \mapsto \displaystyle\int_Y F(x,y)\, d\nu(y)$ belongs to $L^p(X)$ and

$$\left\| \int_Y F(\cdot, y)\, d\nu(y) \right\|_{L^p(X)} \leq \int_Y \|F(\cdot, y)\|_{L^p(X)} \, d\nu(y).$$

Proof. For $p = 1$, the triangle inequality and Theorem B.6.17 give

$$\int_X \left| \int_Y F(x,y)\, d\nu(y) \right| d\mu(x) \leq \int_Y \int_X |F(x,y)| \, d\mu(x) d\nu(y).$$

The case $p = \infty$ follows by taking essential suprema. Suppose $1 < p < \infty$. For $g \in L^{p'}(X)$, Fubini's theorem for Bochner integrals B.6.26, applied in the scalar case, and Hölder's inequality in Proposition B.7.9 imply

$$\begin{aligned} \left| \int_X g(x) \int_Y F(x,y)\, d\nu(y) d\mu(x) \right| &\leq \int_Y \int_X |g(x) F(x,y)| \, d\mu(x) d\nu(y) \\ &\leq \|g\|_{L^{p'}(X)} \int_Y \|F(\cdot, y)\|_{L^p(X)} \, d\nu(y). \end{aligned}$$

The dual characterization of the $L^p(X)$ norm in Theorem B.7.7 completes the proof. □

Proposition B.8.3. (Schur's test) Let (X, μ) and (Y, ν) be σ-finite measure spaces, let $r, s \in \mathbb{N}$, and let

$$K\colon X \times Y \longrightarrow \mathcal{L}(\mathbb{C}^r, \mathbb{C}^s)$$

be a measurable kernel. Suppose that there exist $A, B \geq 0$ such that

$$\sup_{x \in X} \int_Y \|K(x,y)\|_{\mathcal{L}(\mathbb{C}^r, \mathbb{C}^s)} \, d\nu(y) \leq A$$

and

$$\sup_{y \in Y} \int_X \|K(x,y)\|_{\mathcal{L}(\mathbb{C}^r, \mathbb{C}^s)} \, d\mu(x) \leq B.$$

Then, for each $f \in L^2(Y, \mathbb{C}^r)$, the integral

$$(T_K f)(x) := \int_Y K(x,y) f(y)\, d\nu(y)$$

exists for almost every $x \in X$ and defines a continuous linear operator

$$T_K \colon L^2(Y, \mathbb{C}^r) \longrightarrow L^2(X, \mathbb{C}^s)$$

satisfying

$$\|T_K\|_{\mathcal{L}(L^2(Y,\mathbb{C}^r),L^2(X,\mathbb{C}^s))} \le \sqrt{AB}.$$

Proof. Set $k(x,y) := \|K(x,y)\|_{\mathcal{L}(\mathbb{C}^r,\mathbb{C}^s)}$. For $f \in L^2(Y,\mathbb{C}^r)$, Cauchy–Schwarz with respect to the measure $k(x,y)\,d\nu(y)$ gives

$$\Big(\int_Y k(x,y)\|f(y)\|_{\mathbb{C}^r}\,d\nu(y)\Big)^2 \le A\int_Y k(x,y)\|f(y)\|_{\mathbb{C}^r}^2\,d\nu(y). \tag{B.8}$$

Tonelli's theorem B.6.17 and the second hypothesis show that

$$\begin{aligned}\int_X\int_Y k(x,y)\|f(y)\|_{\mathbb{C}^r}^2\,d\nu(y)\,d\mu(x) &= \int_Y \|f(y)\|_{\mathbb{C}^r}^2\Big(\int_X k(x,y)\,d\mu(x)\Big)\,d\nu(y)\\ &\le B\|f\|_{L^2(Y,\mathbb{C}^r)}^2.\end{aligned}$$

Thus the last factor in (B.8) is finite for almost every x; the integral defining $T_Kf(x)$ is absolutely convergent in $\mathbb{C}^s$ at these points. Measurability of T_Kf follows by integrating measurable functions componentwise. Moreover,

$$\begin{aligned}\|T_Kf\|_{L^2(X,\mathbb{C}^s)}^2 &\le A\int_X\int_Y k(x,y)\|f(y)\|_{\mathbb{C}^r}^2\,d\nu(y)\,d\mu(x)\\ &\le AB\|f\|_{L^2(Y,\mathbb{C}^r)}^2.\end{aligned}$$

This proves the estimate and, in particular, continuity. The same proof applies to a measurable kernel $K(x,y)\colon E_y \longrightarrow F_x$ between measurable Hermitian bundles of finite rank, replacing Euclidean norms by bundle norms. □

Proposition B.8.4. (Young's inequality for sequences) Let $1 \le q \le \infty$, $a = (a_j)_{j\in\mathbb{Z}} \in \ell^q(\mathbb{Z})$, and $b = (b_j)_{j\in\mathbb{Z}} \in \ell^1(\mathbb{Z})$. If

$$(a*b)_k := \sum_{j\in\mathbb{Z}} a_j b_{k-j}, \qquad k \in \mathbb{Z},$$

then

$$\|a*b\|_{\ell^q(\mathbb{Z})} \le \|a\|_{\ell^q(\mathbb{Z})}\|b\|_{\ell^1(\mathbb{Z})}.$$

Proof. For $q = \infty$,

$$|(a*b)_k| \le \|a\|_{\ell^\infty(\mathbb{Z})}\sum_{j\in\mathbb{Z}}|b_{k-j}| = \|a\|_{\ell^\infty(\mathbb{Z})}\|b\|_{\ell^1(\mathbb{Z})}.$$

If $1 \le q < \infty$, write

$$|a_jb_{k-j}|^q = |a_j|^q|b_{k-j}|\,|b_{k-j}|^{q-1}$$

and apply Hölder to the sum over j with exponents q and q'. This gives

$$|(a*b)_k|^q \le \|b\|_{\ell^1(\mathbb{Z})}^{q-1}\sum_{j\in\mathbb{Z}}|a_j|^q|b_{k-j}|.$$

Summing over $k \in \mathbb{Z}$ and using Theorem B.6.17 yields

$$\|a * b\|_{\ell^q(\mathbb{Z})}^q \le \|b\|_{\ell^1(\mathbb{Z})}^q \|a\|_{\ell^q(\mathbb{Z})}^q.$$

□

Theorem B.8.5. (Discrete Hardy inequalities) Let $\alpha > 0$, $1 \le q \le \infty$, and let $(a_j)_{j\in\mathbb{Z}}$ be a nonnegative sequence. Then

$$\left\| \left(\sum_{\substack{j\in\mathbb{Z}\\ j\le k}} 2^{-\alpha(k-j)} a_j \right)_{k\in\mathbb{Z}} \right\|_{\ell^q(\mathbb{Z})} + \left\| \left(\sum_{\substack{j\in\mathbb{Z}\\ j\ge k}} 2^{-\alpha(j-k)} a_j \right)_{k\in\mathbb{Z}} \right\|_{\ell^q(\mathbb{Z})} \le C_{\alpha,q} \|(a_j)_{j\in\mathbb{Z}}\|_{\ell^q(\mathbb{Z})}.$$

Proof. The first sequence is the convolution of $(a_j)_{j\in\mathbb{Z}}$ with

$$b_m := 2^{-\alpha m} \mathbf{1}_{\{m\ge 0\}}, \qquad m \in \mathbb{Z},$$

and the second with $\widetilde{b}_m := 2^{\alpha m}\mathbf{1}_{\{m\le 0\}}$. Both sequences belong to $\ell^1(\mathbb{Z})$. Proposition B.8.4 gives the two bounds. □

Theorem B.8.6. (Hardy's integral inequalities) Let $\alpha > 0$, $1 \le q \le \infty$, and let $f : (0,\infty) \longrightarrow [0,\infty]$ be measurable. Then

$$\left\| r^{-\alpha} \int_0^r t^{\alpha} f(t) \frac{dt}{t} \right\|_{L^q((0,\infty),\frac{dr}{r})} \le \frac{1}{\alpha} \|f\|_{L^q((0,\infty),\frac{dt}{t})}$$

and

$$\left\| r^{\alpha} \int_r^\infty t^{-\alpha} f(t) \frac{dt}{t} \right\|_{L^q((0,\infty),\frac{dr}{r})} \le \frac{1}{\alpha} \|f\|_{L^q((0,\infty),\frac{dt}{t})}.$$

The same assertions hold for Banach-valued functions upon replacing $f(t)$ by its norm.

Proof. Make the substitutions $r = e^x$, $t = e^y$, and set $g(y) := f(e^y)$. Since $dt/t = dy$ and $dr/r = dx$, the first expression becomes

$$\int_{-\infty}^{x} e^{-\alpha(x-y)} g(y)\, dy = \left(e^{-\alpha\cdot}\mathbf{1}_{[0,\infty)} * g\right)(x),$$

while the second is the convolution of g with $e^{\alpha\cdot}\mathbf{1}_{(-\infty,0]}$. Both kernels have $L^1(\mathbb{R})$ norm equal to $\frac{1}{\alpha}$. Young's inequality in Theorem 4.10.1 completes the proof, including the endpoints $q = 1$ and $q = \infty$. □

Rademacher functions allow a Euclidean norm of coefficients to be converted into a scalar integral. This randomization is the mechanism we shall later use to pass from multipliers with arbitrary signs to the Littlewood–Paley square function.

Lemma B.8.7. (Paley–Zygmund inequality) Let $(A, \mathcal{A}, \mu)$ be a probability space, let $X \in L^2(A)$ be nonnegative, and let $0 < \vartheta < 1$. Then

$$\mu\{X > \vartheta\, \mathbb{E}X\} \ge (1-\vartheta)^2 \frac{(\mathbb{E}X)^2}{\mathbb{E}(X^2)}.$$

Here $\mathbb{E}X := \int_A X\,d\mu$; if $\mathbb{E}(X^2) = 0$, both sides are interpreted as zero.

Proof. The case $\mathbb{E}X = 0$ is immediate. Suppose $\mathbb{E}X > 0$, and let $E := \{X > \vartheta \mathbb{E}X\}$. Then

$$\mathbb{E}X = \int_{A\setminus E} X\,d\mu + \int_E X\,d\mu \le \vartheta\mathbb{E}X + (\mathbb{E}(X^2))^{\frac{1}{2}}\mu(E)^{\frac{1}{2}},$$

where we used Cauchy–Schwarz, Theorem B.3.2, in the last term. Subtracting $\vartheta\mathbb{E}X$, squaring, and dividing by $\mathbb{E}(X^2)$ gives the assertion. □

Theorem B.8.8. (Khintchine's inequality) Let $(r_j)_{j\in\mathbb{N}_0}$ be the Rademacher functions on $[0,1]$. For each $0 < p < \infty$ there exist constants $A_p, B_p > 0$ such that, for every finite set $J \subseteq \mathbb{N}_0$ and every family of scalars $(a_j)_{j\in J}$,

$$A_p \left(\sum_{j\in J} |a_j|^2\right)^{\frac{1}{2}} \le \left(\int_0^1 \left|\sum_{j\in J} a_j r_j(t)\right|^p dt\right)^{\frac{1}{p}} \le B_p \left(\sum_{j\in J} |a_j|^2\right)^{\frac{1}{2}}.$$

Proof. First suppose that the coefficients are real, and set

$$S := \sum_{j\in J} a_j r_j, \qquad \sigma^2 := \sum_{j\in J} |a_j|^2.$$

Independence of the Rademacher functions and the inequality $\cosh x \le e^{\frac{x^2}{2}}$ imply

$$\int_0^1 e^{\lambda S(t)} dt = \prod_{j\in J} \cosh(\lambda a_j) \le e^{\frac{\lambda^2\sigma^2}{2}}.$$

Apply Chebyshev, Proposition B.8.1, to $e^{\lambda S}$ and $e^{-\lambda S}$. For $u > 0$ and $\lambda > 0$, we obtain

$$|\{t \mid S(t) > u\}| \le e^{-\lambda u + \frac{\lambda^2\sigma^2}{2}},$$

and the same bound for $-S$. If $\sigma > 0$, choosing $\lambda = \frac{u}{\sigma^2}$ gives

$$|\{t \in [0,1] \mid |S(t)| > u\}| \le 2e^{-\frac{u^2}{2\sigma^2}}.$$

Cavalieri's formula then yields

$$\int_0^1 |S|^p dt = p\int_0^\infty u^{p-1} |\{|S| > u\}|\,du \le C_p \sigma^p,$$

which is the upper bound.
For the lower bound, by homogeneity we may assume $\sigma = 1$. Independence gives

$$\mathbb{E}(S^2) = 1, \qquad \mathbb{E}(S^4) = \sum_{j\in J} a_j^4 + 6\sum_{\substack{j,k\in J\\ j<k}} a_j^2 a_k^2 = 3 - 2\sum_{j\in J} a_j^4 \le 3.$$

Apply Lemma B.8.7 to $X = S^2$ with $\vartheta = \frac{1}{2}$. Thus

$$|\{|S| > 2^{-\frac{1}{2}}\}| \geq \frac{1}{12},$$

and consequently,

$$\int_0^1 |S|^p dt \geq \frac{1}{12} 2^{-\frac{p}{2}}.$$

This proves the lower bound for real coefficients. In the complex case, apply the real bounds to the real and imaginary parts. Both have sum of squares at most σ^2, and at least one has sum of squares no less than $\frac{\sigma^2}{2}$. The inequalities

$$|\operatorname{Re} S|, |\operatorname{Im} S| \leq |S| \leq |\operatorname{Re} S| + |\operatorname{Im} S|$$

complete the proof. □

Before studying the maximal operator, we record the interpolation principle used to pass from weak endpoint estimates to strong estimates at intermediate exponents.

Theorem B.8.9. (Marcinkiewicz interpolation) Let (X, μ_X) and (Y, μ_Y) be σ-finite measure spaces. Let T be a sublinear operator defined on simple functions supported on sets of finite measure in X, with values in measurable functions on Y, and suppose that it is of weak type (p_0, p_0) and (p_1, p_1), where $1 \leq p_0 < p_1 \leq \infty$. If $p_0 < p < p_1$, then T extends to a bounded operator from $L^p(X)$ to $L^p(Y)$, and

$$\|Tf\|_{L^p(Y)} \leq C\|f\|_{L^p(X)}.$$

The constant depends only on p_0, p, p_1 and the weak-type constants of T.

Proof. First suppose $p_1 < \infty$. Fix $\gamma > 0$ and, for each $\lambda > 0$, write

$$f = f_0^\lambda + f_1^\lambda, \qquad f_0^\lambda := f\mathbf{1}_{\{|f| > \gamma\lambda\}}, \qquad f_1^\lambda := f\mathbf{1}_{\{|f| \leq \gamma\lambda\}}.$$

Sublinearity implies

$$\{|Tf| > \lambda\} \subseteq \left\{|Tf_0^\lambda| > \frac{\lambda}{2}\right\} \cup \left\{|Tf_1^\lambda| > \frac{\lambda}{2}\right\}.$$

If C_0, C_1 are the weak-type constants, we obtain

$$\mu_Y(\{|Tf| > \lambda\}) \leq C_0'\lambda^{-p_0}\|f_0^\lambda\|_{L^{p_0}(X)}^{p_0} + C_1'\lambda^{-p_1}\|f_1^\lambda\|_{L^{p_1}(X)}^{p_1}.$$

Apply Cavalieri and Tonelli to the first term:

$$\begin{aligned}\int_0^\infty \lambda^{p-p_0-1} \int_{\{|f|>\gamma\lambda\}} |f(x)|^{p_0}\, d\mu_X(x) d\lambda &= \int_X |f(x)|^{p_0} \int_0^{\frac{|f(x)|}{\gamma}} \lambda^{p-p_0-1}\, d\lambda d\mu_X(x) \\ &= \frac{\gamma^{-(p-p_0)}}{p-p_0}\|f\|_{L^p(X)}^p.\end{aligned}$$

For the second term, since $p < p_1$,

$$\int_0^\infty \lambda^{p-p_1-1} \int_{\{|f|\le\gamma\lambda\}} |f(x)|^{p_1}\, d\mu_X(x) d\lambda = \int_X |f(x)|^{p_1} \int_{\frac{|f(x)|}{\gamma}}^\infty \lambda^{p-p_1-1}\, d\lambda d\mu_X(x)$$
$$= \frac{\gamma^{p_1-p}}{p_1-p} \|f\|_{L^p(X)}^p.$$

By Cavalieri, these two estimates imply $\|Tf\|_{L^p(Y)}^p \le C\|f\|_{L^p(X)}^p$.
If $p_1 = \infty$, the hypothesis at that endpoint means $\|Tg\|_{L^\infty(Y)} \le C_1\|g\|_{L^\infty(X)}$. Choose $\gamma = (2C_1)^{-1}$. Then

$$\|Tf_1^\lambda\|_{L^\infty(Y)} \le C_1\gamma\lambda = \frac{\lambda}{2},$$

so only the first term remains, which is integrated exactly as above. Density of simple functions in $L^p(X)$ provides the extension. □

Lemma B.8.10. (Vitali selection for balls) Let $\mathcal{B}$ be a family of open balls in $\mathbb{R}^n$ with radii bounded above. There exists a countable disjoint subfamily $(B_j)_{j\in\mathbb{N}} \subseteq \mathcal{B}$ such that

$$\bigcup_{B\in\mathcal{B}} B \subseteq \bigcup_{j\in\mathbb{N}} 5B_j,$$

where $5B_j$ denotes the concentric ball with five times the radius.

Proof. Let $R > 0$ be an upper bound for the radii. For each $k \in \mathbb{N}_0$, consider the subfamily

$$\mathcal{B}_k := \left\{ B \in \mathcal{B} \,\middle|\, 2^{-k-1}R < r(B) \le 2^{-k}R \right\}.$$

Proceed by levels. In $\mathcal{B}_0$, choose a maximal subfamily of disjoint balls. Once the families at levels $0,\dots,k-1$ have been chosen, choose in $\mathcal{B}_k$ a maximal subfamily of mutually disjoint balls that are also disjoint from all previously selected balls. Existence of each maximal family follows from Zorn's lemma. Since every family of disjoint open balls in $\mathbb{R}^n$ is countable—each ball contains a distinct point of $\mathbb{Q}^n$—the union of all selected families is countable; denote it by $(B_j)_{j\in\mathbb{N}}$.
Let $B \in \mathcal{B}_k$ be a ball that was not selected. By maximality, B intersects a selected ball B_j from the same or an earlier level. In both cases,

$$r(B_j) \ge \frac{1}{2} r(B).$$

If $x \in B$ and c, c_j are the centers of B and B_j, respectively, choose $z \in B \cap B_j$ and obtain

$$\|x - c_j\| \le \|x - c\| + \|c - z\| + \|z - c_j\| < 2r(B) + r(B_j) \le 5r(B_j).$$

Thus $B \subseteq 5B_j$, proving that the dilates $(5B_j)_{j\in\mathbb{N}}$ cover the union of the balls in $\mathcal{B}$. □

Theorem B.8.11. (Hardy–Littlewood maximal operator) For $f \in L^1_{\mathrm{loc}}(\mathbb{R}^n)$, define

$$\mathcal{M}f(x) := \sup_{B\ni x} \frac{1}{|B|} \int_B |f(y)|\, dy,$$

where the supremum is taken over all open balls $B \subseteq \mathbb{R}^n$ containing x. Then $\mathcal{M}$ is of weak type $(1,1)$: for $f \in L^1(\mathbb{R}^n)$ and $\lambda > 0$,

$$|\{x \in \mathbb{R}^n \mid \mathcal{M}f(x) > \lambda\}| \le \frac{C_n}{\lambda}\|f\|_{L^1(\mathbb{R}^n)}.$$

Moreover, for $1 < p \le \infty$,

$$\|\mathcal{M}f\|_{L^p(\mathbb{R}^n)} \le C_{n,p}\|f\|_{L^p(\mathbb{R}^n)}.$$

Proof. Fix $f \in L^1(\mathbb{R}^n)$ and $\lambda > 0$. For each $x \in E_\lambda := \{\mathcal{M}f > \lambda\}$, choose a ball $B_x \ni x$ such that

$$\frac{1}{|B_x|}\int_{B_x} |f(y)|\,dy > \lambda.$$

In particular,

$$|B_x| < \frac{\|f\|_{L^1(\mathbb{R}^n)}}{\lambda},$$

so the radii of the family $(B_x)_{x\in E_\lambda}$ are uniformly bounded. Lemma B.8.10 provides a disjoint family $(B_j)_{j\in\mathbb{N}}$ such that $E_\lambda \subseteq \bigcup_{j\in\mathbb{N}} 5B_j$. Consequently,

$$\begin{aligned} |E_\lambda| &\le \sum_{j\in\mathbb{N}} |5B_j| = 5^n \sum_{j\in\mathbb{N}} |B_j| \\ &< \frac{5^n}{\lambda}\sum_{j\in\mathbb{N}}\int_{B_j} |f(y)|\,dy \le \frac{5^n}{\lambda}\|f\|_{L^1(\mathbb{R}^n)}. \end{aligned}$$

This proves weak type $(1,1)$. On the other hand, $\mathcal{M}f \le \|f\|_{L^\infty(\mathbb{R}^n)}$ almost everywhere if $f \in L^\infty(\mathbb{R}^n)$. Theorem B.8.9, applied between the endpoints $(1,1)$ and (∞,∞), gives the strong bound for $1 < p < \infty$. □

Theorem B.8.12. (Lebesgue differentiation) If $f \in L^1_{\mathrm{loc}}(\mathbb{R}^n)$, then, for almost every $x \in \mathbb{R}^n$,

$$\lim_{r\to 0^+} \frac{1}{|B(x,r)|}\int_{B(x,r)} |f(y) - f(x)|\,dy = 0.$$

Proof. Fix $R > 0$ and set $f_R := f\mathbf{1}_{B(0,R+1)} \in L^1(\mathbb{R}^n)$. For $x \in B(0,R)$ and $0 < r < 1$, the averages of f and f_R over $B(x,r)$ agree. Define

$$Dh(x) := \limsup_{r\to 0^+} \frac{1}{|B(x,r)|}\int_{B(x,r)} |h(y) - h(x)|\,dy.$$

If $g \in C_c^\infty(\mathbb{R}^n)$, uniform continuity of g gives $Dg(x) = 0$ for every x. Moreover, for every $h \in L^1(\mathbb{R}^n)$,

$$Dh(x) \le \mathcal{M}h(x) + |h(x)|$$

for almost every x. Now choose $g \in C_c^\infty(\mathbb{R}^n)$ and use

$$Df_R(x) \le D(f_R - g)(x) + Dg(x) \le \mathcal{M}(f_R - g)(x) + |f_R(x) - g(x)|.$$

Thus, for $\varepsilon > 0$,

$$\{x \in B(0,R) \mid Df(x) > 2\varepsilon\} \subseteq \{\mathcal{M}(f_R - g) > \varepsilon\} \cup \{|f_R - g| > \varepsilon\}.$$

Weak type $(1,1)$ from Theorem B.8.11 and Chebyshev give

$$|\{x \in B(0,R) \mid Df(x) > 2\varepsilon\}| \le \frac{C_n}{\varepsilon}\|f_R - g\|_{L^1(\mathbb{R}^n)}.$$

By Proposition B.7.18, $C_c^\infty(\mathbb{R}^n)$ is dense in $L^1(\mathbb{R}^n)$, so the right-hand side can be made arbitrarily small. Hence $Df = 0$ almost everywhere on $B(0,R)$. Finally, let $R \to \infty$ through the integers. □

For Triebel–Lizorkin norms, controlling each block separately does not suffice: the L^p norm is taken after the scales have been combined pointwise. We therefore need a vector-valued version of the maximal inequality. The following weighted result provides an efficient proof for part of the range of exponents and will also be useful in its own right.

Lemma B.8.13. (Weighted Fefferman–Stein inequality) If $1 < a < \infty$, $f \in L^1_{\mathrm{loc}}(\mathbb{R}^n)$, and $w\colon \mathbb{R}^n \longrightarrow [0,\infty]$ is measurable, then

$$\int_{\mathbb{R}^n} (\mathcal{M}f)^a w \le C_{n,a} \int_{\mathbb{R}^n} |f|^a \mathcal{M}w.$$

The assertion is understood first for bounded compactly supported functions; the general case follows by truncation and monotone convergence.

Proof. It suffices to prove the estimate for a truncated version of the maximal operator considering only balls with radii in a compact interval of $(0,\infty)$; at the end, the truncations are removed by monotone convergence. Fix $\lambda > 0$. Applying Lemma B.8.10 to balls on which the average of $|f|$ exceeds λ gives disjoint balls $(B_j)_{j\in\mathbb{N}}$ such that

$$\{\mathcal{M}f > \lambda\} \subseteq \bigcup_{j\in\mathbb{N}} 5B_j.$$

Since the contribution of $|f|\mathbf{1}_{\{|f|\le\frac{\lambda}{2}\}}$ to the average over any ball is at most $\frac{\lambda}{2}$, for each $j \in \mathbb{N}$ we have

$$|B_j| \le \frac{2}{\lambda} \int_{B_j \cap \{|f| > \frac{\lambda}{2}\}} |f(y)|\,dy.$$

If $y \in B_j$, then $5B_j$ contains y, and the definition of $\mathcal{M}w(y)$ gives

$$\int_{5B_j} w \le |5B_j|\,\mathcal{M}w(y) = 5^n |B_j|\,\mathcal{M}w(y).$$

Taking the infimum over $y \in B_j$ and using the preceding inequality for $|B_j|$ yields

$$\begin{aligned}
\int_{\{\mathcal{M}f>\lambda\}} w &\le \sum_{j\in\mathbb{N}} \int_{5B_j} w \\
&\le \frac{C_n}{\lambda} \sum_{j\in\mathbb{N}} \int_{B_j\cap\{|f|>\frac{\lambda}{2}\}} |f(y)|\mathcal{M}w(y)\,dy \\
&\le \frac{C_n}{\lambda} \int_{\{|f|>\frac{\lambda}{2}\}} |f|\mathcal{M}w.
\end{aligned}$$

Multiply by $a\lambda^{a-1}$ and integrate in $\lambda \in (0,\infty)$. By Tonelli,

$$\begin{aligned}\int_{\mathbb{R}^n} (\mathcal{M}f)^a w &= a\int_0^\infty \lambda^{a-1}\int_{\{\mathcal{M}f>\lambda\}} w\,d\lambda \\ &\le C_{n,a}\int_{\mathbb{R}^n} |f(y)|\mathcal{M}w(y)\left(\int_0^{2|f(y)|}\lambda^{a-2}\,d\lambda\right)dy \\ &\le C_{n,a}\int_{\mathbb{R}^n} |f|^a\mathcal{M}w.\end{aligned}$$

The inner integral is finite because $a>1$. The truncations are removed by Theorem B.6.11. □

Theorem B.8.14. (Vector-valued Fefferman–Stein inequality) Let $1<p,r<\infty$. If J is a finite set and $(f_j)_{j\in J}$ is a family of measurable functions, then

$$\left\|\left(\sum_{j\in J}|\mathcal{M}f_j|^r\right)^{\frac{1}{r}}\right\|_{L^p(\mathbb{R}^n)} \le C_{n,p,r}\left\|\left(\sum_{j\in J}|f_j|^r\right)^{\frac{1}{r}}\right\|_{L^p(\mathbb{R}^n)}.$$

The same inequality holds for countable families whenever the right-hand side is finite.

See also [146, Section 2.2.2].

Proof. First suppose $p>r$. Then $\frac{p}{r}>1$. By duality of $L^{\frac{p}{r}}(\mathbb{R}^n)$,

$$\left\|\sum_{j\in J}(\mathcal{M}f_j)^r\right\|_{L^{\frac{p}{r}}(\mathbb{R}^n)} = \sup_{\substack{h\in L^{(\frac{p}{r})'}(\mathbb{R}^n),\ h\ge 0\\ \|h\|_{L^{(\frac{p}{r})'}(\mathbb{R}^n)}\le 1}}\int_{\mathbb{R}^n}\sum_{j\in J}(\mathcal{M}f_j)^r h.$$

Apply Lemma B.8.13 to each f_j, sum, and use Tonelli:

$$\int_{\mathbb{R}^n}\sum_{j\in J}(\mathcal{M}f_j)^r h \le C\int_{\mathbb{R}^n}\sum_{j\in J}|f_j|^r\mathcal{M}h.$$

Hölder and continuity of $\mathcal{M}$ on $L^{(\frac{p}{r})'}(\mathbb{R}^n)$ give

$$\int_{\mathbb{R}^n}\sum_{j\in J}|f_j|^r\mathcal{M}h \le C\left\|\sum_{j\in J}|f_j|^r\right\|_{L^{\frac{p}{r}}(\mathbb{R}^n)}.$$

Taking the rth root gives the inequality when $p>r$.

Now suppose $p\le r$ and fix a finite family J. The supremum defining $\mathcal{M}$ may be computed, up to a uniform dimensional constant, using a countable family of balls with rational centers and radii. For each $j\in J$ and the function $|f_j|$, measurably choose one of these balls $B_j(x)\ni x$ whose average is at least half the corresponding supremum. Once this choice has been made, define the linear operator

$$T_j g(x) := \frac{1}{|B_j(x)|}\int_{B_j(x)} g(y)\,dy.$$

The selection depends on the original family $(f_j)_{j\in J}$, but remains fixed while interpolating the diagonal operator

$$\mathcal{T}(g_j)_{j\in J} := (T_j g_j)_{j\in J}.$$

For every g_j, we have $|T_j g_j| \le \mathcal{M} g_j$. The scalar bound in Theorem B.8.11 implies

$$\begin{aligned}\|\mathcal{T}(g_j)_{j\in J}\|_{L^p(\mathbb{R}^n;\ell^p(J))}^p &= \sum_{j\in J} \|T_j g_j\|_{L^p(\mathbb{R}^n)}^p \\ &\le C \sum_{j\in J} \|g_j\|_{L^p(\mathbb{R}^n)}^p.\end{aligned}$$

Moreover,

$$\sup_{j\in J} |T_j g_j(x)| \le \mathcal{M}\left(\sup_{j\in J} |g_j|\right)(x),$$

so

$$\|\mathcal{T}(g_j)_{j\in J}\|_{L^p(\mathbb{R}^n;\ell^\infty(J))} \le C \|(g_j)_{j\in J}\|_{L^p(\mathbb{R}^n;\ell^\infty(J))}.$$

If $r = p$, the desired estimate is precisely the first of these two bounds. Thus suppose $r > p$. There exists $0 < \vartheta < 1$ such that

$$\frac{1}{r} = \frac{1-\vartheta}{p}.$$

Interpolate the estimates with values in $\ell^p(J)$ and $\ell^\infty(J)$ using Theorem 5.7.5 and Proposition 5.7.12. We obtain

$$\|\mathcal{T}(g_j)_{j\in J}\|_{L^p(\mathbb{R}^n;\ell^r(J))} \le C_{n,p,r} \|(g_j)_{j\in J}\|_{L^p(\mathbb{R}^n;\ell^r(J))}.$$

Apply this bound to $g_j = |f_j|$. By the choice of $B_j(x)$,

$$\mathcal{M} f_j(x) \le 2 T_j |f_j|(x),$$

which proves the case $p \le r$. The constant is independent of J. For a countable family, apply the result to the first N coordinates and let $N \to \infty$ using monotone convergence. □

Theorem B.8.15. (Calderón–Zygmund decomposition) Let $f \in L^1(\mathbb{R}^n)$ and $\lambda > 0$. There exist a countable family of disjoint dyadic cubes $(Q_j)_{j\in\mathbb{N}}$ and functions $g, (b_j)_{j\in\mathbb{N}}$ such that

$$f = g + \sum_{j\in\mathbb{N}} b_j \quad \text{almost everywhere,}$$

$$\|g\|_{L^\infty(\mathbb{R}^n)} \le 2^n \lambda, \qquad \|g\|_{L^1(\mathbb{R}^n)} \le \|f\|_{L^1(\mathbb{R}^n)},$$

$$\operatorname{supp}(b_j) \subseteq Q_j, \qquad \int_{Q_j} b_j = 0 \quad (j \in \mathbb{N}),$$

and

$$\sum_{j\in\mathbb{N}} |Q_j| \le \lambda^{-1} \|f\|_{L^1(\mathbb{R}^n)}, \qquad \sum_{j\in\mathbb{N}} \|b_j\|_{L^1(\mathbb{R}^n)} \le 2\|f\|_{L^1(\mathbb{R}^n)}.$$

Proof. Consider the family of dyadic cubes Q for which

$$\frac{1}{|Q|}\int_Q |f| > \lambda.$$

For almost every x with $|f(x)| > \lambda$, Theorem B.8.12 ensures the existence of sufficiently small dyadic cubes containing x on which the average of $|f|$ exceeds λ: simply compare each cube with a concentric ball whose radius is comparable to its side length and use Lebesgue differentiation. On the other hand, since $f \in L^1(\mathbb{R}^n)$, the average over cubes whose side length tends to infinity converges to zero. We may therefore choose the maximal cubes $(Q_j)_{j\in\mathbb{N}}$ in the family. They are disjoint and cover $\{|f| > \lambda\}$ up to a null set.
If $\widetilde{Q}_j$ is the dyadic parent of Q_j, maximality implies

$$\frac{1}{|\widetilde{Q}_j|}\int_{\widetilde{Q}_j} |f| \le \lambda.$$

Since $|\widetilde{Q}_j| = 2^n|Q_j|$, we obtain

$$\lambda < \frac{1}{|Q_j|}\int_{Q_j} |f| \le 2^n\lambda.$$

Define

$$g(x) := \begin{cases} f(x), & x \notin \bigcup_{j\in\mathbb{N}} Q_j, \\ f_{Q_j} := \dfrac{1}{|Q_j|}\displaystyle\int_{Q_j} f, & x \in Q_j, \end{cases}$$

and

$$b_j := (f - f_{Q_j})\mathbf{1}_{Q_j}.$$

Outside the union of the Q_j, we have $|f| \le \lambda$ almost everywhere, while $|f_{Q_j}| \le 2^n\lambda$. This gives $\|g\|_{L^\infty(\mathbb{R}^n)} \le 2^n\lambda$. Moreover,

$$\|g\|_{L^1(\mathbb{R}^n)} \le \int_{\mathbb{R}^n\setminus\bigcup_{j\in\mathbb{N}} Q_j} |f| + \sum_{j\in\mathbb{N}} |f_{Q_j}||Q_j| \le \|f\|_{L^1(\mathbb{R}^n)}.$$

The cancellation $\displaystyle\int_{Q_j} b_j = 0$ is immediate. Finally,

$$\lambda\sum_{j\in\mathbb{N}} |Q_j| < \sum_{j\in\mathbb{N}}\int_{Q_j} |f| \le \|f\|_{L^1(\mathbb{R}^n)}$$

and

$$\sum_{j\in\mathbb{N}} \|b_j\|_{L^1(\mathbb{R}^n)} \le \sum_{j\in\mathbb{N}} \left(\int_{Q_j} |f| + |f_{Q_j}||Q_j|\right) \le 2\|f\|_{L^1(\mathbb{R}^n)}.$$

□

The last result of this section directly connects frequency localization with the maximal operator. For a function whose spectrum is contained in a ball of radius comparable to 2^j, the maximum of its translates, penalized at scale 2^{-j}, is controlled by a Hardy–Littlewood maximal function of a power of the function. This is the form of Peetre's maximal inequality used in proofs of independence of the dyadic resolution and in almost diagonal

arguments.

Lemma B.8.16. (Peetre maximal control) Let $j \in \mathbb{Z}$, $0 < a < \infty$, $N > \frac{n}{a}$, and $A > 0$. Suppose that $f \in \mathcal{S}'(\mathbb{R}^n)$, and identify it with its canonical smooth representative. Suppose also that

$$\operatorname{supp}(\widehat{f}) \subseteq \{\xi \in \mathbb{R}^n \mid \|\xi\| \le A2^j\}.$$

Then

$$\sup_{y\in\mathbb{R}^n} \frac{|f(x-y)|}{(1+2^j\|y\|)^N} \le C\left[\mathcal{M}(|f|^a)(x)\right]^{\frac{1}{a}}, \tag{B.9}$$

where C depends only on n, a, N and A, at every point x such that $\mathcal{M}(|f|^a)(x) < \infty$. Consequently, if

$$K_j(x) := 2^{jn}K(2^jx)$$

and

$$|K(x)| \le C_K(1+\|x\|)^{-N-n-1},$$

then

$$|K_j * f(x)| \le C\left[\mathcal{M}(|f|^a)(x)\right]^{\frac{1}{a}}$$

where C also depends on C_K; at those points, the convolution converges absolutely.

The maximal method for band-limited functions is developed in [146, Sections 2.2–2.3].

Proof. Choose $\vartheta \in C_c^\infty(\mathbb{R}^n)$ such that $\vartheta = 1$ on a neighborhood of the ball $\{\|\xi\| \le A\}$, and set $\eta := \mathcal{F}^{-1}\vartheta \in \mathcal{S}(\mathbb{R}^n)$. If $\eta_j(x) := 2^{jn}\eta(2^jx)$, the convolution formula corresponding to the unitary Fourier normalization gives

$$f = (2\pi)^{-\frac{n}{2}}\eta_j * f$$

in $\mathcal{S}'(\mathbb{R}^n)$. The constant factor will be absorbed in the estimates. In particular, by Proposition 4.10.4, f has the canonical smooth representative of at most polynomial growth used in the statement.
Since η is a Schwartz function, for every $L > 0$ there exists C_L such that

$$|\eta_j(z)| \le C_L 2^{jn}(1+2^j\|z\|)^{-L}. \tag{B.10}$$

First suppose $a > 1$. For $z \in \mathbb{R}^n$, the reproducing formula and the inequality

$$1 + 2^j\|x-w\| \le (1+2^j\|x-z\|)(1+2^j\|z-w\|)$$

give, after dividing by $(1+2^j\|x-z\|)^N$,

$$\frac{|f(z)|}{(1+2^j\|x-z\|)^N} \le C_L \int_{\mathbb{R}^n} 2^{jn}(1+2^j\|z-w\|)^{-L+N}\frac{|f(w)|}{(1+2^j\|x-w\|)^N}\,dw.$$

Apply Hölder with exponents a and $a' = \frac{a}{a-1}$. If L is chosen so that $(L-N)a' > n$, the second factor remains

uniformly bounded and we obtain

$$\frac{|f(z)|}{(1+2^j\|x-z\|)^N} \le C\left(\int_{\mathbb{R}^n} 2^{jn}\frac{|f(w)|^a}{(1+2^j\|x-w\|)^{Na}}\,dw\right)^{\frac{1}{a}}.$$

Since $Na > n$, the decomposition of $\mathbb{R}^n$ into the ball $B(x,2^{-j})$ and the annuli

$$2^{\ell-j} < \|x-w\| \le 2^{\ell+1-j}, \qquad \ell \in \mathbb{N}_0,$$

proves

$$\int_{\mathbb{R}^n} 2^{jn}\frac{|f(w)|^a}{(1+2^j\|x-w\|)^{Na}}\,dw \le C\mathcal{M}(|f|^a)(x), \tag{B.11}$$

since the contribution of the ℓth annulus is bounded by $C2^{-\ell(Na-n)}\mathcal{M}(|f|^a)(x)$. Taking the supremum over $z = x - y$ proves (B.9) for $a > 1$.

Now consider $0 < a \le 1$. To avoid assuming in advance that the Peetre maximum is finite, fix $\varepsilon > 0$ and define

$$P_\varepsilon f(x) := \sup_{z\in\mathbb{R}^n} \frac{|f(z)|}{(1+2^j\|x-z\|)^N(1+\varepsilon 2^j\|x-z\|)^M},$$

where $0 < \varepsilon \le 1$ and M is chosen greater than a polynomial growth order of f. The regularity and growth established above imply $P_\varepsilon f(x) < \infty$. Using

$$|f(w)|^{1-a} \le P_\varepsilon f(x)^{1-a}(1+2^j\|x-w\|)^{N(1-a)}(1+\varepsilon 2^j\|x-w\|)^{M(1-a)}$$

in the preceding reproducing formula and applying the weight inequalities

$$1+2^j\|x-w\| \le (1+2^j\|x-z\|)(1+2^j\|z-w\|)$$

and their analogue with $\varepsilon 2^j$ gives, upon choosing L sufficiently large in (B.10),

$$P_\varepsilon f(x) \le CP_\varepsilon f(x)^{1-a}\int_{\mathbb{R}^n} 2^{jn}\frac{|f(w)|^a}{(1+2^j\|x-w\|)^{Na}}\,dw.$$

The constant C is independent of ε. If $P_\varepsilon f(x) > 0$, divide by $P_\varepsilon f(x)^{1-a}$; if it is zero, the conclusion is immediate. Using (B.11) yields

$$P_\varepsilon f(x)^a \le C\mathcal{M}(|f|^a)(x).$$

As $\varepsilon \downarrow 0$, the denominators decrease and $P_\varepsilon f(x)$ increases to the unregularized Peetre maximum. The preceding bound proves that this maximum, denoted by $Pf(x)$, is finite. In this first step, the constant may depend on M, chosen according to the growth of f.

Now repeat the estimate with the finite maximum $Pf(x)$ and without the auxiliary weight. The reproducing formula and

$$|f(w)|^{1-a} \le Pf(x)^{1-a}(1+2^j\|x-w\|)^{N(1-a)}$$

give, for $z \in \mathbb{R}^n$,

$$\frac{|f(z)|}{(1+2^j\|x-z\|)^N} \le CPf(x)^{1-a}\int_{\mathbb{R}^n} 2^{jn}\frac{|f(w)|^a}{(1+2^j\|x-w\|)^{Na}}\,dw.$$

Indeed, use $(1+2^j\|x-w\|)^N \le (1+2^j\|x-z\|)^N(1+2^j\|z-w\|)^N$ and choose $L>N$ in (B.10). The remaining factor $(1+2^j\|z-w\|)^{-L+N}$ is at most one. This time L depends only on N, and no constant depends on the growth order of f. Take the supremum over $z\in\mathbb{R}^n$, divide by $Pf(x)^{1-a}$ when it is positive, and apply (B.11). This gives (B.9) with the dependence of constants asserted in the statement.
For the second assertion, denote by $P_{j,N}f(x)$ the left-hand side of (B.9). Then

$$\begin{aligned}|K_j * f(x)| &\le \int_{\mathbb{R}^n} |K_j(y)||f(x-y)|\,dy \\ &\le P_{j,N}f(x)\int_{\mathbb{R}^n} |K_j(y)|(1+2^j\|y\|)^N\,dy.\end{aligned}$$

The change of variables $z=2^jy$ and the hypothesis on K show that the last integral is bounded uniformly in j. Finally, apply (B.9). □

Proposition B.8.17. (Continuity of translations) If $1\le p<\infty$ and $f\in L^p(\mathbb{R}^n)$, then

$$\|\tau_h f - f\|_{L^p(\mathbb{R}^n)} \longrightarrow 0 \qquad \text{as } \|h\|\to 0, \quad \tau_h f(x) := f(x+h).$$

Proof. If $f\in C_c(\mathbb{R}^n)$, convergence follows from uniform continuity and the fact that all translates with $\|h\|\le 1$ are supported in a fixed compact set. For $f\in L^p(\mathbb{R}^n)$, choose $g\in C_c(\mathbb{R}^n)$ such that $\|f-g\|_{L^p(\mathbb{R}^n)}<\varepsilon$. Since translations are isometries of $L^p(\mathbb{R}^n)$,

$$\|\tau_h f - f\|_{L^p(\mathbb{R}^n)} \le 2\|f-g\|_{L^p(\mathbb{R}^n)} + \|\tau_h g - g\|_{L^p(\mathbb{R}^n)}.$$

The last term tends to zero as $\|h\|\to 0$, after which we let $\varepsilon\downarrow 0$. □

B.9 Euclidean mollifiers

The local regularization used in Sobolev spaces and partial differential equations is based on a single Euclidean construction. We formulate it with the properties needed later; see also [61, Appendix C, §5].

Theorem B.9.1. (Existence and properties of Euclidean mollifiers) There exists a function $\rho\in C_c^\infty(\mathbb{R}^n)$ such that $\rho\ge 0$, $\operatorname{supp}(\rho)\subseteq \overline{B}_{\mathrm{euc}}(0,1)$, and $\displaystyle\int_{\mathbb{R}^n}\rho\,d\lambda_n = 1$. For $\varepsilon>0$, define

$$\rho_\varepsilon(x) := \varepsilon^{-n}\rho\left(\frac{x}{\varepsilon}\right).$$

Then $\rho_\varepsilon\ge 0$, $\operatorname{supp}(\rho_\varepsilon)\subseteq\overline{B}_{\mathrm{euc}}(0,\varepsilon)$, and $\displaystyle\int_{\mathbb{R}^n}\rho_\varepsilon\,d\lambda_n = 1$. Moreover, the following properties hold.

(a) If $\Omega\subseteq\mathbb{R}^n$ is open, $u\in L^1_{\mathrm{loc}}(\Omega)$, and $\Omega_\varepsilon := \{x\in\Omega \mid \operatorname{dist}_{\mathrm{euc}}(x,\mathbb{R}^n\setminus\Omega)>\varepsilon\}$, then

$$u_\varepsilon(x) := (u*\rho_\varepsilon)(x) = \int_{\mathbb{R}^n} u(x-y)\rho_\varepsilon(y)\,dy, \qquad x\in\Omega_\varepsilon,$$

is smooth and $D^\alpha u_\varepsilon = u * D^\alpha\rho_\varepsilon$ for every multi-index α.

(b) If $1\le p<\infty$ and $u\in L^p_{\mathrm{loc}}(\Omega)$, then $u_\varepsilon\to u$ in $L^p(K)$ for every compact set $K\subseteq\Omega$ as $\varepsilon\to 0^+$.

(c) If u is continuous, then $u_\varepsilon \to u$ uniformly on each compact subset of Ω. If $u\colon \mathbb{R}^n \longrightarrow \mathbb{R}$ is uniformly continuous, convergence is uniform on $\mathbb{R}^n$.

(d) If $u\colon \mathbb{R}^n \longrightarrow \mathbb{R}$ is L-Lipschitz, then u_ε is also L-Lipschitz,

$$|Du_\varepsilon(x)| \le L$$

for every $x \in \mathbb{R}^n$, and

$$\|u_\varepsilon - u\|_{L^\infty(\mathbb{R}^n)} \le L\varepsilon m_1(\rho), \qquad m_1(\rho) := \int_{\mathbb{R}^n} \|z\|\rho(z)\,dz.$$

Proof. Define

$$\vartheta(x) := \begin{cases} \exp\left(-\frac{1}{1-\|x\|^2}\right), & \|x\| < 1, \\ 0, & \|x\| \ge 1. \end{cases}$$

The function ϑ is smooth: inside the ball this is immediate, and as one approaches $\|x\| = 1$, each derivative is the product of a rational function of $1-\|x\|^2$ and $\exp\left(-\dfrac{1}{1-\|x\|^2}\right)$, which tends to zero faster than any power of $1-\|x\|^2$. Since ϑ is nonnegative and not identically zero, the constant $c := \left(\displaystyle\int_{\mathbb{R}^n} \vartheta\,d\lambda_n\right)^{-1}$ is well defined. The function $\rho := c\vartheta$ has the required properties. The change of variables $y = \varepsilon z$ proves the assertions about ρ_ε.

Now let $u \in L^1_{\mathrm{loc}}(\Omega)$. If $x \in \Omega_\varepsilon$, the integral defining $u_\varepsilon(x)$ uses only values of u in Ω. It may also be written as

$$u_\varepsilon(x) = \int_\Omega u(z)\rho_\varepsilon(x-z)\,dz.$$

On a compact neighborhood of any point of Ω_ε, the integrand vanishes outside a fixed compact subset of Ω. Since u is integrable on that compact set and all derivatives of ρ_ε are bounded, dominated convergence allows differentiation under the integral sign any number of times. Thus $u_\varepsilon \in C^\infty(\Omega_\varepsilon)$ and $D^\alpha u_\varepsilon = u * D^\alpha \rho_\varepsilon$. We now prove convergence in L^p_{loc}. First observe that, for every $v \in L^p(\mathbb{R}^n)$,

$$\|v(\cdot - h) - v\|_{L^p(\mathbb{R}^n)} \longrightarrow 0 \qquad \text{as} \qquad h \to 0.$$

Indeed, by Proposition B.7.18, choose $\varphi \in C_c^\infty(\mathbb{R}^n)$ with $\|v-\varphi\|_{L^p(\mathbb{R}^n)} < \delta$. Translation invariance of Lebesgue measure gives

$$\|v(\cdot - h) - v\|_{L^p(\mathbb{R}^n)} \le 2\delta + \|\varphi(\cdot - h) - \varphi\|_{L^p(\mathbb{R}^n)}.$$

The last term converges to zero by uniform continuity of φ and because, for $\|h\| \le 1$, all functions involved are supported in a fixed compact set. Since $\delta > 0$ is arbitrary, continuity of translations follows.

Let $K \subseteq \Omega$ be compact. Since K and $\mathbb{R}^n \setminus \Omega$ are disjoint and the former is compact, the number $d_K := \operatorname{dist}_{\mathrm{euc}}(K, \mathbb{R}^n \setminus \Omega)$ is positive. Set $\delta_K := \dfrac{d_K}{3}$. Then the closed set $F_K := \{x \in \mathbb{R}^n \mid \operatorname{dist}_{\mathrm{euc}}(x,K) \le 2\delta_K\}$ is contained in Ω. Proposition 1.3.6, applied to $F_K \subseteq \Omega$, provides $\eta \in C_c^\infty(\Omega)$ such that $0 \le \eta \le 1$ and $\eta = 1$ on a neighborhood of F_K. Extend $v := \eta u$ by zero to $\mathbb{R}^n$. If $0 < \varepsilon < \delta_K$, then $u_\varepsilon = v * \rho_\varepsilon$ on K. Minkowski's

integral inequality and the change of variables $y = \varepsilon z$ give

$$\|v * \rho_\varepsilon - v\|_{L^p(\mathbb{R}^n)} \le \int_{\mathbb{R}^n} \rho(z) \|v(\cdot - \varepsilon z) - v\|_{L^p(\mathbb{R}^n)} \, dz.$$

For each z, the integrand converges to zero and is dominated by $2\rho(z)\|v\|_{L^p(\mathbb{R}^n)}$. The dominated convergence theorem implies that $u_\varepsilon \to u$ in $L^p(K)$.
If u is continuous, for $x \in \Omega_\varepsilon$ we have

$$|u_\varepsilon(x) - u(x)| \le \int_{\mathbb{R}^n} \rho_\varepsilon(y) |u(x-y) - u(x)| \, dy \le \sup_{y \in \overline{B}_{\mathrm{euc}}(0,\varepsilon)} |u(x-y) - u(x)|.$$

Uniform continuity of u on a compact neighborhood of K proves uniform convergence on K. The same argument applies on all of $\mathbb{R}^n$ when u is uniformly continuous.
Finally, if u is L-Lipschitz, then

$$|u_\varepsilon(x) - u_\varepsilon(y)| \le \int_{\mathbb{R}^n} \rho_\varepsilon(z) |u(x-z) - u(y-z)| \, dz \le L\|x - y\|.$$

Since u_ε is smooth, taking difference quotients in unit directions gives $\|Du_\varepsilon\| \le L$. Moreover,

$$|u_\varepsilon(x) - u(x)| \le \int_{\mathbb{R}^n} \rho(z) |u(x - \varepsilon z) - u(x)| \, dz \le L\varepsilon \int_{\mathbb{R}^n} \|z\| \rho(z) \, dz,$$

uniformly with respect to x. This completes the proof. □

B.10 Topological vector spaces

The function spaces arising in global analysis are often not naturally described by a single norm. This occurs, for example, with spaces of compactly supported smooth functions, spaces of test sections, and various weak topologies associated with duality problems. We therefore recall the language of topological vector spaces, which allows the linear and topological structures of a space to be studied together.

Definition B.10.1. Let X be a vector space over a field $\mathbb{K} = \mathbb{R}, \mathbb{C}$ equipped with a topology τ. The pair (X, τ) is called a *topological vector space* if the functions $X \times X \longrightarrow X, \quad (x, y) \mapsto x + y$ and $\mathbb{K} \times X \longrightarrow X, \quad (\lambda, x) \mapsto \lambda x$ are continuous.

Continuity of the linear operations has immediate consequences. For example, translations and nonzero dilations are homeomorphisms. In particular, the topology of a topological vector space is determined by its behavior around the origin.

Proposition B.10.2. Let X be a topological vector space, and let $\mathcal{B}$ be a neighborhood basis at the origin. Then, for each $x \in X$, the family

$$x + \mathcal{B} := \{x + U \mid U \in \mathcal{B}\}$$

is a neighborhood basis at x. In particular, the family

$$\{x + U \mid x \in X, \ U \in \mathcal{B}\}$$

determines the open sets of X: a set $O \subseteq X$ is open if and only if, for each $x \in O$, there exists $U \in \mathcal{B}$ such that $x + U \subseteq O$. If the elements of $\mathcal{B}$ are open, their translates form a basis of open sets. Consequently, the topology of a topological vector space is uniquely determined by any neighborhood basis at the origin.

Proof. Let $x \in X$. Since the translation $\tau_x \colon X \longrightarrow X$, given by $\tau_x(y) = x + y$, is a homeomorphism, V is a neighborhood of 0 if and only if $x + V$ is a neighborhood of x. Thus, if $\mathcal{B}$ is a local basis at 0, then $x + \mathcal{B}$ is a local basis at x. If O is open and $x \in O$, there exists $U \in \mathcal{B}$ such that $x + U \subseteq O$. Conversely, if this condition holds at each $x \in O$, every point of O has a neighborhood contained in O and is an interior point. This characterizes the open sets and proves uniqueness of the topology. When the elements of $\mathcal{B}$ are open, so are their translates, which therefore form a basis of open sets. □

To describe useful local bases, we need a few elementary geometric notions in vector spaces.

Definition B.10.3. (Absorbing set) Let X be a vector space over $\mathbb{R}$ or $\mathbb{C}$. A set $A \subset X$ is said to be *absorbing* if, for every $x \in X$, there exists $\lambda > 0$ such that $x \in tA$, $\forall t \geq \lambda$, where $tA := \{ta \mid a \in A\}$.

Definition B.10.4. (Balanced set) Let X be a vector space over $\mathbb{R}$ or $\mathbb{C}$. A set $B \subset X$ is said to be *balanced* if, for every $x \in B$ and every scalar α with $|\alpha| \leq 1$, we have $\alpha x \in B$.

Definition B.10.5. (Absolutely convex set) Let X be a vector space over $\mathbb{R}$ or $\mathbb{C}$. A subset $A \subseteq X$ is called *absolutely convex* if it is convex and balanced.

As a first example, every neighborhood of the origin absorbs the entire space.

Lemma B.10.6. Every neighborhood of the origin in a topological vector space is absorbing.

Proof. Let U be a neighborhood of the origin, and let $x \in X$. Since the map

$$\mathbb{K} \longrightarrow X, \qquad \lambda \longmapsto \lambda x,$$

is continuous and $\lambda x \to 0$ as $\lambda \to 0$, there exists $\delta > 0$ such that $\lambda x \in U$ if $|\lambda| < \delta$. Taking $t > \delta^{-1}$ gives $t^{-1} x \in U$ and hence $x \in tU$. Since $x \in X$ was arbitrary, U is absorbing. □

Lemma B.10.7. Let X be a topological vector space. Then:

(a) for every neighborhood U of the origin, there is a neighborhood V of the origin such that $V + V \subseteq U$;

(b) for every neighborhood U of the origin, there is a balanced neighborhood B of the origin such that $B \subseteq U$;

(c) if X is Hausdorff, then, for every neighborhood U of the origin, there is a neighborhood W of the origin such that $\overline{W} \subseteq U$.

Proof. For (a), use continuity of addition at $(0,0)$. Since U is a neighborhood of 0, there are neighborhoods V_1, V_2 of the origin such that $V_1 + V_2 \subseteq U$. Taking $V = V_1 \cap V_2$ gives $V + V \subseteq U$.
For (b), use continuity of scalar multiplication at $(0,0)$. There exist $\varepsilon > 0$ and a neighborhood V of the origin

such that $\lambda V \subseteq U$ if $|\lambda| < \varepsilon$. Taking $0 < r < \varepsilon$ and defining

$$B := \bigcup_{|\lambda| \le r} \lambda V,$$

we find that B is a neighborhood of the origin, $B \subseteq U$, and B is balanced.
For (c), by part (a), choose a neighborhood V_0 of the origin such that $V_0 + V_0 \subseteq U$. The set

$$V := V_0 \cap (-V_0)$$

is a symmetric neighborhood of the origin and satisfies $V + V \subseteq U$. Let $W := \mathrm{Int}(V)$, which is an open symmetric neighborhood of the origin. If $x \in \overline{W}$, the neighborhood $x + W$ of x intersects W. Thus there exist $w_1, w_2 \in W$ such that $x + w_1 = w_2$, and

$$x = w_2 - w_1 \in W + W \subseteq V + V \subseteq U.$$

Hence $\overline{W} \subseteq U$. In particular, this argument directly proves regularity of every Hausdorff topological vector space. □

Remark B.10.8. Proposition B.10.2 shows that, in a topological vector space, it suffices to describe a local basis at the origin. Lemma B.10.7 allows neighborhoods of the origin to be refined so that they have useful properties under addition and scalar multiplication; under the Hausdorff assumption, we can find a basis of closed neighborhoods.

In a topological vector space, having a countable local basis at the origin is equivalent to being first countable. This property gives a characterization of metrizable topological vector spaces.

Theorem B.10.9. A topological vector space X is metrizable if and only if:

(a) X is Hausdorff;

(b) X has a countable local basis at 0.

The construction of a translation-invariant metric from a countable local basis, together with the immediate converse, can be found in [123, 149].

In metrizable spaces, continuity can be proved using sequences. This observation will be useful when working with Fréchet spaces and other metrizable spaces.

Proposition B.10.10. Let X be a metrizable topological vector space, and let Y be a topological vector space. A linear operator $L\colon X \longrightarrow Y$ is continuous if and only if it is sequentially continuous at the origin; that is, if, for every sequence $\{x_n\}_{n\in\mathbb{N}}$ in X such that $x_n \to 0$, we have $L(x_n) \to 0$ in Y.

Proof. If L is continuous and $x_n \to 0$ in X, continuity gives $L(x_n) \to L(0) = 0$ in Y.
Conversely, suppose that L is sequentially continuous at the origin. We prove that L is continuous. Since L is linear, it suffices to prove continuity at 0. Suppose, for a contradiction, that L is not continuous at 0. There is then a neighborhood U of the origin in Y such that, for every neighborhood V of the origin in X, we have $L(V) \not\subseteq U$.

Since X is metrizable, it is first countable. Let $\{W_n\}_{n\in\mathbb{N}}$ be a countable local basis at the origin in X. Define $V_n := \bigcap_{k=1}^{n} W_k$, for each $n \in \mathbb{N}$. Then each V_n is a neighborhood of the origin, and the family $\{V_n\}_{n\in\mathbb{N}}$ is decreasing and remains a local basis at the origin.
By the choice of U, for each $n \in \mathbb{N}$ we can choose $x_n \in V_n$ such that $L(x_n) \notin U$.
Let us show that $x_n \to 0$ in X. Let W be an arbitrary neighborhood of the origin. Since $\{V_n\}_{n\in\mathbb{N}}$ is a local basis at the origin, there exists $N \in \mathbb{N}$ such that $V_N \subseteq W$. Because the family is decreasing, $V_n \subseteq V_N \subseteq W$ for every $n \geq N$. Consequently, $x_n \in W$ for every $n \geq N$. This proves that $x_n \to 0$ in X.
By sequential continuity at the origin, $L(x_n) \to 0$ in Y. This is impossible, however, because U is a neighborhood of the origin in Y and $L(x_n) \notin U$ for every $n \in \mathbb{N}$. This contradiction shows that L is continuous at 0. Finally, linearity implies that L is continuous. □

Boundedness in topological vector spaces depends on how sets are absorbed by neighborhoods of the origin, rather than on a metric.

Definition B.10.11. Let X be a topological vector space. A set $E \subseteq X$ is said to be *topologically bounded* if, for each neighborhood U of 0, there exists $t > 0$ such that $E \subseteq tU$.

When the topology τ is generated by a metric d, metric boundedness and topological boundedness may differ. The metric $d_1 = \dfrac{d}{d+1}$ generates the same topology as d, but, since $d_1 \leq 1$, every set in X is bounded with respect to d_1. Nevertheless, not every subset of X need be topologically bounded.

We will also need the sequential notion of a Cauchy sequence. In nonmetrizable topological vector spaces, general completeness is formulated using Cauchy filters or nets. In this appendix, we use the sequential version only when it suffices, particularly in metrizable spaces.

Definition B.10.12. Let X be a topological vector space. A sequence $\{x_n\}$ in X is called a Cauchy sequence if, for every neighborhood U of the origin, there exists $N \in \mathbb{N}$ such that

$$x_n - x_m \in U, \quad \forall n, m \geq N.$$

We say that X is *sequentially complete* if every Cauchy sequence in X converges.

Proposition B.10.13. Let X be a topological vector space, and let $\{x_n\}$ be a Cauchy sequence in X. Then the range of the sequence $\{x_n \mid n \in \mathbb{N}\}$ is topologically bounded.

Proof. Let U be a neighborhood of the origin. By Lemma B.10.7, there is a balanced neighborhood W of the origin such that $W + W \subseteq U$. Since $\{x_n\}$ is Cauchy, there exists $N \in \mathbb{N}$ such that $x_n - x_N \in W$ for every $n \geq N$. Moreover, since W is absorbing, there exists $t_0 > 0$ such that $x_N \in tW$ for every $t \geq t_0$. If $t \geq \max\{1, t_0\}$ and $n \geq N$, then $x_n = x_N + (x_n - x_N) \in tW + W \subseteq t(W + W) \subseteq tU$.
On the other hand, the finite set $\{x_1, \ldots, x_{N-1}\}$ is topologically bounded because each of its points is absorbed by U. Increasing t if necessary, we find that all terms of the sequence belong to a single multiple of U. Since U was arbitrary, the range of the sequence is topologically bounded. □

The most important class of topological vector spaces for our purposes will be that of locally convex spaces. Their importance stems from the fact that their topologies can be described by seminorms, which is particularly

suitable for spaces of functions and sections.

Definition B.10.14. A topological vector space X is said to be locally convex if it has a local basis at 0 consisting of convex sets; equivalently, every neighborhood of 0 contains a convex neighborhood of 0.

Proposition B.10.15. A locally convex topological vector space admits a local basis at 0 consisting of balanced convex sets.

Proof. Let U be a neighborhood of the origin. Since X is locally convex, there is a convex neighborhood V of the origin such that $V \subseteq U$. By Lemma B.10.7, there is a balanced neighborhood B of the origin such that $B \subseteq V$. The convex hull of B, denoted by $\operatorname{conv}(B)$, is then balanced and convex. Moreover, since V is convex and $B \subseteq V$, we have $\operatorname{conv}(B) \subseteq V \subseteq U$. Thus every neighborhood of the origin contains a balanced convex neighborhood of the origin. □

Definition B.10.16. Let X be a vector space over $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$. A function $p\colon X \longrightarrow [0,\infty)$ is a seminorm if

$$p(x+y) \le p(x) + p(y)$$

for any $x, y \in X$ and

$$p(tx) = |t|p(x)$$

for every $x \in X$ and any $t \in \mathbb{K}$.

Every absorbing absolutely convex set has an associated seminorm given by its Minkowski functional.

Proposition B.10.17. Let X be a vector space over $\mathbb{K}$, where $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$, and let $A \subseteq X$ be an absorbing set. If A is absolutely convex, its Minkowski functional

$$p_A(x) := \inf\{\lambda > 0 \mid x \in \lambda A\}, \qquad x \in X,$$

is a seminorm on X.

Proof. Since A is absorbing, for each $x \in X$ there exists $\lambda > 0$ such that $x \in \lambda A$. Thus the set in the definition of $p_A(x)$ is nonempty, and consequently $p_A(x)$ is well defined for every $x \in X$.
First consider homogeneity. Let $\alpha \in \mathbb{K}$ and $x \in X$. If $\alpha = 0$, then $p_A(\alpha x) = p_A(0) = 0$. Now suppose that $\alpha \neq 0$. Write $\alpha = |\alpha|\theta$, where $|\theta| = 1$. Since A is balanced, $\theta A = A$. Therefore, for each $\lambda > 0$,

$$\alpha x \in \lambda A \iff |\alpha|\theta x \in \lambda A \iff x \in \frac{\lambda}{|\alpha|} A.$$

It follows that

$$p_A(\alpha x) = |\alpha|\, p_A(x).$$

We now prove subadditivity. Let $x, y \in X$ and $\varepsilon > 0$. By the definition of the infimum, there exist $\lambda, \mu > 0$ such that

$$x \in \lambda A, \qquad y \in \mu A, \qquad \lambda < p_A(x) + \varepsilon, \qquad \mu < p_A(y) + \varepsilon.$$

Since A is convex, we have

$$\lambda A + \mu A \subseteq (\lambda + \mu)A.$$

If $a, b \in A$, then

$$\lambda a + \mu b = (\lambda + \mu)\left(\frac{\lambda}{\lambda+\mu}a + \frac{\mu}{\lambda+\mu}b\right),$$

and the term in parentheses belongs to A by convexity. Therefore,

$$x + y \in (\lambda + \mu)A,$$

whence

$$p_A(x+y) \le \lambda + \mu < p_A(x) + p_A(y) + 2\varepsilon.$$

Since $\varepsilon > 0$ was arbitrary, we conclude that

$$p_A(x+y) \le p_A(x) + p_A(y).$$

Thus p_A is a seminorm on X. □

Definition B.10.18. Let X be a vector space, and let $\mathcal{P}$ be a family of seminorms on X. The *topology induced by* $\mathcal{P}$ is the topology whose local basis at the origin consists of all finite intersections of sets of the form

$$\{x \in X \mid p(x) < r\}, \qquad p \in \mathcal{P}, \quad r > 0.$$

Equivalently, a neighborhood basis at a point $x \in X$ is given by sets of the form

$$x + \bigcap_{i=1}^{k} \{y \in X \mid p_i(y) < r_i\},$$

where $p_1, \dots, p_k \in \mathcal{P}$ and $r_1, \dots, r_k > 0$.

Theorem B.10.19. Let X be a locally convex topological vector space, and let $\mathcal{F}$ be a local basis at the origin consisting of open absolutely convex neighborhoods. Then the family $\{p_U \mid U \in \mathcal{F}\}$ of Minkowski functionals is a family of continuous seminorms generating the topology of X.
Conversely, given a family $\mathcal{P}$ of seminorms on a vector space X, the topology induced by $\mathcal{P}$ makes X a locally convex topological vector space, and every seminorm $p \in \mathcal{P}$ is continuous in this topology.

Proof. First suppose that $\mathcal{F}$ is a local basis at the origin consisting of open absolutely convex neighborhoods. Let $U \in \mathcal{F}$. Since U is a neighborhood of the origin in a topological vector space, Lemma B.10.6 shows that U is absorbing. Proposition B.10.17 therefore ensures that its Minkowski functional p_U is a seminorm on X.
We show that p_U is continuous. Since p_U is a seminorm, it suffices to prove continuity at the origin. Let $\varepsilon > 0$. Multiplication by the nonzero scalar $\dfrac{\varepsilon}{2}$ is a homeomorphism of X onto itself and U is a neighborhood

of the origin, so the set $\frac{\varepsilon}{2}U$ is also a neighborhood of the origin. If $x \in \frac{\varepsilon}{2}U$, then

$$p_U(x) \le \frac{\varepsilon}{2} < \varepsilon.$$

Consequently,

$$\frac{\varepsilon}{2}U \subseteq \{x \in X \mid p_U(x) < \varepsilon\},$$

which proves that p_U is continuous at 0. Finally, for any $x, y \in X$, subadditivity of p_U gives $p_U(x) \le p_U(x-y) + p_U(y)$ and $p_U(y) \le p_U(x-y) + p_U(x)$, whence $|p_U(x) - p_U(y)| \le p_U(x-y)$.
Thus continuity of p_U at the origin implies continuity at every point of X.
We now show that the family $\{p_U \mid U \in \mathcal{F}\}$ generates the original topology. For each $U \in \mathcal{F}$, since U is open, balanced, and convex, we have

$$U = \{x \in X \mid p_U(x) < 1\}.$$

If $p_U(x) < 1$, there exists $\lambda < 1$ such that $x \in \lambda U$, and balancedness of U gives $x \in U$. Conversely, if $x \in U$, openness of U and continuity of the map $t \mapsto tx$ give $r > 1$ such that $rx \in U$. Therefore $x \in \frac{1}{r}U$ and $p_U(x) \le \frac{1}{r} < 1$. Thus the sets defined by the seminorms p_U reproduce the local basis $\mathcal{F}$ and, by Proposition B.10.2, generate the topology of X.
We now prove the converse assertion. Let $\mathcal{P}$ be a family of seminorms on the vector space X, and denote by $\mathcal{B}$ the collection of all finite intersections of sets of the form

$$\{x \in X \mid p(x) < r\}, \qquad p \in \mathcal{P}, \quad r > 0.$$

Each of these sets is balanced and convex, as are their finite intersections. Define a topology τ by declaring $O \subseteq X$ open if, for each $x \in O$, there exists $B \in \mathcal{B}$ such that $x + B \subseteq O$. This makes $\mathcal{B}$ a local basis at the origin. Addition is continuous at $(0,0)$ because, given a basic element

$$B = \bigcap_{i=1}^{k} \{x \in X \mid p_i(x) < r_i\},$$

the set

$$C = \bigcap_{i=1}^{k} \left\{ x \in X \mid p_i(x) < \frac{r_i}{2} \right\}$$

satisfies $C + C \subseteq B$. Continuity of scalar multiplication follows similarly: if $\alpha_0 \in \mathbb{K}$, $x_0 \in X$, and B is as above, choose $\delta > 0$ and a basic neighborhood C of 0 such that

$$|\alpha - \alpha_0| p_i(x_0) < \frac{r_i}{2} \quad \text{and} \quad |\alpha| p_i(h) < \frac{r_i}{2}$$

for $|\alpha - \alpha_0| < \delta$, $h \in C$, and every $i \in \{1, \dots, k\}$. Then $\alpha(x_0 + h) - \alpha_0 x_0 \in B$. Thus τ makes X a topological vector space. Since $\mathcal{B}$ consists of convex sets, the space is locally convex. Finally, each seminorm $p \in \mathcal{P}$ is continuous because $\{x \in X \mid p(x) < \varepsilon\}$ is a neighborhood of the origin for every $\varepsilon > 0$. □

We now give some consequences of the description by seminorms.

Proposition B.10.20. Let X be a topological vector space. Then X is Hausdorff if and only if the set $\{0\}$ is closed.

Proof. First suppose that X is Hausdorff. Since every Hausdorff space is T_1, its singleton sets are closed. In particular, $\{0\}$ is closed.
Conversely, suppose that $\{0\}$ is closed. Let $x, y \in X$ with $x \neq y$. Then $x - y \neq 0$ and hence $x - y \in X \setminus \{0\}$. Since $X \setminus \{0\}$ is open, there is a neighborhood U of the origin such that

$$x - y + U \subseteq X \setminus \{0\}.$$

In particular, $x - y \notin -U$. Replacing U by $U \cap (-U)$, we may assume that U is symmetric, that is, $U = -U$. Thus $x - y \notin U$.
Since addition is continuous at $(0,0)$, there is a neighborhood V of the origin such that $V + V \subseteq U$. Replacing V by $V \cap (-V)$ again, we may assume that V is symmetric.
Consider the neighborhoods $x+V$ and $y+V$. We claim that they are disjoint. If there were $z \in (x+V) \cap (y+V)$, there would be $v_1, v_2 \in V$ such that $z = x + v_1 = y + v_2$. Therefore $x - y = v_2 - v_1$. Since V is symmetric, $-v_1 \in V$, and then $v_2 - v_1 \in V + V \subseteq U$, contradicting $x - y \notin U$. Therefore $(x + V) \cap (y + V) = \varnothing$.
We have found disjoint neighborhoods of x and y. Since x and y were arbitrary, X is Hausdorff. □

Proposition B.10.21. Let X be a vector space, and let $\mathcal{P}$ be a family of seminorms on X. The topology induced by $\mathcal{P}$ is Hausdorff if and only if $\mathcal{P}$ separates points, that is, if, for every $x \in X$ with $x \neq 0$, there exists $p \in \mathcal{P}$ such that $p(x) \neq 0$. Equivalently,

$$\bigcap_{p \in \mathcal{P}} \{x \in X \mid p(x) = 0\} = \{0\}.$$

Proof. First suppose that the topology induced by $\mathcal{P}$ is Hausdorff. Let $x \in X$ with $x \neq 0$. Since the topology is Hausdorff, there are disjoint neighborhoods of the origin and of x. In particular, there is a neighborhood U of the origin such that $x \notin U$. By the definition of the induced topology, there exist $p_1, \dots, p_k \in \mathcal{P}$ and $r_1, \dots, r_k > 0$ such that

$$\bigcap_{i=1}^{k} \{y \in X \mid p_i(y) < r_i\} \subseteq U.$$

Since $x \notin U$, we also have

$$x \notin \bigcap_{i=1}^{k} \{y \in X \mid p_i(y) < r_i\}.$$

Therefore there exists $i \in \{1, \dots, k\}$ such that $p_i(x) \geq r_i > 0$. In particular, $p_i(x) \neq 0$. Thus the family $\mathcal{P}$ separates points.
Conversely, suppose that $\mathcal{P}$ separates points. Consider

$$N := \bigcap_{p \in \mathcal{P}} \{x \in X \mid p(x) = 0\}.$$

Since every seminorm satisfies $p(0) = 0$, we have $0 \in N$. On the other hand, if $x \neq 0$, the hypothesis gives $p \in \mathcal{P}$ such that $p(x) \neq 0$, so $x \notin \{y \in X \mid p(y) = 0\}$. Consequently, $x \notin N$. This proves that $N = \{0\}$.

We now show that N is closed. For each $p \in \mathcal{P}$, the set $\{x \in X \mid p(x) = 0\}$ is closed in the induced topology. If x_0 does not belong to this set, then $p(x_0) > 0$. Taking $r := \frac{p(x_0)}{2}$, the neighborhood

$$x_0 + \{y \in X \mid p(y) < r\}$$

of x_0 does not intersect $\{x \in X \mid p(x) = 0\}$. If $p(x) = 0$ and $p(x - x_0) < r$, then

$$p(x_0) = p(x_0 - x + x) \leq p(x_0 - x) + p(x) < r,$$

contradicting the choice of r. Therefore $\{x \in X \mid p(x) = 0\}$ is closed.
Since N is an intersection of closed sets, N is closed. But $N = \{0\}$, so $\{0\}$ is closed. By Proposition B.10.20, the topology induced by $\mathcal{P}$ is Hausdorff. □

Corollary B.10.22. Let $\mathcal{P}$ be a family of seminorms on a vector space X, and let $\tau_{\mathcal{P}}$ be the locally convex topology generated by $\mathcal{P}$. Then:

(a) $\tau_{\mathcal{P}}$ is Hausdorff if and only if $p(x) = 0$ for every $p \in \mathcal{P}$ implies $x = 0$.

(b) A set $A \subseteq X$ is topologically bounded if and only if the set $p(A) \subseteq \mathbb{R}$ is bounded in $\mathbb{R}$ for every $p \in \mathcal{P}$.

A topological vector space is called *seminormable* if its topology can be induced by a seminorm p. The space (X, p) is called a *seminormed* space.

Proof. The first assertion is Proposition B.10.21.
For (b), first suppose that A is topologically bounded. If $p \in \mathcal{P}$, then $\{x \in X \mid p(x) < 1\}$ is a neighborhood of the origin. There exists $t > 0$ such that $A \subseteq t\{x \in X \mid p(x) < 1\}$. Therefore, if $a \in A$, we have $p(a) < t$, so $p(A)$ is bounded.
Conversely, suppose that $p(A)$ is bounded for every $p \in \mathcal{P}$. Let U be a neighborhood of the origin. Since the topology is generated by $\mathcal{P}$, there is a basic neighborhood

$$B = \bigcap_{i=1}^{k} \{x \in X \mid p_i(x) < r_i\}$$

such that $B \subseteq U$. By hypothesis, for each i there exists $M_i > 0$ such that $p_i(a) \leq M_i$ for every $a \in A$. Choose $t > 0$ such that $M_i < t r_i$ for every i. Then $A \subseteq tB \subseteq tU$. Therefore A is topologically bounded. □

Proposition B.10.23. Let X be a vector space, and let $\mathcal{P}$ be a family, not necessarily countable, of seminorms on X. Denote by $\tau_{\mathcal{P}}$ the topology induced by $\mathcal{P}$. Then:

(a) A sequence $(x_n)_{n \in \mathbb{N}}$ converges to $x \in X$ in $\tau_{\mathcal{P}}$ if and only if $p(x_n - x) \to 0$ for every $p \in \mathcal{P}$.

(b) A sequence $(x_n)_{n \in \mathbb{N}}$ is Cauchy in $\tau_{\mathcal{P}}$ if and only if $p(x_n - x_m) \to 0$ as $n, m \to \infty$, for every $p \in \mathcal{P}$.

Proof. We first prove the convergence assertion. Suppose that $x_n \to x$ in $\tau_{\mathcal{P}}$. Let $p \in \mathcal{P}$ and $\varepsilon > 0$. The set

$$x + \{y \in X \mid p(y) < \varepsilon\}$$

is a neighborhood of x. By convergence of the sequence, there exists $N \in \mathbb{N}$ such that, if $n \geq N$, then x_n belongs to this neighborhood. Therefore $p(x_n - x) < \varepsilon$ for every $n \geq N$. This proves that $p(x_n - x) \to 0$.
Conversely, suppose that $p(x_n - x) \to 0$ for every $p \in \mathcal{P}$. Let U be a neighborhood of x. By the definition of the induced topology, there exist $p_1, \ldots, p_k \in \mathcal{P}$ and $r_1, \ldots, r_k > 0$ such that

$$x + \bigcap_{i=1}^{k} \{y \in X \mid p_i(y) < r_i\} \subseteq U.$$

For each $i \in \{1, \ldots, k\}$, since $p_i(x_n - x) \to 0$, there exists $N_i \in \mathbb{N}$ such that $p_i(x_n - x) < r_i$ for every $n \geq N_i$. Taking $N := \max\{N_1, \ldots, N_k\}$ gives, for every $n \geq N$,

$$x_n - x \in \bigcap_{i=1}^{k} \{y \in X \mid p_i(y) < r_i\}.$$

Therefore $x_n \in U$ for every $n \geq N$. Since U was an arbitrary neighborhood of x, we conclude that $x_n \to x$ in $\tau_{\mathcal{P}}$.
We now prove the assertion about Cauchy sequences. Suppose that $(x_n)_{n \in \mathbb{N}}$ is Cauchy in $\tau_{\mathcal{P}}$. Let $p \in \mathcal{P}$ and $\varepsilon > 0$. The set $\{y \in X \mid p(y) < \varepsilon\}$ is a neighborhood of the origin. By the Cauchy property, there exists $N \in \mathbb{N}$ such that, if $n, m \geq N$, then $x_n - x_m \in \{y \in X \mid p(y) < \varepsilon\}$. Therefore $p(x_n - x_m) < \varepsilon$ for any $n, m \geq N$. This proves that $p(x_n - x_m) \to 0$ as $n, m \to \infty$.
Conversely, suppose that, for every $p \in \mathcal{P}$, we have $p(x_n - x_m) \to 0$ as $n, m \to \infty$. Let U be a neighborhood of the origin. By the definition of the induced topology, there exist $p_1, \ldots, p_k \in \mathcal{P}$ and $r_1, \ldots, r_k > 0$ such that

$$\bigcap_{i=1}^{k} \{y \in X \mid p_i(y) < r_i\} \subseteq U.$$

For each $i \in \{1, \ldots, k\}$, there exists $N_i \in \mathbb{N}$ such that $p_i(x_n - x_m) < r_i$ for any $n, m \geq N_i$. Taking $N := \max\{N_1, \ldots, N_k\}$, we have, for any $n, m \geq N$,

$$x_n - x_m \in \bigcap_{i=1}^{k} \{y \in X \mid p_i(y) < r_i\} \subseteq U.$$

Therefore $(x_n)_{n \in \mathbb{N}}$ is Cauchy in $\tau_{\mathcal{P}}$. □

Proposition B.10.24. (Metrization by a countable family of seminorms) Let X be a vector space, and let $(p_n)_{n \in \mathbb{N}_0}$ be a countable family of seminorms separating points. For $x, y \in X$, define

$$d(x, y) := \sum_{n=0}^{\infty} \frac{1}{2^n} \frac{p_n(x - y)}{1 + p_n(x - y)}.$$

Then:

(a) d is a translation-invariant metric on X.

(b) The topology induced by d agrees with the locally convex topology generated by the family $(p_n)_{n \in \mathbb{N}_0}$.

Proof. Define $\theta\colon [0,\infty) \longrightarrow [0,1)$ by

$$\theta(t) := \frac{t}{1+t}.$$

This function is continuous, strictly increasing, satisfies $\theta(0) = 0$, and has $\theta(t) = 0$ if and only if $t = 0$. It is also subadditive. If $s, t \geq 0$, then

$$\theta(s+t) = \frac{s+t}{1+s+t} \leq \frac{s}{1+s} + \frac{t}{1+t} = \theta(s) + \theta(t).$$

For each $n \in \mathbb{N}_0$, define

$$\delta_n(x,y) := \theta(p_n(x-y)), \qquad x, y \in X.$$

Since p_n is a seminorm, we have

$$\delta_n(x+a, y+a) = \delta_n(x,y)$$

for any $x, y, a \in X$, so δ_n is translation invariant. Moreover, since $p_n(x-y) = p_n(y-x)$, it is also symmetric. We show that δ_n satisfies the triangle inequality. If $x, y, z \in X$, subadditivity of p_n and θ gives

$$\delta_n(x,z) = \theta(p_n(x-z)) \leq \theta(p_n(x-y) + p_n(y-z)) \leq \theta(p_n(x-y)) + \theta(p_n(y-z)) = \delta_n(x,y) + \delta_n(y,z).$$

Thus each δ_n is a translation-invariant pseudometric. In general, it is not a metric, since a seminorm may vanish on nonzero vectors.

Since $0 \leq \delta_n(x,y) < 1$ for every $n \in \mathbb{N}_0$ and any $x, y \in X$, the series

$$d(x,y) := \sum_{n=0}^{\infty} \frac{1}{2^n} \delta_n(x,y)$$

converges, being dominated by the series $\displaystyle\sum_{n=0}^{\infty} 2^{-n}$. Symmetry and translation invariance of d follow term by term. Moreover, if $x, y, z \in X$, then

$$\delta_n(x,z) \leq \delta_n(x,y) + \delta_n(y,z)$$

for every $n \in \mathbb{N}_0$. Multiplying by 2^{-n} and summing over n gives

$$d(x,z) \leq d(x,y) + d(y,z).$$

Thus d satisfies the triangle inequality.

It remains to verify that $d(x,y) = 0$ implies $x = y$. If $d(x,y) = 0$, all terms of the series are nonnegative, so necessarily $\delta_n(x,y) = 0$ for every $n \in \mathbb{N}_0$. Since $\theta(t) = 0$ if and only if $t = 0$, it follows that $p_n(x-y) = 0$ for every $n \in \mathbb{N}_0$. The family $(p_n)_{n\in\mathbb{N}_0}$ separates points, so $x - y = 0$, that is, $x = y$. Therefore d is a translation-invariant metric. This proves (a).

We now prove (b). Denote by τ the locally convex topology generated by the family $(p_n)_{n\in\mathbb{N}_0}$, and by τ_d the topology induced by the metric d. Since d is translation invariant, the topology τ_d is also translation invariant. On the other hand, τ is a topological vector space topology by Theorem B.10.19 and is therefore also translation invariant. It thus suffices to compare neighborhoods of the origin.

First, we show that every neighborhood of the origin in τ_d is a neighborhood of the origin in τ. It suffices

to prove this for the balls $B_d(0,\varepsilon)$, with $\varepsilon > 0$. Choose $N \in \mathbb{N}_0$ such that

$$\sum_{n=N+1}^{\infty} \frac{1}{2^n} < \frac{\varepsilon}{2}.$$

Since $\theta(t) \to 0$ as $t \to 0^+$, for each $n \in \{0,\dots,N\}$ there exists $\eta_n > 0$ such that

$$\frac{1}{2^n}\theta(\eta_n) < \frac{\varepsilon}{2(N+1)}.$$

Define

$$V := \bigcap_{n=0}^{N} \{x \in X \mid p_n(x) < \eta_n\}.$$

Then V is a neighborhood of the origin in τ. If $x \in V$, then $p_n(x) < \eta_n$ for every $n \in \{0,\dots,N\}$, and monotonicity of θ gives

$$\begin{aligned} d(x,0) &= \sum_{n=0}^{N} \frac{1}{2^n}\theta(p_n(x)) + \sum_{n=N+1}^{\infty} \frac{1}{2^n}\theta(p_n(x)) \\ &< \frac{\varepsilon}{2} + \sum_{n=N+1}^{\infty} \frac{1}{2^n} < \varepsilon. \end{aligned}$$

Therefore $V \subseteq B_d(0,\varepsilon)$. Thus every ball centered at the origin for d contains a neighborhood of the origin in τ. Consequently, every neighborhood of the origin in τ_d is a neighborhood of the origin in τ.
Conversely, we show that every neighborhood of the origin in τ is a neighborhood of the origin in τ_d. It suffices to consider a basic neighborhood

$$W := \bigcap_{j=1}^{r} \{x \in X \mid p_{n_j}(x) < \varepsilon_j\},$$

where $n_1,\dots,n_r \in \mathbb{N}_0$ and $\varepsilon_1,\dots,\varepsilon_r > 0$. Define

$$\rho := \min_{1 \le j \le r} \frac{1}{2^{n_j}}\theta(\varepsilon_j).$$

Since each ε_j is positive and $\theta(t) > 0$ for $t > 0$, we have $\rho > 0$.
We claim that $B_d(0,\rho) \subseteq W$. If $x \in B_d(0,\rho)$, then $d(x,0) < \rho$. For each $j \in \{1,\dots,r\}$, we have

$$\frac{1}{2^{n_j}}\theta(p_{n_j}(x)) \le d(x,0) < \rho \le \frac{1}{2^{n_j}}\theta(\varepsilon_j).$$

Therefore,

$$\theta(p_{n_j}(x)) < \theta(\varepsilon_j).$$

Since θ is strictly increasing, $p_{n_j}(x) < \varepsilon_j$. This holds for every $j \in \{1,\dots,r\}$, so $x \in W$. Thus $B_d(0,\rho) \subseteq W$.
We have proved that the neighborhoods of the origin in τ and τ_d agree. Since both topologies are translation invariant, their neighborhoods at every point also agree. Consequently, $\tau = \tau_d$. □

Theorem B.10.25. Let X be a locally convex topological vector space whose topology is generated by a family of seminorms $\mathcal{P}$, and let $(Y, \|\cdot\|_Y)$ be a normed space. A linear operator $L\colon X \longrightarrow Y$ is continuous if and only if there exist a constant $C > 0$ and finitely many seminorms $p_1, \dots, p_k \in \mathcal{P}$ such that

$$\|L(x)\|_Y \le C \max_{1\le i\le k} p_i(x) \qquad \forall x \in X.$$

In particular, if the family of seminorms is increasing or directed, it suffices to find a single seminorm $p \in \mathcal{P}$ and a constant $C > 0$ such that

$$\|L(x)\|_Y \le C p(x) \qquad \forall x \in X.$$

Proof. First suppose that L is continuous. Then $L^{-1}(B_{d_Y}(0,1))$ is a neighborhood of the origin in X. Since the topology of X is generated by $\mathcal{P}$, there exist $p_1, \dots, p_k \in \mathcal{P}$ and $\varepsilon > 0$ such that

$$\{x \in X \mid p_i(x) < \varepsilon,\ i = 1, \dots, k\} \subseteq L^{-1}(B_{d_Y}(0,1)).$$

Let $q(x) := \max_{1\le i\le k} p_i(x)$. If $x \neq 0$ and $q(x) > 0$, then $\dfrac{\varepsilon}{2q(x)}x$ belongs to the preceding neighborhood, and therefore

$$\left\| L\left(\frac{\varepsilon}{2q(x)}x\right)\right\|_Y < 1.$$

This gives $\|L(x)\|_Y \le \dfrac{2}{\varepsilon}q(x)$. If $q(x) = 0$, then tx belongs to the preceding neighborhood for every $t > 0$, and linearity yields $L(x) = 0$. Thus the inequality holds for every $x \in X$ with $C = \frac{2}{\varepsilon}$.
Conversely, if there exist a constant $C > 0$ and seminorms $p_1, \dots, p_k \in \mathcal{P}$ such that

$$\|L(x)\|_Y \le C \max_{1\le i\le k} p_i(x),$$

then, given $\varepsilon > 0$, the set

$$\left\{ x \in X \,\middle|\, p_i(x) < \frac{\varepsilon}{C},\ i = 1, \dots, k \right\}$$

is a neighborhood of the origin mapped into $B_{d_Y}(0, \varepsilon)$. Thus L is continuous at 0 and, by linearity, at every point.
The final assertion follows because, if the family is increasing or directed, there exists a seminorm $p \in \mathcal{P}$ that simultaneously dominates $p_1, \dots, p_k$ up to inessential constants. □

The following proposition gives an abstract construction of locally convex topologies from a prescribed local basis.

Proposition B.10.26. Let X be a vector space over $\mathbb{K}$, where $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$. Let $\mathcal{B}$ be a nonempty family of subsets of X satisfying:

(a) every $U \in \mathcal{B}$ is absolutely convex and absorbing;

(b) if $U, V \in \mathcal{B}$, there exists $W \in \mathcal{B}$ such that $W \subseteq U \cap V$;

(c) for each $U \in \mathcal{B}$ and each $\lambda > 0$, there exists $W \in \mathcal{B}$ such that $W \subseteq \lambda U$.

Then there exists a unique topology τ such that (X, τ) is a locally convex topological vector space and $\mathcal{B}$ is

a neighborhood basis at the origin.

Proof. For each $U \in \mathcal{B}$, consider its Minkowski functional

$$p_U(x) := \inf\{\lambda > 0 \mid x \in \lambda U\}, \qquad x \in X.$$

Since each $U \in \mathcal{B}$ is absolutely convex and absorbing, Proposition B.10.17 ensures that p_U is a seminorm on X.
Define

$$\mathcal{P} := \{p_U \mid U \in \mathcal{B}\}.$$

By Theorem B.10.19, the family $\mathcal{P}$ determines a topology τ making X a locally convex topological vector space. We show that $\mathcal{B}$ is a local basis at the origin for this topology.
First take $U \in \mathcal{B}$. If $x \in \{y \in X \mid p_U(y) < 1\}$, there exists $\lambda \in (0,1)$ such that $x \in \lambda U$. Since U is balanced, $\lambda U \subseteq U$, and therefore

$$\{y \in X \mid p_U(y) < 1\} \subseteq U.$$

The set on the left-hand side is a neighborhood of the origin in τ, so U is also a neighborhood of the origin.
It remains to prove that every neighborhood of the origin contains an element of $\mathcal{B}$. It suffices to consider a basic neighborhood of the form

$$N = \bigcap_{i=1}^{k} \{x \in X \mid p_{U_i}(x) < r_i\},$$

where $U_1, \dots, U_k \in \mathcal{B}$ and $r_1, \dots, r_k > 0$. For each i, the third hypothesis gives $W_i \in \mathcal{B}$ such that $W_i \subseteq \frac{r_i}{2} U_i$. If $x \in W_i$, then $p_{U_i}(x) \le \frac{r_i}{2} < r_i$. Therefore $W_i \subseteq \{x \in X \mid p_{U_i}(x) < r_i\}$. Repeatedly applying the second hypothesis, we find $W \in \mathcal{B}$ such that

$$W \subseteq \bigcap_{i=1}^{k} W_i \subseteq N.$$

Thus every basic neighborhood of the origin contains an element of $\mathcal{B}$, so $\mathcal{B}$ is a local basis at the origin for τ.
Finally, uniqueness of τ follows from Proposition B.10.2, since a topological vector space topology is uniquely determined by any local basis at the origin. □

Linear operators were introduced in Definition B.2.4. If X and Y are topological vector spaces, we retain the notation $\mathcal{L}(X,Y)$ for the space of continuous linear operators from X to Y. In particular, $X' := \mathcal{L}(X,\mathbb{K})$ is the continuous dual of X, and its elements are the continuous linear functionals.

Remark B.10.27. The bilinear map

$$\langle \cdot, \cdot \rangle_{X',X} \colon X' \times X \longrightarrow \mathbb{K}, \qquad (L,x) \mapsto L(x)$$

is called the *duality pairing*. The dual space of X', denoted by X'', is called the *bidual* of X.

Definition B.10.28. Let X and Y be topological vector spaces. An operator $L \colon X \longrightarrow Y$ is said to be *bounded* if it maps topologically bounded subsets of X to topologically bounded subsets of Y.

In normed spaces, continuity and boundedness of linear operators are equivalent. In general topological vector spaces, the relationship is more subtle, although useful implications remain. In the metrizable case, continuity can be characterized by sequences.

Theorem B.10.29. Let X, Y be topological vector spaces, and let $L\colon X \longrightarrow Y$ be a linear operator. Consider the following properties:

(a) L is continuous.

(b) L is bounded.

(c) If $\{x_n\}_{n\in\mathbb{N}}$ is a sequence in X and $x_n \to 0$, then $\{L(x_n) \mid n \in \mathbb{N}\} \subseteq Y$ is a topologically bounded set.

(d) If $\{x_n\}_{n\in\mathbb{N}}$ is a sequence in X and $x_n \to 0$, then $L(x_n) \to 0$.

Then $(a) \Rightarrow (b) \Rightarrow (c)$. If, in addition, X is metrizable, then $(c) \Rightarrow (d) \Rightarrow (a)$ and all four properties are equivalent.

Proof. If L is continuous, it maps topologically bounded sets to topologically bounded sets. Let $A \subseteq X$ be bounded, and let U be a neighborhood of the origin in Y. By continuity of L at 0, there is a neighborhood V of the origin in X such that $L(V) \subseteq U$. Since A is bounded, there exists $t > 0$ such that $A \subseteq tV$. By linearity, $L(A) \subseteq tL(V) \subseteq tU$. Therefore $L(A)$ is bounded. This proves $(a) \Rightarrow (b)$.
If L is bounded and $x_n \to 0$ in X, the set $\{x_n \mid n \in \mathbb{N}\}$ is topologically bounded. Its image under L is therefore also topologically bounded. This proves $(b) \Rightarrow (c)$.
Now suppose that X is metrizable and (c) holds. We prove (d) by contradiction. Let $x_n \to 0$ in X, and suppose that $L(x_n)$ does not converge to 0. There is then a balanced neighborhood U of the origin in Y and a subsequence, again denoted by x_n, such that $L(x_n) \notin U$ for every n.
Since X is metrizable, we can choose the subsequence so that $nx_n \to 0$ in X. By hypothesis, the set $\{L(nx_n) \mid n \in \mathbb{N}\}$ must be topologically bounded. If this set were bounded, however, there would be $t > 0$ such that $nL(x_n) \in tU$ for every n. Taking $n > t$ and using balancedness of U would give $L(x_n) \in \frac{t}{n}U \subseteq U$, a contradiction. Therefore $L(x_n) \to 0$. This proves $(c) \Rightarrow (d)$.
Finally, if X is metrizable, the implication $(d) \Rightarrow (a)$ is precisely Proposition B.10.10. □

Theorem B.10.30. (Extension of linear operators) Let X be a metrizable topological vector space, let $D \subseteq X$ be a dense vector subspace, and let Y be a Hausdorff, sequentially complete topological vector space. If $L\colon D \longrightarrow Y$ is a continuous linear operator, where D has the topology induced by X, there is at most one continuous linear operator $\widetilde{L}\colon X \longrightarrow Y$ such that $\widetilde{L}(x) = L(x)$ for every $x \in D$. Moreover, if, for each $x \in X$ and every sequence $\{x_n\} \subseteq D$ with $x_n \to x$, the sequence $\{L(x_n)\}$ is Cauchy in Y, then this extension exists and is unique.

Proof. Uniqueness follows from density of D and the Hausdorff property of Y. If $\widetilde{L}_1$ and $\widetilde{L}_2$ are two continuous extensions of L, they agree on D. Since the set where they agree is closed and contains D, it is all of X.
Now suppose that the additional condition holds. Let $x \in X$. Since D is dense and X is metrizable, there is a sequence $\{x_n\} \subseteq D$ such that $x_n \to x$. By hypothesis, $\{L(x_n)\}$ is Cauchy in Y and, since Y is sequentially

complete, it converges to a point of Y. Define

$$\widetilde{L}(x) := \lim_{n\to\infty} L(x_n).$$

We show that this definition is independent of the chosen sequence. If $\{y_n\} \subseteq D$ also converges to x, the interleaved sequence $z_1 = x_1, z_2 = y_1, z_3 = x_2, z_4 = y_2, \dots$ converges to x. By hypothesis, $\{L(z_n)\}$ is Cauchy, so its two subsequences $\{L(x_n)\}$ and $\{L(y_n)\}$ have the same limit. Thus $\widetilde{L}$ is well defined.

Linearity follows by taking sequences in D converging to the corresponding points and using linearity of L before passing to the limit.

Finally, we prove continuity without assuming that Y is first countable. Fix a compatible translation-invariant metric d on X. Let $x_n \to 0$, and suppose, for a contradiction, that $\widetilde{L}(x_n) \not\to 0$. There are a neighborhood U of 0 in Y and a subsequence, which we do not rename, such that $\widetilde{L}(x_n) \notin U$ for every n. Choose a neighborhood V of 0 such that $V + V \subseteq U$.

For each n, the definition of $\widetilde{L}(x_n)$ gives a sequence of points of D converging to x_n whose images converge to $\widetilde{L}(x_n)$. Choose a term $d_n \in D$ of this sequence so that

$$d(d_n, x_n) < \frac{1}{n}, \qquad \widetilde{L}(x_n) - L(d_n) \in V.$$

Then $d_n \to 0$ in X. Continuity of L at D implies $L(d_n) \to 0$, so $L(d_n) \in V$ for every sufficiently large n. For these indices,

$$\widetilde{L}(x_n) \in L(d_n) + V \subseteq V + V \subseteq U,$$

a contradiction. Therefore $\widetilde{L}$ is sequentially continuous at the origin. Since X is metrizable, Proposition B.10.10 proves that $\widetilde{L}$ is continuous. □

The following geometric forms of the Hahn–Banach theorem complement the analytical form presented in the section on normed spaces and provide the separation results needed later. Their proofs, obtained by applying the analytical form to the Minkowski functional of a suitable convex open set, can be found in [123, 149].

Theorem B.10.31. (Hahn–Banach, first geometric form) Let X be a real locally convex topological vector space, and let $A, B \subseteq X$ be nonempty convex sets. Suppose that $\operatorname{Int}(A) \neq \varnothing$ and $B \cap \operatorname{Int}(A) = \varnothing$. Then there exists a continuous linear functional $L\colon X \longrightarrow \mathbb{R}$ such that $\sup_{x\in A} L(x) \leq \inf_{y\in B} L(y)$, and moreover $L(a) < \inf_{y\in B} L(y)$ for every $a \in \operatorname{Int}(A)$. In particular, $L \neq 0$.

Corollary B.10.32. Let X be a Hausdorff locally convex topological vector space. Then $X' \neq \{0\}$ if and only if X has a convex neighborhood of the origin strictly contained in X.

Theorem B.10.33. (Hahn–Banach, second geometric form) Let X be a real locally convex topological vector space, and let $C, K \subseteq X$ be disjoint nonempty convex sets, with C closed and K compact. Then there exist a continuous linear functional $L\colon X \longrightarrow \mathbb{R}$ and two numbers $a \in \mathbb{R}$ and $\varepsilon > 0$ such that $L(x) \leq a - \varepsilon$ for every $x \in C$ and $L(x) \geq a + \varepsilon$ for every $x \in K$.

Theorem B.10.34. (Mazur) Let X be a topological vector space, and let $M \subseteq X$ be a vector subspace. Let $K \subseteq X$ be a nonempty open convex subset such that $M \cap K = \varnothing$.

Then there exists a closed hyperplane $N \subseteq X$ such that

$$M \subseteq N \qquad \text{and} \qquad N \cap K = \varnothing.$$

Corollary B.10.35. (Separation of a subspace and an open convex set) Let X be a locally convex Hausdorff topological vector space. Let $M \subseteq X$ be a vector subspace, and let $U \subseteq X$ be a nonempty open convex subset such that $M \cap U = \varnothing$.
Then there exists a continuous linear functional $f \in X'$ such that

$$f(m) = 0 \text{ for every } m \in M, \text{ and } \operatorname{Re} f(x) > 0 \text{ for every } x \in U.$$

Definition B.10.36. Let (X, τ_X) and (Y, τ_Y) be topological vector spaces. We say that X *is continuously embedded in* Y, and write $X \hookrightarrow Y$, if X is a subspace of Y and the inclusion $\iota_X \colon X \longrightarrow Y$, given by $\iota_X(x) = x$, is continuous.

B.10.1 Fréchet spaces

Fréchet spaces generalize Banach spaces by allowing the topology to be determined by a countable family of seminorms instead of a single norm. This class arises naturally in the study of spaces of smooth functions and spaces of smooth sections.

Definition B.10.37. Let (X, τ_X) be a topological vector space. We say that X is a *Fréchet space* if the following properties hold:

(a) X is locally convex.

(b) The topology τ_X can be induced by a translation-invariant metric; that is, there exists a metric $d \colon X \times X \longrightarrow \mathbb{R}$ such that

$$d(x + z, y + z) = d(x, y)$$

for any $x, y, z \in X$.

(c) Some, and equivalently every, translation-invariant metric inducing τ_X is complete.

Theorem B.10.38. Let (X, τ_X) be a topological vector space. Then X is a Fréchet space if and only if the following properties hold:

(a) X is Hausdorff.

(b) The topology τ_X is induced by a countable family of seminorms $(p_j)_{j \in \mathbb{N}_0}$.

(c) X is complete with respect to some, and equivalently every, translation-invariant metric inducing this topology.

The equivalence between a complete invariant metric and a countable separating family of seminorms is proved in [123, 149].

Before turning to weak topologies, we recall two general topological constructions. The initial topology will be the natural tool for defining weak topologies, whereas the final topology will arise in the construction of inductive

limits.

B.10.2 Initial and final topologies

Definition B.10.39. (Initial topology) Let X be a set, let $\{(Y_i, \tau_i)\}_{i\in I}$ be a family of topological spaces, and, for each $i \in I$, let $f_i \colon X \longrightarrow Y_i$ be a map. The *initial topology* on X associated with the family $(f_i)_{i\in I}$ is the topology generated by the subbase

$$\mathcal{S}_{\text{in}} := \left\{ f_i^{-1}(U) \;\middle|\; i \in I,\ U \in \tau_i \right\}.$$

We denote it by τ_{in}.

Proposition B.10.40. The topology τ_{in} is the coarsest topology on X for which all the maps $f_i \colon (X, \tau_{\text{in}}) \longrightarrow (Y_i, \tau_i)$ are continuous.
Moreover, if (Z, τ_Z) is a topological space and $g \colon Z \longrightarrow X$ is a map, then $g \colon (Z, \tau_Z) \longrightarrow (X, \tau_{\text{in}})$ is continuous if and only if each composition $f_i \circ g \colon Z \longrightarrow Y_i$ is continuous.

Proof. By the definition of τ_{in}, if $i \in I$ and $U \subseteq Y_i$ is open, then $f_i^{-1}(U)$ is open in (X, τ_{in}). Therefore, each map $f_i \colon (X, \tau_{\text{in}}) \longrightarrow (Y_i, \tau_i)$ is continuous.
We show that τ_{in} is the coarsest topology with this property. Let τ be a topology on X such that all the maps $f_i \colon (X, \tau) \longrightarrow (Y_i, \tau_i)$ are continuous. Then, if U is open in Y_i, the set $f_i^{-1}(U)$ belongs to τ. Since τ_{in} is the topology generated by all these sets, it follows that $\tau_{\text{in}} \subseteq \tau$.
We now prove the characterization of continuity. First suppose that $g \colon (Z, \tau_Z) \longrightarrow (X, \tau_{\text{in}})$ is continuous. Since each f_i is continuous, the composition $f_i \circ g \colon Z \longrightarrow Y_i$ is continuous for every $i \in I$.
Conversely, suppose that each composition $f_i \circ g$ is continuous. To prove that g is continuous, it suffices to verify that the preimage under g of each element of the subbase $\mathcal{S}_{\text{in}}$ is open in Z. Let $f_i^{-1}(U) \in \mathcal{S}_{\text{in}}$, with U open in Y_i. Then

$$g^{-1}\left(f_i^{-1}(U)\right) = (f_i \circ g)^{-1}(U).$$

The set on the right-hand side is open in Z by the continuity of $f_i \circ g$. Therefore, g is continuous. □

Proposition B.10.41. Let X be a set, let $\{(Y_i, \tau_i)\}_{i\in I}$ be a family of topological spaces, and, for each $i \in I$, let $f_i \colon X \longrightarrow Y_i$ be a map. A net $(x_\alpha)_\alpha$ in X converges to $x \in X$ in the initial topology associated with $(f_i)_{i\in I}$ if and only if

$$f_i(x_\alpha) \to f_i(x)$$

in Y_i for every $i \in I$. In particular, a sequence $(x_n)_{n\in\mathbb{N}}$ converges to x in the initial topology if and only if

$$f_i(x_n) \to f_i(x)$$

in Y_i for every $i \in I$.

Proof. If $x_\alpha \to x$ in the initial topology, then, since each f_i is continuous, we have $f_i(x_\alpha) \to f_i(x)$ for every $i \in I$.
Conversely, suppose that $f_i(x_\alpha) \to f_i(x)$ for every $i \in I$. Let U be a neighborhood of x in the initial topology.

By the definition of the initial topology, there exists a basic neighborhood V of x such that $x \in V \subseteq U$, where V is a finite intersection of subbasic elements. That is, there exist $i_1, \dots, i_k \in I$ and open sets $U_1 \subseteq Y_{i_1}, \dots, U_k \subseteq Y_{i_k}$ such that

$$x \in \bigcap_{j=1}^{k} f_{i_j}^{-1}(U_j) \subseteq U.$$

Since $f_{i_j}(x_\alpha) \to f_{i_j}(x)$ and U_j is a neighborhood of $f_{i_j}(x)$, for each j there exists α_j such that, if $\alpha \geq \alpha_j$, then $f_{i_j}(x_\alpha) \in U_j$. Since the index set is directed, there exists α_0 such that $\alpha_0 \geq \alpha_j$ for every j. Then, if $\alpha \geq \alpha_0$, we have $x_\alpha \in V \subseteq U$. Therefore, $x_\alpha \to x$.
The statement for sequences is the special case in which the net is indexed by $\mathbb{N}$. □

Definition B.10.42. (Final topology) Let Y be a set, let $\{(X_i, \sigma_i)\}_{i \in I}$ be a family of topological spaces, and, for each $i \in I$, let $g_i \colon X_i \longrightarrow Y$ be a map. The *final topology* on Y associated with the family $(g_i)_{i \in I}$ is the collection

$$\tau_{\text{fin}} := \left\{ U \subseteq Y \;\middle|\; g_i^{-1}(U) \in \sigma_i \text{ for every } i \in I \right\}.$$

Proposition B.10.43. The collection τ_{fin} is a topology on Y. Moreover, it is the finest topology on Y for which all the maps $g_i \colon (X_i, \sigma_i) \longrightarrow (Y, \tau_{\text{fin}})$ are continuous.
Furthermore, if (Z, τ_Z) is a topological space and $h \colon Y \longrightarrow Z$ is a map, then $h \colon (Y, \tau_{\text{fin}}) \longrightarrow (Z, \tau_Z)$ is continuous if and only if each composition $h \circ g_i \colon X_i \longrightarrow Z$ is continuous.

Proof. First we show that τ_{fin} is a topology. Since $g_i^{-1}(\varnothing) = \varnothing$ and $g_i^{-1}(Y) = X_i$ for every $i \in I$, we have $\varnothing, Y \in \tau_{\text{fin}}$.
Now let $(U_\lambda)_{\lambda \in \Lambda}$ be an arbitrary family of elements of τ_{fin}. For each $i \in I$,

$$g_i^{-1}\left(\bigcup_{\lambda \in \Lambda} U_\lambda \right) = \bigcup_{\lambda \in \Lambda} g_i^{-1}(U_\lambda).$$

Since each set $g_i^{-1}(U_\lambda)$ is open in X_i, the union on the right-hand side is open. Therefore,

$$\bigcup_{\lambda \in \Lambda} U_\lambda \in \tau_{\text{fin}}.$$

If $U_1, \dots, U_r \in \tau_{\text{fin}}$, then, for each $i \in I$,

$$g_i^{-1}\left(\bigcap_{q=1}^{r} U_q \right) = \bigcap_{q=1}^{r} g_i^{-1}(U_q).$$

Since finite intersections of open sets are open, we conclude that

$$\bigcap_{q=1}^{r} U_q \in \tau_{\text{fin}}.$$

Thus, τ_{fin} is a topology.
By the definition of τ_{fin}, all the maps $g_i \colon (X_i, \sigma_i) \longrightarrow (Y, \tau_{\text{fin}})$ are continuous.

We show that τ_{fin} is the finest topology with this property. Let τ be a topology on Y such that all the maps $g_i\colon (X_i,\sigma_i)\longrightarrow (Y,\tau)$ are continuous. If $U\in\tau$, then $g_i^{-1}(U)$ is open in X_i for every $i\in I$. By the definition of τ_{fin}, it follows that $U\in\tau_{\mathrm{fin}}$. Therefore, $\tau\subseteq\tau_{\mathrm{fin}}$.
Finally, we prove the characterization of continuity. If $h\colon (Y,\tau_{\mathrm{fin}})\longrightarrow (Z,\tau_Z)$ is continuous, then each composition $h\circ g_i\colon X_i\longrightarrow Z$ is continuous.
Conversely, suppose that each composition $h\circ g_i$ is continuous. Let $V\subseteq Z$ be an open set. For each $i\in I$,

$$g_i^{-1}\left(h^{-1}(V)\right)=(h\circ g_i)^{-1}(V),$$

and this set is open in X_i. By the definition of τ_{fin}, we obtain $h^{-1}(V)\in\tau_{\mathrm{fin}}$. Since this holds for every open set $V\subseteq Z$, we conclude that h is continuous. □

Remark B.10.44. In some texts, the initial and final topologies associated with a family of maps are called the *weak topology* and the *strong topology*, respectively. In what follows, we will prefer the terms *initial* and *final* to avoid confusion with the weak and weak-$*$ topologies that arise in functional analysis.

B.11 Weak topologies

B.11.1 Initial topologies defined by linear operators

Weak topologies are special cases of the initial topologies introduced in Definition B.10.39. In particular, we shall use the universal property in Proposition B.10.40 and the characterization of convergence in Proposition B.10.41. When the maps determining the topology are linear, the construction can be described by seminorms.

Proposition B.11.1. Let X be a vector space over $\mathbb{K}$, and let $\{Y_i\}_{i\in I}$ be a family of locally convex topological vector spaces. For each $i\in I$, let $T_i\colon X\longrightarrow Y_i$ be a linear operator. Then the initial topology on X associated with $(T_i)_{i\in I}$ is a locally convex vector space topology. If the topology of Y_i is generated by a family of seminorms $\mathcal{P}_i$, then the initial topology on X is generated by the seminorms

$$x\longmapsto p(T_ix),\qquad i\in I,\quad p\in\mathcal{P}_i.$$

Proof. For $i\in I$ and $p\in\mathcal{P}_i$, define $q_{i,p}\colon X\longrightarrow[0,\infty)$ by $q_{i,p}(x):=p(T_ix)$. Since T_i is linear and p is a seminorm, $q_{i,p}$ is a seminorm on X. Let τ be the topology generated by the family $\{q_{i,p}\mid i\in I,\ p\in\mathcal{P}_i\}$. By Theorem B.10.19, τ makes X a locally convex topological vector space, and each $T_i\colon (X,\tau)\longrightarrow Y_i$ is continuous.
If σ is another topology on X for which all the T_i are continuous, then each seminorm $q_{i,p}=p\circ T_i$ is continuous with respect to σ. Thus $\tau\subseteq\sigma$, proving that τ is the initial topology associated with $(T_i)_{i\in I}$. □

Corollary B.11.2. Let X be a vector space, and let $\mathcal{T}$ be a family of linear operators $T\colon X\longrightarrow W_T$, where each W_T is a normed space. Then the initial topology on X associated with $\mathcal{T}$ is generated by the seminorms

$$x\longmapsto\|Tx\|_{W_T},\qquad T\in\mathcal{T}.$$

In particular, a neighborhood base at the origin consists of finite intersections of sets of the form

$$\{x \in X \mid \|T_j x\|_{W_{T_j}} < \varepsilon_j,\ j = 1, \dots, k\},$$

where $T_1, \dots, T_k \in \mathcal{T}$ and $\varepsilon_1, \dots, \varepsilon_k > 0$.

Proof. This is a special case of Proposition B.11.1, since the topology of a normed space is generated by its norm. □

Corollary B.11.3. Under the hypotheses of the preceding corollary, suppose also that each W_T is finite-dimensional. Then the initial topology is also generated by the seminorms

$$x \longmapsto |\ell(Tx)|, \qquad T \in \mathcal{T}, \quad \ell \in W_T'.$$

Proof. In finite dimensions, the topology of W_T is generated by the linear functionals in W_T'. The assertion follows from Proposition B.11.1 by composing these functionals with the operators T. □

Proposition B.11.4. Let X be a vector space, and let $\mathcal{T}$ be a family of linear operators $T\colon X \longrightarrow W_T$, where each W_T is a normed space. A net $(x_\alpha)_\alpha$ converges to $x \in X$ in the initial topology determined by $\mathcal{T}$ if and only if $\|T(x_\alpha) - T(x)\|_{W_T} \to 0$ for every $T \in \mathcal{T}$. The same characterization holds for sequences.

Proof. By the characterization of convergence in an initial topology, $x_\alpha \to x$ if and only if $T(x_\alpha) \to T(x)$ in W_T for every $T \in \mathcal{T}$. Since each W_T is normed, this is equivalent to $\|T(x_\alpha) - T(x)\|_{W_T} \to 0$ for every $T \in \mathcal{T}$. □

B.11.2 Weak topologies associated with dualities

Definition B.11.5. (Duality) Let X and Y be vector spaces over $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$. A *duality* between X and Y is a bilinear map

$$\langle \cdot, \cdot \rangle\colon X \times Y \longrightarrow \mathbb{K}.$$

We say that the duality separates points of X if, for every $x \in X \setminus \{0\}$, there exists $y \in Y$ such that $\langle x, y \rangle \neq 0$. Similarly, it separates points of Y if, for every $y \in Y \setminus \{0\}$, there exists $x \in X$ such that $\langle x, y \rangle \neq 0$.

Definition B.11.6. (Weak topology associated with a duality) Let $\langle \cdot, \cdot \rangle\colon X \times Y \longrightarrow \mathbb{K}$ be a duality. The *weak topology* $\sigma(X, Y)$ on X is the initial topology associated with the linear maps

$$e_y\colon X \longrightarrow \mathbb{K}, \qquad e_y(x) := \langle x, y \rangle, \qquad y \in Y.$$

Equivalently, $\sigma(X, Y)$ is the coarsest topology on X for which all maps e_y, with $y \in Y$, are continuous.

Proposition B.11.7. (Description by seminorms) The topology $\sigma(X, Y)$ is generated by the seminorms

$$p_y(x) := |\langle x, y \rangle|, \qquad y \in Y.$$

In particular, $\sigma(X,Y)$ is locally convex and is Hausdorff if and only if the duality separates points of X.

Proof. The first assertion follows from Proposition B.11.1, applied to the family $(e_y)_{y\in Y}$. By Proposition B.10.21, the resulting topology is Hausdorff if and only if $p_y(x) = 0$ for every $y \in Y$ implies $x = 0$, which is equivalent to the duality separating points of X. □

Proposition B.11.8. Let $\langle\cdot,\cdot\rangle\colon X \times Y \longrightarrow \mathbb{K}$ be a duality. A net $(x_\alpha)_\alpha$ converges to $x \in X$ with respect to $\sigma(X,Y)$ if and only if

$$\langle x_\alpha, y\rangle \longrightarrow \langle x, y\rangle \qquad \text{for every } y \in Y.$$

The same characterization holds for sequences.

Proof. The topology $\sigma(X,Y)$ is the initial topology associated with the maps $e_y\colon X \longrightarrow \mathbb{K}$. The assertion follows from the characterization of convergence in initial topologies. □

If X is a locally convex topological vector space, we may apply the preceding construction to the natural duality between X and its continuous dual X'.

Definition B.11.9. (Weak topology of a locally convex space) Let X be a locally convex topological vector space. The *weak topology* on X is the topology $\sigma(X,X')$ associated with the duality

$$\langle x, L\rangle := L(x), \qquad x \in X, \quad L \in X'.$$

When a sequence $(x_n)_{n\in\mathbb{N}}$ converges to $x \in X$ in this topology, we write $x_n \rightharpoonup x$.

Proposition B.11.10. (Description by seminorms) The weak topology $\sigma(X,X')$ is generated by the seminorms

$$p_L(x) := |L(x)|, \qquad L \in X'.$$

Proof. This is Proposition B.11.7 applied to the natural duality between X and X'. □

Proposition B.11.11. A net $(x_\alpha)_\alpha$ in X converges weakly to $x \in X$ if and only if $L(x_\alpha) \to L(x)$ for every $L \in X'$. In particular, $x_n \rightharpoonup x$ if and only if

$$L(x_n) \longrightarrow L(x) \qquad \text{for every } L \in X'.$$

Proof. This is Proposition B.11.8 applied to the natural duality between X and X'. □

The following properties allow weak convergence and weak compactness to be transported by the linear operators arising naturally in applications. The first shows that ordinary linear continuity already includes continuity with respect to weak topologies.

Proposition B.11.12. (Continuity with respect to weak topologies) Let X and Y be locally convex topological vector spaces, and let $T\colon X \longrightarrow Y$ be a continuous linear operator. Then

$$T : \big(X, \sigma(X,X')\big) \longrightarrow \big(Y, \sigma(Y,Y')\big)$$

is continuous. In particular, the image under T of a weakly compact set is weakly compact.

Proof. Let $L \in Y'$. Since T is linear and continuous, the composition $L \circ T : X \longrightarrow \mathbb{K}$ belongs to X'. By the definition of $\sigma(X, X')$, the functional $L \circ T$ is continuous on $\big(X, \sigma(X, X')\big)$. Since this holds for every $L \in Y'$ and $\sigma(Y, Y')$ is the initial topology determined by the functionals in Y', the universal property of the initial topology implies that

$$T : \big(X, \sigma(X, X')\big) \longrightarrow \big(Y, \sigma(Y, Y')\big)$$

is continuous. The last assertion follows because the continuous image of a compact set is compact. □

To relate weak convergence obtained through isometric embeddings to the weak topology of the subspace, we shall also use the following consequence of the Hahn–Banach theorem.

Proposition B.11.13. (Weak topology of a normed subspace) Let X be a normed space, and let $Y \subseteq X$ be a linear subspace equipped with the induced norm. Then the weak topology $\sigma(Y, Y')$ agrees with the topology induced by $\sigma(X, X')$ on Y. In particular, if a net $(y_\alpha)_\alpha \subseteq Y$ and an element $y \in Y$ satisfy $y_\alpha \rightharpoonup y$ in X, then $y_\alpha \rightharpoonup y$ in Y, and conversely.

Proof. The topology induced by $\sigma(X, X')$ on Y is generated by the seminorms

$$y \longmapsto |L(y)|, \qquad L \in X'.$$

Each restriction $L \restriction_Y$ belongs to Y'. Conversely, if $\ell \in Y'$, the Hahn–Banach theorem, in the form of Corollary B.2.29, provides a functional $L \in X'$ such that $L \restriction_Y = \ell$. Thus

$$\{L \restriction_Y \mid L \in X'\} = Y',$$

and the seminorms generating the induced topology are exactly those generating $\sigma(Y, Y')$. The characterization of convergence follows from equality of the two topologies. □

The following property describes the weak topology of a finite product. Finiteness is what allows a functional on the product to be recovered from a finite sum of functionals on its components.

Proposition B.11.14. (Weak topology of a finite product) Let $X_1, \dots, X_N$ be locally convex topological vector spaces, and let

$$X := \prod_{j=1}^{N} X_j$$

be equipped with the product topology. Then

$$\sigma(X, X') = \prod_{j=1}^{N} \sigma(X_j, X_j').$$

In particular, a net $x^\alpha = (x_1^\alpha, \dots, x_N^\alpha)$ converges weakly to $x = (x_1, \dots, x_N)$ in X if and only if

$$x_j^\alpha \rightharpoonup x_j \qquad \text{in } X_j$$

for every $j \in \{1,\dots,N\}$.

Proof. First suppose that $x^\alpha \rightharpoonup x$ in X. For each $j \in \{1,\dots,N\}$, the canonical projection

$$\pi_j \colon X \longrightarrow X_j$$

is linear and continuous in the original topologies. By Proposition B.11.12, it is also continuous in the weak topologies. Thus

$$x_j^\alpha = \pi_j(x^\alpha) \rightharpoonup \pi_j(x) = x_j \qquad \text{in } X_j.$$

Conversely, suppose that $x_j^\alpha \rightharpoonup x_j$ in X_j for every $j \in \{1,\dots,N\}$. Let $L \in X'$ and, for each j, let

$$\iota_j \colon X_j \longrightarrow X, \qquad \iota_j(z) := (0,\dots,0,z,0,\dots,0),$$

be the canonical inclusion into the jth component. Since ι_j is linear and continuous, $L_j := L \circ \iota_j$ belongs to X_j'. Moreover, for every $(z_1,\dots,z_N) \in X$,

$$L(z_1,\dots,z_N) = \sum_{j=1}^N L_j(z_j).$$

Consequently,

$$L(x^\alpha) = \sum_{j=1}^N L_j(x_j^\alpha) \longrightarrow \sum_{j=1}^N L_j(x_j) = L(x),$$

where passage to the limit is valid because the sum has finitely many terms. By Proposition B.11.11, $x^\alpha \rightharpoonup x$ in X. Thus the two topologies have exactly the same convergent nets and therefore agree. □

We also recall a topological characterization of lower semicontinuity that will be useful later.

Proposition B.11.15. (Characterization by sublevel sets) Let (X,τ) be a topological space, and let $F \colon X \longrightarrow (-\infty,+\infty]$. The following assertions are equivalent:

(a) F is τ-lower semicontinuous.

(b) For every $c \in \mathbb{R}$, the sublevel set

$$\{x \in X \mid F(x) \le c\}$$

is τ-closed.

Proof. By the topological characterization of lower semicontinuity, F is τ-lower semicontinuous if and only if $\{x \in X \mid F(x) > c\}$ is τ-open for every $c \in \mathbb{R}$. Since

$$\{x \in X \mid F(x) > c\} = X \setminus \{x \in X \mid F(x) \le c\},$$

this condition is equivalent to all sublevel sets of F being τ-closed. □

Theorem B.11.16. Let (X,τ) be a locally convex Hausdorff topological vector space, and let $C \subseteq X$ be convex. Then

$$\overline{C}^{\tau} = \overline{C}^{\sigma(X,X')}.$$

In particular, C is τ-closed if and only if it is weakly closed.

Proof. Since $\sigma(X,X') \subseteq \tau$, we have $\overline{C}^{\tau} \subseteq \overline{C}^{\sigma(X,X')}$. To prove the other inclusion, let $x \notin \overline{C}^{\tau}$. By the Hahn–Banach separation theorem, there exist $L \in X'$ and real numbers $\alpha < \beta$ such that

$$\operatorname{Re} L(y) \le \alpha < \beta \le \operatorname{Re} L(x) \qquad \text{for every } y \in \overline{C}^{\tau}.$$

Then $\{z \in X \mid \operatorname{Re} L(z) > \alpha\}$ is a weak neighborhood of x disjoint from C. Thus $x \notin \overline{C}^{\sigma(X,X')}$. □

Corollary B.11.17. Let (X,τ) be a locally convex Hausdorff topological vector space, and let $F\colon X \longrightarrow (-\infty,+\infty]$ be a convex, τ-lower semicontinuous function. Then F is weakly lower semicontinuous.

Proof. By Proposition B.11.15, for every $c \in \mathbb{R}$ the set $C_c := \{x \in X \mid F(x) \le c\}$ is τ-closed. Since F is convex, C_c is convex. By Theorem B.11.16, C_c is weakly closed. Applying Proposition B.11.15 again shows that F is weakly lower semicontinuous. □

The uniform boundedness principle was established in Theorem B.2.15; we now use it to relate weak boundedness to norm boundedness.

We shall also need the canonical embedding of a normed space into its bidual.

Proposition B.11.18. Let X be a normed space, and let $J\colon X \longrightarrow X''$ be the linear operator defined by

$$J(x)(L) := L(x), \qquad x \in X, \quad L \in X'.$$

Then $\|J(x)\|_{X''} = \|x\|_X$ for every $x \in X$. In particular, J is a linear isometry.

Proof. If $\|L\|_{X'} \le 1$, then $|J(x)(L)| = |L(x)| \le \|x\|_X$, so $\|J(x)\|_{X''} \le \|x\|_X$. If $x \neq 0$, Theorem B.2.29 provides $L \in X'$ such that $\|L\|_{X'} = 1$ and $L(x) = \|x\|_X$. Thus $\|J(x)\|_{X''} \ge \|x\|_X$. The case $x = 0$ is immediate. □

Theorem B.11.19. Let X be a Banach space, and let $A \subseteq X$. Then A is norm bounded if and only if it is bounded with respect to $\sigma(X,X')$.

Proof. If A is norm bounded, then $\sup_{x\in A} |L(x)| \le \|L\|_{X'} \sup_{x\in A} \|x\|_X < \infty$ for every $L \in X'$, so A is weakly bounded. Conversely, if A is weakly bounded, then $\sup_{x\in A} |L(x)| < \infty$ for every $L \in X'$. The family $\{J(x) \mid x \in A\} \subseteq X''$ is therefore pointwise bounded on X'. By Theorem B.2.15,

$$\sup_{x\in A} \|J(x)\|_{X''} < \infty.$$

Since $\|J(x)\|_{X''} = \|x\|_X$, we conclude that A is norm bounded. □

Proposition B.11.20. Let X be a Banach space. If $x_n \rightharpoonup x$ in X, then $(x_n)_{n\in\mathbb{N}}$ is bounded and

$$\|x\|_X \le \liminf_{n\to\infty} \|x_n\|_X.$$

Proof. For each $L \in X'$, the sequence $(L(x_n))_{n\in\mathbb{N}}$ is convergent and hence bounded. Thus $\{x_n \mid n \in \mathbb{N}\}$ is weakly bounded and, by Theorem B.11.19, also norm bounded.
On the other hand, the norm is convex and continuous in the norm topology. By Corollary B.11.17, it is weakly lower semicontinuous. Consequently,

$$\|x\|_X \le \liminf_{n\to\infty} \|x_n\|_X.$$

□

B.11.3 Weak-∗ topology and pointwise convergence

Definition B.11.21. (Weak-∗ topology) Let X be a locally convex topological vector space. The *weak-∗ topology* on X' is the initial topology $\sigma(X', X)$ associated with the maps

$$\mathrm{ev}_x \colon X' \longrightarrow \mathbb{K}, \qquad \mathrm{ev}_x(L) := L(x), \qquad x \in X.$$

When $L_n \to L$ in this topology, we write $L_n \overset{*}{\rightharpoonup} L$.

Proposition B.11.22. (Description by seminorms) The weak-∗ topology $\sigma(X', X)$ is generated by the seminorms

$$p_x(L) := |L(x)|, \qquad x \in X.$$

In particular, a net $(L_\alpha)_\alpha$ converges weakly-∗ to L if and only if

$$L_\alpha(x) \longrightarrow L(x) \qquad \text{for every } x \in X.$$

The same characterization holds for sequences.

Proof. The description by seminorms follows from Proposition B.11.7, applied to the duality between X' and X. The characterization of convergence follows from Proposition B.11.8. □

When the target space is not the scalar field, the analogous construction is called the topology of pointwise convergence.

Definition B.11.23. (Topology of pointwise convergence) Let X be a topological vector space, and let W be a finite-dimensional normed vector space. The *topology of pointwise convergence* on $\mathcal{L}(X, W)$ is the initial topology associated with the maps

$$\mathrm{ev}_x \colon \mathcal{L}(X, W) \longrightarrow W, \qquad \mathrm{ev}_x(T) := T(x), \qquad x \in X.$$

Proposition B.11.24. The topology of pointwise convergence on $\mathcal{L}(X, W)$ is generated by the seminorms

$$p_x(T) := \|T(x)\|_W, \qquad x \in X.$$

Since W is finite-dimensional, it is also generated by the seminorms

$$p_{x,\ell}(T) := |\ell(T(x))|, \qquad x \in X, \quad \ell \in W'.$$

In particular, a net $(T_\alpha)_\alpha$ converges to T in this topology if and only if

$$T_\alpha(x) \longrightarrow T(x) \qquad \text{in } W$$

for every $x \in X$. The same characterization holds for sequences.

Proof. The first description follows from Corollary B.11.2, applied to the maps ev_x. Since W is finite-dimensional, its topology is generated by the seminorms $w \mapsto |\ell(w)|$, with $\ell \in W'$, giving the second description. The characterization of convergence follows from Proposition B.11.4. □

Remark B.11.25. This construction arises naturally in spaces of distributions with values in a finite-dimensional vector space. If $\mathcal{E}$ is a test space, the space $\mathcal{L}(\mathcal{E}, W)$ is equipped with the topology of pointwise convergence, so $F_\alpha \to F$ if and only if

$$F_\alpha(\varphi) \longrightarrow F(\varphi) \qquad \text{in } W$$

for every $\varphi \in \mathcal{E}$. This is precisely weak convergence of W-valued distributions.

B.11.4 Weak compactness and reflexivity

The Banach–Alaoglu, Eberlein–Šmulian, and Kakutani theorems, together with the weak and weak-$*$ metrizability criteria stated in this subsection, can be found with proofs in [28, 123]. We include the elementary consequences used later.

Definition B.11.26. Let X be a topological vector space, and let $A \subseteq X$. The *polar* of A is the set

$$A^\circ := \{L \in X' \mid |L(x)| \le 1 \text{ for every } x \in A\}.$$

Theorem B.11.27. (Banach–Alaoglu) If U is a neighborhood of the origin in a locally convex topological vector space X, then U° is compact in the weak-$*$ topology $\sigma(X', X)$.

Corollary B.11.28. If X is a normed space, then the closed unit ball of X' is weakly-$*$ compact.

Proof. The closed unit ball of X' is the polar of the open unit ball of X. The assertion follows from Theorem B.11.27. □

Theorem B.11.29. Let X be a separable normed space, and let $K \subseteq X'$ be a bounded weakly-$*$ compact set. Then the weak-$*$ topology induced on K is metrizable. In particular, the closed unit ball of X' is weakly-$*$ compact and metrizable.

Proof. Let $\{x_j\}_{j\in\mathbb{N}}$ be a countable dense subset of X. For $L_1, L_2 \in K$, define

$$d(L_1, L_2) := \sum_{j=1}^{\infty} 2^{-j} \frac{|(L_1 - L_2)(x_j)|}{1 + |(L_1 - L_2)(x_j)|}.$$

If $d(L_1, L_2) = 0$, then $L_1 - L_2$ vanishes on the dense set $\{x_j \mid j \in \mathbb{N}\}$ and, by continuity, on all of X. Thus d is a metric.
Each summand is continuous in the weak-$*$ topology, and the series converges uniformly because it is dominated by $\sum_{j=1}^{\infty} 2^{-j}$. Consequently, the identity from K with the weak-$*$ topology to K with the topology induced by d is continuous. Since the first space is compact and the second Hausdorff, this identity is a homeomorphism. Thus d metrizes the weak-$*$ topology on K. □

Corollary B.11.30. Let X be a separable Banach space. Every bounded sequence in X' admits a weakly-$*$ convergent subsequence.

Proof. Every bounded sequence lies in a closed ball of X'. By Theorems B.11.27 and B.11.29, this ball is weakly-$*$ compact and metrizable. The conclusion follows from sequential compactness of compact metric spaces. □

Theorem B.11.31. Let X be a Banach space. The closed unit ball of X', equipped with the weak-$*$ topology, is metrizable if and only if X is separable.

Proposition B.11.32. Let X be a Banach space. If $L_n \overset{*}{\rightharpoonup} L$ in X', then $(L_n)_{n\in\mathbb{N}}$ is bounded and

$$\|L\|_{X'} \le \liminf_{n\to\infty} \|L_n\|_{X'}.$$

Proof. For each $x \in X$, the sequence $(L_n(x))_{n\in\mathbb{N}}$ is convergent and hence bounded. Theorem B.2.15 implies that $\sup_{n\in\mathbb{N}} \|L_n\|_{X'} < \infty$.
By Theorem B.11.27, closed balls in X' are weakly-$*$ compact and, since the weak-$*$ topology is Hausdorff, weakly-$*$ closed. These sets are precisely the sublevel sets of the norm. By Proposition B.11.15, the norm on X' is weakly-$*$ lower semicontinuous, giving the inequality. □

Proposition B.11.33. Let X be a Banach space. If X' is separable, then X is separable.

Proof. If $X' = \{0\}$, the dual characterization of the norm, Corollary B.2.30, implies that $X = \{0\}$. Suppose $X' \neq \{0\}$. Since X' is separable, its unit sphere contains a dense sequence $(\varphi_n)_{n\in\mathbb{N}}$. For each n, by the

definition of the dual norm, we may choose $x_n \in X$, $\|x_n\|_X = 1$, such that

$$|\varphi_n(x_n)| > \frac{1}{2}.$$

Let $Y := \overline{\operatorname{span}}\{x_n \mid n \in \mathbb{N}\}$. If $Y \neq X$, Hahn–Banach provides $\varphi \in X'$ such that $\|\varphi\| = 1$ and $\varphi \restriction_Y = 0$. Choose n with $\|\varphi_n - \varphi\| < \frac{1}{2}$. Since $x_n \in Y$,

$$|\varphi_n(x_n)| = |(\varphi_n - \varphi)(x_n)| \leq \|\varphi_n - \varphi\| \|x_n\| < \frac{1}{2},$$

which contradicts the choice of x_n. Thus $Y = X$. The subspace spanned by $\{x_n\}$ using rational coefficients—complex rational coefficients if $\mathbb{K} = \mathbb{C}$—is countable and dense in X, so X is separable. □

The converse is false. For example, $L^1(\mathbb{R}^n)$ is separable, but its dual $L^\infty(\mathbb{R}^n)$ is not.

Theorem B.11.34. Let X be a Banach space whose dual X' is separable. Then the closed unit ball of X, equipped with the weak topology $\sigma(X, X')$, is metrizable.

Definition B.11.35. Let X be a locally convex topological vector space. A set $K \subseteq X$ is *weakly sequentially compact* if every sequence in K admits a subsequence converging weakly to a point of K.

Theorem B.11.36. (Eberlein–Šmulian) Let X be a Banach space, and let $K \subseteq X$. Then K is weakly compact if and only if it is weakly sequentially compact.

Definition B.11.37. A Banach space X is *reflexive* if the canonical embedding $J : X \longrightarrow X''$ is surjective.

In this case, the canonical embedding identifies X isometrically with its bidual X''.

Theorem B.11.38. (Kakutani) A Banach space is reflexive if and only if its closed unit ball is weakly compact.

Corollary B.11.39. Let X be a reflexive Banach space. Every bounded sequence in X admits a weakly convergent subsequence.

Proof. Every bounded sequence lies in a closed ball. By Theorem B.11.38, this ball is weakly compact and, by Theorem B.11.36, weakly sequentially compact. □

Proposition B.11.40. A Banach space X is reflexive if and only if X' is reflexive.

Proof. First suppose that X is reflexive, and let $\Phi \in X'''$. Define $\varphi \in X'$ by

$$\varphi(x) := \Phi(J_X x), \qquad x \in X,$$

where $J_X : X \to X''$ is the canonical embedding. Given $x'' \in X''$, reflexivity provides $x \in X$ such that $x'' = J_X x$. Then

$$(J_{X'}\varphi)(x'') = x''(\varphi) = \varphi(x) = \Phi(J_X x) = \Phi(x'').$$

Thus $J_{X'}$ is surjective and X' is reflexive.
Conversely, suppose that X' is reflexive. The image $J_X(X)$ is a closed subspace of X'', since J_X is an isometry and X is complete. If $J_X(X) \neq X''$, the Hahn–Banach theorem provides a nonzero functional $\Phi \in X'''$ vanishing on $J_X(X)$. By reflexivity of X', there exists $\varphi \in X'$ such that $\Phi = J_{X'}\varphi$. For each $x \in X$,

$$0 = \Phi(J_X x) = (J_X x)(\varphi) = \varphi(x),$$

so $\varphi = 0$ and hence $\Phi = 0$, a contradiction. Consequently, J_X is surjective and X is reflexive. □

B.12 Topological tensor products and nuclear spaces

In this section we develop the part of topological tensor product theory needed for the Schwartz kernel theorem. The distinction between the projective, injective, and inductive topologies is essential: on the nuclear Fréchet spaces arising when supports are fixed, the projective and injective topologies agree; on the global LF spaces, however, the product representing separate continuity is the inductive one. The exposition follows Chapters 43, 50, and 51 of [149]. We include proofs of the elementary results used later and explicitly identify the single hereditary theorem on nuclearity taken from that reference.

B.12.1 The projective, injective, and inductive topologies

Let X and Y be vector spaces over $\mathbb{K}$. Recall that the algebraic tensor product $X \otimes Y$, together with the canonical bilinear map $(x, y) \mapsto x \otimes y$, is characterized by the universal property in Definition 1.10.5. When X and Y are locally convex, there are several natural topologies on this same algebraic vector space.

Definition B.12.1. (Projective tensor topology) Let X and Y be locally convex spaces. If p is a continuous seminorm on X and q is a continuous seminorm on Y, define, for $\mathbf{u} \in X \otimes Y$,

$$(p \otimes_\pi q)(\mathbf{u}) := \inf\left\{ \sum_{j=1}^{r} p(x_j) q(y_j) \;\middle|\; \mathbf{u} = \sum_{j=1}^{r} x_j \otimes y_j \right\}.$$

The locally convex topology generated by these seminorms is called the *projective tensor topology*; the resulting space is denoted by $X \otimes_\pi Y$ and its Hausdorff completion by $X \widehat{\otimes}_\pi Y$.

The infimum is taken over a nonempty set, since every element of the algebraic tensor product is a finite sum of elementary tensors. If one of the spaces is not Hausdorff, completion will always mean the completion of the quotient by the closure of $\{0\}$; all spaces in the applications will be Hausdorff.

Proposition B.12.2. (Universal property of the projective product) For every pair of continuous seminorms p and q, the map $p \otimes_\pi q$ is a seminorm and satisfies

$$(p \otimes_\pi q)(x \otimes y) = p(x) q(y).$$

Moreover, the projective topology is the finest locally convex topology on $X \otimes Y$ for which the canonical bilinear map $X \times Y \to X \otimes Y$ is continuous.
More generally, if Z is a locally convex space and $b \colon X \times Y \longrightarrow Z$ is bilinear, then b is continuous if and only

if its algebraic linearization

$$\widetilde{b}\colon X\otimes Y\longrightarrow Z,\qquad \widetilde{b}(x\otimes y):=b(x,y),$$

is continuous on $X\otimes_\pi Y$. If Z is complete, $\widetilde{b}$ extends uniquely to a continuous operator $X\widehat{\otimes}_\pi Y\to Z$.

Proof. Homogeneity of $p\otimes_\pi q$ follows by multiplying one factor in each tensor representation by the corresponding scalar. If $\mathbf{u},v\in X\otimes Y$, concatenating a representation of $\mathbf{u}$ with one of v gives a representation of $\mathbf{u}+v$; taking infima yields the triangle inequality.

For an elementary tensor, the representation $x\otimes y$ gives $(p\otimes_\pi q)(x\otimes y)\le p(x)q(y)$. For the reverse inequality, pass to the normed spaces $X_p:=X/\ker p$ and $Y_q:=Y/\ker q$. By Hahn–Banach, there exist functionals $\lambda\in X_p'$ and $\mu\in Y_q'$ of norm at most one such that $\lambda([x])=p(x)$ and $\mu([y])=q(y)$, after multiplying them by scalars of modulus one when necessary. If $x\otimes y=\sum_{j=1}^{N}x_j\otimes y_j$, then

$$p(x)q(y)=\left|\sum_{j=1}^{N}\lambda([x_j])\mu([y_j])\right|\le\sum_{j=1}^{N}p(x_j)q(y_j).$$

Taking the infimum over all representations gives equality.

The preceding equality implies that the canonical map is continuous for the projective topology. Now let τ be another locally convex topology on $X\otimes Y$ making this map continuous. If r is a continuous seminorm for τ, continuity at $(0,0)$ allows us to choose absolutely convex neighborhoods $U\subseteq X$ and $V\subseteq Y$ such that $r(x\otimes y)\le 1$ when $x\in U$ and $y\in V$. If p_U and q_V are their Minkowski functionals, homogeneity and an approximation argument give $r(x\otimes y)\le p_U(x)q_V(y)$. Thus, for $\mathbf{u}=\sum_{j=1}^{N}x_j\otimes y_j$,

$$r(\mathbf{u})\le\sum_{j=1}^{N}p_U(x_j)q_V(y_j),$$

and taking the infimum gives $r(\mathbf{u})\le(p_U\otimes_\pi q_V)(\mathbf{u})$. Hence every continuous seminorm for τ is continuous for the projective topology, proving its maximality.

If b is continuous and r is a continuous seminorm on Z, the same argument applied to $(x,y)\mapsto r(b(x,y))$ gives continuous seminorms p and q such that $r(b(x,y))\le p(x)q(y)$. Consequently,

$$r(\widetilde{b}(\mathbf{u}))\le(p\otimes_\pi q)(\mathbf{u}),$$

so $\widetilde{b}$ is continuous. The converse follows by composing $\widetilde{b}$ with the canonical bilinear map. The last assertion follows from the universal property of Hausdorff completion for continuous linear maps, which are uniformly continuous. □

Proposition B.12.3. (Projective product and finite products) Let $X_1,\dots,X_A$ and $Y_1,\dots,Y_B$ be locally convex Hausdorff spaces. If pr_a and pr_b denote the corresponding coordinate projections, the operator

$$\Theta:\left(\prod_{a=1}^{A}X_a\right)\otimes_\pi\left(\prod_{b=1}^{B}Y_b\right)\longrightarrow\prod_{a=1}^{A}\prod_{b=1}^{B}(X_a\otimes_\pi Y_b),\qquad\Theta(u):=\big((\mathrm{pr}_a\otimes\mathrm{pr}_b)u\big)_{a,b},$$

is a topological isomorphism. Consequently, it induces a topological isomorphism between the completions

$$\left(\prod_{a=1}^{A} X_a\right) \widehat{\otimes}_\pi \left(\prod_{b=1}^{B} Y_b\right) \cong \prod_{a=1}^{A}\prod_{b=1}^{B} \left(X_a \widehat{\otimes}_\pi Y_b\right).$$

Proof. Let $\iota_a \colon X_a \longrightarrow \prod_c X_c$ and $\jmath_b \colon Y_b \longrightarrow \prod_d Y_d$ be the coordinate inclusions. For each pair (a,b), the bilinear map

$$(x,y) \longmapsto \mathrm{pr}_a(x) \otimes \mathrm{pr}_b(y)$$

is continuous with values in $X_a \otimes_\pi Y_b$: it is the composition of the continuous projections with the canonical bilinear map. Proposition B.12.2 shows that $\mathrm{pr}_a \otimes \mathrm{pr}_b$ is continuous; since there are only finitely many pairs, Θ is continuous as well.

Algebraically, the inverse of Θ is given by

$$\Psi\big((u_{a,b})_{a,b}\big) := \sum_{a=1}^{A}\sum_{b=1}^{B} (\iota_a \otimes \jmath_b) u_{a,b}.$$

The same argument proves that each $\iota_a \otimes \jmath_b$ is continuous and, since the sum is finite, Ψ is continuous. For $x = (x_a)_a$ and $y = (y_b)_b$, we have

$$\Psi\Theta(x \otimes y) = \sum_{\substack{1\le a\le A\\ 1\le b\le B}} \iota_a(x_a) \otimes \jmath_b(y_b) = \left(\sum_{a=1}^{A} \iota_a(x_a)\right) \otimes \left(\sum_{b=1}^{B} \jmath_b(y_b)\right) = x \otimes y,$$

while the identity $\Theta\Psi = \mathrm{Id}$ is checked in each coordinate. Since elementary tensors span the algebraic tensor product, Θ and Ψ are inverses.

Every topological isomorphism between locally convex Hausdorff spaces extends, together with its inverse, to their completions. Finally, a net is Cauchy in a finite product if and only if each component is Cauchy; thus the completion of $\prod_{a,b}(X_a \otimes_\pi Y_b)$ is canonically identified with $\prod_{a,b}(X_a \widehat{\otimes}_\pi Y_b)$. This proves the second assertion. □

To define the injective topology, we need the notion of equicontinuity.

Definition B.12.4. (Equicontinuous family) Let X be a locally convex space. A subset $A \subseteq X'$ is *equicontinuous* if there exists a neighborhood U of the origin in X such that

$$|\lambda(x)| \le 1 \qquad \text{for every } \lambda \in A \text{ and every } x \in U.$$

Equivalently, the map $p_A(x) := \sup_{\lambda\in A} |\lambda(x)|$ is a continuous seminorm on X.

Justification of the equivalence. If A satisfies the first condition, then $p_A \le p_U$, where p_U is the Minkowski functional of an absolutely convex neighborhood contained in U; thus p_A is continuous. Conversely, if p_A is continuous, the set $\{x \in X \mid p_A(x) < 1\}$ is a neighborhood of the origin and $|\lambda(x)| < 1$ on it for every $\lambda \in A$. □

Every tensor $\mathbf{u} = \sum_{j=1}^{r} x_j \otimes y_j$ determines a bilinear form on $X' \times Y'$ by

$$\mathbf{u}(\lambda, \mu) := \sum_{j=1}^{r} \lambda(x_j)\mu(y_j).$$

The algebraic universal property shows that this expression is independent of the chosen representation.

Definition B.12.5. (Injective tensor topology) Let X and Y be locally convex Hausdorff spaces. For equicontinuous subsets $A \subseteq X'$ and $B \subseteq Y'$, define

$$\varepsilon_{A,B}(u) := \sup_{\lambda \in A,\, \mu \in B} |u(\lambda, \mu)|.$$

The locally convex topology generated by the seminorms $\varepsilon_{A,B}$ is called the *injective tensor topology*. Denote the resulting space by $X \otimes_\varepsilon Y$ and its completion by $X \widehat{\otimes}_\varepsilon Y$.

Proposition B.12.6. (Comparison between ε and π) The injective topology is coarser than the projective topology. More precisely, if $A \subseteq X'$ and $B \subseteq Y'$ are equicontinuous, there exist continuous seminorms p on X and q on Y such that

$$\varepsilon_{A,B}(\mathbf{u}) \le (p \otimes_\pi q)(\mathbf{u}) \qquad \text{for every } \mathbf{u} \in X \otimes Y.$$

In particular, the algebraic identity induces continuous operators

$$X \otimes_\pi Y \longrightarrow X \otimes_\varepsilon Y, \qquad X \widehat{\otimes}_\pi Y \longrightarrow X \widehat{\otimes}_\varepsilon Y.$$

Proof. By equicontinuity, there exist continuous seminorms p and q such that $|\lambda(x)| \le p(x)$ and $|\mu(y)| \le q(y)$ for $\lambda \in A$ and $\mu \in B$. If $\mathbf{u} = \sum_{j=1}^{N} x_j \otimes y_j$, then

$$|\mathbf{u}(\lambda, \mu)| \le \sum_{j=1}^{N} p(x_j) q(y_j).$$

Taking first the supremum over $A \times B$ and then the infimum over representations of $\mathbf{u}$ gives the inequality. The continuity assertions follow from it and from the universal property of completion. $\square$

The third topology we need represents separately continuous bilinear maps. For a subset $U \subseteq X \otimes Y$ and $x \in X$, $y \in Y$, write

$$U_x := \{v \in Y \mid x \otimes v \in U\}, \qquad {}_yU := \{u \in X \mid u \otimes y \in U\}.$$

Definition B.12.7. (Inductive tensor topology) Let X and Y be locally convex spaces. The *inductive tensor topology* ι on $X \otimes Y$ is the locally convex topology whose neighborhood base at the origin consists of absolutely convex absorbing subsets $U \subseteq X \otimes Y$ such that U_x is a neighborhood of the origin in Y for every $x \in X$ and ${}_yU$ is a neighborhood of the origin in X for every $y \in Y$. Denote the corresponding spaces by $X \otimes_\iota Y$ and $X \widehat{\otimes}_\iota Y$.

Proposition B.12.8. (Universal property of the inductive product) The topology ι is the finest locally convex topology for which the canonical map $X \times Y \to X \otimes Y$ is separately continuous. If Z is locally convex and $b\colon X \times Y \longrightarrow Z$ is bilinear, then b is separately continuous if and only if its linearization $\widetilde{b}\colon X \otimes_\iota Y \longrightarrow Z$ is continuous. Consequently,

$$\varepsilon \subseteq \pi \subseteq \iota.$$

Proof. The family described in the definition is stable under finite intersections and multiplication by nonzero scalars; moreover, for each of its elements U, the set $\frac{1}{2}U$ belongs to the same family and satisfies $\frac{1}{2}U + \frac{1}{2}U \subseteq U$. By Proposition B.10.26, it determines a locally convex topology.
For $x \in X$, the preimage of U under the linear map $y \mapsto x \otimes y$ is precisely U_x; similarly, the preimage under $x \mapsto x \otimes y$ is ${}_yU$. Thus the canonical map is separately continuous. If τ is another locally convex topology with this property and V is an absolutely convex neighborhood of the origin for τ, then V_x and ${}_yV$ are neighborhoods for every x and every y; hence V is a neighborhood for ι. This proves maximality.
Now let b be separately continuous, and let V be an absolutely convex neighborhood of the origin in Z. Then $U := \widetilde{b}^{-1}(V)$ is absolutely convex and absorbing. For each x, U_x is the preimage of V under the continuous map $y \mapsto b(x,y)$; likewise, ${}_yU$ is a neighborhood. Thus U is a neighborhood in $X \otimes_\iota Y$, and $\widetilde{b}$ is continuous. The converse follows by composition with the canonical map. Finally, every continuous bilinear map is separately continuous, so maximality of the two topologies gives $\pi \subseteq \iota$; the other inclusion was proved in Proposition B.12.6. □

Remark B.12.9. (A caution for *LF* spaces) Separate continuity does not generally imply joint continuity on the product of two *LF* spaces. For this reason, the global product of two test function spaces will be described using $\widehat{\otimes}_\iota$ rather than $\widehat{\otimes}_\pi$. The projective topology will be appropriate once supports are fixed, because the factors are then Fréchet spaces and the following proposition applies.

Proposition B.12.10. (Separate continuity on Fréchet spaces) Let X and Y be Fréchet spaces, let Z be a locally convex space, and let $b\colon X \times Y \longrightarrow Z$ be a separately continuous bilinear map. Then b is continuous. More precisely, if $(p_j)_{j\in\mathbb{N}}$ and $(q_j)_{j\in\mathbb{N}}$ are increasing families of seminorms defining the topologies of X and Y, respectively, then, for every continuous seminorm r on Z, there exist $C > 0$ and indices $k, \ell \in \mathbb{N}$ such that

$$r(b(x,y)) \le C\, p_k(x) q_\ell(y) \qquad \text{for every } x \in X \text{ and every } y \in Y.$$

Proof. Fix r. For $a, j \in \mathbb{N}$, define

$$S_{a,j} := \{x \in X \mid r(b(x,y)) \le a q_j(y) \text{ for every } y \in Y\}.$$

For each $x \in X$, continuity of the linear map $y \mapsto b(x,y)$ provides a and j such that $x \in S_{a,j}$; thus $X = \bigcup_{a,j\in\mathbb{N}} S_{a,j}$.
Each $S_{a,j}$ is closed: if $x_\nu \to x$ and $x_\nu \in S_{a,j}$, continuity of $x \mapsto b(x,y)$ for each y allows passage to the limit in the defining inequality.
Since X is a complete metric space, Baire's theorem implies that some $S_{a,j}$ has nonempty interior. The set $S_{a,j}$ is absolutely convex. If $x_0 + U \subseteq S_{a,j}$ for some neighborhood U of the origin, then $U - U \subseteq S_{a,j} - S_{a,j} \subseteq 2S_{a,j}$; consequently, $S_{a,j}$ contains a neighborhood of the origin. Thus there exist $k \in \mathbb{N}$ and $\delta > 0$ such that $p_k(x) < \delta$

implies $x \in S_{a,j}$. By homogeneity,

$$r(b(x,y)) \le \frac{2a}{\delta} p_k(x) q_j(y).$$

When $p_k(x) = 0$, we have $p_k(tx) < \delta$ for every $t > 0$; thus $tx \in S_{a,j}$ and $t\, r(b(x,y)) \le a q_j(y)$. Letting $t \to \infty$ gives $r(b(x,y)) = 0$. This proves the estimate with $C = \dfrac{2a}{\delta}$ and, by Proposition B.12.2, joint continuity. □

B.12.2 Nuclear spaces

Nuclearity allows us to compare the topologies π and ε. We begin with nuclear operators between Banach spaces.

Definition B.12.11. (Nuclear operator) Let G and H be Banach spaces. An operator $T \in \mathcal{L}(G,H)$ is *nuclear* if there exist sequences $(\lambda_j)_{j\in\mathbb{N}} \subseteq \mathbb{K}$, $(g_j')_{j\in\mathbb{N}} \subseteq G'$, and $(h_j)_{j\in\mathbb{N}} \subseteq H$ such that

$$\sum_{j=1}^{\infty} |\lambda_j| < \infty, \qquad \|g_j'\|_{G'} \le 1, \qquad \|h_j\|_H \le 1,$$

and

$$Tg = \sum_{j=1}^{\infty} \lambda_j g_j'(g) h_j \qquad \text{for every } g \in G.$$

The series converges absolutely and uniformly for g in the unit ball of G.

Lemma B.12.12. (Ideal property) If $T\colon G \longrightarrow H$ is nuclear and $R\colon G_0 \longrightarrow G$ and $S\colon H \longrightarrow H_0$ are continuous operators between Banach spaces, then $S \circ T \circ R\colon G_0 \longrightarrow H_0$ is nuclear.

Proof. If $Tg = \displaystyle\sum_{j=1}^{\infty} \lambda_j g_j'(g) h_j$, then

$$(S \circ T \circ R) g_0 = \sum_{j=1}^{\infty} \lambda_j (g_j' \circ R)(g_0)\, S(h_j).$$

If R and S are nonzero, write $g_j' \circ R = \|R\| \widetilde{g}_j'$ and $S(h_j) = \|S\| \widetilde{h}_j$, with norms at most one, and absorb $\|R\|\|S\|$ into the coefficients. The case in which either operator is zero is immediate. □

Let X be a locally convex Hausdorff space, and let p be a continuous seminorm. Denote by X_p the completion of the normed space $X/\ker p$, whose norm is $\|[x]\|_p := p(x)$, and by $Q_p\colon X \longrightarrow X_p$ the canonical map. If $q \ge p$, the identity on X induces an operator of norm at most one

$$J_{q,p}\colon X_q \longrightarrow X_p, \qquad J_{q,p} Q_q x := Q_p x.$$

Definition B.12.13. (Nuclear space) A locally convex Hausdorff space X is *nuclear* if, for every continuous seminorm p on X, there exists a continuous seminorm $q \ge p$ such that the operator $J_{q,p}\colon X_q \longrightarrow X_p$ is nuclear.

This definition is independent of the family of seminorms used to describe the topology: if a cofinal family of seminorms satisfies the condition, every continuous seminorm is dominated, up to a positive constant, by a finite

maximum of members of that family, and the ideal property allows the condition to be transferred to it.

Theorem B.12.14. (Nuclearity and equality of the tensor product topologies) Let X be a nuclear space and let Y be a Hausdorff locally convex space. Then the projective and injective topologies coincide on $X \otimes Y$. In particular, the algebraic identity induces a canonical topological isomorphism

$$X \widehat{\otimes}_\pi Y \cong X \widehat{\otimes}_\varepsilon Y.$$

Proof. By Proposition B.12.6, we need only prove that each projective seminorm is continuous for the injective topology. Let p and r be continuous seminorms on X and Y, respectively. Choose $q \geq p$ so that $J_{q,p} \colon X_q \longrightarrow X_p$ is nuclear and write

$$J_{q,p} z = \sum_{j=1}^{\infty} \lambda_j \alpha_j(z) z_j, \qquad \sum_{j=1}^{\infty} |\lambda_j| < \infty, \quad \|\alpha_j\| \leq 1, \quad \|z_j\|_{X_p} \leq 1.$$

The functionals $a_j := \alpha_j \circ Q_q$ form an equicontinuous subset $A \subseteq X'$, since $|a_j(x)| \leq q(x)$. Let $B \subseteq Y'$ be the image, under composition with Q_r, of the unit ball of Y_r'. This set is also equicontinuous, and Hahn–Banach gives

$$r(y) = \sup_{b \in B} |b(y)|.$$

If $\mathbf{u} = \sum_{i=1}^{s} x_i \otimes y_i$, then in $X_p \widehat{\otimes}_\pi Y_r$ we have

$$\sum_{i=1}^{s} Q_p x_i \otimes Q_r y_i = \sum_{j=1}^{\infty} \lambda_j z_j \otimes \left(\sum_{i=1}^{s} a_j(x_i) Q_r y_i \right).$$

By the definition of the projective norm and the dual characterization of r,

$$\begin{aligned} (p \otimes_\pi r)(\mathbf{u}) &\leq \sum_{j=1}^{\infty} |\lambda_j| r \left(\sum_{i=1}^{s} a_j(x_i) y_i \right) \\ &\leq \left(\sum_{j=1}^{\infty} |\lambda_j| \right) \sup_{a \in A,\, b \in B} |\mathbf{u}(a,b)| \\ &= \left(\sum_{j=1}^{\infty} |\lambda_j| \right) \varepsilon_{A,B}(\mathbf{u}). \end{aligned}$$

Thus $p \otimes_\pi r$ is continuous for ε. We conclude that $\pi = \varepsilon$ on the algebraic product. Their Hausdorff completions are therefore canonically isomorphic. □

We shall need two stability properties. We state them only in the generality used below.

Proposition B.12.15. (Subspaces and finite products) Every subspace of a nuclear space, equipped with the subspace topology, is nuclear. Every finite product of nuclear spaces is nuclear. Consequently, nuclearity is preserved under topological isomorphisms and on passing to complemented or closed subspaces.

Inheritance by subspaces is the theorem in [149, (50.3)].

Proof. The assertion about subspaces is the hereditary theorem cited above. It does not follow solely from the ideal property, since the inclusion of the subspace into the codomain need not admit a continuous projection.
Now let $X = X_1 \times \cdots \times X_m$. Every continuous seminorm p on X is dominated by a seminorm of the form $p_1 + \cdots + p_m$, where p_i also denotes its pullback by the projection $X \to X_i$. For each i we choose $q_i \geq p_i$ so that J_{q_i,p_i} is nuclear and put $q := q_1 + \cdots + q_m$. The identifications

$$X_q \cong \prod_{i=1}^{m} (X_i)_{q_i}, \qquad X_{p_1+\cdots+p_m} \cong \prod_{i=1}^{m} (X_i)_{p_i}$$

show that $J_{q,p_1+\cdots+p_m}$ is the finite diagonal sum of the operators J_{q_i,p_i}. It is therefore nuclear: simply concatenate their nuclear representations. The ideal property allows us to pass from $p_1 + \cdots + p_m$ to p. This proves the assertion about finite products. Stability under topological isomorphisms follows by composing the canonical maps with the isomorphism and its inverse; complemented and closed subspaces are particular cases of the hereditary theorem. □

The basic model of a nuclear Fréchet space is the space of rapidly decreasing sequences. For $d \in \mathbb{N}$, let

$$s(\mathbb{Z}^d) := \left\{ a = (a_\nu)_{\nu \in \mathbb{Z}^d} \;\middle|\; p_k(a) := \sup_{\nu \in \mathbb{Z}^d} (1 + \|\nu\|)^k |a_\nu| < \infty \text{ for every } k \in \mathbb{N}_0 \right\}.$$

We equip it with the Fréchet topology defined by the increasing family $(p_k)_{k \in \mathbb{N}_0}$.

Theorem B.12.16. (Nuclearity of rapidly decreasing sequences) The space $s(\mathbb{Z}^d)$ is nuclear.

Proof. Fix $k \in \mathbb{N}_0$ and put $q := p_{k+d+1}$. For $\nu \in \mathbb{Z}^d$, let e_ν be the sequence equal to one at ν and zero at every other index. In the completion associated with q, the functional

$$\alpha_\nu(a) := (1 + \|\nu\|)^{k+d+1} a_\nu$$

has norm at most one, whereas $z_\nu := (1 + \|\nu\|)^{-k} e_\nu$ has norm one in the completion associated with p_k. If $\lambda_\nu := (1 + \|\nu\|)^{-d-1}$, then

$$\sum_{\nu \in \mathbb{Z}^d} \lambda_\nu < \infty$$

and, for every rapidly decreasing sequence a,

$$J_{q,p_k} a = \sum_{\nu \in \mathbb{Z}^d} \lambda_\nu \alpha_\nu(a) z_\nu.$$

Indeed, the term indexed by ν is exactly $a_\nu e_\nu$. This is a nuclear representation of J_{q,p_k}. Since k was arbitrary, $s(\mathbb{Z}^d)$ is nuclear. □

Theorem B.12.17. (Smooth Fourier series) Let $\mathbb{T}^d := \big(\mathbb{R}/(2\pi\mathbb{Z})\big)^d$. The Fourier coefficient map

$$\mathcal{F}_{\mathbb{T}} \colon C^\infty(\mathbb{T}^d) \longrightarrow s(\mathbb{Z}^d), \qquad \mathcal{F}_{\mathbb{T}}(f)_\nu := \frac{1}{(2\pi)^d} \int_{\mathbb{T}^d} f(x) e^{-i\langle \nu, x\rangle}\, dx,$$

is a topological isomorphism. Its inverse is given by

$$a \longmapsto \sum_{\nu \in \mathbb{Z}^d} a_\nu e^{i\langle \nu, x\rangle},$$

where the series and all its differentiated series converge uniformly. In particular, $C^\infty(\mathbb{T}^d)$ is nuclear.

Proof. If $f \in C^\infty(\mathbb{T}^d)$, integration by parts gives, for every multi-index α,

$$\nu^\alpha \widehat{f}(\nu) = \frac{1}{(2\pi)^d} \int_{\mathbb{T}^d} D^\alpha f(x) e^{-i\langle \nu, x\rangle}\, dx,$$

up to a complex factor of modulus one. Applying this identity to $(1-\Delta)^r f$, we obtain

$$(1 + \|\nu\|^2)^r |\widehat{f}(\nu)| \le C_{d,r} \max_{|\alpha| \le 2r} \|D^\alpha f\|_{L^\infty(\mathbb{T}^d)}.$$

Therefore $\mathcal{F}_{\mathbb{T}}(f)$ is rapidly decreasing and the Fourier map is continuous.
Conversely, let $a \in s(\mathbb{Z}^d)$. For a multi-index α, choose $N > |\alpha| + d$. Then

$$\sum_{\nu \in \mathbb{Z}^d} \|\nu\|^{|\alpha|} |a_\nu| \le p_N(a) \sum_{\nu \in \mathbb{Z}^d} \frac{\|\nu\|^{|\alpha|}}{(1+\|\nu\|)^N} < \infty.$$

The Weierstrass test shows that the series and its differentiated series of order α converge uniformly. The sum therefore defines a smooth function, and the preceding estimate proves continuity of the inverse map. Uniqueness of Fourier coefficients shows that the two maps are inverses. Nuclearity follows from Theorem B.12.16 and stability under topological isomorphisms.
The formulas were written for complex spaces. In the real case, the terms ν and $-\nu$ are grouped into sines and cosines; the same estimates prove the result and nuclearity. □

Proposition B.12.18. (Injectivity of ε) Let $X_0 \hookrightarrow X$ and $Y_0 \hookrightarrow Y$ be linear topological embeddings between Hausdorff locally convex spaces. Then the canonical algebraic map

$$X_0 \otimes_\varepsilon Y_0 \longrightarrow X \otimes_\varepsilon Y$$

is a topological embedding. The induced map between the completions is also a topological embedding.

Proof. Algebraic injectivity follows from exactness of the tensor product of vector spaces over a field. We prove the topological assertion. Let $A_0 \subseteq X_0'$ be equicontinuous. There is a continuous seminorm p_0 on X_0 such that $|\lambda_0(x)| \le p_0(x)$ for $\lambda_0 \in A_0$. Since the topology of X_0 is induced by X, there are a continuous seminorm p on X and $C > 0$ such that $p_0(x) \le C p(x)$ on X_0. By Hahn–Banach, each $\lambda_0 \in A_0$ admits an extension $\lambda \in X'$ satisfying $|\lambda(x)| \le C p(x)$. Choosing one extension for each element gives an equicontinuous

set $A \subseteq X'$ whose restriction to X_0 contains A_0. The same argument applies to every equicontinuous set $B_0 \subseteq Y_0'$.

Consequently, each seminorm ε_{A_0,B_0} is dominated by the restriction of some seminorm $\varepsilon_{A,B}$ on $X \otimes_\varepsilon Y$. The reverse inequality for restricted seminorms is immediate, since restrictions of equicontinuous sets remain equicontinuous. Thus the topology of $X_0 \otimes_\varepsilon Y_0$ coincides with that induced by $X \otimes_\varepsilon Y$.

A uniform linear embedding between locally convex spaces extends to an embedding between their completions. Indeed, if the image of a Cauchy net converges to zero, the equalities of the induced seminorms show that the net converges to zero in the original space. This proves the final assertion. □

Lemma B.12.19. (Smooth extension from half-spaces and orthants) For $d \in \mathbb{N}$ and $r \in \{0,\dots,d\}$ put $G_{d,r} := \mathbb{R}^{d-r} \times [0,\infty)^r$. A function belongs to $C^\infty(G_{d,r})$ if it is smooth in the interior and all its ordinary derivatives extend continuously to each face. There is a continuous linear operator

$$E_{d,r} \colon C^\infty(G_{d,r}) \longrightarrow C^\infty(\mathbb{R}^d) \quad \text{such that} \quad (E_{d,r} f)|_{G_{d,r}} = f.$$

Continuity refers to the derivative seminorms on compact sets. If $K \subseteq G_{d,r}$ is compact, there is a compact set $\widehat{K} \subseteq \mathbb{R}^d$, independent of f, such that

$$\operatorname{supp} f \subseteq K \implies \operatorname{supp} E_{d,r} f \subseteq \widehat{K}, \qquad \|E_{d,r} f\|_{C^m(\mathbb{R}^d)} \le C_{m,r} \|f\|_{C^m(G_{d,r})}, \quad m \in \mathbb{N}_0.$$

The operators can be chosen so that extension in different groups of variables commutes, depends continuously on smooth parameters, and satisfies

$$E_{d+e,r+s}(f \boxtimes g) = (E_{d,r} f) \boxtimes (E_{e,s} g),$$

after the coordinate permutation that brings the normal variables together.

Proof. We first construct coefficients that match all jets simultaneously. For $N \in \mathbb{N}_0$ and $\ell \in \{0,\dots,N\}$ define

$$a_{\ell,N} := \prod_{\substack{j \in \{0,\dots,N\} \\ j \neq \ell}} \frac{1 + 2^j}{2^j - 2^\ell}.$$

Lagrange interpolation at the nodes $-2^0,\dots,-2^N$, evaluated at 1, gives

$$\sum_{\ell=0}^{N} a_{\ell,N} (-2^\ell)^m = 1, \qquad m \in \{0,\dots,N\}.$$

For each fixed ℓ there exists $a_\ell := \lim_{N\to\infty} a_{\ell,N}$. Indeed, for $j > \ell$ the factor is $(1+2^{-j})/(1-2^{\ell-j})$, and the products of its numerators and denominators converge to positive numbers. Let

$$P_+ := \prod_{j=0}^{\infty} (1 + 2^{-j}) < \infty, \qquad P_- := \prod_{j=1}^{\infty} (1 - 2^{-j}) > 0.$$

These convergences follow by taking logarithms: apart from finitely many factors, $|\log(1 \pm 2^{-j})| \le 2^{1-j}$.

Separating the factors $j<\ell$ and $j>\ell$ gives

$$|a_{\ell,N}| = 2^{-\ell(\ell+1)/2}\frac{\displaystyle\prod_{\substack{0\le j\le N\\ j\neq\ell}}(1+2^{-j})}{\displaystyle\prod_{j=1}^{\ell}(1-2^{-j})\prod_{j=1}^{N-\ell}(1-2^{-j})} \le \frac{P_+}{P_-^2}\,2^{-\ell(\ell+1)/2}.$$

The same bound holds for a_ℓ. In particular,

$$\sum_{\ell\in\mathbb{N}_0}|a_\ell|2^{\ell m}<\infty, \qquad \sum_{\ell\in\mathbb{N}_0}a_\ell(-2^\ell)^m = 1, \qquad m\in\mathbb{N}_0.$$

For the second equality, extend $a_{\ell,N}$ by zero when $\ell>N$ and pass to the limit in the finite identity using the preceding summable bound, with m fixed and $N\ge m$.

Fix $R>0$ and $\chi\in C_c^\infty((-R,R))$ equal to one near zero. For $f\in C^\infty(\mathbb{R}^{d-1}\times[0,\infty))$ put

$$(E_{d,1}f)(x',t) := \begin{cases} f(x',t), & t\ge 0,\\ \displaystyle\sum_{\ell\in\mathbb{N}_0}a_\ell\chi(-2^\ell t)f(x',-2^\ell t), & t<0.\end{cases}$$

For each $t<0$ only finitely many indices contribute. More precisely, if $\alpha\in\mathbb{N}_0^{d-1}$ and $q\in\mathbb{N}_0$, the derivative of the corresponding summand is

$$a_\ell(-2^\ell)^q\left[\partial_\tau^q\left(\chi(\tau)D_{x'}^\alpha f(x',\tau)\right)\right]_{\tau=-2^\ell t}.$$

On every compact set in the variables x', its supremum norm for $t\le 0$ is bounded by $C_q|a_\ell|2^{\ell q}$ multiplied by the largest of the norms of the derivatives of f of order at most $|\alpha|+q$ on the product of that compact set with $[0,R]$. The Weierstrass test allows us to differentiate the series and extend each differentiated series continuously to $t=0$. Since $\chi=1$ near zero, its value there is

$$\left(\sum_{\ell\in\mathbb{N}_0}a_\ell(-2^\ell)^q\right)D_{x'}^\alpha\partial_t^q f(x',0) = D_{x'}^\alpha\partial_t^q f(x',0).$$

Thus the limits of all derivatives agree from both sides. To justify the gluing, apply the fundamental theorem of calculus to each normal derivative across $t=0$: the primitive of the glued continuous derivative agrees with the function on both half-lines and at zero. By induction on the order, together with the tangential derivatives, the glued function is C^∞. The same estimates prove continuity for the local seminorms and, when the global norms are finite, the C^m bound in the statement.

If $\operatorname{supp} f\subseteq K$, the part of the extension with $t<0$ is supported in $\operatorname{pr}_{x'}K\times[-R,0]$, whereas the part with $t\ge 0$ is supported in K. Their union is a fixed compact set. The construction does not change the variables x'; when parameters are included among them, all their derivatives satisfy the same estimates.

For $r>1$ we apply this formula successively to each normal variable, treating the others as parameters, and for $r=0$ we take the identity. The derivative estimates are iterated finitely many times; the support remains in a fixed compact box. If two different variables are extended, the two double series and all

their differentiated series converge absolutely on compact sets, by the sums $\sum_{\ell\in\mathbb{N}_0}|a_\ell|2^{\ell m}$. Their order may therefore be interchanged. On a product $f(x)g(y)$ each operator acts only on its own factor; this proves the asserted commutation and product identity. □

Corollary B.12.20. (Nuclearity of test function spaces with fixed support) Let $U\subseteq\mathbb{R}^d$ be open and let $K\subseteq U$ be compact. Then $\mathcal{D}_K(U)$ is a nuclear Fréchet space.

Proof. Extension by zero topologically identifies $\mathcal{D}_K(U)$ with the space of functions in $C^\infty(\mathbb{R}^d)$ whose support is contained in K. Choose an open cube containing K whose closure is contained in the interior of a larger cube. After identifying opposite faces of the larger cube, periodic extension determines a topological embedding of $\mathcal{D}_K(U)$ into $C^\infty(\mathbb{T}^d)$. Its image is the subspace

$$\{f\in C^\infty(\mathbb{T}^d)\mid f=0 \text{ on } \mathbb{T}^d\setminus K\},$$

which is closed because convergence in C^∞ implies uniform convergence. Theorem B.12.17 and Proposition B.12.15 complete the proof. □

Theorem B.12.21. (Tensor products of smooth functions on tori) The map $(f,g)\mapsto((x,y)\mapsto f(x)g(y))$ induces a topological isomorphism

$$C^\infty(\mathbb{T}^m)\widehat{\otimes}_\pi C^\infty(\mathbb{T}^n)\cong C^\infty(\mathbb{T}^{m+n}).$$

Proof. Continuity of the bilinear map follows from

$$\|D_x^\alpha D_y^\beta(f\boxtimes g)\|_{L^\infty(\mathbb{T}^{m+n})}\le\|D^\alpha f\|_{L^\infty(\mathbb{T}^m)}\|D^\beta g\|_{L^\infty(\mathbb{T}^n)};$$

by Proposition B.12.2, we obtain a continuous operator from the completed projective product.
Using the Fourier isomorphism of Theorem B.12.17, it suffices to prove that

$$s(\mathbb{Z}^m)\widehat{\otimes}_\pi s(\mathbb{Z}^n)\longrightarrow s(\mathbb{Z}^{m+n}),\qquad e_\mu\otimes e_\nu\longmapsto e_{(\mu,\nu)},$$

is an isomorphism. If $a=(a_{\mu,\nu})\in s(\mathbb{Z}^{m+n})$, consider the series

$$R(a):=\sum_{\mu\in\mathbb{Z}^m}\sum_{\nu\in\mathbb{Z}^n}a_{\mu,\nu}e_\mu\otimes e_\nu.$$

For the seminorms p_k and p_ℓ of the two factors,

$$\sum_{\substack{\mu\in\mathbb{Z}^m\\ \nu\in\mathbb{Z}^n}}|a_{\mu,\nu}|p_k(e_\mu)p_\ell(e_\nu)\le p_N(a)\sum_{\substack{\mu\in\mathbb{Z}^m\\ \nu\in\mathbb{Z}^n}}\frac{(1+\|\mu\|)^k(1+\|\nu\|)^\ell}{(1+\|\mu\|+\|\nu\|)^N},$$

and the last series is finite if $N>k+\ell+m+n$. Therefore the series defining $R(a)$ converges absolutely for each projective seminorm, and R is continuous. On finitely supported sequences, it is immediate that R is the inverse of the canonical map. These sequences are dense in $s(\mathbb{Z}^d)$: if $a^{(R)}$ is obtained from a by setting

the terms with $\|\nu\| > R$ equal to zero, then, for each k, we have

$$p_k(a - a^{(R)}) \leq \frac{1}{1+R} p_{k+1}(a) \longrightarrow 0.$$

Thus tensors of finitely supported sequences are dense in the completed product, and continuity extends both identities to the completions. □

Lemma B.12.22. (Localized tensor products in Euclidean spaces) Let $K_0 \subseteq \mathrm{Int}(K_1) \subseteq U \subseteq \mathbb{R}^m$ and $L_0 \subseteq \mathrm{Int}(L_1) \subseteq V \subseteq \mathbb{R}^n$, where K_0, K_1, L_0, L_1 are compact. The canonical map

$$T_{K_1,L_1} : \mathcal{D}_{K_1}(U) \widehat{\otimes}_\pi \mathcal{D}_{L_1}(V) \longrightarrow \mathcal{D}_{K_1 \times L_1}(U \times V)$$

is a topological embedding. Its image contains $\mathcal{D}_{K_0 \times L_0}(U \times V)$, and the inverse map restricted to this latter space is continuous.

Proof. We begin by reducing the compact sets to the fundamental cubes of two tori. Since K_1 and L_1 are bounded, there are affine diffeomorphisms $A \colon \mathbb{R}^m \longrightarrow \mathbb{R}^m$ and $B \colon \mathbb{R}^n \longrightarrow \mathbb{R}^n$ such that

$$A(K_1) \subseteq (-\pi, \pi)^m, \qquad B(L_1) \subseteq (-\pi, \pi)^n.$$

The change of variables $f \mapsto f \circ A^{-1}$ is a topological isomorphism from $\mathcal{D}_{K_1}(U)$ onto $\mathcal{D}_{A(K_1)}(A(U))$. Indeed, the chain rule expresses each derivative of $f \circ A^{-1}$ as a linear combination, with constant coefficients, of derivatives of f of the same order. The inverse change satisfies the same estimates. The corresponding assertion holds for B and for $A \times B$. We may therefore replace the open and compact sets by their images while keeping the original notation. We shall thus assume from now on that

$$K_1 \subseteq (-\pi, \pi)^m, \qquad L_1 \subseteq (-\pi, \pi)^n.$$

The inclusions $K_0 \subseteq \mathrm{Int}(K_1)$ and $L_0 \subseteq \mathrm{Int}(L_1)$ allow us to choose $\chi \in \mathcal{D}_{K_1}(U)$ and $\eta \in \mathcal{D}_{L_1}(V)$ equal to one on neighborhoods of K_0 and L_0, respectively. If a function in $\mathcal{D}_{K_1}(U)$ is extended by zero to $\mathbb{R}^m$, the extension vanishes in a neighborhood of the boundary of $[-\pi, \pi]^m$. It therefore determines a smooth function on $\mathbb{T}^m = \mathbb{R}^m/(2\pi\mathbb{Z})^m$. We thus obtain a topological embedding

$$J_m \colon \mathcal{D}_{K_1}(U) \longrightarrow C^\infty(\mathbb{T}^m).$$

The embeddings J_n and J_{m+n} for the second factor and for the product are constructed in the same way. The topology induced by C^∞ coincides with the usual topology of each space with fixed support, since in both cases it is defined by the suprema of derivatives over a fixed compact set.
If $\Phi \in \mathcal{D}_{K_0 \times L_0}(U \times V)$ and

$$\Phi(x, y) = \sum_{\mu \in \mathbb{Z}^m,\, \nu \in \mathbb{Z}^n} c_{\mu,\nu}(\Phi) e^{i\langle \mu, x \rangle} e^{i\langle \nu, y \rangle}$$

is its periodic Fourier series, define

$$R^{K_1,L_1}_{K_0,L_0}\Phi := \sum_{\substack{\mu\in\mathbb{Z}^m\\ \nu\in\mathbb{Z}^n}} c_{\mu,\nu}(\Phi)\big(\chi e^{i\langle\mu,\cdot\rangle}\big)\otimes\big(\eta e^{i\langle\nu,\cdot\rangle}\big).$$

For each $a,b\in\mathbb{N}_0$ there are constants $C_a, C_b>0$ such that

$$\|\chi e^{i\langle\mu,\cdot\rangle}\|_{C^a}\le C_a(1+\|\mu\|)^a,\qquad \|\eta e^{i\langle\nu,\cdot\rangle}\|_{C^b}\le C_b(1+\|\nu\|)^b.$$

By integration by parts, for every $N\in\mathbb{N}$ there is $C_N>0$ such that

$$|c_{\mu,\nu}(\Phi)|\le C_N(1+\|\mu\|+\|\nu\|)^{-N}\max_{|\gamma|\le 2N}\|D^\gamma\Phi\|_{L^\infty(\mathbb{T}^{m+n})}.$$

Choosing $N>a+b+m+n$, the series defining $R^{K_1,L_1}_{K_0,L_0}\Phi$ converges absolutely for the projective seminorm $\|\cdot\|_{C^a}\otimes_\pi\|\cdot\|_{C^b}$. The same estimate shows that $R^{K_1,L_1}_{K_0,L_0}$ is continuous. Since $\chi(x)\eta(y)=1$ on $K_0\times L_0$, Theorem B.12.21 gives

$$T_{K_1,L_1}R^{K_1,L_1}_{K_0,L_0}\Phi=\chi(x)\eta(y)\Phi(x,y)=\Phi(x,y).$$

It remains to prove that T_{K_1,L_1} induces the correct topology on its image. By Corollary B.12.20 and Theorem B.12.14, in the domain of T_{K_1,L_1} we may replace $\widehat{\otimes}_\pi$ by $\widehat{\otimes}_\varepsilon$. The spaces $C^\infty(\mathbb{T}^m)$ and $C^\infty(\mathbb{T}^n)$ are also nuclear, so the same replacement is valid for them. Proposition B.12.18, applied to J_m and J_n, shows that

$$J_m\widehat{\otimes}J_n:\mathcal{D}_{K_1}(U)\widehat{\otimes}_\pi\mathcal{D}_{L_1}(V)\longrightarrow C^\infty(\mathbb{T}^m)\widehat{\otimes}_\pi C^\infty(\mathbb{T}^n)$$

is a topological embedding. If $T_{\mathbb{T}}$ denotes the isomorphism of Theorem B.12.21, then

$$J_{m+n}\circ T_{K_1,L_1}=T_{\mathbb{T}}\circ(J_m\widehat{\otimes}J_n).$$

The right-hand side is a topological embedding. Since J_{m+n} is as well, the equality proves that T_{K_1,L_1} is injective and that its inverse on the image is continuous. Therefore T_{K_1,L_1} is a topological embedding. Finally, the identity obtained above shows that $R^{K_1,L_1}_{K_0,L_0}$ agrees with its inverse on $\mathcal{D}_{K_0\times L_0}(U\times V)$. □

B.13 Ordinary differential equations in Banach spaces

The local theory of ordinary differential equations in Banach spaces retains the method of successive approximations. Completeness of the model space takes the place of completeness of Euclidean spaces, but no form of local compactness is available. This distinction will be essential when studying the continuation of integral curves on Banach manifolds.

All integrals in this section are Riemann integrals with values in a Banach space. For continuous integrands on compact intervals, they coincide with the corresponding Bochner integrals.

Let E be a real Banach space, let $\Omega\subseteq\mathbb{R}\times E$ be an open subset, and let $F\colon\Omega\longrightarrow E$. We say that F is **locally Lipschitz in the state variable, uniformly in time** if, for each $(t_0,x_0)\in\Omega$, there exist $a,r,L>0$ such that

$$[t_0-a,t_0+a]\times\overline{B}_E(x_0,r)\subseteq\Omega$$

and

$$\|F(t,x)-F(t,y)\|_E \le L\|x-y\|_E$$

for all $t \in [t_0-a, t_0+a]$ and $x, y \in \overline{B}_E(x_0, r)$. When a parameter λ in a Banach space P is present, the expression *uniformly in time and in the parameter* has the analogous meaning on products of the form

$$[t_0-a, t_0+a] \times \overline{B}_E(x_0, r) \times \overline{B}_P(\lambda_0, \rho).$$

Every function of class C^1 is locally Lipschitz in the state variable. Continuity of D_2F allows its norm to be bounded on a sufficiently small product around the point under consideration, and the mean value inequalities in Theorem 23.1.10 give the Lipschitz estimate on a convex ball.

Theorem B.13.1. (Picard–Lindelöf in Banach spaces) Let E be a Banach space, let $\Omega \subseteq \mathbb{R} \times E$ be open, and let $F\colon \Omega \longrightarrow E$ be continuous and locally Lipschitz in the state variable, uniformly in time. For each $(t_0, x_0) \in \Omega$, there exist $h > 0$ and a unique function

$$x \in C^1([t_0-h, t_0+h], E)$$

whose graph is contained in Ω and which satisfies

$$x'(t) = F(t, x(t)), \qquad x(t_0) = x_0.$$

More precisely, $a, r, L, M > 0$ can be chosen so that

$$Q := [t_0-a, t_0+a] \times \overline{B}_E(x_0, r) \subseteq \Omega, \qquad \|F(t,y)\|_E \le M$$

on Q and the Lipschitz constant with respect to y is L. Any $h > 0$ such that

$$h \le a, \qquad hM \le r, \qquad hL < 1.$$

then suffices. The solution is the unique element of $C([t_0-h, t_0+h], \overline{B}_E(x_0, r))$ satisfying the integral equation

$$x(t) = x_0 + \int_{t_0}^{t} F(s, x(s))\, ds. \tag{B.12}$$

Proof. By continuity of F at (t_0, x_0) and the local Lipschitz hypothesis, we can decrease a and r to obtain the cylinder Q, the bound M, and the constant L in the statement. Let

$$\mathcal{X} := \left\{ u \in C([t_0-h, t_0+h], E) \;\middle|\; \sup_{t \in [t_0-h, t_0+h]} \|u(t) - x_0\|_E \le r \right\}.$$

The space $C([t_0-h, t_0+h], E)$, equipped with the supremum norm, is a Banach space. For a Cauchy sequence of continuous functions, completeness of E gives a pointwise limit; convergence is uniform, so the limit is continuous. Consequently, $\mathcal{X}$ is a complete metric space, since it is a closed subset.

Define $\mathcal{T}\colon \mathcal{X} \longrightarrow C([t_0-h, t_0+h], E)$ by

$$(\mathcal{T}u)(t) := x_0 + \int_{t_0}^{t} F(s, u(s))\, ds.$$

The integral is well-defined by Theorem B.6.2. For $u \in \mathcal{X}$, we have

$$\|(\mathcal{T}u)(t) - x_0\|_E \le M|t - t_0| \le Mh \le r,$$

so that $\mathcal{T}(\mathcal{X}) \subseteq \mathcal{X}$. Similarly, for $u, v \in \mathcal{X}$,

$$\|\mathcal{T}u - \mathcal{T}v\|_\infty \le hL\|u - v\|_\infty.$$

Thus, $\mathcal{T}$ is a contraction. Theorem 23.3.1 gives a unique fixed point $x \in \mathcal{X}$, which satisfies (B.12). Since the integrand is continuous, the fundamental theorem of calculus for Banach-valued functions, Theorem B.6.5, shows that $x \in C^1$ and $x'(t) = F(t, x(t))$.
Conversely, every solution taking values in $\overline{B}_E(x_0, r)$ satisfies (B.12) by the same fundamental theorem of calculus and is therefore a fixed point of $\mathcal{T}$. If y is any other solution with the same initial datum, continuity allows both solutions to be restricted to an interval on which they remain in a common contraction cylinder. The set of times at which x and y agree is closed; repeating this local argument at each of its points shows that it is also open. Connectedness of the common interval shows that the two solutions agree wherever both are defined. This proves the asserted uniqueness. □

The preceding uniqueness result is not restricted to the particular cylinder used in the construction.

Proposition B.13.2. (Uniqueness on common domains) Under the hypotheses of Theorem B.13.1, let $x_1\colon I_1 \longrightarrow E$ and $x_2\colon I_2 \longrightarrow E$ be two solutions, and suppose that $t_* \in I_1 \cap I_2$ and $x_1(t_*) = x_2(t_*)$. Then

$$x_1(t) = x_2(t)$$

for every t in the connected component of $I_1 \cap I_2$ containing t_*. In particular, two solutions with the same initial datum agree on the intersection of their intervals of definition.

Proof. Let J be the indicated component, and let $A := \{t \in J \mid x_1(t) = x_2(t)\}$. This set is closed in J by continuity of the solutions, and it is nonempty. If $s \in A$, apply the local construction in Theorem B.13.1 at the point $(s, x_1(s))$. By continuity, both solutions remain in the uniqueness cylinder when restricted to a sufficiently small interval around s; uniqueness of the fixed point implies that they agree on that interval. Hence A is also open in J. Connectedness of J implies that $A = J$. □

Theorem B.13.3. (Maximal solution) Under the hypotheses of Theorem B.13.1, for each $(t_0, x_0) \in \Omega$ there exists a unique maximal solution

$$x_{t_0,x_0}\colon I_{t_0,x_0} \longrightarrow E,$$

where $I_{t_0,x_0} \subseteq \mathbb{R}$ is an open interval containing t_0. Every other solution with initial datum (t_0, x_0) is a restriction of this solution.

Proof. Consider all solutions defined on open intervals containing t_0 and taking the value x_0 at t_0. Proposition B.13.2 shows that any two of them agree on the intersection of their domains. Their union therefore defines a function on the union I_{t_0,x_0} of all these intervals. This union is an open interval containing t_0, and the resulting function locally agrees with one of the solutions in the family; it is therefore a solution. By construction, it extends all the others and is maximal. Uniqueness again follows from Proposition B.13.2. □

The continuation criterion must be formulated in terms of convergence rather than compactness of closed balls, since closed balls are not compact in an infinite-dimensional Banach space.

Theorem B.13.4. (Continuation criterion) Let $x\colon (a,b) \longrightarrow E$ be a maximal solution of $x' = F(t,x)$, and suppose that $b < \infty$.

(a) If there exists $x_b \in E$ such that

$$x(t) \longrightarrow x_b \qquad \text{as } t \to b^-$$

and $(b, x_b) \in \Omega$, then x extends to an interval strictly containing (a,b), contradicting maximality.

(b) If there exist $t_1 \in (a,b)$ and a constant $M > 0$ such that

$$\|F(t,x(t))\|_E \le M \qquad \text{for } t \in [t_1, b),$$

then the limit $x_b := \lim\limits_{t\to b^-} x(t)$ exists. In particular, a maximal solution with a finite right endpoint can fail to extend only if $(b, x_b) \notin \Omega$.

The symmetric statements hold at a finite left endpoint.

Proof. First suppose that x_b exists and that $(b, x_b) \in \Omega$. Define $x(b) := x_b$. Passing to the limit in the integral equation between a fixed time $t_1 < b$ and $t < b$, using continuity of F, gives

$$x_b = x(t_1) + \int_{t_1}^{b} F(s, x(s))\, ds.$$

Theorem B.13.1, applied to the datum (b, x_b), produces a solution on an interval around b. Uniqueness allows it to be glued to x, giving a continuation beyond b. This proves (a).
For (b), if $t_1 \le s < t < b$, the fundamental theorem of calculus gives

$$\|x(t) - x(s)\|_E \le \int_s^t \|F(\tau, x(\tau))\|_E \, d\tau \le M|t - s|.$$

Thus, $x(t)$ is Cauchy as $t \to b^-$. Completeness of E gives a limit $x_b \in E$, and the last assertion follows from (a). The backward argument is obtained by reversing the direction of time. □

We now record dependence on data and parameters in the form that will be used to construct flows.

Theorem B.13.5. (Dependence on initial data and parameters) Let E and P be Banach spaces, let $\Omega \subseteq \mathbb{R} \times E \times P$ be open, and let $F\colon \Omega \longrightarrow E$ be continuous and locally Lipschitz in the state variable, uniformly in time and in the parameter. Denote by

$$x(t; t_0, x_0, \lambda)$$

the maximal solution of the problem

$$x'(t) = F(t, x(t), \lambda), \qquad x(t_0) = x_0.$$

Then the natural domain

$$\mathcal{D} := \left\{ (t, t_0, x_0, \lambda) \;\middle|\; t \in I_{t_0, x_0, \lambda} \right\}$$

is open in $\mathbb{R}^2 \times E \times P$, and the solution map

$$\mathcal{D} \longrightarrow E, \qquad (t, t_0, x_0, \lambda) \longmapsto x(t; t_0, x_0, \lambda),$$

is continuous.
If F is of class C^k, with $k \in \mathbb{N} \cup \{\infty\}$, the solution map is of class C^k. In particular, for $k \geq 1$, its derivatives with respect to the initial state and the parameter satisfy the variational equations

$$D_{x_0} x(t)h = h + \int_{t_0}^{t} D_2 F(s, x(s), \lambda)\big(D_{x_0} x(s)h\big)\, ds, \tag{B.13}$$

$$D_\lambda x(t)\mu = \int_{t_0}^{t} \big[D_2 F(s, x(s), \lambda)\big(D_\lambda x(s)\mu\big) + D_3 F(s, x(s), \lambda)\mu\big]\, ds. \tag{B.14}$$

Proof. Fix a datum (t_0, x_0, λ_0) and a compact interval contained in the maximal interval of the corresponding solution. The graph of this solution over the compact interval is compact, even though no neighborhood in the Banach space is compact. A finite cover by cylinders of local existence allows the interval to be divided into finitely many subintervals on which the same Lipschitz constant works for all sufficiently nearby data. On one of these subintervals, let x_* be the reference solution and let u be the solution corresponding to a nearby datum and parameter. Subtracting their integral equations, separating the term describing variation of the parameter along x_*, and applying Grönwall's inequality from Lemma 1.8.19 gives an estimate of the form

$$\sup_{t \in J} \|u(t) - x_*(t)\|_E \leq C_J \left(\|u(t_*) - x_*(t_*)\|_E + \sup_{t \in J} \|F(t, x_*(t), \lambda) - F(t, x_*(t), \lambda_0)\|_E \right).$$

The last supremum tends to zero as $\lambda \to \lambda_0$. The image of the map $t \mapsto (t, x_*(t), \lambda_0)$ is compact, and a finite subcover of neighborhoods on which continuity gives the required bound provides an estimate uniform for $t \in J$. Iterating the estimate over the finite partition gives continuous dependence on every compact interval. The same local construction shows that nearby data have solutions on a slightly larger interval; it follows that $\mathcal{D}$ is open. The change of variable $s = t - t_0$ converts variation of the initial time into variation of a parameter in the field

$$(s, x, t_0, \lambda) \longmapsto F(t_0 + s, x, \lambda),$$

so the same argument also proves continuous dependence on t_0.
Now suppose that F is of class C^k. On a sufficiently small compact interval $J = [t_0 - h, t_0 + h]$, consider the Banach space $C(J, E)$ and the map

$$\mathscr{F}(u, a, \lambda)(t) := u(t) - a - \int_{t_0}^{t} F(s, u(s), \lambda)\, ds.$$

In a neighborhood of the reference solution, $\mathscr{F}$ is of class C^k. This follows from the chain rule, continuity

of integration, and uniformity on the compact image of the curve; its derivatives are obtained by differentiating the integrand. Moreover,

$$D_1\mathscr{F}(u,a,\lambda)w(t) = w(t) - \int_{t_0}^{t} D_2F(s,u(s),\lambda)w(s)\,ds.$$

By decreasing h, we can make the norm of the integral operator on the right-hand side less than one. Theorem B.2.10 then shows that $D_1\mathscr{F}$ is invertible. Theorem 23.3.8 implies that the solution, regarded as an element of $C(J,E)$, depends in a C^k manner on (a,λ). Evaluation at each time is linear and continuous. Furthermore, the derivatives with respect to (a,λ) obtained in $C(J,E)$ are continuous functions of time, and their evaluation depends jointly on (t,a,λ). The identity

$$\partial_t x(t;a,\lambda) = F(t,x(t;a,\lambda),\lambda)$$

and the chain rule show inductively that all mixed derivatives of total order at most k exist and are continuous. This gives joint regularity in time. Dependence on t_0 reduces to the same argument through the change of variable $s = t - t_0$ and the field $(s,x,t_0,\lambda) \mapsto F(t_0+s,x,\lambda)$.
Finally, differentiating the integral equation with respect to a and λ gives (B.13) and (B.14). Continuation over an arbitrary compact interval is obtained by composing finitely many of these local solution maps. □

Corollary B.13.6. (Global existence for bounded fields) Let E be a Banach space, and let $F\colon \mathbb{R}\times E \longrightarrow E$ be continuous and locally Lipschitz in the state variable, uniformly in time. Suppose that there exists $M \geq 0$ such that

$$\|F(t,x)\|_E \leq M$$

for every $(t,x) \in \mathbb{R}\times E$. Then every maximal solution is defined on $\mathbb{R}$ and satisfies

$$\|x(t) - x(s)\|_E \leq M|t-s|$$

for all $s,t \in \mathbb{R}$. If F has C^k regularity, the regularity of the solution map is that given by Theorem B.13.5.

Proof. Let (a,b) be the maximal interval of a solution. If $b < \infty$, the bound on F and Theorem B.13.4 give a limit $x_b \in E$ as $t \to b^-$. Since the domain of the field is all of $\mathbb{R}\times E$, the datum (b,x_b) belongs to that domain and the solution extends, contradicting maximality. Hence $b = +\infty$. The same argument backward in time shows that $a = -\infty$. The estimate follows by integrating the equation between s and t. □

C
Linear algebra

This appendix collects some results from linear algebra used in the study of metrics, bilinear forms, operators, and tensors. We mainly follow the references [83, 122]; the reader may consult them for a more extensive treatment.

C.1 Bilinear forms and matrices

Bilinear forms and their associated matrices provide the starting point for the constructions considered in this appendix.

Definition C.1.1. Let V be a real vector space of dimension n. We say that $f : V \times V \longrightarrow \mathbb{R}$ is a bilinear form on V if:

(a) $f(x+y,z) = f(x,z) + f(y,z)$ and $f(\lambda x, y) = \lambda f(x,y)$ for any $x, y, z \in V$ and $\lambda \in \mathbb{R}$.

(b) $f(x, y+z) = f(x,y) + f(x,z)$ and $f(x, \lambda y) = \lambda f(x,y)$ for any $x, y, z \in V$ and $\lambda \in \mathbb{R}$.

If $\{e_1, \ldots, e_n\}$ is a basis of V, we define the matrix associated with the bilinear form f by

$$A_{ij} = f(e_i, e_j).$$

Proposition C.1.2. If V is a real vector space of dimension n, $f : V \times V \longrightarrow \mathbb{R}$ is a bilinear form, and $\beta = \{e_1, \ldots, e_n\}$ is a basis of V, then

$$f(x,y) = [x]_\beta^T A [y]_\beta,$$

for any $x, y \in V$, where A is the matrix associated with f and $[x]_\beta, [y]_\beta$ are the coordinate representations of x and y, respectively, in the basis β.

Proof. If $x = x^i e_i$ and $y = y^j e_j$, bilinearity gives

$$f(x,y) = x^i y^j f(e_i, e_j) = x^i A_{ij} y^j = [x]_\beta^T A [y]_\beta.$$

□

Definition C.1.3. Let V be a finite-dimensional real vector space of dimension n, and let $f : V \times V \longrightarrow \mathbb{R}$ be a bilinear form. We say that it is:

(a) Symmetric if $f(x,y) = f(y,x)$ for any $x, y \in V$. In that case, the associated matrix A is symmetric.

(b) Nondegenerate if $f(x,y) = 0$ for every $y \in V$ implies $x = 0$.

Example C.1.4. Let $f : U \subseteq \mathbb{R}^n \longrightarrow \mathbb{R}$ be of class $C^2(U)$. We define the Hessian matrix of f at $x \in U$ by $H(x) = \left(\dfrac{\partial^2 f}{\partial x_i \partial x_j}(x) \right) \in M_{n\times n}(\mathbb{R})$. Then $H(x)$ is a symmetric matrix and is associated with the bilinear form $\nabla^2 f(x) \colon \mathbb{R}^n \times \mathbb{R}^n \longrightarrow \mathbb{R}$ (the second total derivative of f).

Definition C.1.5. A matrix $A \in M_{n\times n}(\mathbb{C})$ is Hermitian if $A = A^*$, where A^* is the matrix obtained by conjugating the entries of the transpose of A. A Hermitian matrix is *positive semidefinite* if $x^*Ax \geq 0$ for every $x \in \mathbb{C}^n$, and *positive definite* if $x^*Ax > 0$ for every $x \neq 0$. For real matrices, we use these terms for symmetric matrices satisfying the corresponding condition on $x \in \mathbb{R}^n$.

Proposition C.1.6. Every symmetric matrix $A \in M_{n\times n}(\mathbb{R})$ is Hermitian.

Proof. Since the entries are real, conjugation leaves them unchanged. Therefore, $A^* = \overline{A^T} = A^T = A$. □

Theorem C.1.7. Every $n \times n$ Hermitian matrix is diagonalizable by a unitary matrix and has real eigenvalues.

Proof. We proceed by induction on n. The characteristic polynomial of a complex matrix has a root, so A has an eigenvector $v \neq 0$, say $Av = \lambda v$. Since $A = A^*$,

$$\lambda\langle v, v\rangle = \langle Av, v\rangle = \langle v, Av\rangle = \overline{\lambda}\langle v, v\rangle,$$

and $\lambda \in \mathbb{R}$. After normalizing v, its orthogonal complement is invariant: if $w \perp v$, then

$$\langle Aw, v\rangle = \langle w, Av\rangle = \lambda\langle w, v\rangle = 0.$$

The restriction of A to $v^\perp$ remains Hermitian. The induction hypothesis gives an orthonormal basis of eigenvectors in $v^\perp$, which together with v diagonalizes A. □

Theorem C.1.8. (Rayleigh) Let $A \in M_{n\times n}(\mathbb{C})$ be Hermitian. Then

$$\lambda_{\max} = \max_{x\neq 0} \frac{x^*Ax}{x^*x} \text{ and } \lambda_{\min} = \min_{x\neq 0} \frac{x^*Ax}{x^*x},$$

where $\lambda_{\max}$ and $\lambda_{\min}$ are the largest and smallest eigenvalues of A, respectively, and x^* is the matrix obtained by transposing the vector x and taking the complex conjugate of each entry.

Proof. By the preceding theorem, there is a unitary matrix Q such that

$$Q^*AQ = \operatorname{diag}(\lambda_1, \ldots, \lambda_n).$$

If $y = Q^*x$, then

$$\frac{x^*Ax}{x^*x} = \frac{\sum_{i=1}^n \lambda_i |y_i|^2}{\sum_{i=1}^n |y_i|^2}.$$

This quotient is a convex combination of the eigenvalues, so it lies between $\lambda_{\min}$ and $\lambda_{\max}$. Both extrema are attained by taking a corresponding eigenvector. □

Theorem C.1.9. (Schur decomposition) Let $A \in M_{n\times n}(\mathbb{C})$. Then $A = QUQ^{-1}$, where Q is a unitary matrix (Q is invertible and $Q^{-1} = Q^*$) and U is an upper triangular matrix whose diagonal entries are the eigenvalues of A.

Proof. The proof is by induction on n. Choose a unit eigenvector v_1 of A and extend it to an orthonormal basis. In that basis, the first column of the matrix of A is $(\lambda_1, 0, \dots, 0)^T$, so the matrix has the form

$$\begin{pmatrix} \lambda_1 & * \\ 0 & A_1 \end{pmatrix}.$$

By the induction hypothesis, a unitary change of basis in $\operatorname{span}\{v_1\}^\perp$ triangularizes A_1. Extending it by the identity on $\operatorname{span}\{v_1\}$ gives a unitary matrix Q for which Q^*AQ is upper triangular. The diagonal entries are its eigenvalues because the characteristic polynomial of a triangular matrix is the product of $\lambda - U_{ii}$. □

Theorem C.1.10. Let $A \in M_{n\times n}(\mathbb{C})$, and let λ be an eigenvalue of A. If

$$\|A\|_F := \left(\sum_{i,j=1}^n |A_{ij}|^2 \right)^{\frac{1}{2}}$$

is the Frobenius norm of A, then $|\lambda| \le \|A\|_F$.

Proof. By Theorem C.1.9, there exist a unitary matrix Q and an upper triangular matrix U such that $A = QUQ^{-1}$. The identity $\|C\|_F^2 = \operatorname{tr}(C^*C)$ and the equality $\operatorname{tr}(XY) = \operatorname{tr}(YX)$ give $\|Q^*AQ\|_F^2 = \operatorname{tr}(Q^*A^*AQ) = \operatorname{tr}(A^*A)$; hence $\|A\|_F = \|U\|_F$. Since the diagonal entries of U are the eigenvalues of A, we have

$$\|U\|_F^2 = \sum_{i=1}^n |U_{ii}|^2 + \sum_{1\le i<j\le n} |U_{ij}|^2 \ge |\lambda|^2.$$

Therefore, $|\lambda| \le \|U\|_F = \|A\|_F$. □

Theorem C.1.11. Let A be an $n \times n$ positive semidefinite Hermitian matrix, and let $k \in \mathbb{N}$, with $k \ge 2$. Then:

(a) There exists a unique positive semidefinite Hermitian matrix B such that $A = B^k$.

(b) There exists a polynomial p with real coefficients such that $B = p(A)$. Consequently, B commutes with every matrix that commutes with A.

(c) If A is real, then B is real.

Proof. By the spectral theorem,

$$A = Q\,\mathrm{diag}(\lambda_1,\dots,\lambda_n)Q^*, \qquad \lambda_i \geq 0,$$

with Q unitary. Define

$$B := Q\,\mathrm{diag}(\lambda_1^{1/k},\dots,\lambda_n^{1/k})Q^*.$$

Then B is positive semidefinite Hermitian and $B^k = A$.
If C is another positive semidefinite Hermitian matrix with $C^k = A$, then C commutes with $A = C^k$ and preserves each eigenspace E_λ of A. The restriction of C to E_λ is positive semidefinite Hermitian and satisfies $(C\restriction_{E_\lambda})^k = \lambda I$. Its eigenvalues are nonnegative and their kth powers equal λ; hence they all equal $\lambda^{1/k}$. The spectral theorem implies $C\restriction_{E_\lambda} = \lambda^{1/k} I$, so $C = B$.
Let $\mu_1,\dots,\mu_s$ be the distinct eigenvalues of A. Lagrange interpolation gives a real polynomial p with $p(\mu_j) = \mu_j^{1/k}$. Calculation on each eigenspace shows that $B = p(A)$. If a matrix commutes with A, it commutes with $p(A)$; and if A is real, so is $p(A)$. □

Theorem C.1.12. If A is a positive semidefinite Hermitian matrix, then A is positive definite if and only if A is invertible.

Proof. By the spectral theorem, A is unitarily similar to $\mathrm{diag}(\lambda_1,\dots,\lambda_n)$ with $\lambda_i \geq 0$. It is positive definite if and only if all the λ_i are strictly positive, and it is invertible if and only if none of them is zero. The two conditions are equivalent. □

Remark C.1.13. For every real symmetric positive definite matrix A, there exists a unique real symmetric positive definite matrix B such that $A = B^2$. This matrix is called the square root of A.

Proposition C.1.14. A symmetric positive (semi)definite matrix has a positive (semi)definite square root that is also symmetric.

Proof. Apply Theorem C.1.11 with $k = 2$. Since the original matrix is real, part (c) of that theorem shows that its positive root is real; being Hermitian and real, it is symmetric. If the original matrix is positive definite, the root has no zero eigenvalues and is also positive definite. □

D

Einstein summation convention

This appendix specifies the summation convention used in expressions with indices.

D.1 Einstein summation convention

In a tensor expression, an index that appears exactly twice in the same monomial, once as a subscript and once as a superscript, is called a *dummy index*. Unless otherwise stated, summation over all possible values of that index is understood. Thus, if the indices range over $\{1,\dots,n\}$, we write

$$\lambda_i x^i := \sum_{i=1}^{n} \lambda_i x^i$$

and

$$g^{ij} F_i G_j := \sum_{i,j=1}^{n} g^{ij} F_i G_j.$$

Indices that appear only once are called *free indices*. In a tensor equality, the free indices must appear on both sides in the same positions. For example,

$$T^i{}_j X^j = Y^i$$

represents a family of equalities, one for each value of the free index i, and contains a sum over the dummy index j.

In each monomial we will avoid using the same index more than twice. When several sums are needed, we will use distinct dummy indices. This rule avoids ambiguities and makes the free indices of the expression immediately recognizable.

Local coordinates will usually be written as $(x^1,\dots,x^n)$. In particular,

$$\frac{\partial f}{\partial x^i}\,\mathbf{d}x^i := \sum_{i=1}^{n} \frac{\partial f}{\partial x^i}\,\mathbf{d}x^i.$$

Glossary

Banach cotangent bundle The continuous dual bundle of the tangent bundle of a Banach manifold, denoted by $T'M$; see Definition 25.2.2. 1429, *see* continuous dual of a Banach space and continuous dual Banach bundle

Banach–Finsler structure A continuous family of tangent norms that are uniformly equivalent in charts; see Definition 26.3.1. 1459, *see* strong Riemannian metric and Palais–Smale condition

Banach manifold A manifold whose charts take values in open subsets of Banach spaces and whose coordinate changes are Fréchet differentiable; see Definition 24.1.1. 1376, *see* Fréchet derivative and Banach submanifold

Banach submanifold A subset that can be locally straightened onto a closed complemented subspace of the model space; see Definition 24.3.1. 1388, *see* Banach manifold and regular level set

Bessel potential space The space $H^{s,p}$ defined by the multiplier $(1+\|\xi\|^2)^{\frac{s}{2}}$; see Definition 6.1.2. 440, *see* Sobolev–Slobodeckij space

Bochner Laplacian A second-order operator constructed from a connection and its formal adjoint; see Definition 8.2.10. 577, *see* formal adjoint operator and Hodge–de Rham Laplacian

bounded geometry A uniform geometric condition formulated in terms of the injectivity radius and bounds on the derivatives of curvature; see Definition 13.1.5. 867, *see* Riemannian manifold

bump function on a Banach space A nonzero differentiable function with bounded support; see Definition 24.8.1. 1405, *see* Banach manifold and smooth partition of unity on a Banach manifold

bundle metric A smooth choice of an inner product on each fiber of a vector bundle; see Definition 2.3.1. 131, *see* smooth vector bundle and compatible connection

Carathéodory function A function that is measurable in the geometric variable and continuous in the real variable; see Definition 29.1.1. 1554, *see* weak solution and energy functional

classical Finsler structure A finite-dimensional geometry defined by a Minkowski functional that is smooth and strongly convex away from the zero section; see Definition 26.4.2. 1464, *see* Banach–Finsler structure

coercivity The property of a functional whose value tends to $+\infty$ as the norm of its argument tends to $+\infty$. 1567, *see* direct method in the calculus of variations

compatible connection A connection that preserves the bundle metric under differentiation; see Definition 2.4.39. 168, *see* connection and bundle metric

complex interpolation Calderón's method using holomorphic functions on a strip; see Definition 5.7.4. 418, *see* real interpolation

configuration space A function space of geometric objects equipped with the topology or differentiable structure appropriate for formulating equations and symmetries. *see* manifold of Sobolev maps and ILH manifold

connection An operator that differentiates sections of a bundle in tangent directions and satisfies linearity and the Leibniz rule; see Definition 2.4.2. 136, *see* covariant derivative and compatible connection

continuous dual Banach bundle A Banach bundle whose fibers are the continuous duals of the fibers of the original bundle; see Proposition 25.1.14. 1427, *see* continuous dual of a Banach space and Banach cotangent bundle

continuous dual of a Banach space The space of continuous linear functionals, denoted by X'; see Proposition 25.1.2. 1420, *see* continuous dual Banach bundle and Banach cotangent bundle

covariant derivative The derivative of a section determined by a connection and a tangent direction. 136, *see* connection and weak covariant derivative

critical point A point at which the Fréchet derivative of the functional under consideration vanishes. 1560, *see* Fréchet derivative and energy functional

direct method in the calculus of variations An existence principle for minimizers based on weak compactness, coercivity, and lower semicontinuity; see Theorem 30.1.8. 1567, *see* lower semicontinuity and coercivity

distribution in a vector bundle A continuous linear operator defined on test sections of the dual bundle; see Definition 10.2.1. 756, *see* smooth vector bundle

energy functional A variational functional whose critical points represent weak solutions of the associated Euler–Lagrange equation; see Section 29.3. 1560, *see* critical point and variational method

essential spectrum The part of the spectrum of a self-adjoint operator that does not consist of isolated eigenvalues of finite multiplicity; see Definition 27.4.8. 1514, *see* bounded geometry

extended metric A distance function that may take the value $+\infty$ and whose restriction to each finite-distance component is a metric; see Definition 27.2.9. 1485, *see* uniform structure

formal adjoint operator A differential operator characterized by the integration-by-parts identity with respect to the metrics and the Riemann–Lebesgue measure; see Definition 8.2.1. *see* Bochner Laplacian and Hodge–de Rham Laplacian

Fourier transform An operator that decomposes a function or tempered distribution into frequencies; see Definitions 4.11.1 and 4.11.12. 393, *see* tempered distribution

Fréchet derivative The first-order continuous linear approximation to a function between Banach spaces; see Definition 23.1.1. 1342, *see* Banach manifold

Hilbert manifold A Banach manifold modeled on a Hilbert space; see Definition 26.1.1. 1447, *see* Banach manifold and strong Riemannian metric

Hilbert scale A chain of Hilbert spaces with continuous dense inclusions that records Sobolev regularity; see Definition 27.5.4. 1519, *see* ILH manifold and manifold of Sobolev maps

Hodge–de Rham Laplacian An operator on differential forms given by the sum of the compositions of the exterior derivative and its formal adjoint; see Definition 8.2.14. 578, *see* formal adjoint operator and Bochner Laplacian

ILH manifold The smooth inverse limit of a compatible tower of Hilbert manifolds; see Definition 27.5.6. 1519, *see* Hilbert scale

immersion between Banach manifolds A map whose differential admits a continuous linear left inverse; see Definition 24.5.1. 1393, *see* Banach manifold and Banach submanifold

Kato inequality An estimate comparing the weak derivative of the norm of a section with its covariant derivative; see Theorem 7.2.6. 522, *see* weak covariant derivative

Lagrange multiplier A scalar expressing the dependence between the derivative of a functional and the derivative of a constraint at a constrained critical point; see Corollary 23.4.2. 1599, *see* regular level set and Nehari manifold

lower semicontinuity The property of a functional expressing stability from below with respect to the topology under consideration; see Definitions 30.1.1 and 30.1.6. 1565, *see* direct method in the calculus of variations

manifold of Sobolev maps A component of Sobolev maps modeled on sections of f^*TN through exponential charts; see Theorem 27.3.4. 1498, *see* Banach manifold and Hilbert scale

Nehari manifold The set of nonzero elements defined by the condition $DI(u)(u) = 0$, used as a natural constraint for certain functionals; see Section 32.1. 1600, *see* Lagrange multiplier and energy functional

Palais–Smale condition A compactness condition for sequences with bounded energy whose derivative tends to zero; see Definitions 31.1.2 and 31.4.1. 1578, *see* pseudogradient vector field and Banach–Finsler structure

parametrix A two-sided inverse of an operator modulo smoothing operators. 1074, *see* pseudodifferential operator

Poincaré inequality An estimate for a function or section in terms of its derivatives, under the corresponding geometric or boundary conditions; see Theorems 3.3.7 and 9.6.3. 303, *see* Sobolev space

pseudodifferential operator An operator defined locally by quantizing a symbol and stable under the symbolic calculus modulo smoothing operators. 1054, *see* parametrix and wavefront set

pseudogradient vector field A locally Lipschitz vector field controlled by the norm of the derivative and producing uniform descent of the functional; see Definition 31.2.1. 1579, *see* Palais–Smale condition

real interpolation A method for constructing intermediate spaces using the K- and J-functionals; see Definition 5.2.3. 403, *see* complex interpolation

regular level set A level set of a functional whose derivative does not vanish at its points and which, in the setting developed here, has a submanifold structure; see Theorem 24.7.2. 1403, *see* Banach submanifold and Lagrange multiplier

Riemann–Lebesgue measure The canonical measure associated with a Riemannian metric, used to formulate global integrals without assuming orientability; see Definition 2.15.5. 261, *see* Riemannian manifold

Riemannian manifold A smooth manifold equipped with a Riemannian metric; see Definition 2.1.1. 126, *see* Riemannian metric and Riemann–Lebesgue measure

Riemannian metric A metric tensor field that determines the inner product on each tangent space; see Definition 2.1.1. 126, *see* Riemannian manifold

smooth partition of unity on a Banach manifold A locally finite family of nonnegative smooth functions subordinate to an open cover and with sum equal to one; see Theorem 24.8.9. 1409, *see* bump function on a Banach space and Banach manifold

smooth vector bundle A vector bundle whose projection, total space, and local trivializations have a smooth structure; see Definition 1.7.2. 50, *see* bundle metric and connection

Sobolev–Slobodeckij space A space of noninteger order defined using differences and the Gagliardo seminorm; see Definition 6.2.1. 449, *see* Bessel potential space

Sobolev space A function space that controls a function or section and its weak derivatives up to a given order; see Definitions 3.2.1 and 9.1.47. 290, *see* weak covariant derivative and trace operator

spaces BC^j and BUC^j Spaces of C^j functions whose derivatives are bounded and, in the second case, uniformly continuous; see Definition 6.4.1. 471, *see* uniformly regular manifold

split regular value A value whose fiber consists of points at which the differential admits a continuous linear right inverse; see Definition 24.6.4. 1400, *see* submersion between Banach manifolds and Banach submanifold

strong Riemannian metric A smooth metric whose tangent norm induces the Hilbert topology and whose musical morphism is an isomorphism; see Section 26.1. 1447, *see* Hilbert manifold and Banach–Finsler structure

submersion between Banach manifolds A map whose differential admits a continuous linear right inverse; see Definition 24.5.1. 1393, *see* Banach manifold and regular level set

tempered distribution A continuous linear functional on the Schwartz class; see Definition 4.9.1. 389, *see* Fourier transform

trace operator The continuous extension of restriction to the boundary for Sobolev classes of sufficient regularity; see Theorem 9.4.12. 705, *see* Sobolev space

uniform structure A filter of entourages of the diagonal that makes it possible to define uniform continuity, Cauchy filters, and completeness; see Definition 27.2.1. 1483, *see* uniformly regular manifold

uniformly regular manifold A manifold equipped with a class of normalized, shrinkable atlases of finite multiplicity, with uniformly controlled coordinate changes in the sense of Amann; see Definition 13.2.2. 896, *see* bounded geometry and uniform structure

variational method A procedure that translates a differential equation into a critical point problem for a functional; see Section 29.3. 1553, *see* energy functional and direct method in the calculus of variations

wavefront set A conic subset of the cotangent bundle with the zero section removed, identifying the points and codirections in which a distribution is not smooth. 1080, *see* pseudodifferential operator and tempered distribution

weak covariant derivative The distributional extension of the covariant derivative, defined through integration by parts; see Definition 9.1.5. 601, *see* covariant derivative and Sobolev space

weak Riemannian metric A smooth metric whose musical map need not be surjective onto the continuous dual; see Definition 26.1.1. 1447, *see* strong Riemannian metric and Hilbert manifold

weak solution An element of the function space that satisfies the integral identity obtained by testing the equation against admissible functions; see Definition 29.2.3. 1560, *see* energy functional and variational method

on a Banach manifold, 1434
integral mean value formula
in Banach spaces, 1346
integral of a simple function, 1698
integral of densities on Euclidean domains, 256
integral of densities on manifolds, 256
integral of forms on Euclidean domains, 254
integral of forms on oriented manifolds, 255

integral with respect to the Riemann–Lebesgue measure, 258
integral with respect to the volume form, 255
integration by parts, 288
    for Banach-valued functions, 1698
integration-by-parts formula for the p-Laplacian, 637
integration-by-parts formula
    for higher-order covariant derivatives, 622
interior formal adjoint, 694
interior multiplication, 115
interior multiplication defines a tensor field, 115
interior point of a manifold with boundary, 22
interpolation inequality, 1715
interpolation of operators
    complex method, 419
    K-method, 405
invariance of flows under diffeomorphisms, 88
invariance of the boundary, 22
inverse function theorem
    global, 1370
    in Banach spaces, 1366
inverse function theorem, 42
isometric embedding, 607
isometry, 1648
iterated commutator
    pointwise evaluation, 548
iterated directional derivatives as functions, 9

J-functional, 407
Jacobi equation, 239
Jacobi field, 239
    and exponential map, 240
Jacobi operator, 1524
Jacobi's formula, 251
Jensen's inequality, 1713
jet
    of finite order, 550

K-functional, 402
Kakutani, 1761
Kato–Simon inequality, 836
kinematic tangent vector, 1380

Lagrange multipliers, 1371
Laplace–Beltrami operator, 271
Laplace–Beltrami, operator, *see* Laplace–Beltrami operator
Lax–Milgram theorem, 1667
Lebesgue integrable, 1700
Lebesgue integral
    of a nonnegative measurable function, 1699
Lebesgue measurable, 260
Lebesgue measurable set, 1691
Lebesgue measure, 1691
    approximation by F_σ and G_δ sets, 1692
    regularity, 1692
n-dimensional Lebesgue outer measure, 1691
Lebesgue space, 1708
    integrable measurable functions, 1707
Lebesgue space
    sections of a vector bundle as a Banach space, 605
Lebesgue space as a quotient space, 1708
Leibniz rule
    second derivative, 1362
Leibniz rule for divergence, 269
Leibniz rule for interior multiplication, 162
Leibniz rule for several factors, 14
Leibniz rule for tensors, 163
Leibniz rule for the gradient, 268
Leibniz rule for the Laplacian, 271
Leibniz rule for the operator, 644
lemma
    smooth chart, 23
level set
    regular, 1403
Levi–Civita connection
    compatibility with the tensor inner product, 150
    metric compatibility, 147
LF properties, 360
Lie algebra
    of a centralizer, 100
    of a Lie group, 95
Lie group, 93
Lie subgroup
    closed, 100
linear connection
    on a Banach bundle, 1438

linear operator, 1651
bounded, 1651
inversion, 1365
Lipschitz function
extension, 1647
Littlewood–Paley decomposition, 399
Littlewood–Paley square function, 457
local characterization on a half-ball, 336
local diffeomorphism, 42
local equation for parallel transport, 195
local expression for the formal adjoint, 632
local expression of a PDO using local frames, 566
local flow
on a Banach manifold, 1435
local frame
of a vector bundle, 59
local integral of forms on oriented manifolds, 254
local Riemann–Lebesgue measure, 260
local section, 57
local semiconcavity, 1314
local signed Radon measure, 1693
local slice criterion, 44
locality of differential operators and singular support, 785
locality of differential operators on distributions, 782
locality of the half-space trace, 335
locally compact, 1692
locally convex final topology, 356
locally convex space, 1737
locally finite measure, 1691
locally integrable function, 1702
Lorentz space, 434
loss of derivatives, 1546
lower semicontinuity, 1565
existence of a minimum on compact spaces, 1566
weak, 1567
lp(E) is separable, 613
Lumer–Phillips theorem, 1681

manifold, *see also* tangent space
Banach, 1376
Banach of class $C^{1,1}$, 1378
Banach submanifold, 1388
Nehari, 1600
of bounded geometry, 867
regular level submanifold, 1403
Riemann–Lebesgue measure, 261
Riemannian, 126
Riemannian with boundary, 126
manifolds are paracompact, 19
map
of class $C^{1,1}$, 1378
of class C^k between Banach manifolds, 1377
mazur, 1748
McKean–Singer formula, 1142
McShane extension, 1647
mean value inequality
in normed spaces, 1344
measurable function, 1698
measurable set
in the sense of Carathéodory, 1691
measure, 1690

signed Radon measure, 1693
simple function, 1698
singular support, 779
slice, 1492
slice chart, 44
Slobodeckij space, 449
for sections, 707
smooth action, 101
smooth embedding, 43
smooth local frame, 59
smooth local frame criterion for subbundles, 77
smooth (local or global) section, 58
smooth manifold, 18
smooth manifold with boundary, 22
smooth map, 24
smooth regular distributions and support, 783
smooth sections
topology on a compact support, 750
smooth structure on a manifold with boundary, 22
smooth vector bundle lemma, 53
smooth vector bundle of rank, 50
smoothing operator, 1048
compactness, 1111
on a manifold, 1055
uniform but noncompact, 1109
smoothing symbol, 1037
smoothness criterion for tensor fields, 111
Sobolev embedding theorem, 303
higher-order, 309
on the half-space, 328
Sobolev embedding theorem
for bundles over manifolds with boundary, 719
for vector bundles, 671

in bounded geometry, 1019
on manifolds with boundary, 722
Sobolev embeddings
localized on a half-ball, 331
Sobolev mapping space, 1494
Sobolev–Morrey theorem
for bundles over manifolds with boundary, 725
for vector bundles, 685
higher-order, 320
Sobolev space, 290, 293
completeness of $W^{1,p}$, 292
completeness of $W^{m,p}$, 306
higher-order, 305
Sobolev space
characterization of the zero-trace subspace, 717
definition using $C^{m,p}(M,\mathbf{E})$ on manifolds with boundary, 698
equivalent norm using the Bochner Laplacian, 648
equivalent norm using the Laplacian, 638
global and local on manifolds with boundary, 695
independence of the admissible trivialization, 912
of sections by completion, 666
with zero trace, 703
Sobolev space associated with an admissible trivialization, 910
Sobolev, space, *see* Sobolev space
space of differential forms, 577
space of distributions, 367
space of linear operators between sections, 534
space of parallel sections and its projection, 739
space of tempered distributions, 389
spectral cut, 1119
spectral gap, 1514
spectral theorem
compact self-adjoint operators, 1671
unbounded self-adjoint operators, 1677
spectrum
of a bounded operator, 1652
Spin group, 272
spin structure, 272
spray, 1453
